WESTERN REGIONAL CLIMATE ACTION INITIATIVE

WHEREAS, western states are experiencing the effects of a hotter, drier climate, including prolonged droughts, excessive heat waves, reduced snow packs, increased snowmelts, decreased spring runoffs, altered precipitation patterns, more severe forest and rangeland fires, widespread forest diseases, and other serious impacts; and

WHEREAS, scientific consensus has developed that increasing emissions of human-caused greenhouse cases (GHGs), including carbon dioxide, methane and other GHGs, that are released into the atmosphere are affecting the Earth's climate; and

WHEREAS, the Western Governors Association (WGA) has declared that climate change could have severe economic and environmental impacts on the Western States in coming decades; and

WHEREAS, the WGA also has declared that action is needed to reduce GHG emissions and that many of these actions can have significant economic and environmental benefits for the Western States, including increased energy efficiency, increased renewable energy generation, improved air quality, cost savings, job growth, increased state revenues, and reduced water pollution; and

WHEREAS, we support the development of national, regional, tribal, state and local programs to reduce GHG emissions; and

WHEREAS, we support national, regional, tribal, state and local level policies on global climate change that are consistent with efforts to develop cost-effective alternative energy sources and more efficient use of energy; and

WHEREAS, we recognize the need for collaboration among states to develop climate change policies that provide consistent approaches to recognize and give credit for actions to reduce GHG emissions; and

WHEREAS, we have already adopted or committed to adopt clean tailpipe standards for passenger vehicles that will result in major reductions in GHG emissions and other pollutants; and

WHEREAS, we support market-based policies to reduce GHG emissions in the most cost-effective manner; and

WHEREAS, we have set goals to significantly reduce GHG emissions from our respective states; and

WHEREAS, we welcome expanding the partners to this initiative to other states, tribes, Canadian provinces and Mexican states and offer monitoring status to any state, tribe or province interested in observing the initiative;

NOW, THEREFORE, we, the undersigned Governors, jointly establish the Western Regional Climate Action Initiative and agree to collaborate in identifying, evaluating and implementing ways to reduce GHG emissions in our states collectively and to achieve related co-benefits. This collaboration shall include, but is not limited to:

- Setting an overall regional goal, within six months of the effective date of this initiative, to reduce emissions from our states collectively, consistent with state-by-state goals;

- Developing, within eighteen months of the effective date of this agreement, a design for a regional market-based multi-sector mechanism, such as a load-based cap and trade program, to achieve the regional GHG reduction goal; and

- Participating in a multi-state GHG registry to enable tracking, management, and crediting for entities that reduce GHG emissions, consistent with state GHG reporting mechanisms and requirements.

In addition, we commit to continue our independent and collaborative efforts to reduce GHG emissions through:

- Promoting the development and use of clean and renewable energy within the region;

- Increasing the efficiency of energy use within our jurisdictions;

- Advocating regional and national climate policies that reflect the needs and interests of western states, tribes and provinces; and

- Identifying measures in our states, tribes and provinces to adapt to the impacts of climate change.

We will direct our staffs and the appropriate state agencies to meet as soon as is practicable to develop a work plan to move forward with this initiative.

DONE, in five (5) duplicate originals, this 26th day of February, 2007, in Washington, D.C.

Governor Christine O. Gregoire

Western Climate Initiative

Western Climate Initiative Update

August 27, 2007

On February 26, 2007, Governors Gregoire (WA), Kulongoski (OR), Napolitano (AZ), Richardson (NM) and Schwarzenegger (CA) signed an agreement establishing the Western Climate Initiative (WCI). The purpose of the initiative is to collaborate in identifying, evaluating and implementing ways to reduce GHG emissions and to achieve related co-benefits.

Since February, Premier Gordon Campbell of British Columbia, Utah Governor Jon Huntsman, and Premier Gary Doer of Manitoba have joined the Initiative as full partners.

Currently the following jurisdictions are participating as official observers: the U.S. States of Colorado, Kansas, Nevada, and Wyoming; the Canadian Provinces of Ontario, Quebec, and Saskatchewan; and the Mexican State of Sonora.

On August 22, 2007, the WCI partners released their regional goal to collectively reduce emissions, consistent with previously established state and provincial goals. Details on the WCI regional goal (to reduce emissions 15% below 2005 levels by 2020) can be found at www.westernclimateinitiative.org.

By August 2008, the partners will design a regional market-based multi-sector mechanism, such as a load-based cap and trade program, to help achieve the goal. Each of the partners has joined the newly formed GHG registry (The Climate Registry). The Climate Registry is expected to be operational by January, 2008. More information about The Climate Registry can be found at www.theclimateregistry.org.

Five WCI subcommittees have recently been established to work on various aspects of the regional program. The five subcommittees are: Reporting, Scope, Electricity, Allocations, and Offsets. Staff from WCI states and provinces will serve on the subcommittees. The subcommittee chairs will establish a process for obtaining input from technical experts and stakeholders.

It is the intention of the Governors and the Premiers to expand the partners in the initiative to include other states, tribes, and provinces who share their commitment to aggressively address climate change.

New partners are invited to sign the February 26, 2007 agreement, committing to the goals of the initiative. As stated in the agreement, it is expected that any state or province wishing to become a partner will have set a goal to significantly reduce GHG emissions and committed to adopt clean tailpipe standards for passenger vehicles, in addition to committing to the overall goals of the initiative.

The partners have also offered observer status to states, tribes, or provinces that are interested in pursuing greenhouse gas reductions.

Each of the WCI partners will separately conduct stakeholder outreach and involvement with interested parties in their jurisdictions. In addition, the partners will collectively host periodic conference calls and provide written updates on the progress of the initiative. Documents will be posted to the WCI website as they become available.

Western Climate Initiative

Statement of Regional Goal

August 22, 2007

1. Regional Goals. The Western Climate Initiative (WCI) regional greenhouse gas emission reduction goal is an aggregate reduction of 15% below 2005 levels by 2020.

- This regional, economy-wide goal is consistent with the emission goals of WCI partners and does not replace the partners' existing goals.

- The WCI partners acknowledge that new entrants and updates to data may result in some incremental changes to the regional goal.

- The metrics for establishing this goal are documented in Attachment A.

The WCI partners commit to do their share to reduce regional GHG emissions sufficient over the long term to significantly lower the risk of dangerous threats to the climate. Current science suggests that this will require worldwide reductions between 50% and 85% in carbon dioxide emissions from current levels by 2050.[1]

2. New Entrants. The WCI encourages participation by additional US states, tribes, Canadian provinces, and Mexican states that are making comparable efforts to combat climate change. In determining whether the new entrant is undertaking comparable efforts to meet the challenge of climate change, the partners shall consider whether the proposed new entrant:

a. Has adopted an economy-wide greenhouse gas reduction goal. The goal shall reflect a level of effort that is consistent with that of the WCI partners;

[1] IPCC Fourth Assessment Report, Working Group III, Mitigation of Climate Change

b. Has developed or is developing a comprehensive multi-sector climate action plan to achieve the goal;

c. Has committed to adopt greenhouse gas tailpipe standards for passenger vehicles; and

d. Is participating in The Climate Registry.

When deciding whether to accept a new entrant, the partners may consider other factors they deem appropriate. The partners will establish a decision-making process on adopting new entrants.

3. Coverage of Actions in the Goal. Emissions reduction activities by which partners achieve the regional reduction goal should be comprehensive and economy-wide, including:

a. Regional multi-sector market-based mechanisms;

b. Actions in all sectors, including but not limited to: stationary sources, energy supply, residential, commercial, industrial, transportation, waste management, agriculture, and forestry; and

c. Reduction in emission of any GHG reported to the UN Framework Convention on Climate Change by the USEPA and Environment Canada, i.e., carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6).

4. Reporting Requirements. Each partner will update the other WCI partners on their climate action plan and GHG emissions inventories every two years to ensure that actions are underway at levels consistent with full achievement of the 2020 goal.

Attachment A: Metrics used to Establish WCI Regional Goal

The WCI aggregate greenhouse gas emission reduction goal of 15% below 2005 levels by 2020 is based on:

- The aggregation of GHG emissions and emissions goals of WCI partners that have thus far established a 2020 goal (Arizona, British Columbia, California, New Mexico, Oregon, and Washington) and Manitoba's short-term goal, as shown in the Table 1 below.

- Currently available state or provincial emissions inventories. Some of these inventories are currently under revision, and the values shown in Table 2 below will be periodically updated. While further changes to specific emissions estimates are likely, the aggregate regional emission reduction goal for the current partners is unlikely to deviate substantially from 15% below 2005 levels by 2020.

- Gross emissions estimates, across all sectors, for the six greenhouse gases reported to the UN Framework Convention on Climate Change by the USEPA in the U.S. Greenhouse Gas Inventory and by Environment Canada in the Canada National Inventory Report: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6). These estimates are presented in terms of CO_2 equivalence (CO_2e), which indicates the relative contribution of each gas to global average radiative forcing on a 100-year Global Warming Potential (GWP) weighted basis. Gross emissions estimates do not include changes in biological carbon stocks due to agriculture, forestry, and land use change. In addition, GHG emissions associated with international aviation and international bunker fuels are generally excluded.

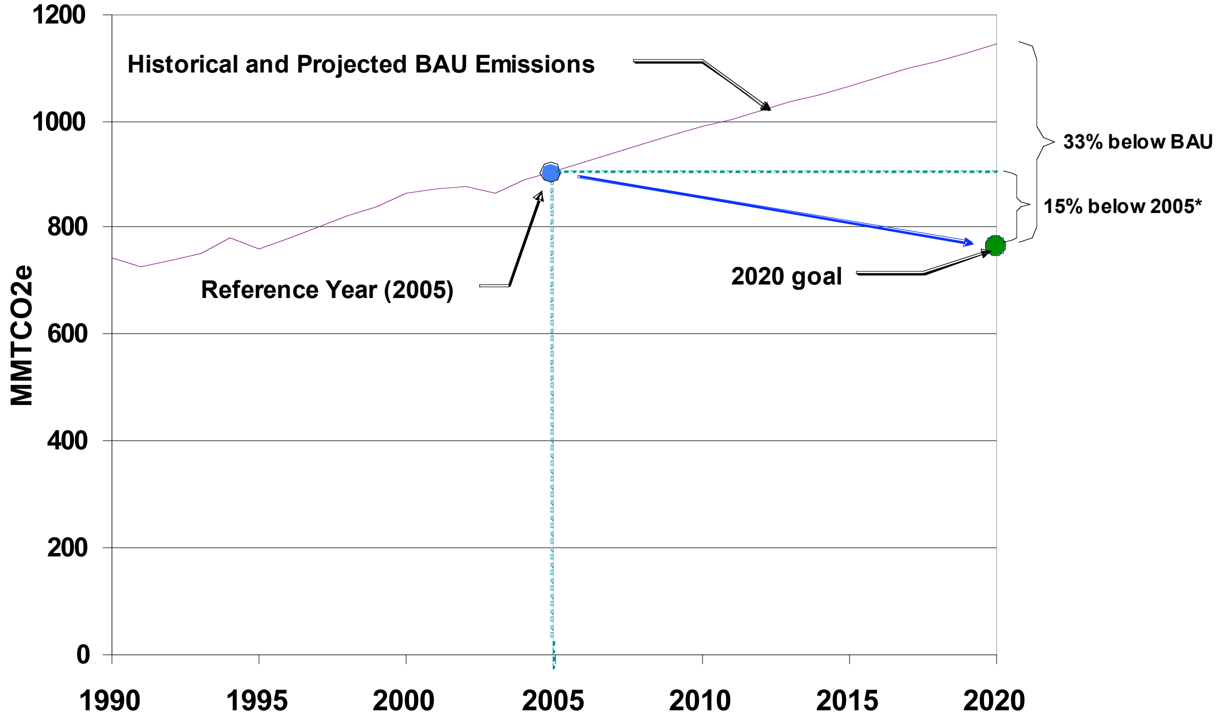
- Consumption-based (or "load-based") emissions estimates for the electricity sector, except where such estimates are currently unavailable, in which case production-based estimates are used (British Columbia). Consumption-based estimates reflect the emissions associated with generating the electricity delivered to consumers in each state or province whether the electricity was generated in state/province or out of state/province. Considerable work is currently underway to further develop and improve consumption-based estimates.

Table 1. State and Provincial Goals for GHG Reductions

	Short Term (2010-12)	Medium Term (2020)	Long Term (2040-50)
Arizona	not established	2000 levels by 2020	50% below 2000 by 2040
British Columbia	not established	33% below 2007 by 2020	not established
California	2000 levels by 2010	1990 levels by 2020	80% below 1990 by 2050
Manitoba	6% below 1990	6% below 1990[2]	not established
New Mexico	2000 levels by 2012	10% below 2000 by 2020	75% below 2000 by 2050
Oregon	arrest emissions growth	10% below 1990 by 2020	>75% below 1990 by 2050
Utah	Will set goals by June 2008		
Washington	not established	1990 levels by 2020	50% below 1990 by 2050

[2] Manitoba has not yet established a formal goal for 2020, but expects to meet or do better than its short term goal.

WCI Partner GHG Emissions and Regional Goal[3]



BAU = Business-as-usual (projections).

The arrow shown is purely directional: it illustrates the where regional emissions will need to be by 2020 rather than the specific path emissions are expected to follow during the 2007-2020 period.

* See footnote c in the Table 2 below.

[3] Note that this chart does not include Manitoba emissions, which will be added when 2020 projections are available.

Table 2 compiles and compares WCI partner goals for the year 2020, and indicates the relative percentage emissions reduction below historical (1990, 2000, and 2005) or projected (business-as-usual or "BAU" in 2020) levels that these goals imply. Also shown are the absolute emission reductions below projected BAU levels in 2020 in million metric tons of CO2 equivalents (MMtCO2e) that are needed to meet these goals. The final column indicates how fast greenhouse gas emissions would be expected to grow from 1990 to 2020 were no action taken to reduce them. The final row shows the aggregate result for the WCI partners that have established 2020 goals (percents are based on total emissions for the partners shown). As illustrated, the compilation of partner goals represents an aggregate 16% reduction below 2005 levels by 2020. This figure has been rounded to 15% for the regional goal, as stated above.

Table 2. Summary Compilation and Comparison of 2020 goals (Estimates as of July 2007[a])

	Goals					1990-2020 BAU growth
	Relative to 1990	Relative to 2000	Relative to 2005	Relative to 2020 BAU[b]	Absolute Reductions from BAU (MMtCO2e)	
Arizona	35%	0%	-11%	-45%	72	144%
British Columbia	-9%	-27%	-30%	-46%	40	69%
California	0%	-10%	-14%	-28%	170	40%
Manitoba	-6%	-16%	-17%	TBD	TBD	TBD
New Mexico	14%	-10%	-14%	-31%	28	65%
Oregon	-10%	-29%	-32%	-44%	40	61%
Washington	0%	-16%	-11%	-28%	33	40%
Total	**2%**	**-12%**	**-16%**[c]	**-33%**[d]	**383**[d]	**54%**[d]

[a] Methodologies for estimating electricity emissions may not be fully comparable. State electricity emissions estimates used to develop the figures shown above are consumption-based (i.e. "load-based"); methodologies for consumption-based electricity emissions vary among states. Provincial electricity emission estimates are currently available only on a production basis.

[b] Current BAU forecasts (2020 estimates) may not be fully comparable. Two factors, in particular, may need to be further examined with respect to assessing comparability of effort: a) underlying socioeconomic projections, most notably population and economic activity; and, b) the extent to which emission reduction actions are included in BAU projections.

[c] The WCI goal of 15% below 2005 levels reflects a rounding of this figure, which may change slightly as partner states and provinces continue to refine their GHG inventories.

[d] These totals do not include Manitoba emissions, since projections are not currently available.

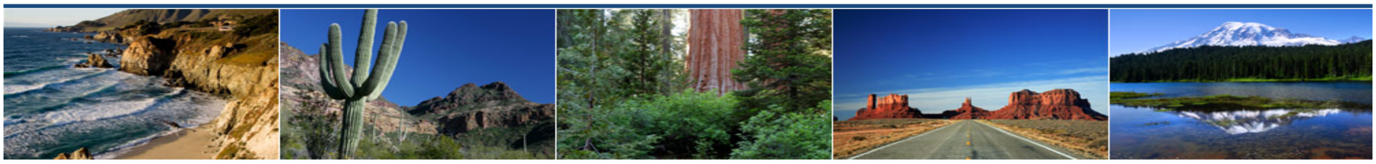
Western Climate Initiative



October 29, 2007

TO: All Interested Parties

The Western Climate Initiative (WCI) Partners are pleased to release the attached work plan of WCI activities through August 2008. As directed by our Governors and Premiers (http://www.westernclimateinitiative.org/ewebeditpro/items/O104F12775.pdf), this work plan describes our process for developing design recommendations for a proposed cap-and-trade program, as one element of our collaboration to identify, evaluate, and implement ways to reduce GHG emissions and to achieve related co-benefits.

The WCI Partners encourage stakeholder and public participation, and toward that end have included a description of the proposed stakeholder process in the work plan. This process includes three workshops, planned for January, May, and July 2008, as well as regular conference calls and other activities. These activities will supplement the outreach being conducted individually by each of the states and provinces.

Included in the attached work plan is a list of program design questions and issues on which we are particularly interested in receiving input at this time. The WCI Partners request that you submit input regarding these questions and issues by November 30, 2007. Instructions for submitting comments are posted on the WCI website: www.westernclimateinitiative.org.

Throughout our work, the WCI Partners will solicit written input, including feedback on preliminary materials as they are developed. Comments and input will be posted to our website. Input is welcome at any time on issues related to the WCI.

The WCI Partners appreciate your interest and involvement in this initiative. We look forward to working with all stakeholders to achieve WCI's objectives.

Sincerely,

Janice Adair, Special Assistant	Steve Owens, Director
Washington Department of Ecology	Arizona Department of Environmental Quality
Chair, Western Climate Initiative	Co-Chair, Western Climate Initiative

I. INTRODUCTION

This document presents the plan for the Western Climate Initiative (WCI) activities through August 2008.

- Section II presents a brief summary of the WCI and its objectives.
- Section III presents the design principles adopted by the WCI Partners to guide the development of recommendations for a cap-and-trade program.
- Section IV presents the process for involving stakeholders and the public in the WCI deliberations.
- Section V presents a summary of the overall timeline and milestones for developing the program design recommendations.
- Section VI presents design questions and issues on which public input is solicited at this time. Please note that input on additional questions and issues will be solicited during the development of the program recommendations and that input is welcome at any time on issues related to the WCI.
- Section VII describes the subcommittees created by the WCI Partners.
- Section VIII presents the work plans for each of the subcommittees.

II. BACKGROUND

On February 26, 2007, Governors Gregoire (WA), Kulongoski (OR), Napolitano (AZ), Richardson (NM) and Schwarzenegger (CA) signed an agreement establishing the Western Climate Initiative (WCI). The purpose of the initiative is to collaborate in identifying, evaluating and implementing ways to reduce GHG emissions and to achieve related co-benefits.

Since February, Premier Gordon Campbell of British Columbia, Utah Governor Jon Huntsman, and Premier Gary Doer of Manitoba have all joined the Initiative as full Partners.

It is the intention of the Governors and the Premiers to expand the Partners in the initiative to include other states, tribes, and provinces who share their commitment to aggressively address climate change.

Currently the following jurisdictions are participating as official observers: the U.S. States of Alaska, Colorado, Idaho, Kansas, Nevada, and Wyoming; the Canadian Provinces of Ontario, Quebec, and Saskatchewan; and the Mexican State of Sonora.

On August 22, 2007, the WCI Partners released their regional goal to collectively reduce emissions, consistent with previously established state and provincial goals. Details on the WCI regional goal (to reduce emissions 15% below 2005 levels by 2020) can be found at www.westernclimateinitiative.org.

Each of the Partners has joined the newly formed GHG registry (The Climate Registry). The Climate Registry builds on the existing California Climate Action Registry and will begin accepting data in early 2008. More information about The Climate Registry can be found at www.theclimateregistry.org. The Climate Registry will play an important role in establishing an accurate reporting mechanism and accounting infrastructure on which to base the WCI cap-and-trade program.

Five WCI subcommittees have recently been established to work on various aspects of the regional program. The five subcommittees are: Reporting, Scope, Electricity, Allocations, and Offsets. Staff from WCI states and provinces serve on the subcommittees, and each subcommittee will obtain input from technical experts and stakeholders.

Each of the WCI Partners will separately conduct stakeholder outreach and involvement with interested parties in their jurisdictions. In addition, the Partners will collectively host periodic conference calls, provide written updates on the progress of the initiative, and conduct other communications and outreach activities.

By August 2008, the Western Climate Initiative Partners will develop design recommendations for a regional cap-and-trade program to:

1. Reduce greenhouse gas emissions in each Partner jurisdiction; and
2. Help achieve the Partners' overall greenhouse gas emissions reduction goals.

III. DESIGN PRINCIPLES FOR A REGIONAL CAP AND TRADE PROGRAM

To attain the Western Climate Initiative's greenhouse gas reduction goal, the members are committed to designing a system that:

1. Is equitable, administratively simple for government and private participants, minimizes administrative costs, and has a clear compliance path;
2. Maximizes total benefits throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts;
3. Requires all reductions to be real, surplus/additional, verifiable, permanent, and enforceable;
4. Stimulates investment, especially in low carbon technologies, and rewards innovations that will lead to long-term permanent greenhouse gas reductions;
5. Covers as many sources as is practical, while encouraging pollution reductions beyond the capped sources and sectors;
6. Provides appropriate recognition and incentives for early emissions reductions;
7. Assures a transparent and robust accounting system that will measure and report emissions rigorously and consistently across all sectors and throughout the region;
8. Minimizes the potential for leakage; and
9. Facilitates linkage to similarly rigorous regional and international greenhouse gas reduction markets and encourages other states, provinces, and countries to join the market.

IV. COMMUNICATIONS AND STAKEHOLDER OUTREACH

The Western Climate Initiative Partners are committed to maintaining an open and transparent process that integrates public participation and stakeholder input. Therefore, the WCI Partners will conduct a regional communications and stakeholder outreach process during the design phase to:

1. Supplement the individual state and province communication and outreach efforts.
2. Inform the public and stakeholders of the WCI Partners' deliberations, and draft and final work products.
3. Provide a mechanism for subcommittees to obtain timely input from the public and stakeholders on key design elements of the regional cap-and-trade initiative to support their deliberations and recommendations.
4. Establish opportunities for the public and stakeholders to communicate through oral and/or written comments to the WCI Partners prior to key decision points in the process, including integration of design elements from subcommittees into the final program design.
5. Maintain an ongoing dialogue between WCI Partners and stakeholders in the process.

The WCI Partners will carry out the following actions.

1. Website. The WCI Partners have established a Western Climate Initiative website at www.westernclimateinitiative.org. The website will serve as the primary vehicle for the WCI Partners to make their draft and final work products available for public review and comment. In addition, the WCI Partners intend to post the written comments received from members of the public and stakeholders on the website.
2. Listserv. The WCI Partners have established a regional Listserv to which members of the public and stakeholders may subscribe by visiting the WCI website (www.westernclimateinitiative.org). Subscribers to the regional Listserv will receive email notifications when new content is added to the website, including the availability of draft and final work products, as well as notifications of public information sessions.
3. Public Information Sessions. In addition to making draft and final work products available on the WCI website, the WCI Partners will hold public meetings by teleconference and in-person, as follows:
   - Teleconferences. The purpose of the teleconferences is to provide information to interested members of the public and stakeholders. The WCI Partners will hold periodic teleconferences to relate the subject of their ongoing deliberations on areas of focus in the initiative. In general, these teleconferences will occur shortly after the periodic meetings of the WCI Partners, though additional teleconferences will be held as necessary. Call information will be posted on the website and notifications will be sent vial the Listserv. The current schedule for WCI teleconferences is as follows:
     - Thursday, October 31, 2007 at 2 pm PDT / 3 pm MDT
     - Thursday, December 6, 2007 at 2 pm PST / 3 pm MST
     - Thursday, March 6, 2008 at 2 pm PST / 3 pm MST

- Workshops. The WCI Partners will conduct public workshops at various locations in the WCI region beginning in January 2008. Workshops will be webcast.
    - At the first session (early January), the subcommittees will present the status of their deliberations, including identifying the major options that are under consideration and the pros and cons of the alternatives. Public input on the options will be solicited.
    - The second workshop will occur in May 2008. At the second session, the subcommittees will present their recommendations on key elements of the regional cap-and-trade program. Public input on the recommendations will be solicited.
    - The third workshop will occur in July 2008. At the third session, the Partners will present the preferred fully integrated plan that is being considered. Public input on the proposed plan will be solicited.
    - Interested members of the public and stakeholders will have the opportunity to provide oral comments at public information sessions. Participants will be encouraged to submit written comments to supplement oral comments. Comments that are submitted in electronic format will be posted to the WCI website.

(Note: The dates for teleconferences and in-person meetings are subject to change, and any changes will be promptly posted on the WCI website and sent out on the WCI listserv.)

- Public Input to Subcommittee Deliberations. The purpose of this activity is to provide a mechanism by which the subcommittees can solicit stakeholder and public input. As necessary, each subcommittee will prepare written requests for input that will be posted on the website and announced via the Listserv. Written input will be received, reviewed, and posted on the website.
- State and Provincial Stakeholder Processes. This section describes communication and outreach that the WCI Partners will undertake together at the regional level. These regional communications are intended to supplement and not replace individual state and provincial communications and do not supplant any public comment periods required in connection with the adoption of laws and regulations in specific Partner jurisdictions.

The WCI Partners will revisit this Communications Plan from time to time and consider appropriate revisions to the plan based on comments received by interested members of the public and stakeholders, or on their own initiative.

V. TIMELINE AND MILESTONES

October 2007	Release work plan and major design issues for review and comment • Subcommittees identify specific issues on which input is sought
November 2007	Initial written stakeholder feedback on work plan and major design issues requested by November 30.
January 2008	Subcommittees describe major options under consideration • Workshop to discuss options with interested stakeholders
May 2008	Subcommittee recommendations on key elements of regional cap-and-trade program • Workshop to discuss subcommittee recommendations
July 2008	Proposed design of regional cap-and-trade program • Workshop to discuss proposed design
August 2008	Partners release design recommendations for a regional cap-and-trade program

VI. DESIGN QUESTIONS FOR STAKEHOLDER REVIEW & COMMENT

The WCI Partners are broadly framing their discussions around the following set of design questions and seek input from stakeholders and interested members of the public to guide the development of the program.

Program Scope and Timing

A. What sectors and gases should be covered by the cap-and-trade program, and within each covered sector, what point of regulation is most appropriate?

1. Electricity:
   - (a) At the generator level?
   - (b) At the retail provider level?
   - (c) A "first seller"[1] approach (covering both emissions that occur inside the jurisdiction as well as the emissions attributable to the electricity generated outside the jurisdiction)?
   - (d) A generator-retail provider hybrid approach?
   - (e) Other?
   - (f) For all of the above, which gases should be considered for the electricity sector?

2. Others sectors: Referring to Table 1 in the work plan (see page 18), are the options shown properly defined? Should additional options be added? What combination of options should be considered?

B. Should all sectors/gases be covered by the program on the same launch date, or should sectors/gases be added over time, and why?

Setting Cap Level(s), Scheduling Reductions & Distributing Allowances

A. What factors should be considered in determining the relative role of the cap-and-trade program as compared with complementary policies in reaching regional emission reduction goals?

B. How should the initial emissions cap(s) for the cap-and-trade program be established at the regional, state and provincial and/or sectoral levels, and what schedule of reductions should be set?

C. What are the key objectives that WCI Partners should address through allowance distribution (e.g., cost minimization, equity, technology incentives, etc.)?

D. How should the allowances be distributed (e.g. auction or free allocation), and should the distribution process be common to all Partners?

[1] For discussion of the first seller, retail provider, and other electricity sector scope options see http://www.climatechange.ca.gov/documents/2007-06-29_MAC_FINAL_REPORT.PDF

E. How should recognition and incentives for early emission reductions be provided?

Offsets

A. What roles and key objectives, if any, should an offsets mechanism play in WCI?

B. How should a WCI offset mechanism be designed?

1. How should greenhouse gas offsets be defined for use within the WCI cap and trade system?

2. How should the WCI design principles that reductions be real, surplus/additional, verifiable, permanent, and enforceable be translated into practice?

3. What approaches should be used to develop project baselines and monitoring methodologies?

4. Should there be limits on the extent to which offsets can be used to meet compliance obligations? Should such limits change over time?

5. What issues should be considered in determining issues such as project start dates, offset expiration, and project crediting periods?

6. What project types and locations should be eligible, and on what basis should eligibility be determined? Should offsets from other programs be eligible (e.g. Clean Development Mechanism, Regional Greenhouse Gas Initiative)?

C. How should the WCI administer an offset mechanism? Are there useful models and protocols to follow?

Other Flexibility and Cost-Containment Mechanisms

A. What should the length of the compliance periods be, and why?

B. What are the pros and cons of allowance banking?

C. What are the pros and cons of allowance borrowing?

D. Should the program include other cost-containment mechanisms such as a safety valve, allowance price cap, or other instruments? If so, how should these be designed?

Emissions and Allowance Data, Monitoring, Reporting and Tracking

A. What are the best sources of data to use in establishing emission baselines?

B. Should mandatory emissions reporting precede establishment of an emissions baseline in one or more of the sectors to be covered by the program?

C. How should emissions, allowances, and offsets be measured, monitored, reported and/or tracked by the program?

D. Are there additional objectives for a reporting systems beyond assessing compliance with the cap-and-trade program, and if so, what should they be?

E. What are the best ways to assure consistency in reporting throughout the WCI? How should mandatory reporting under the WCI be best integrated with The Climate Registry?

Miscellaneous Issues

A. How should the cap-and-trade program be designed to enhance the benefits from complementary policies in the Partner jurisdictions?

B. How should the WCI ensure compliance with program goals? What non-compliance penalties would be appropriate for entities that are covered under the cap?

C. Should the WCI partners establish regional organization(s) to coordinate aspects of program implementation, and if so, what aspects?

D. Which design elements should be common, and which should be allowed to vary, across WCI partner jurisdictions?

E. How should the program be designed to facilitate linkage with other trading systems outside the WCI region (e.g. EU Emission Trading System, Regional Greenhouse Gas Initiative)?

F. Are there additional issues that should be considered to ensure that the cap-and-trade system conforms to the WCI principles?

VII. SUBCOMMITTEES

In order to carry out their mission, the Partners have established five subcommittees which are briefly described below. Section VIII of this work plan provides a more detailed description of the subcommittee work plans.

Reporting Subcommittee. The mission of the Reporting Subcommittee is to identify and/or develop a consistent mechanism for mandatory reporting of GHG emissions that will provide the measurement and accounting structure for the regional cap-and-trade program to be developed and implemented by the WCI. The Reporting Subcommittee is chaired by Jim Norton of the State of New Mexico.

Scope Subcommittee. The Scope Subcommittee will recommend the scope and points of regulation for the cap-and-trade program, with the exception of the electricity sector which is being assessed by the Electricity Subcommittee. The Scope Committee is chaired by Michael Gibbs of the State of California.

Electricity Subcommittee. The Electricity Subcommittee will recommend the scope and point of regulation for the electric sector. The Electricity Subcommittee is chaired by David Van't Hof of the State of Oregon.

Allocations Subcommittee. The Allocations Subcommittee will recommend options for establishing emissions allowance budgets in each Partner jurisdiction, as well as how to distribute allowances within Partner jurisdictions among covered sectors and sources within each sector. The Allocations Subcommittee is chaired by Steve Owens of the State of Arizona.

Offsets Subcommittee. The Offsets Subcommittee will make recommendations on the inclusion, design, scope and operation of the greenhouse gas offset system as an element of the cap-and-trade program. The Offsets Subcommittee is chaired by Tim Lesiuk of the Province of British Columbia.

In general, the Subcommittees will carry out the following tasks:

- *Information Gathering and Learning*. Each Subcommittee will take primary responsibility for gathering information and learning about the Subcommittee's areas of focus.
- *Identify Policy Questions*. The Subcommittees will collectively identify the relevant policy questions that should be assessed in order to develop design recommendations for the cap-and-trade program.
- *Evaluate Policy Options.* Each Subcommittee will evaluate potential approaches for within the Subcommittee's area of focus. The Subcommittees will present these potential options together with an explanation of the benefits and challenges associated with each approach.
- *Propose Policy Decisions*. The Subcommittees will make policy recommendations within their focus areas for consideration by the Partners.

Based on the work of the subcommittees, the Partners will develop a proposal containing all key elements of a regional cap-and-trade program for review and comment prior to reaching final agreement on the recommendations for program design.

VIII. SUBCOMMITTEE WORK PLANS

A) Reporting Subcommittee

i. Mission

The mission of the Reporting Subcommittee is to identify and/or develop a consistent mechanism for mandatory reporting of GHG emissions that will provide the measurement and accounting structure for the regional cap-and-trade program to be developed and implemented by the WCI. This reporting mechanism will be consistent with the protocols of The Climate Registry (TCR) and utilize TCR to the maximum extent possible. It will also echo or align with existing or emerging reporting systems within partner jurisdictions to the greatest degree possible. It is anticipated that this reporting mechanism will form the basis of regulations to be adopted or updated by all partner jurisdictions with respect to the reporting of GHG emissions.

In developing this mechanism, the subcommittee will likely need to design a reporting system that balances multiple objectives, consistent with the design principles laid out in Section II, and reflects key decisions of other subcommittees.

The subcommittee may consider a phased-in approach for reporting that mirrors any phase-in that may be employed for including sectors and sources under the cap or as part of an offset provision, so that the reporting system may encompass additional sectors, sources, or GHGs over time.

ii. Tasks

Task 1: Identify the roles, objectives and principles that will guide design of the reporting mechanism.

The subcommittee will need to consider the full range of potential roles and objectives for reporting within the WCI program. While the primary objective is to provide the measurement and accounting system for emissions that will allow partner jurisdictions to assess the compliance of sectors and sources under the cap within their regions, there are other possible roles for a reporting system that should be considered. These include gathering data that could be used to assess early reductions, preparing sectors and sources that are not initially covered by the program for eventual inclusion, informing decisions about expansion of the program or the allocation of allowances, monitoring offset project performance, etc. Early decisions from other subcommittees will be critical to identifying additional objectives.

The subcommittee will also need to identify what principles will be employed in balancing multiple objectives. In addition to the overall design principles in Section II above, the subcommittee will need to consider factors such as the availability of credible quantification approaches for any given sector or source, the reporting burden associated with including a given sector or source, tradeoffs between the cost and rigor associated with employing a given quantification approach, etc.

Task 2: Identify and assess existing reporting systems that can inform development of a WCI reporting mechanism.

A number of credible reporting systems exist, both within the WCI region and outside, that can be drawn upon in developing a uniform WCI reporting mechanism. The subcommittee will identify and assess these systems, comparing them on the basis of a range of key design decisions. This process will both inform how the key objectives identified in task 1 can be met and identify those sources and sectors for which reliable quantification and reporting exists, and those for which the subcommittee would need to develop such guidance. The analysis will focus at a minimum on existing and emerging systems within the WCI region, but may also examine reporting systems in other regions and nations. One key output of this task will be a comparison matrix that summarizes the key features of existing reporting systems.

Task 3: Ensure that the WCI reporting mechanism aligns with existing and emerging mandatory GHG reporting rules and The Climate Registry.

Of particular importance will be identifying how the WCI reporting mechanism can be aligned with existing reporting systems and ongoing rulemaking processes in the WCI region. The strategy developed in this task will also identify options for how updates to the WCI reporting mechanism (if a phase-in is employed) are expected to be rolled out and incorporated by partner jurisdictions.

Task 4: Frame key elements of a WCI mandatory GHG reporting mechanism and identify options for sectors and sources that could be included.

This task will center on developing an outline for a reporting mechanism that includes a range of options as to key reporting parameters. These options will be based on existing reporting programs assessed in Task 2 and objectives identified in Task1. The outline will also include a list of proposed sources and sectors for which reliable and practicable quantification guidance exists and which should be included in the reporting mechanism, based on input from other subcommittees.

Task 5: Consider whether a model rule should be developed, and if so, what it should include and what its development schedule should be.

Based on input from other subcommittees and feedback from stakeholders on the outline, the subcommittee will consider the development of a model rule that includes at a minimum, all sources and sectors to be included in the initial phase of a WCI cap. Any such model rule will utilize TCR to the greatest extent possible and will align with existing and emerging reporting programs to the greatest degree possible. It may also include reporting provisions developed by the Offset Subcommittee around offset projects and other sectors and sources that are identified for eventual inclusion in the WCI program, to the extent that reliable methodologies are identified. Any draft model rule developed will be refined based on stakeholder feedback, as appropriate.

Task 6: Identify expected updates to the WCI reporting mechanism.

Based on input from the Scope Subcommittee and any concrete plans for expansion of the WRI program, the Reporting Subcommittee will develop a plan for updating its reporting mechanism over time. This will involve identifying and prioritizing additional sectors/sources for inclusion in the mechanism, as well as a process for developing reliable reporting methodologies where none exist. The subcommittee will also work to develop a schedule for the development of these updates.

iii. Coordination with Other Subcommittees

Reporting of GHG emissions and reductions will ultimately form the basis for evaluating progress toward meeting WCI goals and compliance for covered sources. Key input from the Scope Subcommittee and the Electricity Subcommittee will be necessary to achieve this goal. The reporting rule could also be designed to collect data for the purposes of monitoring offset projects or informing other aspects of the WCI program, such as offset baselines, expansion of the cap, allocation of allowances etc. Accordingly, the Reporting Subcommittee will have to coordinate closely with the other subcommittees and require their input, almost immediately.

Areas for coordination include:

- Scope: The Scope Subcommittee will need to provide guidance on gases and sectors covered (including thresholds) and points of regulation, and coordinate with the Reporting Subcommittee on developing a schedule for including sectors/sources where credible quantification methodologies are not readily available.
- Offsets: Offset reporting rules and eligibility requirements will need to be propagated to WCI partners, perhaps as a component of the reporting mechanism; reporting in some sectors might also be included in an initial model rule in order to inform baseline development for future offset development.
- Allocations: The emissions reporting mechanism, as well as future transaction processing systems, will need to be closely aligned to ensure reconciliation of emissions and allowances in determining compliance of covered sources.
- Electricity: The Electricity Subcommittee will need to provide direction to the Reporting Subcommittee on the nature and details of an approach for capturing emissions from this sector both within the WCI region and outside.

B) Scope Subcommittee

i. Mission

The mission of the Scope Subcommittee is to recommend the scope of a proposed cap and trade program. The scope must be defined so that the following are clear:

- The sectors that fall under the cap.
- The emissions sources that fall under the cap.
- The greenhouses gases that fall under the cap.
- The point(s) of regulation where the cap would be enforced.

From the scope definition, any entity or facility must be able to tell whether it has a compliance obligation under the cap, and which of its emissions are subject to the obligation.

To make this recommendation, the subcommittee must balance multiple objectives, consistent with the design principles presented above.

The subcommittee acknowledges that phasing over time may be considered, so that the program scope can encompass additional sectors, sources, or GHGs over time.

The subcommittee will examine all sectors, sources, and GHGs with the exception of the electric sector (which is being addressed in a separate subcommittee). "Sector" refers to all elements of the economy, including residential, commercial, industrial, transportation, forestry, waste management, agriculture, and others. Sources refer to the activities that create emissions, including fuel combustion, process emissions, and fugitive emissions. GHGs refer to the full set of Kyoto gases, including carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6).

ii. Tasks

Task 0: Emissions Inventory Dataset

The purpose of this task is to develop an emissions inventory dataset that the subcommittee can use in its assessment of the implications of including/excluding sectors, sources, and GHGs from the proposed scope. To support the Scope Subcommittee's deliberations, the subcommittee directs that the data include the following:

- Geography: The data are required for the WCI partner and observer states and provinces. To put the region into context, the other states and provinces in the west should be included. If possible, the states and provinces in the Western Electric Coordinating Council would be appropriate to cover, in part to be consistent with the Electricity Subcommittee work.[2] As a reference, the national totals for the United States, Canada, and Mexico would also be valuable.
- Time Period: The data should be summarized for a range of years, such as 1990-2020.
- Sectors: The data should divide the emissions into major sectors that can be considered as options for coverage.
- GHGs: The data should summarize each of the six Kyoto GHGs.

[2] The WECC includes: British Columbia; Alberta; Washington; Oregon; California; Idaho; Utah; Nevada; Arizona; New Mexico; Colorado; Wyoming; Montana; and Baja California.

The level of detail and the categories included will be driven by the available data. The data, including both emissions totals and estimates of the number of entities with potential compliance obligations, will facilitate the Scope Subcommittee's initial deliberation regarding the implications of alternative scope definitions.

Additional detail may be needed to focus on specific alternatives. For example, we may want to collect additional detailed data on emissions from industrial natural gas consumption to set a size or emissions cut off for inclusion in the scope.

Task 1: Initial Options for Consideration

The purpose of this task is to define a short list of major options that will be considered. While there is a very broad range of possibilities, several realities narrow the field, including (*inter alia)*:

- The significance of sectors/sources in the overall inventory (regionally, and within individual states/provinces);
- The inability to measure/monitor emissions adequately to support inclusion in a cap and trade program (e.g., some fugitive emissions and certain process emissions);
- The existence of reasonable points of regulation capable of addressing the sector/sources;
- The existence or expectation of other regulatory approaches for the source/sector.

There are multiple resources available to use for this task, including the Market Advisory Committee (MAC) Report from California,[3] U.S. EPA Guidance on the design of cap and trade programs,[4] the Nicholas Institute report on reporting thresholds for greenhouse gas emission regulation,[5] and many academic and related reports.

The output from this task will be a set of three to five major options that will be evaluated more thoroughly. Table 1 provides an initial list of options for program elements that can be used to initiate the Scope Subcommittee's discussions. This list was developed based on a review of background material regarding the design of cap-and-trade types of programs for greenhouse gases. The list includes most, if not all, of the major program elements that have been discussed in recent years.

Each of the options in Table 1 defines a set of sources and GHGs that may be considered for coverage. Some of the elements can be combined into a program that covers multiple elements, while others are mutually exclusive and cannot be combined. In all cases, the consideration of options for covering the electric sector is deferred to the Electricity Subcommittee.

---

[3] *Recommendations for Designing a Greenhouse Gas Cap-and-Trade System for California*, Recommendations of the Market Advisory Committee to the Air Resources Board, available at: http://www.climatechange.ca.gov/documents/index.html.
[4] *Tools of the Trade: A Guide To Designing and Operating a Cap and Trade Program For Pollution Control*, U.S. Environmental Protection Agency, available at: http://www.epa.gov/airmarkets/resource/cap-trade-resource.html.
[5] *Size Thresholds for Greenhouse Gas Regulation: Who Would be Affected by a 10,000-ton CO2 Emissions Rule?*, the Nicholas Institute for Environmental Policy Solutions, Duke University, available at: http://www.nicholas.duke.edu/institute/knowledge-energy.html.

Table 1 represents a starting point for discussion. Additional options may be defined and considered as part of the subcommittee deliberations, and through public input and comment.

Task 2: Description of Each Major Option

The purpose of this task is to prepare detailed descriptions that flesh out each of the major options being considered. The descriptions would include:

- General description of the option, including the sectors, sources, and GHGs covered, and the point(s) of regulation.
- Estimate of the portion of the total emission inventory included, with estimates for each state and the region as a whole.
- Estimate of the number of entities expected to have compliance obligations, by state and for the region as a whole. If possible these data should be estimated by sector.
- Assessment of the potential interactions with other regulatory initiatives or programs, including other initiatives reducing GHG emissions.
- Administrative complexity and burden.

The output from this task will be a detailed description of each major option, which will be released for public review and comment.

Task 3: Option Evaluation

The purpose of this task is to evaluate each of the major options using the detailed descriptions. The program design principles will be the starting point for the evaluation criteria to use. Additional criteria may be identified by the subcommittee and may come from public input and comment. Prior to evaluating the options, the subcommittee will produce a public review draft of the evaluation criteria for review and comment.

This evaluation will consider whether there is flexibility for states/provinces to vary in their implementation of the option. This evaluation will identify those aspects for which flexibility is possible, and those aspects for which identical implementation is necessary.

The output of this task will be a summary evaluation of the pros and cons of each of the major options, which will be released for public review and comment.

Task 4: Option Recommendation

The purpose of this task is to develop a consensus recommendation from the Scope Subcommittee. The draft of the recommendation will be presented for public review and input, including the factors that were important in making the decision.

iii. Coordination with Other Subcommittees

There are several key points where the Scope Subcommittee will need to coordinate with the other subcommittees:

- The Scope Subcommittee's assessment of which sources can be measured/monitored adequately for purposes of inclusion in a cap and trade program should be consistent with the Reporting Subcommittee's findings on which sources can report emissions.
- Prior to making a recommendation, we will review the Scope Subcommittee's major options with the Electricity Subcommittee to identify any inconsistencies or conflicts.
- The Offsets and Allocations Subcommittees require an understanding of the major options under consideration by this subcommittee.

Table 1: Initial Program Design Elements for Public Comment and Discussion

Elements	Sectors[1]	Sources	GHGs	Comments
A. Large stationary combustion sources regulated at the point of emission.	All large stationary sources, including oil refining and other industrial facilities.	Fossil fuel combustion in stationary equipment only.	CO_2 only. Could be expanded to other combustion related GHGs (N_2O and CH_4).	This is a downstream option, similar to traditional pollution control programs. Typically an emissions threshold is used to exclude small sources.
B. Liquid fuels (**i.e., transportation fuels)** regulated upstream where they enter into commerce (i.e., upstream at the "terminal rack" or the point of refining or import of refined products).	This can be focused on transport sectors, including fossil fuels used in some or all of: on-road vehicles; off-road vehicles; air; marine, rail.	Liquid fossil fuel combustion.	Addresses CO_2 emissions. (Indirectly affects N_2O and CH_4 emissions from fuel combustion.)	Upstream approach to capture the transport sector. Note: some liquid fuels are used both in transport and stationary sources. Note also: gaseous fuels and electricity also used in transport.
C. Residential and commercial natural gas combustion regulated at the local distribution company (LDC).	Residential and commercial customers of LDCs.	Natural gas combustion only.	CO_2 only. (Indirectly affects N_2O and CH_4 emissions from natural gas combustion.)	This is a midstream option for covering residential and commercial combustion sites that are too small to be considered large stationary combustion sources.
D. Industrial process and waste management emissions regulated at the point of emission.	Specifically defined industrial processes, such as oil refining, cement production, aluminum smelting, adipic acid production, nitric acid production, lime production, natural gas transmission and distribution, wastewater treatment; landfill operations; others.	Specific industrial processes.	GHG relevant to each industrial and waste management process.	Downstream option to cover process emissions that can be measured or computed reliably. Wide variety of facility types.
E. Fossil fuel industry regulated at the "facility" level, such as a production field, pipeline, coal mine, or other.	Oil and gas exploration, production, gathering, and processing. Coal mining.	Fugitive and vented emissions. May include emissions from flaring if not covered elsewhere.	CO_2, CH_4	Includes exploration activities, oil and gas production wells, gathering pipelines, gas processing plants and related facilities (such as dehydrators), coal mine ventilation, coal processing.

Elements	Sectors[1]	Sources	GHGs	Comments
F. Fossil carbon content of fuels regulated at the appropriate upstream or midstream choke point for the fuel.	All sectors that use fuels with fossil carbon.	Fossil fuel combustion.	CO_2 only. (Indirectly affects N_2O and CH_4 emissions from fossil fuel combustion.)	"Choke point" option, primarily considered upstream, to cover all fossil carbon emissions.
G. Passenger cars and light duty trucks regulated at the manufacturer sales level.	Transportation sector, covering passenger cars and light duty trucks.	All GHGs from the use of the relevant vehicles, including fuel combustion and refrigerant fugitive emissions.	CO_2, CH_4; N_2O, HFCs	Tradable emission caps associated with the vehicles sold by the manufacturer. May be incompatible with the vehicle emissions intensity standards adopted by CA and others. Requires estimates of vehicle emissions when sold.
H. Large transportation fleets regulated at the fleet management level.	Transportation.	Fossil fuel combustion from fleet vehicles (could be defined as on-road only).	CO_2 only. Could be expanded to other combustion related GHGs (N_2O and CH_4).	This is a focused downstream transport sector option, treating "fleets" like large stationary sources.
I. Agriculture emissions regulated at the producer or "farm" level.	All agricultural sectors.	Livestock, soils (does not include fuel combustion emissions)	CO_2; CH_4; N_2O	Most emissions are diffuse and not conducive to measurement and quantification at the farm level.
J. Forestry and land use change emissions regulated at the land owner level.	Forested lands owned privately and publicly (could be segmented by ownership).	Change in carbon stock on the land.	CO_2	Requires protocols to measure changes in carbon stock relative to baseline conditions over time.
K. Production of high GWP gases regulated at the point of production.	Chemical manufacturing, particularly HCFC-22 production.	Fugitive process emissions.	High GWP gases	Small number of production facilities nationally and internationally.
1. Under all options, the Electricity Subcommittee is assessing how best to cover the electric sector.				

C) Electricity Subcommittee

i. Mission

The mission of the WCI Electricity Subcommittee is to recommend a point of regulation, a market-based compliance mechanism design, and an accounting structure to incorporate the electricity sector into a proposed cap-and-trade program.

ii. Tasks

The Electricity Subcommittee proposes to take on the following tasks:

1. Recommend whether and how an electricity sector market mechanism should include greenhouse gases beyond CO_2.
2. Gather and share information for each partner jurisdiction on (a) historical and projected future sales and emissions from the electricity sector within the partner jurisdiction, (b) historical and projected future electricity imports into the partner jurisdiction, and (c) available data concerning the emissions and ownership attributes of the imported electricity.
3. Establish criteria, evaluate, and propose cap-and-trade compliance option(s), including the point of regulation and compliance structure (e.g., first-seller, hybrid load/source, load based, etc.). Options would focus on structures that maximize coverage of emissions attributable to electricity consumed in the partner jurisdictions, facilitate end-use energy efficiency, and meet other criteria determined by the group.
4. Based on the compliance structures evaluated, develop a consistent regional inventory methodology for CO_2 emissions from the generation of electricity that does not lead to double counting of emissions (e.g. overlapping claims) and provides a robust baseline for a cap-and-trade system.
5. Propose detailed design elements specific to an electricity sector cap-and-trade structure, including those design elements that should be consistent across states and provinces.

iii. Emissions Scope

Electricity sector emissions are tentatively defined as the greenhouse gas emissions from all generating plants that serve WCI Partners, including generation outside the borders of the WCI Partners that serve end users in WCI states and provinces.

iv. Coordination with Other Subcommittees

This committee will work closely with the Scope Sub-Committee, but as a starting point for the work of this committee we will assume the Scope Sub-Committee will not recommend upstream regulation at the point of entry of fossil fuels into the WCI region. However, this possibility is recognized. For example, the WCI Partners might choose to regulate upstream CO_2 and methane emissions from facilities that provide fuel for generating plants (e.g., coal mines and liquefied natural gas import facilities).

Close coordination with the Allocation Sub-Committee will also be needed. An electric cap-and-trade design proposal, the potential allocation of free allowances and the potential distribution of revenues from allowance auctions could affect the distribution of benefits and costs among the WCI Partners if such a system were implemented. Also, allocation decisions could affect the program's ability to accomplish end-use energy efficiency, a key element in reducing greenhouse gas emissions from the electric sector.

Finally, the accounting structures and methodologies evaluated (proposed), as well as cap-and-trade designs, will have numerous implications for the Reporting Committee.

<u>D)</u> ***<u>Allocations Subcommittee</u>***

i. Mission

The mission of the WCI Allocation Subcommittee is:

1. To recommend a methodology for determining the number of allowances to be apportioned, either individually to each WCI partner and thereby establishing each Partner's overall emissions allowance budget for the WCI program, or regionally for the WCI region overall; and
2. To determine whether to recommend that the Partners establish a common method for distributing the budgeted emissions allowances (a) among covered sectors; and (b) within each sector to covered entities. If a common allowance distribution method is recommended, the Subcommittee will recommend a distribution method or methods for consideration by the WCI Partners.

ii. Tasks

To accomplish its mission, the Subcommittee proposes to take on the following tasks:

1. Identify the Subcommittee's preliminary information needs.
2. Before deliberating on potential options for establishing the budgeted allowances (for either the WCI region overall or each individual Partner), and recommending whether and how to distribute allowances within covered sectors and entities, the Subcommittee will develop recommended design principles to guide the Subcommittee in its deliberations.
3. Determine whether an allowance budget should be established for each WCI Partner individually or whether a regional allowance budget should be set for the WCI region overall with allowances allocated to sectors within the region.
4. Develop and recommend a methodology for determining the amount of overall allowances to be apportioned either regionally or to each WCI Partner's allowance budget.
5. Determine whether and what to recommend concerning how individual allowance budgets should be divided among individual sectors within the WCI region or each Partner jurisdiction (i.e. establish specific allowance budgets for each sector within each the WCI region overall or each Partner jurisdiction.
6. Determine whether and what to recommend concerning how allowances are distributed, either by each Partner throughits allowance budget(s) or regionally by sector within the WCI region overall, including:
    - Examine existing approaches and evaluate, at a minimum, the following options: distribution by:
        - free allocation;
        - auction; and
        - a hybrid of free allocation and auction.

- If a free allocation methodology is recommended in whole or in part:
    - Recommend the parties to whom the allowances will be allocated (i.e., emitters only, consumers, product generators/producers, and/or governmental entities);
    - Recommend a formula for calculating the allowances to be allocated to each covered entity, considering:
        - The factors on which the allocation of allowances should be based (i.e., emissions, fuel or other input, product output and/or some other benchmark); and
        - The baseline for the allocations (i.e., based on a single year emissions, an average of multiple years' emissions, or the maximum emissions over a period of years) and whether the baseline should be updated periodically.
- If an auction is recommended, in whole or in part:
    - Recommend the percentage of allowances to be auctioned;
    - Recommend criteria/parameters for uses of the funds generated by the auctions; and
    - Recommend such other auction design parameters as the Subcommittee deems appropriate, for example a reserve price, specific timing of auctions and/or eligibility for participation in the auctions, etc.

7. Determine whether the method used for allocating allowances (i.e. free, auction or hybrid) should be the same for all sectors or may/should vary by sector.

8. Determine whether the amount of allowances allocated to each sector and/or WCI Partner should decline, and if so, at what rate and pace.

9. Determine whether and what to recommend concerning how appropriate recognition and incentives for early emissions reductions can/should be considered in distributing allowances.

10. Determine whether banking of allowances should be permitted, and if so, the criteria and condition for banking, including:
    - The length of time for which allowances may be banked; and
    - The amount of allowances that may be banked;

11. Determine whether borrowing of allowances should be permitted, and if so, the criteria and condition for borrowing, including:
    - The length of time for which allowances may be borrowed;
    - The amount of allowances that may be borrowed; and
    - The rate of repayment of borrowed allowances (i.e., 2 for 1)

iii. Working Process

General Approach

- Subcommittee members and technical staff will develop one or more working documents to frame and evaluate various options for apportioning Partner allowance budgets and allocating emissions among covered sectors and entities within Partner jurisdictions.
- A plan for soliciting input from stakeholders will be developed in connection with the pending discussion on stakeholder involvement by the committee as a whole.
- The subcommittee will forward one or more straw proposals and will include an evaluation of the preferred and other options for the WCI Partners to consider.

iv. Gathering Information Gathering and Support Resources

- Data. Regarding apportionment to each state, and after conferral with the Scope Subcommittee, the baseline emissions for all Partners from the proposed sectors to be developed with the data group. A series of allocation algorithms will allow members to look at the allocations in various ways.
- Expertise. The group will generate a list of useful experts to offer presentations on a bi-weekly basis (as needed). Include discussions with people with expertise in other emissions trading systems: for example, the U.S. EPA Acid Rain Program, the Northeast NOx Emissions Trading Program, the Irish program,, the UK Emissions Trading Scheme and also their auction experience, RGGI, the EU/ETS.
- Consultants. The subcommittee will identify projects and consultants that it may need to perform its missions and develop a proposed subcommittee budget that identifies the potential costs for this assistance.

v. Coordination with Other Subcommittees

- The Allocations Subcommittee will need to work closely with the Scope Subcommittee, to settle on the sectors among which reduction targets will be set based on which sectors are included in the program.
- The Allocations Subcommittee will also need also need to work jointly with the Electricity Subcommittee.

E) Offsets Subcommittee

i. Mission

The mission of the WCI Offsets Subcommittee is to make recommendations on whether to include a greenhouse gas offset mechanism as an element of the Western Climate Initiative cap and trade system, and, if so, on the design, scope and operation of such a mechanism.

ii. Tasks

Task 1: Role and objectives of a WCI offset mechanism

This task involves the development of clear definitions of an offset, the role of a WCI offset mechanism, and the objectives that will guide its design in the overall WCI cap-and-trade system.

The subcommittee will examine a number of potential roles an offset mechanism could play in the WCI including economic, environmental and social aspects of a cap and trade system that may influence or be influenced by an associated offset mechanism. Potential roles may include:

- Encouraging emission reductions and other benefits across the economy
- Distributing economic and environmental benefits of emission reductions across the economy
- Enabling the Partners to achieve more aggressive reduction targets than would otherwise be technologically or economically possible at capped entities alone
- Containing overall costs and competitiveness concerns for emitters and WCI partners
- Maintaining or enhancing the environmental integrity of the regional cap and trade system.

The subcommittee will also review and determine design objectives that should guide the development of a potential WCI offset mechanism and may include:

- Spurring innovation outside the regulated sectors
- Providing incentive for partnership in the WCI
- Enhancing market liquidity
- Minimizing administrative complexity, fees and transaction costs (managing barriers to entry)
- Providing environmental and social co-benefits
- Ensuring transparency
- Avoiding unintended outcomes, including negative interaction with current and future government policies

As part of this task, the subcommittee will also outline broad options that could frame the overall role and contribution of offsets to meeting compliance obligations and containing overall costs, including whether and what types of quantitative limits might be considered.

Task 2: Core design elements of a WCI offset mechanism

This task involves the development of specific technical criteria and/or requirements for projects that may be eligible in the WCI offset mechanism, and to translate into practice the WCI design principle that reductions be real, surplus/additional, verifiable, permanent, and enforceable.

The subcommittee will review potential design elements and optional aspects of those design elements including:

- Components to ensure reductions are real
- Ways to show projects or actions satisfy the principles of being surplus to other requirements and additional/incremental
- Methods to measure quantify and report emission reductions (baseline and monitoring methodologies)
- How to establish the boundary of a project and ways to account for leakage or increases in emissions outside the boundary
- How long carbon must be stored, biologically or geologically, to be considered permanent, and what tools and procedures should be used to address the loss of stored carbon from offset projects
- Ways to simplify accounting and use comparable accounting approaches across project types
- Ways to provide adequate assurance that project activities and emissions reductions or removals are taking place as claimed (validation and verification)

The subcommittee has anticipated some of the basic design criteria that will need to be reviewed and will seek input on additional design criteria as required and considered.

Task 3: Offset eligibility and fungibility

This task involves the development of any specific criteria and/or requirements that will determine the offset project types and locations, and, if relevant, other existing tradable emission commodities from other regional or international programs that would be eligible within the overall system.

The subcommittee will review a) offset project types and locations (WCI region, North America, global) and b) existing tradable emissions commodities with respect to the robustness of quantification and verification protocols, environmental integrity (permanence, leakage, incrementality/additionality), potential interaction with existing and future policies and regulations, and ability to contribute to WCI goals and principles. As part of this review, the subcommittee will examine the eligibility decisions taken in other mandatory compliance jurisdictions and their rationale. The subcommittee will also review options for eligible project start dates, and the crediting periods over which the project developers can expect to benefit from offset revenues.

Decision options may include one or more of the following:

- Determination of offset type (or commodity) eligibility subject to the availability of sufficiently robust quantification and verification protocols.
- Specification of the process by which the adequacy of protocols is determined, i.e. by the WCI itself or by other programs or standards (see also Task 4).

- Preferences and/or restrictions on eligible project and commodity types and/or locations, based on goals, principles and design elements (as developed in the Tasks 1 and 2), in addition to the robustness of protocols. (The subcommittee may also consider the possibility of rewarding or discounting specific project types or locations)
- Determination of eligible project starting date, i.e. the earliest date at which the implementation of a project activity could begin (or have begun) in order to qualify.
- Establishment of offset crediting periods, specifying the time period over which project emission reductions would be verified and/or certified, and, if relevant, offset credit expiration dates

Task 4: Offset program structure and authority

This task involves the development of operational guidelines and recommended program structure and authority to oversee and manage an offset mechanism, if and as appropriate depending on the recommendations developed above regarding the extent to which the WCI should administer its own offset program or to otherwise develop specific (e.g. minimum) criteria.

The subcommittee may consider, among other issues:

- Procedures for project validation and verification, approval of validators/verifiers, and whether appropriate and sufficient protocols are currently available.
- The process for registering and/or certifying offsets, issuing credits and maintaining transaction records
- How initial and ongoing operational questions, such as adequacy of project documentation, certification or accreditation of operational entities would be addressed and decided, including which activities should be left to third parties or other institutions.
- The institutional requirements related to the above tasks, and how that influences the path forward

iii. Coordination with other subcommittees

The Offsets Subcommittee will:

- Coordinate with the Reporting Subcommittee in the development of validation, verification and reporting requirements for the offset mechanism;
- Reflect the recommendations of the Scope Subcommittee in the definition of offset mechanism boundaries and in determining eligible project types;
- Ensure the recommendations of the Scope, Allocation and Electricity Subcommittees do not lead to double counting, gaming or perverse incentives when implemented in coordination with the offset mechanism (or vice-versa).

Allocations Subcommittee

Stakeholder Discussion Document

The WCI Allocations Subcommittee is studying the program design options governing the apportionment of allowances among the participating states and provinces, or Partners, and the distribution of allowances to covered sectors and entities. In addition, the committee is considering options for accomplishing the WCI mandate to “provide appropriate recognition and incentives for early emissions reductions.” The Allocations Subcommittee will consider additional program design requirements after guidance is received from other subcommittees on key questions currently under consideration.

The Allocations Subcommittee seeks to recommend a program design that maximizes program simplicity, minimizes unfair competition among covered industries across the region, provides for state and provincial flexibility, promotes consistent regional program standards and methods, recognizes early emissions reduction actions, maximizes the program’s GHG reduction potential and avoids undue economic impacts on consumers and industries. Some of these goals are potentially in conflict therefore the Subcommittee seeks recommendations that achieve the best balance between them.

The Allocations Subcommittee seeks Partner, observer, stakeholder and public input regarding these options. The issues and questions identified below identify several advantages and disadvantages for each option. The Subcommittee welcomes comment on these questions including additional advantages and disadvantages and other options not identified here. Commenters are encouraged to fully discuss the reasoning behind each response.

1. ***Apportionment of Allowances –*** Apportionment means the subdivision of the regional cap and trade emissions cap among the participating jurisdictions[1]. The question here is whether each Partner should be authorized to distribute allowances equal to that Partner's share of the regional cap, or, whether a regional entity should distribute allowances on behalf of all the Partners without apportioning the regional cap among them.

   a. ***Should allowances be distributed centrally, without apportionment to Partners?***

Advantages
• Reduces the need for a framework to prevent "over allocation" by Partners
• Reduces disputes between Partners over apportionment 'amounts'
• Partners establish regional and possibly sector 'cap(s)', but individual Partner 'caps' are not required
• Centralized distribution increases administrative efficiency
• Ensures equity among same-industry competitors throughout region

Disadvantages
• All Partners must agree on distribution method(s), including allocation among sectors (if required)
• Could require 'regional entity' to assume greater authority
• If allowances are sold, Partners would not have unilateral authority over the sale, and sale proceeds would go to Partners indirectly

   b. ***Or, should allowances be apportioned to, and distributed by Partners individually?***

Advantages
• Partners are free to choose the degree of distribution consistency across the region
• Allows a more conventional role for the regional organization
• Partners receive allowance sale proceeds directly

Disadvantages
• Increases the risk that inconsistent distribution methods create an unfair competitive situation among covered entities across the region
• Decentralized distribution is administratively inefficient
• Partners must agree on the basis of apportionment and potentially individual Partner 'caps'

   c. ***Or, should some combination of centralized distribution and apportionment be pursued?***

   d. ***ISSUE: The Allocations Subcommittee recognizes that centralized distribution will require more intensive cooperation and a different approach to the exercise of provincial, state and tribal authority. Comments, observations and recommendations are being sought to assist the committee with mechanisms for design and implementation of a regional allocation system.***

---

[1] Each of the WCI states and provinces has adopted (or is adopting) an economy wide goal for reducing its greenhouse gas emissions. The cap-and-trade program is expected to be one of the policies used by the states and provinces to achieve their regional and individual economy-wide goals. Given that only a portion of total emissions will be covered by the cap-and-trade program, a method is required to set the cap-and-trade program cap either regionally or for each state and province.

2. ***Distribution of Allowances –*** Distribution or allocation of allowances means the process by which emissions allowances are distributed for use by covered sources under an emissions cap and trade system. The question here is to what degree distribution by the Partners should be made uniform, or standardized, among participating jurisdictions.

   a. ***Assuming allowances are distributed by Partners, should distribution methods be standardized?***

Advantages
• Reduces the need for a framework to prevent "over allocation" by Partners
• Promotes equity among same-industry competitors throughout region
• Promotes consistency among sectors throughout the region
• Promotes greater consistency among the standards and rules applied across the region

Disadvantages
• Partners must agree on distribution methods
• Partners will find it more difficult to tailor distribution methods to accommodate unique circumstances within their internal sectors
• Standardized distribution requires all Partners to secure legislative or other approvals without allowance for dissimilar results

   b. ***Assuming allowances are distributed by Partners, should distribution methods be left to each jurisdiction to decide?***

Advantages
• Partners are free to establish individual distribution methods, allowing legislatures to adopt dissimilar programs and allowing state or province-specific issues to be individually addressed
• The regional program can be enacted without the Partners agreeing on distribution methods

Disadvantages
• Increases the risk that inconsistent distribution methods create an unfair competitive situation among covered entities across the region
• Increases the risk that individual Partner distribution decisions will seek a competitive advantage for particular industries or sectors
• May require creation of regional entity with authority to approve or deny Partner distribution plans to enforce minimum standards of consistency or as a check against the concern raised immediately above

   c. ***Or, should some flexibility be allowed within prescribed limits beyond which all Partners must adopt the same distribution system?***

   d. ***ISSUE: The Allocations Subcommittee recognizes that there are many more detailed questions concerning the distribution of allowances than are asked here. The subcommittee anticipates seeking comment on these questions at a later time.***

   e. ***ISSUE: The Allocations Subcommittee recognizes the special challenges associated with the development of a regional system that could successfully merge into a future national program, and the additional complications of developing a single regional program that can accomplish this in two nations. The subcommittee seeks comments on how to ensure that the proposed and potential future programs will function well together.***

3. ***Allocation Methods –*** There are multiple ways allowances can be distributed or allocated for use by covered sources. The question here is whether and to what degree allowances should be distributed directly to covered sources free of charge.

   a. ***Assuming there is centralized distribution or at least partial standardization of decentralized distribution, should some of the allowances be distributed directly to covered entities free-of-charge?***

Advantages
• Covered entities with fixed contracts or which are otherwise unable to pass-through the allowance cost would be protected from economic hardship
• Covered entities that are price-regulated would be able to comply without seeking to pass the allowance cost along to the consumer

Disadvantages
• Partners need to develop a basis for free distribution, i.e. 'grandfathering', 'benchmarking', etc.
• Partners may need to provide some reserve or other mechanism to accommodate free distribution for new sources to avoid discouraging investment in new plants
• Many existing covered entities may reap a financial benefit without an associated benefit to consumers or GHG reductions

   b. ***Assuming there is centralized distribution or at least partial standardization of decentralized distribution, should some or all of the allowances be auctioned or otherwise sold?***

Advantages
• All covered entities compete equally for allowances
• Reduced risk of financial windfall for covered entities
• Program design is simplified
• Revenues from the auction or sale are controlled by the state or province and can be used to mitigate any financial impact of the program on consumers. Revenues can also finance investment in complimentary GHG reduction measures, research and development of promising technologies or fund other GHG mitigation or adaptation measures.

Disadvantages
• Covered entities with fixed contracts or which are otherwise unable to pass-through the allowance cost may be exposed to economic hardship

   c. ***Should the allowance distribution system have the capacity to change over the life of the program through phasing in particular distribution methods or using different distribution bases?***

   d. ***Should the Partners place restrictions on the use of revenues from auctioned allowances?***

4. ***Early Actions –*** Any cap and trade system implemented by the WCI Partners will take some time to develop, approve and implement. Sources may see a benefit in delaying investments in GHG emission reductions until the program is underway in order to take full advantage of program incentives or credits. WCI Partners wish to recognize early actions through program design and implementation. The question here is how should the cap and trade program either encourage or hold-harmless emission reductions efforts that occur prior to the start of the program. Of course, all qualifying early actions would have to be quantifiable, verifiable, enforceable and permanent.

    a. ***The WCI Design Principles state that the program will "provide appropriate recognition and incentives for early emissions reductions." Should the program accomplish this:***

        i. ***Through the selection of benchmarking and program start dates?***

        ii. ***Through special allocations of allowances?***
            1. ***Drawn from within the cap?***
            2. ***Drawn from outside the cap?***

        iii. ***Through auctioning of allowances?***

        iv. ***By other means?***

Selection of benchmarking and program start dates
• Careful selection of these dates could hold those undertaking early actions harmless, and could offer incentives to undertake these reductions in advance of the program start.

Auctioning of allowances
• If all covered entities are required to purchase allowances from the market, those undertaking early emissions reductions will avoid the need to purchase those allowances. The avoidance of this cost is an economic incentive equal to the one that exists after the program begins.

Special allocations of allowances
• Special allocations of allowances can create a financial incentive if the distribution to those undertaking early reductions occurs over and above that which otherwise occurs after the program begins. • Such special allocations can be created through an allowance set-aside under the cap, or allowances can be made available to early actors over and above the cap (as has been done by RGGI).

WCI ELECTRICITY SUBCOMMITTEE

<u>Update on Subcommittee Activities and Request for Stakeholder Input</u>
January 2, 2007

To: All Interested Parties

The Electricity Subcommittee of the Western Climate Initiative is pleased to provide this update on its activities and progress to date. The Subcommittee will be taking questions and comments on specific topics at the regional stakeholder meeting on January 10, 2008.

<u>Goals and Activities</u>

The WCI Work Plan issued October 29, 2007 calls on the Electricity Subcommittee to make recommendations to the WCI Partners on the scope and point of regulation for the electricity sector portion of a regional cap-and-trade program. To that end, the Subcommittee has undertaken the following tasks:

(1) <u>Data collection</u>. The Subcommittee has been working to assemble as much available data on electricity generation, sales and "imports" into WCI jurisdictions as possible.

(2) <u>Consideration of emissions scope</u>. The Subcommittee is considering whether and how to cover sulfur hexafluoride (SF_6) emissions from the electric sector along with carbon dioxide (CO_2).

(3) <u>Consideration of point of regulation</u>. The Subcommittee has collected information on the various electricity sector options for point of regulation, including for the following:

(a) Pure Load-based.

(b) Pure Generator-based.

(c) Hybrid system covering both generators and retail providers within the WCI jurisdiction.

(d) Hybrid system covering the “first seller” of “first deliverer” of electricity into WCI Partner jurisdictions.

The attached point of regulation table summarizes the information gathered by the Subcommittee on each of the options under consideration. Please note that table seeks to capture the arguments of both those in favor and those against a particular option. The statements in the table therefore do not represent the conclusions of the Subcommittee as a whole.

Stakeholder Input

The Subcommittee is seeking stakeholder input on the point of regulation table. Specifically, the Subcommittee seeks comments on whether the table is complete in its explication of benefits and challenges associated with each potential approach. The Subcommittee also seeks stakeholder input concerning what overall approach is best for the WCI electricity sector.

Timing for Input

The Subcommittee will receive input from stakeholders during its breakout session on January 10 in Portland, Oregon. In addition, the Subcommittee welcomes written input on the options presented in the table, and requests that input no later than January 22, 2008. Please be careful to submit comments to the attention of the WCI Electricity Subcommittee.

On behalf of the members of the Western Climate Initiative Electricity Subcommittee, we thank you for your interest in our Initiative and very much look forward to your input.

Sincerely,

/s/

David Van’t Hof
Oregon Governor’s
Chair, WCI Electricity Subcommittee

ELECTRICITY SUBCOMMITTEE

SUMMARY TABLE COMPARING DIFFERENT
APPROACHES TO ELECTRIC SECTOR CAP-AND-TRADE
(DRAFT 1/2/07)

Load-Based Approaches		**Generator-Based**	**Hybrid Approaches**	
Allowance Trading	**CO2 Reduction Credit Trading**		**Load-Generator Hybrid**	**First Seller (or Deliverer)**
1. Description of Approaches				
A load-based cap-and-trade program puts the compliance obligation on the retail electricity provider. The retail providers are required to hold sufficient allowances to cover the emissions attributable to the electricity delivered by the RP to its retail customers. *It does not cover exports and may or may not cover self-generation.*	*A load-based CO2 crediting program that does not cap emissions, but rather credits emissions reductions at generating plants in the western interconnect region. Retail providers are then required to retire a certain number of the credits, thereby achieving reductions compared to base year emissions.*	*A generator-based cap-and-trade program places the compliance obligation on the generator of the electricity and the source of emissions. Generators must hold sufficient allowances to cover all of the emissions measured and monitored at each facility.* *It covers all generation within the jurisdiction, including self-generation; it does not cover imports. No jurisdiction over generators on tribal lands.*	*A load-generator hybrid cap-and-trade program combines the key features of the load-based and generator-based cap-and-trade programs. It places the compliance obligation on the generators in the jurisdiction and on the load-serving entities for power originating outside the jurisdiction. Both the generators and retail providers are required to hold sufficient allowances to cover the emissions measured at the stack in the case of the generators, and attributed to the electricity imported in the case of the retail providers.*	*A First Seller cap-and-trade program places the compliance obligation on the first entity to sell electricity in the jurisdiction, whether the electricity was generated inside or outside the jurisdiction. This is either the generator who generates the electricity in the WCI state or province, or the entity selling the electricity brought into the WCI jurisdiction from outside the state or province. The First Seller is required to hold sufficient allowances to cover the emissions measured at the stack in the case of generators, or attributed to the electricity in the case of first sellers.*
2. Where have these approaches been implemented or designed?				
No load-based cap-and-trade programs have been implemented, but designs have been developed in Oregon and California. A description of	*Functions very much like mandatory renewable portfolio standard with renewable energy credit trading.* *A description of this approach is*	*Generator-based cap-and-trade programs have been used to reduce sulfur dioxide and nitrogen oxides emissions from power plants nationally, in the*	*No load-generator hybrid has been implemented, though the RGGI states are exploring ways to implement a load-based program to cover imports*	*The First Seller concept was introduced by the California Market Advisory Committee in its report issued in the spring of 2007. California PUC staff has*

Load-Based Approaches		Generator-Based	Hybrid Approaches	
Allowance Trading	**CO2 Reduction Credit Trading**		**Load-Generator Hybrid**	**First Seller (or Deliverer)**
Oregon's design may be found at: *http://www.oregon.gov/ENERGY/GBLWRM/docs/CATF_Proposal.pdf*	*available* *http://www.westernclimateinitiative.org/ewebeditpro/items/O104F14498.pdf*	*Northeast states, and in Ontario. The EU ETS is the first generator-based cap-and-trade program to be implemented for* CO_2*, and RGGI will be the second such program. Information on RGGI is available at www.rggi.org.*	*alongside a generator-based program.*	*been further refining the concept, and has introduced the term "deliverer" as more accurate and descriptive. A copy of the MAC report is available at:* *http://www.climatechange.ca.gov/documents/2007-06-29_MAC_FINAL_REPORT.PDF*
3. What do proponents consider are the key advantages of each program approach? What disadvantages have been noted for each approach?				
Advantages: ▪ Covers all power delivered through the retail provider including both in-jurisdiction generation and imported power ▪ Retail providers are often in the best position to make investments in energy efficiency, with or without a trading component. ▪ Energy regulatory structure exists for oversight in most states. ▪ Some have suggested that retail providers are regulated to keep prices no higher than necessary, unlike merchant generators, whose prices are set by the market. ▪ A successful WCI load-based program could influence a future federal program.		***Advantages:*** ▪ This approach is relatively proven through experience ▪ Emissions inventory structure exists, and emissions can be measured and tracked with high confidence and transparency. No need for default emissions values. ▪ Generators may be in the best position to make technology changes or upgrades to address	***Advantages:*** ▪ Seeks to cover the gaps of both the generator and load-based approaches by placing point of regulation on both generator emissions and emissions from imports at the retail provider level. This allows each state to account for as many emissions as possible within the sector. ▪ Advantage over a pure load-based approach is that it addresses in-state generation more completely and can cover exports. ▪ Advantage over a pure generator-based approach is that it covers imports. ▪ Provisions for generator-based emissions in a hybrid approach could ease transition to a source-based national program, and facilitate linkage to other programs (e.g., RGGI, EU ETS)	

Load-Based Approaches		Generator-Based	Hybrid Approaches	
Allowance Trading	CO2 Reduction Credit Trading		Load-Generator Hybrid	First Seller (or Deliverer)
	Advantages: ▪ May not require emissions attribute tracking ▪ Similar to renewable energy credit trading	carbon emissions. ▪ Easily linked to other existing programs in the U.S. and internationally. ▪ Clear state or provincial-wide emissions baseline to protect sources in the event of a federal program.		
Disadvantages: ▪ Does not cover electricity generated within a jurisdiction for out-of-jurisdiction consumption ▪ Not likely to be adopted on national level, making transition to federal program tricky ▪ Some international programs may not consider load-based reductions the equivalent of generator-based reductions ▪ Some regulatory gaps may exist with retail providers not under PUC jurisdiction		***Disadvantages:*** ▪ Only covers in-state or in-province emissions from power generation; imports not covered, including “imports” from tribal lands. ▪ If not auctioned, free allowances to the generator may not stimulate end-use energy efficiency and may also create windfall profit opportunities.	***Disadvantages****:* ▪ Complexity: design of the program requires both a generator-based component and an imports component. ▪ In regional context, special care is needed to avoid double-counting of emissions from capped jurisdictions.	

Load-Based Approaches		Generator-Based	Hybrid Approaches	
Allowance Trading	**CO2 Reduction Credit Trading**		**Load-Generator Hybrid**	**First Seller (or Deliverer)**
***Disadvantages**:* ▪ Difficult to accurately track emissions associated with power delivered from out-of-jurisdiction sources and from purchases from power pools or short-term transactions. Default values may create distortions.	***Disadvantages**:* ▪ Does not cap emissions *per se*; regulator must adjust credit retirement requirements to ensure overall reductions ▪ Need to have regional authority create and issue credits or states would have to agree how to allocate CO2RCs to generators outside WCI jurisdictions, making state-by-state adoption more difficult ▪ Potentially large transfer of wealth to generating plants outside region; approaches to deal with this are complicated			***Disadvantages**:* ▪ A potential gap exists in the first seller approach where the federal government is the first seller.

<table>
<tr><th colspan="2">Load-Based Approaches</th><th rowspan="2">Generator-Based</th><th colspan="2">Hybrid Approaches</th></tr>
<tr><th>Allowance Trading</th><th>CO2 Reduction Credit Trading</th><th>Load-Generator Hybrid</th><th>First Seller (or Deliverer)</th></tr>
<tr><td colspan="5">4. What specific factors can affect the relative cost-effectiveness of each approach (i.e., lowest reduction cost at lowest price to consumer)?</td></tr>
<tr><td colspan="2">▪ <u>Regulatory oversight</u>: Most retail provider electricity rates regulated under utility commissions in states and provinces
▪ <u>Regulatory incentives</u>: Retail providers have a direct incentive to invest in energy efficiency and non-fossil generation
▪ <u>Regulatory barriers</u>: interconnection charges, stand-by rate barriers, etc.</td><td rowspan="2">▪ <u>Distribution of allowances</u>: Electricity prices for wholesale power from merchant plants are not regulated. Free allowances would not lower wholesale prices paid by retail providers; however if allowances are auctioned, energy efficiency investments administered by utility (or other entity) could lower costs
▪ <u>Generator-based incentives</u>: to invest in technology changes or upgrades
▪ <u>Administrative costs</u>: may be comparatively lower than other approaches due to existing monitoring and reporting requirements</td><td colspan="2" rowspan="2">▪ <u>Regulatory oversight</u>: Most retail provider electricity rates regulated under utility commissions in states and provinces
▪ <u>Incentives</u>: placed both at the generator level and at the LSEs or first seller (deliverer) level.
▪ <u>Administrative costs</u>: Trading administrator would need to administer the program for both generator-based and load-based entities</td></tr>
<tr><td>▪ <u>Perverse incentives</u>: For wholesale power purchases assigned non-specific emission rates, plants supplying this power may face incorrect incentives</td><td></td></tr>
</table>

<table>
<tr><th colspan="2">Load-Based Approaches</th><th rowspan="2">Generator-Based</th><th colspan="2">Hybrid Approaches</th></tr>
<tr><th>Allowance Trading</th><th>CO2 Reduction Credit Trading</th><th>Load-Generator Hybrid</th><th>First Seller (or Deliverer)</th></tr>
<tr><td colspan="5">5. Will the model effectively cover emissions associated with all of the power consumed in the WCI jurisdictions (i.e., generated and imported)?</td></tr>
<tr><td colspan="2">▪ Would cover electricity sold in WCI jurisdictions by retail providers.</td><td rowspan="2">▪ Would cover generation in the WCI jurisdictions.
▪ Gaps in coverage include: emissions attributable to electricity generated outside WCI jurisdictions and imported to serve WCI load.
▪ May lead to incremental increases in imported electricity above current levels (i.e. leakage).</td><td rowspan="2">▪ Would cover electricity sold in WCI jurisdictions by retail providers and cover generation in the WCI jurisdiction.
▪ Gaps in coverage include: emissions that are “shuffled” to serve load outside the WCI jurisdiction. Similar to load-based system except that in-jurisdiction generation issues should be resolved.</td><td rowspan="2">▪ Would cover electricity sold in WCI jurisdictions by regulated first sellers and cover generation in the WCI jurisdiction.
▪ Gaps in coverage include: emissions attributable to power sold and delivered by the U.S. federal government (e.g., BPA, WAPA) and, for the states, by foreign government-owned corporations (e.g., Powerex, Comisión Federal de Electricidad).</td></tr>
<tr><td>▪ Gaps in coverage include: non-specific generation in WCI jurisdictions; generation in WCI jurisdictions that serves load outside WCI jurisdictions; and emissions that are “shuffled” to serve load outside the WCI jurisdiction.</td><td>▪ Does not cap emissions per se; requires periodic adjustment to account for growth in electricity demand WECC-wide</td></tr>
<tr><td colspan="5">6. How would the model position WCI jurisdictions and their sources when national programs emerge in the United States and/or Canada?</td></tr>
<tr><td colspan="2">▪ Load-based model for the electricity sector is not transferable to other sectors.
▪ No federal proposals follow the load-based approach, though this could change.</td><td>▪ Generator-based model is transferable to other sectors.
▪ Most federal proposals focus on emitters (generators), though this could change.</td><td colspan="2">▪ Covering all power delivered through the retail provider allows coverage of both native generation and imported power.
▪ The two-component model makes keeping the generator-based component and phasing out the load-based component in the future a viable option.</td></tr>
</table>

Load-Based Approaches		Generator-Based	Hybrid Approaches	
Allowance Trading	**CO2 Reduction Credit Trading**		**Load-Generator Hybrid**	**First Seller (or Deliverer)**
7. Does the model present specific issues related to the allocation of emissions allowances?				
▪ Energy regulatory agency can prevent a regulated entity from charging for an allowance that it receives at no charge; allocations at no charge to regulated entities therefore possible without charge to consumers.				
▪ No need to auction to prevent windfalls to regulated retail providers, though other reasons to auction may exist.	▪ Proposal suggests that some credits could be sold to prevent transfer of wealth to generators outside WCI	▪ Auction of allowances may be required for those suppliers whose rates are not regulated to prevent increased revenues associated with "free" allowances. ▪ In lieu of auction, a direct allocation to energy efficiency providers or consumers is possible to prevent windfall. ▪ In the case of an auction, long-term electricity power purchase agreements may not allow generator to pass on cost of allowances to power purchaser.	▪ Need to devise allocation method that addresses both generators and retail providers.	
8. Does the model have implications for linking with other programs in North America and internationally?				
▪ Not clear whether load-based allowances or credits would be transferable or valid in other markets. ▪ The lack of transparency between emissions and compliance points may be a challenge.		▪ EU ETS follows emissions source model for all sectors. ▪ RGGI follows emissions source approach.	▪ Generator-based component very similar to existing programs. Load-based component could be seen as additional to what other systems provide. ▪ Load-based allowances may not be transferable or valid in other markets	

<table>
<tr><th colspan="2">Load-Based Approaches</th><th rowspan="2">Generator-Based</th><th colspan="2">Hybrid Approaches</th></tr>
<tr><th>Allowance Trading</th><th>CO2 Reduction Credit Trading</th><th>Load-Generator Hybrid</th><th>First Seller (or Deliverer)</th></tr>
<tr><td colspan="5">9. What are the key practical challenges specific to design and implementation of each model?</td></tr>
<tr><td colspan="2">▪ Price of carbon not included in market price – retail providers must track prices and allowances separately which could increase cost and administrative burden. NOTE: this is not necessarily true[1]
▪ New system required to track and report emissions and trades
▪ Need to distinguish co-generation emissions for electricity versus thermal load</td><td rowspan="2">▪ Most design issues have been covered in existing programs as to emissions sources.
▪ Emissions associated with imports and leakage are still being addressed by RGGI.</td><td rowspan="2">▪ Same issues presented by load-based system.
▪ Need to integrate the generator-based program with the load-based component.
▪ Legal challenges may be most difficult in order to treat power equally between two completely separate components.
▪ New system required to track and report emissions and trades</td><td rowspan="2">▪ Need to understand who are the first sellers for each jurisdiction that can be regulated, and what impacts result from not being able to regulate some first sellers.
▪ Unique legal issues may apply since this would include a new class of regulated entities (power brokers and marketers).
▪ Existing administrative requirements to collect and maintain tracking systems may need to be revised</td></tr>
<tr><td>▪ Tracking emissions associated with non-specific wholesale purchases in a timely, accurate, transparent fashion
▪ Administrative determination of default emission factors</td><td>▪ Regional entity required to issue and allocate credits
▪ May have to rely on federal data reporting requirements and federal quality control, unless WCI jurisdictions imposed reporting requirements on generators as a condition to getting CO2RCs.</td></tr>
</table>

[1] The 'challenge' embodied in this item comes down to the fact that retail providers would have to evaluate 2 factors when selecting bids: the cost and the allowance, in addition to the other performance elements of a proposed resource. The greater the number of factors, the more complications in the selection. While this may not be a top issue at the moment, we should identify it so that all are aware of the issues.

10. What crosscutting considerations need to be addressed under any cap & trade approach?
▪ Emissions tracking - need system and improved reporting ▪ Linkages to other programs ▪ Leakage and contract shuffling issues ▪ Legal issues affecting interstate or international trade and commerce ▪ Interchangeability and transparency of discrete state/provincial program elements and allowances structure, i.e. what is the impact on costs and trading if states have differing targets, hence difference costs of producing allowances ▪ Allowance verification and compliance protocols among partner programs ▪ Use of allowance revenues ▪ Addressing the potential for program redundancy and double counting with related regulatory programs ▪ Inclusion of electricity transmission line losses is a cross-cutting issue.

Scope Subcommittee

January 2, 2008

Summary of Major Design Options Under Consideration

This paper presents the major design options under consideration by the Scope Subcommittee. The mission of the Scope Subcommittee is to recommend the scope of a proposed cap-and-trade program, defining:

- The sectors that fall under the cap-and-trade program.
- The emissions sources that fall under the cap-and-trade program.
- The greenhouse gases that fall under the cap-and-trade program.
- The point(s) of regulation where the cap-and-trade program would be enforced.

To develop options for the program scope, the Scope Subcommittee defined individual design elements for consideration. The list of the design elements was released for public review and comment as part of the WCI work plan (see www.westernclimateinitiative.org).

The Scope Subcommittee is assessing the feasibility of including the design elements as part of the program scope. A brief description of each of the design elements is presented below, starting on page 4. While each of the design elements remains under consideration, the subcommittee's preliminary analysis has been used to identify design elements that appear to be feasible to include in a cap-and-trade program in the near term. These design elements include:

- Electric sector, as defined by the Electricity Subcommittee;[1]
- Large stationary combustion sources;
- Liquid transportation fuels;
- Residential and commercial natural gas combustion;
- Residential and commercial stationary combustion of fuel oil and other liquid fuels;
- Industrial process and waste management emissions; and
- Fossil carbon content of fuels.

While the subcommittee's preliminary analysis indicates that these elements are feasible to include in the program, we note that significant administrative and potential emissions leakage issues remain to be assessed. Additionally, options for phasing in and combining the elements

[1] The Electric Subcommittee is assessing how best to include the electric sector in the program. The major options under consideration by the Electric Subcommittee are reported separately.

must be considered. These issues are being examined through the subcommittee's continuing analysis and assessment.

Combinations of the feasible design elements are presented as five major design options below. These options indicate how the elements could be combined to create a cap-and-trade program with varying levels of coverage. Option 1, with the narrowest scope, would cover the electric sector, large fossil fuel stationary combustion sources, and large industrial process emissions. Option 3 has a significantly broader scope by also including liquid transportation fuels and fossil fuel stationary combustion in the residential and commercial sectors. Option 5 represents an alternative approach, focusing on the fossil carbon content of all fuels.

The subcommittee's preliminary analysis has indicated that several design elements are not likely to be feasible to be included under the cap in a cap-and-trade program in the near term. The factors indicating that these elements are not good candidates for inclusion under the cap-and-trade program are: inability to measure or calculate emissions reliably at the entity level; administrative challenges due to the large number of regulated entities; and significant vulnerability to emissions leakage. These design elements include:

- emission sources at fossil fuel production facilities for which it is difficult to measure or calculate emissions at the entity level;
- passenger cars, light duty trucks and medium duty vehicles regulated at the manufacturer;
- large transportation fleets;
- agriculture emissions and sinks;
- forestry emissions and sinks; and
- high-GWP gases regulated at the point of manufacture.

While the sectors and sources included in these design elements may ultimately not be recommended for inclusion under the cap of a cap-and-trade program, these sectors and sources may be appropriate for inclusion in an offset program, or may be addressed through other policies or measures.

By releasing this preliminary list of major design options, the Scope Subcommittee solicits public comments on these materials. Comments would be particularly appreciated on the following:

1. Feasibility: Do you agree with the subcommittee's assessment of the design elements that are feasible for inclusion in a cap-and-trade program? If not, what would you change?
2. Options: Do you agree with the range of options presented by the subcommittee? If not, what options would you add or delete?
3. Thresholds: What thresholds (e.g., tons of emissions per year) are appropriate to use to define the entities with regulatory obligations under each of the design elements?
4. Phasing: Which design elements, if any, should be phased in over time?

Major Scope Options Under Consideration as of December 2007 – For Public Review and Comment

A. Large Stationary Combustion Sources

1. Description

1.1 Sectors

This sector includes all large stationary combustion sources, including oil refining, cement manufacturing (including clinker production), pulp and paper manufacturing, hydrogen production, and other large combustion sources. Electric power generation is included in the Electric Sector, and is not included in this design element. An annual emissions threshold may be used to define the combustion sources considered "large." Various thresholds have been defined in other programs (such as mandatory greenhouse gas reporting programs). A threshold has not yet been selected for this design element, and is under consideration.

1.2 Emissions Sources

Fossil fuel combustion in stationary equipment only.

1.3 Greenhouse Gases

All six Kyoto gases are included. However, CO_2 comprises the overwhelming majority of the total emissions in this sector (close to 100%).

1.4 Point of Regulation

The point of regulation is the facility where the combustion emissions occur.

2. Emissions and Entity Data

Among the WCI partner states and provinces, fossil fuel combustion at industrial facilities (not including electric power generation) accounted for about 110 MMT of CO_2e in 2005, or about 11% of total gross emissions. This percentage varies from about 4% to 15% across the states and provinces.

The total number of entities that would be covered in this sector depends on whether, and at what level, an annual emissions threshold is set. Table 1 summarizes the emissions for the WCI partners.

3. Emissions at the Entity Level

Greenhouse gas emissions from fossil fuel combustion at large stationary sources can be measured or calculated with an adequate level of precision to support inclusion in a cap-and-trade program. Fuel-based calculations can generally be used to quantify CO_2 emissions, which comprise nearly 100% of the emissions for this sector. Alternatively, continuous emissions monitors (CEMs) can be used to measure emissions.

4. Administration

This sector does not pose significant administrative challenges. Regulatory agencies are able to identify most if not all the entities in this sector with compliance obligations because the facilities typically have other air emission compliance requirements. The covered entities should also have the capability to know their compliance obligations and understand the applicable requirements. The emissions from this sector are reasonably well known, so that an acceptable emission baseline can be developed.

5. Leakage Issues

Vulnerability to significant leakage varies among the facilities that would be covered under this sector. Some facilities require close proximity to their markets, so that significant leakage to locations outside the WCI region is not expected. However, others (such as the cement industry and the pulp and paper industry), may be vulnerable to leakage as their products are traded as commodities internationally. The vulnerability to leakage needs to be assessed individually for each industry.

Table 1: Summary of Stationary Combustion Source Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	5.2	5%
California (2004)	69.8	14%
New Mexico	3.2	4%
Oregon (2004)	7.5	11%
Utah	6.5	9%
Washington	11.0	12%
British Columbia	5.8	9%
Manitoba	1.4	7%
Total WCI Partners	**110.3**	**11%**

MMT = million metric tons

Percent of gross emissions calculated for each state/province. Estimates do not apply an emissions threshold for potentially covered entities.

Preliminary estimates, subject to review and revision.

B. Liquid Transportation Fuels

1. Description

This design element covers CO_2 emissions from the combustion of liquid transportation fuels. The point of regulation being examined is the point at which the fuels enter into commerce in the individual WCI states and provinces. As described below, this point may vary among the states and provinces.

1.1 Sectors

This design element focuses on liquid fossil fuels used in the transportation sector, including but not limited to gasoline, distillate fuels (diesel, etc.), jet fuel, aviation gas, and LPG. The liquid fuels used for stationary combustion by residential, commercial, and industrial customers are described separately. Nevertheless, the manner in which liquid fuels could be covered for these other customers is closely related to how they could be covered for transportation uses. Fuel use in the electricity sector is also not covered in this design element.

1.2 Emissions Sources

The emission source is the combustion of liquid fossil fuels in mobile sources. These sources include on-road and off-road vehicles, including: passenger cars; trucks; rail; marine vessels; and aircraft. Off-road equipment, such as farm equipment and construction equipment could also be included.

1.3 Greenhouse Gases

Carbon dioxide is the dominant GHG produced in this element, accounting for on the order of 97% of emissions from these sources. Nitrous oxide (N_2O) and methane (CH_4) are also emitted.

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for transportation emissions at the point of emission, which would be the individual vehicle owner. Rather, the point of regulation under consideration for this element is the point at which transportation fuels enter into commerce in the individual states and provinces. In selecting this point of regulation, consideration is being given to the fact that most jurisdictions have a mechanism for tracking the sale of transportation fuels for other purposes. Building on the existing fuel tracking procedures in each jurisdiction is expected to simplify program design and implementation requirements.

For some jurisdictions, the point at which liquid fuels are tracked is the fuel distribution terminal, often referred to as the terminal rack. For example, in the United States, federal excise taxes on transportation fuels are collected at the terminal rack. Some states rely on this terminal-rack based tracking system to collect state taxes, thereby providing the capability to track fuel flows into the state.

Some jurisdictions (e.g., Oregon) track gasoline deliveries to retailers for tax purposes. For these jurisdictions, the preferred point of regulation may be the licensed fuel wholesalers that are already required to report the quantity of fuel delivered.

Using this approach, the compliance obligation would be to hold emission allowances to cover the fossil carbon content of the fuel that is entering into commerce in the individual states and provinces. The regulated entity would be the party that enters the fuel into commerce in the state or province, such as the owner of the fuel dispensed at the terminal rack, or the licensed fuel wholesaler that dispenses fuel to retail locations.

2. Emissions and Entity Data

The transportation sector is the largest or second largest source of GHG emissions for each of the WCI partners. The emissions estimate for 2005 is about 353 MMT CO_2e, accounting for about 36% of total gross emissions among the WCI partners. The percentage of total gross emissions varies among the partners from about 21% to 46%. Table 2 summarizes the emissions estimates for the WCI partners.

The total number of entities with a compliance obligation depends on the point of regulation. If terminal racks are the point of regulation for most jurisdictions, the total number of terminals and refineries (where the racks are located) is on the order of about 200 for the WCI partners (see Table 2). If wholesalers are the point of regulation, the number of entities will be larger. For example, Oregon licenses about 160 motor vehicle fuel dealers. The appropriate point of regulation and the number of entities is under investigation.

3. Emissions at the Entity Level

As described above, the point of regulation under consideration is the point at which liquid transportation fuels enter into commerce in the individual states and provinces. At this point, the regulated entity cannot measure or calculate actual GHG emissions from fuel combustion. Rather, the entity can calculate potential CO_2 emissions based on the fossil carbon content of the fuel and the quantity of the fuel. Virtually all the carbon in the fuel is converted to CO_2, so that the carbon content of the fuel is an accurate predictor of CO_2 emissions.

Several issues need to be addressed in order to use this calculation of potential emissions:

- <u>Variations in fossil carbon content</u>: Currently, the fossil carbon content of liquid transportation fuels is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.
- <u>Fuel use for non-combustion purposes</u>: The emission calculation presumes that all the fuel delivered will be combusted. Some fuels may be used to produce products (such as plastics) that sequester carbon. While this eventuality may be unlikely for transportation fuels, the issue remains to be assessed.

Notably, this method of calculating emissions is a proxy only for the CO_2 emissions that occur when the fuel is combusted. The calculation does not include N_2O and CH_4 emissions, although those emissions would also be expected to occur during combustion along with the CO_2 emissions. Additionally, the method does not include the GHG emissions associated with producing the fuel. Rather, this method covers emissions associated with fuel use, but not fuel production. Emissions associated with fuel production (e.g., emissions at the refinery) would be covered separately as stationary combustion or process emissions from the facilities involved in producing the fuel in the WCI states and provinces.

4. Administration

By leveraging existing fuel tracking procedures in states and provinces, the administrative challenges for this design element can be minimized. However, the tracking capabilities of each state and province remain to be examined in detail to assess the comprehensiveness of the existing tracking capabilities. Insofar as the existing procedures provide incomplete coverage of the fuels, additional tracking capabilities may be required.

The potential challenges associated with verifying the fossil and non-fossil carbon components of transportation fuels at the proposed point of regulation remain to be examined.

5. Leakage Issues

The potential for emission leakage is significant for components of the transportation sector:

- Marine: Ocean-going vessels can obtain fuel outside the WCI partner jurisdictions.
- Aviation: Airline operations are particularly sensitive to fuel costs. Opportunities to obtain fuel outside the WCI partner jurisdictions may be significant.

Gasoline use in passenger cars, light duty trucks, and medium duty vehicles is less vulnerable to leakage, as motorists typically obtain fuel in close proximity to their residences and places of employment. On-road gasoline use accounts for about two-thirds of the total emissions from this sector, making it the largest portion of emissions.

Long-haul trucking may also be vulnerable to leakage if trucks can operate within WCI jurisdictions with fuel obtained from outside the WCI jurisdictions. However, the International Fuel Tax Agreement (IFTA) requires diesel trucks operating in multiple jurisdictions to calculate fuels consumed in each state and province based on the miles traveled in each state/province. All the WCI partners are parties to the IFTA.[2] Consequently, the IFTA data could be used to compute a compliance obligation for diesel trucks that operate in multiple jurisdictions, thereby avoiding leakage.[3]

These differences in leakage potential may indicate that the program should consider focusing coverage on the portion of transportation fuels that are least subject to leakage.

Table 2: Summary of Liquid Transportation Fuel CO_2 Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	# Entities	
			Terminals	Refineries
Arizona	39.3	39%	10	--
California (2004)	182.0	37%	84	20
New Mexico	15.6	21%	16	3
Oregon (2004)	23.2	34%	10	1
Utah	17.4	25%	7	5
Washington	43.1	46%	25	5
British Columbia	25.4	39%	3	2
Manitoba	7.4	36%	1	--
Total WCI Partners	**353.4**	**36%**	**156**	**36**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
Preliminary estimates, subject to review and revision.

[2] The 48 contiguous states of the United States and 10 Canadian provinces are parties to IFTA. Yukon Territory, Northwest Territory, Nunavut, and the District of Columbia are not parties to IFTA.

[3] IFTA covers diesel trucks with the following characteristics: (a) has three or more axles; or (b) has two axles and a gross vehicle or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms; or (c) is used in a combination that has a combined or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms. Recreational vehicles are not covered.

C. Residential and Commercial Natural Gas Consumption

1. Description

Under this element, the carbon dioxide emissions associated with residential and commercial combustion of natural gas would be covered. The point of regulation is the local natural gas distribution company (LDC). The LDCs would be required to hold allowances to cover the carbon dioxide emissions associated with the ultimate combustion of the natural gas they sell to their residential and commercial customers, based on the carbon content and volume of the fuel they sell.

LDCs also deliver gas to large industrial and electric utility customers. They would not be required to hold allowances for emissions associated with those deliveries. The expectation is that those emissions would be covered at the source, as described in separate design elements.

1.1 Sectors

The sector covered is part of residential and commercial stationary combustion.

1.2 Emissions Sources

The emissions sources are residential and commercial natural gas combustors, such as boilers and furnaces.

1.3 Greenhouse Gases

The greenhouse gas covered is carbon dioxide. Other combustion-related greenhouse gases would also be affected (e.g., nitrous oxide and methane). However, the other emissions are not addressed explicitly through this design element.

1.4 Point of Regulation

The entities with compliance obligations are local natural gas distribution companies (LDCs). LDCs are typically private companies regulated by state and provincial utility commissions or similar boards. Some LDCs may be municipal utilities. All LDCs, regardless of size or volume of gas delivered, could be included in this program element.

2. Emissions and Entity Data

Based on the information collected to date, there are about 55 LDCs in the WCI partner states and provinces; and about 155 total if WCI observers are included. The CO_2 emissions associated with the natural gas these LDCs distributed in 2005 to residential and commercial customers is 138.7 MMT for the U.S. partners and is currently being estimated for the Canadian partners. Table 3 summarizes this data and the data on the numbers of LDCs.

3. Emissions at the Entity Level

Calculating emissions associated with residential and commercial combustion would be straightforward for LDCs. LDCs already account for the volumes of natural gas they sell by customer class. The LDCs would need to apply the appropriate carbon content factor to these gas volumes to calculate their compliance obligation. The LDC would exclude from this calculation any natural gas that is sold to an entity that has a separate compliance obligation under the program, such as an industrial source that is regulated directly.

4. Administration

Covering LDCs in a cap-and-trade program does not pose unusually significant administrative challenges. LDCs are already subject to economic regulation by the state public utilities commissions in the United States and by provincial authorities in Canada. Thus, a state or provincial regulatory agency can identify all the entities with compliance obligations. The LDCs would have the capability to know that they have compliance obligations and understand their compliance requirements. The number of entities appears manageable. However, there are a number of small LDCs in Kansas (a WCI observer state). An annual emissions threshold, for example 10,000 tons of CO_2, could be used to exclude small LDCs.

5. Leakage Issues

LDCs themselves would not be subject to emission leakage issues. The LDCs are regulated monopolies with defined service territories.

LDC customers may vary with regard to leakage vulnerabilities. Most residential and commercial natural gas customers do not have high greenhouse gas emissions intensities. Consequently internalizing the cost of the carbon content of natural gas into natural gas prices (as would be expected) would not significantly affect the competitiveness of most customers.

However, there are two circumstances of note. First, increased natural gas prices could adversely affect low income residential customers. Assistance programs for low income customers, provided by many LDCs in the United States, could be a mechanism for addressing this impact. Second, there may be some individual large volume gas customers for which carbon emissions are significant. If these customers face competition from regions that do not limit greenhouse gas emissions, they may vulnerable to emissions leakage. The circumstances of these customers would be similar to large stationary source emissions sources that would be covered directly. The number of customers for which this is an issue, and the potential impacts on these customers, remain to be identified.

Table 3: Summary of Residential and Commercial Natural Gas CO_2 Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	# LDCs
Arizona	4.0	4%	8
California (2004)	42.9	9%	11

Total WCI Partners	**67.5**	**8%**	**55**
MMT = million metric tons Percent of gross emissions calculated for each state/province. Emissions data currently being developed for provinces. Preliminary estimates, subject to review and revision.			

C1: Residential and Commercial Stationary Combustion of Fuel Oil and Other Liquid Fuels

1. Description

This design element covers CO_2 emissions from the stationary combustion of fuel oil and other liquid fuels in the residential and commercial sector. The point of regulation being examined is the point at which the fuels enter into commerce in the individual WCI states and provinces. As described below, this point may vary among the states and provinces.

1.1 Sectors

This design element focuses on liquid fossil fuels used for stationary combustion by residential and commercial customers. The fuels include heating oil, propane and liquefied petroleum gas (LPG). The liquid fuels used in the transportation sector are described separately. Nevertheless, the manner in which liquid fuels could be covered for transportation uses is closely related to how they could be covered for these residential and commercial uses. Fuel use in the electricity sector is also not covered in this design element.

1.2 Emissions Sources

The emission source is the combustion of liquid fossil fuels in stationary source equipment, such as furnaces and boilers.

1.3 Greenhouse Gases

Carbon dioxide is the dominant GHG produced in this element, accounting for on the order of 99% of emissions from these sources. Nitrous oxide (N_2O) and methane (CH_4) are also emitted.

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for residential and commercial stationary fuel combustion emissions at the point of emission, which would be the individual building owner. Rather, the point of regulation under consideration for this element is the point at which the relevant fuels enter into commerce in the individual states and provinces. In selecting this point of regulation, consideration is being given to the fact that some jurisdictions have a mechanism for tracking the sale of these fuels for other purposes. Building on the existing fuel tracking procedures in each jurisdiction is expected to simplify program design and implementation requirements.

For some jurisdictions, the point at which liquid fuels are tracked is the fuel distribution terminal, often referred to as the terminal rack. For example, in the United States, federal excise taxes on liquid fuels are collected at the terminal rack. Some states rely on this terminal-rack based tracking system to collect state taxes, thereby providing the capability to track fuel flows into the state.

Some jurisdictions track fuel deliveries to retailers for tax purposes. For these jurisdictions, the preferred point of regulation may be the licensed fuel wholesalers that are already required to report the quantity of fuel delivered.

Using this approach, the compliance obligation would be to hold emission allowances to cover the fossil carbon content of the fuel that is entering into commerce in the individual states and provinces. The regulated entity would be the party that enters the fuel into commerce in the state or province, such as the owner of the fuel dispensed at the terminal rack, or the licensed fuel wholesaler that dispenses fuel to retail locations.

2. *Emissions and Entity Data*

The stationary combustion of liquid fossil fuels in the residential and commercial sectors accounts for a small portion of overall GHG emissions within the WCI partners jurisdictions. Although incomplete data are currently available, these sources appear to account for less than 1% of total emissions in 2005 (see Table 4).

The total number of entities with a compliance obligation depends on the point of regulation. If terminal racks are the point of regulation for most jurisdictions, the total number of terminals and refineries (where the racks are located) is on the order of about 200 for the WCI partners (see Table 4). If wholesalers are the point of regulation, the number of entities will be larger. The compliance obligation for these fuels would likely be closely coordinated with the compliance obligation for the carbon content of liquid transportation fuels, which is described separately.

3. *Emissions at the Entity Level*

As described above, the point of regulation under consideration is the point at which liquid fuels enter into commerce in the individual states and provinces. At this point, the regulated entity cannot measure or calculate actual GHG emissions from fuel combustion. Rather, the entity can calculate potential CO_2 emissions based on the fossil carbon content of the fuel and the quantity of the fuel. Virtually all the carbon in the fuel is converted to CO_2, so that the carbon content of the fuel is an accurate predictor of CO_2 emissions.

Several issues need to be addressed in order to use this calculation of potential emissions:

- Variations in fossil carbon content: Currently, the fossil carbon content of liquid fuels is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.
- Fuel use for non-combustion purposes: The emission calculation presumes that all the fuel delivered will be combusted. Some fuels may be used to produce products (such as plastics) that sequester carbon. While this eventuality may be unlikely for these fuels, the issue remains to be assessed.

Notably, this method of calculating emissions is a proxy only for the CO_2 emissions that occur when the fuel is combusted. The calculation does not include N_2O and CH_4 emissions, although those emissions would also be expected to occur during combustion along with the CO_2 emissions. Additionally, the method does not include the GHG emissions associated with producing the fuel. Rather, this method covers emissions associated with fuel use, but not fuel production. Emissions associated with fuel production (e.g., emissions at the refinery) would be covered separately as stationary combustion or process emissions from the facilities involved in producing the fuel in the WCI states and provinces.

4. *Administration*

By leveraging existing fuel tracking procedures in states and provinces, the administrative challenges for this design element can be minimized. However, the tracking capabilities of each state and province remain to be examined in detail to assess the comprehensiveness of the existing tracking capabilities. Insofar as the existing procedures provide incomplete coverage of the fuels, additional tracking capabilities may be required. As discussed above, the tracking of these fuels would be coordinated closely with the tracking of transportation fuels.

The potential challenges associated with verifying the fossil and non-fossil carbon components of fuels at the proposed point of regulation remain to be examined.

5. Leakage Issues

Fuel oil customers may vary with regard to leakage vulnerabilities. Most residential and commercial fuel oil customers do not have high greenhouse gas emissions intensities. Consequently internalizing the cost of the carbon content of fuel oil into fuel oil prices (as would be expected) would not significantly affect the competitiveness of most customers.

However, there are two circumstances of note. First, increased fuel prices could adversely affect low-income residential customers. Assistance programs for low-income customers could be a mechanism for addressing this impact. Second, there may be some individual commercial customers for which carbon emissions are significant. If these customers face competition from regions that do not limit greenhouse gas emissions, they may vulnerable to emissions leakage. The circumstances of these customers would be similar to large stationary source emissions sources that would be covered directly. The number of customers for which this may be an issue, and the potential impacts on these customers, remain to be identified.

Table 4: Summary of CO_2 Emissions from Residential and Commercial Stationary Combustion of Fuel Oil and Other Liquid Fuels

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	# Entities	
			Terminals	**Refineries**
Arizona	0.7	0.7%	10	--
California (2004)	1.0	0.2%	84	20
New Mexico	1.2	1.6%	16	3
Oregon (2004)	0.8	1.2%	10	1
Utah	0.4	0.6%	7	5
Washington	1.4	1.5%	25	5
British Columbia	(NA)	(NA)	3	2
Manitoba	(NA)	(NA)	1	--
Total WCI Partners	5.6	0.6%	**156**	**36**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
NA = Data not available. Emissions data currently being developed.
Preliminary estimates, subject to review and revision.

D. Industrial Process and Waste Management Emissions

1. Description

This element includes industrial process and waste management emissions regulated at the point of emission.

1.1 Sectors

This sector includes specifically identified industrial processes and waste management activities, such as oil refining, cement production, aluminum smelting, iron and steel production, adipic acid production, nitric acid production, lime production, pulp and paper manufacturing, sawmill kilns, agricultural chemical manufacturing, plastics manufacturing, natural gas transmission and distribution, magnesium smelters and casters, mineral production, silicon chip manufacturing, ammonia production, wastewater treatment facilities; landfill operations, wastewater treatment from food processing; and others. An annual emissions threshold may be used to define the facilities included in the program. This threshold has not been established, and is under consideration. Process emissions from the Electric Sector are included in the Electric Sector, and are not included here.

1.2 Emissions Sources

The emission sources included are process emissions from stationary sources. Process emissions include emissions from chemical, biological, and other non-combustion processes. The emissions may be deliberate (e.g., vented), fugitive (e.g., leaked), or accidental. Fossil fuel combustion emissions are not included in this design element, and are covered in a separate description.

1.3 Greenhouse Gases

All six Kyoto greenhouse gases are included.

1.4 Point of Regulation

The point of regulation is the facility where the emissions occur.

2. Emissions and Entity Data

Among the WCI partner states and provinces, process emissions accounted for about 75 MMT of CO_2e in 2005, or about 8% of total gross emissions. This percentage varies from about 4% to 12% across the states and provinces.

The total number of entities that would be covered in this sector depends on whether, and at what level, an annual emissions threshold is set. The potential number of entities with compliance obligations is currently being assessed. Table 5 summarizes the emissions for the WCI partners.

3. Emissions at the Entity Level

The ability to measure or calculate emissions reliably and precisely at the entity level must be assessed for each of the industrial process and waste management sources in the WCI region. This assessment must examine:

- Is there an existing measurement or calculation protocol or method for the source?
- Is a new protocol or method required?
- What greenhouse gases can be measured or calculated reliably and precisely?

- Are there technical barriers to the entities being able to measure/calculate their emissions with sufficient precision to be covered by the cap-and-trade program? If there are barriers, which sources cannot be included, and how does their exclusion affect the emissions covered?

There are numerous industrial processes that emit greenhouse gases, and the answers to these questions will vary widely among the processes. For example, a protocol has been developed to calculate process emissions from cement manufacturing. Also, emissions of N_2O from nitric acid production can be monitored accurately using measurement devices in the process vent. Alternatively, process emissions at refineries are themselves diverse. Some refinery process emissions may be amenable to measurement or calculation, while others (such as fugitive emissions) may not be suitable for inclusion. This element could cover only those emissions that can be measured or calculated adequately. If needed, processes could be added to the program as methods or protocols are developed over time.

4. Administration

The primary administrative challenge associated with this sector is the inability to measure or calculate emissions precisely from some sources. Most of the large facilities that fall under this design element would already have compliance obligations under other regulatory programs. Consequently, the entities are well known and would be in a position to understand their compliance obligations under a cap-and-trade program. As discussed above, the use of an annual emissions threshold would reduce the number of entities with compliance obligations.

5. Leakage Issues

Vulnerability to leakage varies among the facilities that would be covered under this sector. Some facilities require close proximity to their markets, so that significant leakage to locations outside the WCI region is not expected. However, others (such as the cement industry), may be vulnerable to leakage as their products are traded as commodities internationally. The vulnerability to leakage needs to be assessed individually for each industry.

Table 5: Summary of Industrial Process and Waste Management Emissions

	2005 Emissions (MMT CO_2e)		
State/Province	**Processes**	**Waste Management**	**Percent of 2005 Gross Emissions**
Arizona	4.5	2.1	7%
California (2004)	29.8	9.4	8%
New Mexico	1.5	1.4	4%
Oregon (2004)	3.3	1.9	8%
Utah	3.6	2.0	8%
Washington	3.0	2.4	6%
British Columbia	3.1	5.1	12%
Manitoba	0.4	1.0	7%
Total WCI Partners	**49.2**	**25.4**	**8%**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
Preliminary estimates, subject to review and revision.

E. Fossil Fuel Industry

The Fossil Fuel Industry encompasses oil and gas exploration, production, and processing, and coal mining. This design element includes a broad set of facilities and activities with diverse emissions sources. Some of the emissions sources included here are also part of other design elements (e.g., stationary combustion sources and process emissions). However, the sources are described here to provide a comprehensive description of emissions from this industry.

1.1 Sectors

The Fossil Fuel Industry can be categorized into the following sectors:

- Oil Production: Oil production covers exploration, drilling, production, and transportation of crude oil by pipeline to terminals or refineries. Facilities include well fields, pipelines, and tank batteries. Ships used to transport crude oil are included in the transportation sector. The output of this process is crude oil.
- Natural Gas Production and Processing: Natural gas production and processing covers exploration, production, and treatment of natural gas. Facilities include well fields, pipelines, and processing equipment. The output of this process is natural gas that meets specifications required for injection into natural gas transmission and distribution pipelines.
- Coal Mining: Coal mining covers mine development and operations, including surface mining (i.e., open pit mining) and underground mining. Coal processing facilities are considered a stationary source, and coal transport (e.g., by train) is considered part of the transportation sector.

Oil and gas are often produced from the same wells. In these cases, the distinction between oil production facilities and natural gas production facilities is not meaningful. Additionally, condensate and other liquids are often produced with oil and/or natural gas. The oil and natural gas production and processing facilities listed above encompass the production and processing of these liquids.

Methane recovered from coal seams (often referred to as “coalbed methane”) can also be used to produce pipeline quality natural gas. Coalbed methane production and treatment is included in this design element as part of natural gas production.

Pipelines of various types are also used to transport crude oil, liquid products, and gas. Pipelines are included in this design element, including: gathering lines; crude oil and liquid products pipelines that run to refineries, terminals, and tanks; and gas pipelines that connect to transmission lines. Natural gas transmission and distribution pipelines are not included in this design element.[4] Similarly, refineries and the transport of refined products to market are not included in this design element.[5]

1.2 Emissions Sources

The Fossil Fuel Industry includes a diverse set of greenhouse gas emissions sources. Many of the sources are specialized pieces of equipment found only in this industry. The major emission sources in oil and gas production and processing are listed in Table 6. As shown in the table, the emissions sources can be categorized into six types:

[4] Natural gas transmission and distribution pipelines are considered stationary sources with combustion emissions (i.e., from compressors) and process emissions (i.e., gas venting and fugitive emissions).

[5] Refineries are considered a stationary source with combustion emissions and process emissions. The transport of refined products to market is considered part of the transportation sector.

- Stationary combustion includes all types of fossil fuel combustion, including flaring.
- Process vents include equipment that is designed to vent emissions as part of its normal operation. Amine treatment as part of acid gas removal is an example of a process with this type of venting.
- Maintenance venting includes emissions that occur during scheduled maintenance activities.
- Non-routine venting occurs periodically, often for safety reasons.
- Other venting is associated with specific activities or pieces of equipment, some of which are designed to vent as part of normal operation (e.g., pneumatic devices and chemical injection pumps).
- Fugitive emissions occur from unintended leaks from equipment components.

The relative importance of each of the sources depends on site-specific equipment requirements, operations, and configurations.

The source of coal mining emissions is primarily due to the release of methane from the coal and surrounding strata due to mining activities. In underground mines, methane can create an explosive hazard, so it is removed through a ventilation system. Methane concentrations in ventilation system emissions are typically less than 1%, and consequently the methane is nearly always emitted to the atmosphere. In some mines, a degasification system is used to withdraw methane prior to mining due to large quantities of methane occurring in the coal and surrounding strata. The methane collected by the degasification system may be recovered and used for fuel in some cases.

In surface mining, the methane associated with the coal is emitted directly to the atmosphere as the coal is uncovered. For both underground coal and surface-mined coal, some methane remains in the coal after it is mined. This methane is released subsequently during processing, transport, and storage.

Finally, methane is also emitted from closed or abandoned underground mines. Although mining is no longer active, closed mines can release methane from vents, fissures, or boreholes.

This list of emissions sources for the Fossil Fuel Industry includes only those sources that produce emissions during the production and processing of the fuel (oil, gas, and coal). When the resulting products are combusted (i.e., when refined oil products and natural gas are used as fuel by others), they also produce emissions (primarily carbon dioxide). The emissions from fuel combusted by others are not included in this design element.

1.3 Greenhouse Gases

The predominant GHGs emitted from the Fossil Fuel Industry are:

- Carbon dioxide (CO_2): CO_2 is released from fossil fuel combustion at oil and gas production and processing facilities. This combustion includes emissions from flaring (see Table 6). Also, CO_2 is often mixed with natural gas as it is produced from underground formations, particularly from coalbed methane sources. During gas processing, this CO_2 is typically separated from the natural gas and vented.[6]
- Methane (CH_4): Methane is typically released due to venting and leaks during oil and natural gas production and processing (methane is the primary component of natural gas). Methane is also released from coal mines.

[6] In some cases, CO_2 separated from natural gas is captured and re-injected or used for other purposes.

- Nitrous oxide (N_2O): N_2O emissions are primarily associated with fuel combustion. N_2O emissions are typically a very small portion of total GHG emissions from the Fossil Fuel Industry.

The largest GHG emissions from the Fossil Fuel Industry are CO_2 from combustion of fuel and CO_2 separated from the raw gas stream.

1.4 Point of Regulation

The point of regulation currently under consideration is the facility where the emissions occur. As discussed above, oil and gas production facilities include a diverse set of equipment, processes, and activities. These facilities may also cover large geographic areas, encompassing well fields, pipelines, and tank batteries. Ownership and operational control may be divided among multiple entities as the oil and gas is produced and processed.

2. Emissions and Entity Data

Among the WCI partner states and provinces, Fossil Fuel Industry emissions accounted for about 45 million metric tons (MMT) of CO_2e in 2005, or about 5% of total gross emissions from the WCI partners. However, for New Mexico and British Columbia, emissions from the Fossil Fuel Industry are a larger portion of total gross emissions, accounting for about 26% and 22% respectively of their gross emissions in 2005. Table 7 summarizes the emissions estimates for each province and state.

Although significant improvements have been made in the ability to calculate GHG emissions from the fossil fuel industry, considerable uncertainty remains in national and state/provincial emission inventory estimates. Emissions factors for some types of emissions, such as fugitive emissions, continue to have broad ranges of uncertainty. Additionally, some activity data, such as the quantities of gas flared or vented, are not well measured or reported in some circumstances. Various efforts are ongoing to continue to improve emissions estimates for this industry.

The number of operating oil and gas wells is on the order of 65,000 and 45,000 respectively for the WCI partners (see Table 8). Typically, a small number of well field operators account for a large portion of operating wells and oil and gas production. For example, within the United States in 2005, the top 50 operators account for 77% of oil production and 72% of natural gas production.[7] In British Columbia, five operators account for about 80% of natural gas production, and in New Mexico 20 operators account for about 80% of natural gas production. Similarly, in California, 30 operators account for more than 90% of oil and gas production. Consequently, if a size threshold were adopted for participation in a cap-and-trade program, a large portion of total production could be covered while keeping the number of oil and gas field operators with a regulatory obligation manageable. Assessments of size threshold options and the number of entities covered remains ongoing.

The number of coal mines operating in the WCI jurisdictions is on the order of 29, including 14 underground and 15 surface mines (see Table 8).

3. Emissions at the Entity Level

The ability to measure or calculate emissions reliably and precisely at the facility or entity level varies depending on the activities performed and equipment used at the facility and the manner

[7] U.S. Energy Information Agency, "Operator Information by Size Class" available at: http://tonto.eia.doe.gov/dnav/pet/pet_crd_crpdn_adc_mbbl_m.htm.

in which data are collected and verified. For oil and gas production and processing emissions, several resources have been developed to assist in estimating emissions:

- The American Petroleum Institute's *Compendium of Greenhouse Gas Emissions Estimation Methodologies for the Oil & Gas Industry*[8] promotes consistency in estimating petroleum company's GHG emissions and provides recommendations on ways to improve and streamline GHG emissions estimates among existing methodologies.
- The International Petroleum Industry Environmental Conservation Association (IPIECA), International Association of Oil and Gas Producers (OGP) and API also prepared the *Petroleum Industry Guidelines for Reporting Greenhouse Gas Emissions*[9], a consistent global framework for accounting and reporting of GHG emissions by the industry sector.
- The World Business Council for Sustainable Development (WBCSD) and World Resources Institute (WRI) have developed *The Greenhouse Gas Protocol: a Corporate Accounting and Reporting Standard*[10], a common framework for defining the boundaries of reporting emissions.
- The New Mexico Environment Department, California Air Resources Board, and California Climate Action Registry, in cooperation with the Western Regional Air Partnership, have begun a joint initiative to develop a registry reporting protocol specific to the upstream oil and gas industry sector (i.e., production) and natural gas processing. This protocol, in combination with protocols already developed or soon to be completed for petroleum refining and natural gas transmission and distribution, will provide a basis for accelerated adoption of a complete oil and gas sector protocol by The Climate Registry. The protocol will not be likely to be completed until mid 2009.

While these resources have improved (and are continuing to work to improve) the consistency of emissions calculations and methods, the accuracy of entity-specific emissions calculations remains an issue of concern for certain sources at oil and gas production and processing facilities. Emissions calculations for metered fuel use and process vents amenable to measurement are expected to be as precise as the estimates performed for similar emissions from other stationary sources. However, emissions calculations for unmetered gas use (either flared or vented) and leaks pose challenges. The use of average or representative emissions factors for some sources (such as fugitive emissions) does not enable site-specific conditions to be reflected, and does not allow for improved operation and maintenance to be reflected in reduced emissions estimates.

Based on the information reviewed to date, only a portion of the sources at oil and gas production and processing facilities will likely be feasible to include in a cap-and-trade program at this time. Improved methodologies may enable additional sources to be included in the future. The identification and assessment of those sources remains ongoing.

The ability of individual coal mines to calculate or measure emissions accurately varies. Surface mined coal does not provide an opportunity to measure emissions, although those emissions are typically low. Emissions from underground coal mining can be estimated from

methane concentrations in ventilation air. Additionally, methane collected in degasification systems (prior to mining) is typically quantified.

Emissions from coal mines emitting over 100,000 metric tons CO_2e in Canada report their emissions federally. [11] The Environment Canada National Inventory Report contains data on fugitive emissions from coal mining, but the data for British Columbia is confidential due to the low number of market participants in the province (four). [12]

The ability to calculate emissions precisely from underground coal mining remains under review.

4. Administration

The primary administrative challenge associated with this sector is the inability of entities to measure or calculate emissions precisely from some sources. The entities that own or operate facilities that fall under this design element would already have compliance obligations under other regulatory programs. Consequently, the entities are well known and would be in a position to understand their compliance obligations under a cap-and-trade program.

The number of entities in the oil and gas production and processing industry could be large. Complex ownership and operating arrangements are also typically encountered. As discussed above, the use of a size or annual emissions threshold would reduce the number of entities with compliance obligations.

5. Leakage Issues

Oil, gas, and coal mining activities are undertaken at the locations of the resources themselves. Consequently, the operations cannot relocate to avoid participation in a cap-and-trade program. However, the companies that operate these facilities compete for investment resources. Increased cost or regulatory burdens have the potential to shift investment and production from WCI jurisdictions to other regions. Over time, therefore, production activities could shift to locations without GHG emissions limits, so that no net emission reduction is achieved. The significance of this vulnerability to emissions leakage remains under review.

Table 6: Major Greenhouse Gas Emissions Sources from Oil and Gas Production and Processing

Equipment*	Emissions Type
Boilers/steam generators	Stationary combustion
Heaters/treaters	Stationary combustion
Compressors (internal combustion engines and turbines)	Stationary combustion
Flares	Stationary combustion
Incinerators	Stationary combustion
Gas sweetening processes	Process vent
Gas dehydration	Process vent
Vessel blowdowns	Maintenance venting
Well workovers	Maintenance venting
Compressor starts	Maintenance venting
Compressor blowdowns	Maintenance venting
Gathering pipeline blowdowns	Maintenance venting
Pressure relief valves	Non-routine venting
Well tests and blowdowns (when not flared)	Non-routine venting
Emergency shutdown/emergency safety blowdown	Non-routine venting
Tanks	Other venting
Pneumatic devices	Other venting
Chemical injection pumps	Other venting
Well drilling and testing	Other venting
Leaks from equipment components	Fugitive emissions

* Mobil sources are also used in oil and gas production fields (e.g., supply boats, barges, trucks, and aircraft). Mobil sources are not included in this design element.

Table 7: Summary of Fossil Fuel Industry Greenhouse Gas Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	0.6	1%
California (2004)	4.6	1%
New Mexico	19.5	27%
Oregon (2004)	0.7	1%
Utah	4.1	6%
Washington	0.9	1%
British Columbia	14.3	22%
Manitoba	0.6	3%
Total WCI Partners	**45.4**	**5%**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.

Preliminary estimates, subject to review and revision.

F. Fossil Carbon Content of Fuels

1. Description

1.1 Sectors

This design element covers CO_2 emissions from fossil fuel combustion throughout the economy, including: the electricity sector, transportation fuels, residential and commercial stationary combustion, and industrial stationary combustion.

1.2 Emissions Sources

This design element covers fossil fuel combustion throughout the economy. The fuels include coal, oil, natural gas, and other fossil fuels (such as propane).

1.3 Greenhouse Gases

This design element would cover CO_2 emissions. Other greenhouse gases associated with fuel combustion (nitrous oxide and methane) would be affected, but not covered explicitly. CO_2 emissions are estimated to account for more than 98% of the GHG emissions from fossil fuel combustion.

1.4 Point of Regulation

For some sectors, such as large industrial sources, GHG emissions can be tracked at the point of combustion. For other sectors, such as transportation, it is generally considered impractical to define the point of regulation at the point of emission, which would be the individual vehicle owner. The point of regulation under consideration for this element is to cover all fossil fuels at an appropriate point in their distribution and use. The appropriate point will vary depending on the fuel:

- Liquid Fuels: The preferred point of regulation for liquid fuels (gasoline, diesel, propane) will likely be the point at which these fuels enter into commerce in the individual states and provinces. In examining this point of regulation, consideration is being given to the fact that most jurisdictions have an existing mechanism for tracking the sale of liquid fuels. The manner in which jurisdictions track fuel distribution and sales varies, so that the preferred point of regulation may also vary among jurisdictions. Some states track fuel deliveries through licensed wholesalers. Other states track fuel dispensed from terminals and refineries. Care is needed to ensure that the tracking systems are comprehensive and compatible. Because these tracking systems have generally been developed to support tax collection, building on the existing fuel tracking procedures in each jurisdiction is expected to simplify program design and implementation requirements.

- Natural Gas: The preferred point of regulation for natural gas will likely be a combination of entities. For residential and commercial customers (and some industrial customers), natural gas is delivered by local distribution companies (LDCs). The LDCs are in a position to track and report natural gas delivered to these customers. Some large natural gas users (e.g., some industrial customers) purchase natural gas directly, bypassing the LDCs. The point of regulation for direct purchasers of natural gas would be the direct purchasers themselves. Coordination would be required to ensure the combined set of entities cover natural gas use comprehensively, and without duplication, in each jurisdiction.

- Coal: In most jurisdictions, coal is typically combusted in facilities that are known to regulatory agencies for other environmental control purposes. The preferred point of regulation would likely be the individual facilities that combust coal.

2. Emissions and Entity Data

CO_2 emissions from fossil fuel combustion are the largest component of GHG emissions for each of the WCI partners. The emissions estimate for 2005 is about 780 MMT CO_2e, accounting for about 80% of total gross emissions among the WCI partners. The percentage of total gross emissions varies among the partners from about 55% to 87%. Table 9 summarizes the emissions estimates for the WCI partners.

The number of entities with regulatory obligations under this design element is being assessed. The number of LDCs in the WCI partner states is shown in Table 10, along with the number of refineries and liquid fuel terminals. The number of licensed fuel wholesalers is expected to be larger than the number of terminals. For example, Oregon licenses about 160 motor vehicle fuel dealers. The number of entities that purchase natural gas directly or combust coal remains to be identified, but is expected to be a manageable number for administrative purposes.

3. Emissions at the Entity Level

As described above, the points of regulation under consideration for natural gas and liquid fuels do not coincide with their emissions points. LDCs and fuel distributors (whether at terminals or wholesalers) cannot measure or calculate actual GHG emissions from fuel combustion. Rather, the entity can calculate potential CO_2 emissions based on the fossil carbon content of the fuel and the quantity of the fuel. Virtually all the carbon in the fuel is converted to CO_2, so that the carbon content of the fuel is an accurate predictor of CO_2 emissions.

Several issues need to be addressed in order to use this calculation of potential emissions:

- Variations in fossil carbon content: Currently, the fossil carbon content of liquid fuels and natural gas is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.
- Fuel use for non-combustion purposes: The emission calculation presumes that all the fuel delivered will be combusted. Some fuels may be used to produce products (such as plastics) that sequester carbon. A mechanism is needed to account for this carbon sequestration at the point of use of the fuel.

Notably, this method of calculating emissions is a proxy only for the CO_2 emissions that occur when the fuel is combusted. The calculation does not include N_2O and CH_4 emissions, although those emissions would also be expected to occur during combustion along with the CO_2 emissions. Additionally, the method does not include the GHG emissions associated with producing the fuel. Rather, this method covers emissions associated with fuel use, but not fuel production. Emissions associated with fuel production would be covered separately as emissions from the facilities involved in producing the fuel.

For direct purchasers of natural gas and for coal combustion facilities, the entity would also be capable of measuring or calculating CO_2 emissions. Facilities could use fuel consumption data along with the carbon content of the fuel. Alternatively, some facilities may find it advantageous to measure emissions directly.

4. Administration

This sector does not pose significant administrative challenges. Regulatory agencies are able to identify most if not all the entities in this sector with compliance obligations because the entities typically have other regulatory requirements. LDCs are already subject to economic regulation by the state public utilities commissions in the United States and by provincial authorities in Canada. Thus, a state or provincial regulatory agency can identify all the entities with compliance obligations. Large industrial purchasers of natural gas and coal combustors typically have other air emission compliance requirements, and consequently are known to regulators.

By leveraging existing liquid fuel tracking procedures in states and provinces, the administrative challenges for these fuels can be minimized. However, the tracking capabilities of each state and province remain to be examined in detail to assess the comprehensiveness of the existing tracking capabilities. Insofar as the existing procedures provide incomplete coverage of the fuels, additional tracking capabilities may be required.

The covered entities should also have the capability to know their compliance obligations and understand the applicable requirements. The emissions from this sector are reasonably well known, so that an acceptable emission baseline can be developed.

5. Leakage Issues

This design element covers a very broad set of sectors throughout the economy. Significant vulnerabilities to leakage exist in specific components of fossil fuel use.

- Electric Sector: This design element covers the combustion at fossil fuel power plants either directly (e.g., as direct natural gas purchasers and coal combustion facilities) or indirectly through the inclusion of natural gas LDCs and oil distributors. Because emissions leakage associated with electricity imports from jurisdictions without GHG emissions caps can be significant, such leakage would need to be addressed as part of this approach.
- Transportation fuels: The potential for emission leakage is significant for components of the transportation sector:
  - *Marine:* Ocean-going vessels can easily obtain fuel outside the WCI partner jurisdictions.
  - *Aviation:* Airline operations are particularly sensitive to fuel costs. Opportunities to obtain fuel outside the WCI partner jurisdictions may be significant.

  Gasoline use in passenger cars, light duty trucks, and medium duty vehicles is less vulnerable to leakage, as motorists typically obtain fuel in close proximity to their residences and places of employment.

  Long-haul trucking may also be vulnerable to leakage if trucks can operate within WCI jurisdictions with fuel obtained from outside the WCI jurisdictions. However, the International Fuel Tax Agreement (IFTA) requires diesel trucks operating in multiple jurisdictions to calculate fuels consumed in each state and province based on the miles traveled in each state/province. All the WCI partners are parties to the IFTA.[13] Consequently, the IFTA data could be used to compute a compliance obligation for diesel trucks that operate in multiple jurisdictions, thereby avoiding leakage.[14]

---

[13] The 48 contiguous states of the United States and 10 Canadian provinces are parties to IFTA. Yukon Territory, Northwest Territory, Nunavut, and the District of Columbia are not parties to IFTA.

[14] IFTA covers diesel trucks with the following characteristics: (a) has three or more axles; or (b) has two axles and a gross vehicle or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms; or (c) is used in a combination that has a combined or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms. Recreational vehicles are not covered.

- Industrial Facilities: Vulnerability to leakage varies among the industrial facilities that would be covered under this sector. Some facilities require close proximity to their markets, so that significant leakage to locations outside the WCI region is not expected. However, others (such as the cement industry and the pulp and paper industry), may be vulnerable to leakage as their products are traded as commodities internationally. The vulnerability to leakage needs to be assessed individually for each industry.

Table 9: Summary of CO_2 Emissions from Fossil Fuel Combustion

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	86.6	87%
California (2004)	410.7	85%
New Mexico	43.9	60%
Oregon (2004)	56.0	83%
Utah	54.0	78%
Washington	80.5	86%
British Columbia	39.1	59%
Manitoba	11.1	55%
Total WCI Partners	**781.9**	**80%**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
Preliminary estimates, subject to review and revision.

Table 10: Summary of Number of Potentially Regulated Entities for Fossil Fuels

State/Province	# LDCs (Natural Gas)	# Liquid Fuel Entities	
		Terminals	Refineries
Arizona	8	10	--
California	11	84	20
New Mexico	19	16	3
Oregon	3	10	1
Utah	2	7	5
Washington	7	25	5

G. Passenger Cars, Light Duty Trucks and Medium Duty Vehicles

1. Description

This design element covers emissions from passenger cars, light duty trucks and medium duty vehicles. These emissions could be covered through several different approaches. This design element focuses on vehicle manufacturers as one option for covering these emissions.

1.1 Sectors

The sector covered is the light and medium duty vehicle portion of the transportation sector (cars and trucks less than 14,000 pounds gross vehicle weight rating).

1.2 Emissions Sources

Emission sources include all emissions during the operation of passenger cars, light duty trucks and medium duty vehicles, including: fuel combustion; refrigerant emissions; and evaporative emissions. Emissions associated with producing the vehicles or producing the fuel used by the vehicles are not included in this design element.

1.3 Greenhouse Gases

All six Kyoto gases are included. The primary gases associated with vehicle operations are CO_2, CH_4, N_2O, and high GWP gases (refrigerants).

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for passenger cars, light duty trucks and medium duty vehicles at the point of emission, which would be the individual vehicle owner. Rather, the point of regulation under consideration for this element is the vehicle manufacturer. In considering this point of regulation, the vehicle manufacturer would be assigned responsibility for the expected emissions associated with their new vehicles that are sold in each jurisdiction, or alternatively, for vehicles *delivered for sale* in a jurisdiction. This regulatory obligation could take various forms, including:

- Fleet Requirement: Under this approach, a maximum fleet average emission rate would be defined for each year. The actual fleet average for each manufacturer would be calculated each year based on the new vehicles sold (or delivered for sale) by that manufacturer in that year. Manufacturers would be required to hold allowances for emissions that exceed the fleet average maximum, and could earn credits for attaining average fleet emissions below the maximum. Whether and how these emission allowances and credits could be traded with other components within of a cap-and-trade system remain to be assessed.

- Lifetime Emissions: Under this approach, each manufacturer would be responsible for the expected lifetime emissions associated with its new vehicles sold (or delivered for sale) each year. The manufacturer would be required to hold emission allowances equal to the expected lifetime emissions from the new cars sold in that year.

2. Emissions and Entity Data

The transportation sector is the largest or second largest source of GHG emissions for each of the WCI partners. Table 11 summarizes the emissions estimates for the WCI partners. The total number of entities with compliance obligations is the number of vehicle manufacturers that sell vehicles in the WCI states and provinces. There are approximately 40 manufacturers that sell vehicles in these jurisdictions.

3. Emissions at the Entity Level

As described above, the point of regulation under consideration is the sale of new passenger cars, light duty trucks and medium duty vehicles by manufacturers. At this point, the regulated entity (the manufacturer) cannot measure or calculate actual GHG emissions from vehicle use. Rather, the entity can calculate potential emissions based on the expected operating characteristics of the vehicles sold, including the number of years the vehicles remain in use. These emissions estimates depend, in part, on how owners maintain and use their vehicles (e.g., vehicle miles traveled annually). Additionally, actual emissions will depend on fuel characteristics, including the availability and use of fuels with non-fossil carbon components.

To carry out the necessary emission calculations, the emissions rate associated with each model sold would need to be certified (e.g., emissions per mile traveled). Vehicle testing procedures have been developed to support requirements such as the California vehicle emissions regulations that focus on fleet average emissions. Additional data are required to calculate expected lifetime emissions. Consequently, lifetime emission estimates made at the time of sale by the manufacturers will necessarily have additional uncertainty, which may be a barrier to using the lifetime emissions approach.

4. Administration

There are roughly 40 manufacturers of passenger cars and light duty trucks worldwide. Therefore, the number of entities does not pose an administrative challenge. The manufacturers have the capability to know their compliance obligations and understand the applicable requirements. The potential need to track nearly new vehicles that are registered in the state or province needs to be assessed. For example, to avoid the program requirements, a new vehicle could be sold and registered in a non-WCI jurisdiction and then moved to a WCI jurisdiction and registered. Vehicles with fewer than 15,000 miles (for example) that are registered for the first time in a WCI jurisdiction could be counted as a newly sold vehicle for purposes of the program. Whether this tracking of nearly new vehicles would be needed, and how it would be administered remains to be considered.

In addition to administrative issues, potential legal issues also remain to be examined. The WCI jurisdictions must assess whether they have an adequate regulatory basis for requiring reporting and participation by vehicle manufacturers. If needed, jurisdictions could consider regulating (via permit) automobile manufacturers as “Indirect Sources” of air pollution (for example, Oregon’s regulations at OAR 340-254-0030).

5. Leakage Issues

The sale of new passenger cars and light duty trucks is not particularly vulnerable to leakage because consumers purchase vehicles primarily for local transportation purposes. Concerns have been raised regarding impacts on the rate of turnover of the vehicle fleet. Higher vehicle prices may slow the rate of vehicle replacement, leading to vehicles with higher emissions remaining on the road longer than would otherwise be the case. This impact can be assessed for alternative program designs.

Table 11: Summary of CO_2 Emissions from On-Road Gasoline Combustion

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	25.3	25%
California (2004)	142.3	29%
New Mexico	9.3	13%
Oregon (2004)	13.1	19%
Utah	9.8	14%
Washington	23.5	25%
British Columbia	10.5	16%
Manitoba	3.0	15%
Total WCI Partners	**236.9**	**24%**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
NA = Not Available. Emissions data currently being developed.
Preliminary estimates, subject to review and revision.

H. Large Transportation Fleets

1. Description

This design element covers large transportation fleets. The point of regulation would be entities (e.g., companies, local governments, transit agencies, etc.) that operate fleets of motor vehicles or boats. A key issue in this sector is what constitutes a "fleet" of vehicles or boats. Thresholds in both quantitative (e.g., number of vehicles or boats) and qualitative (e.g. types of vehicles or boats) terms may be applied to limit the scope of regulation within this sector.

1.1 Sectors

Large Transportation Fleets regulated at the fleet management level.

1.2 Emissions Sources

Fossil fuel combustion from fleet vehicles and boats.

1.3 Greenhouse Gases

Carbon dioxide is the dominant GHG produced in this element, accounting for on the order of 97% of emissions from these sources. Nitrous oxide (N_2O) and methane (CH_4) are also emitted.

1.4 Point of Regulation

The point of regulation for this option would be the entity that owns and operates the vehicles that are to be regulated. This entity would be required to hold allowances equal to the emissions of the fleet vehicles. Issues around leased vehicles would need to be clarified.

A threshold for inclusion in the sector would seem to be a practical necessity. Possible thresholds include number of vehicles or boats, combined fleet vehicle miles traveled, total fuel use, or other metrics. However, it may be most appropriate to set an emissions threshold for including fleets in the cap-and-trade program.

Other factors may play into the definition of a "fleet" for the purposes of compliance. Types of vehicles (commercial, off-road, on-road, marine, weights of vehicles, etc.) may be one factor. Geographic range, or the geographic location of a centralized operations base, may also play into a definition of what constitutes a fleet for inclusion in such a program. Inclusion of ferry and other boat fleets (such as those operated by Washington State Ferries, the BC Ferry Corporation and marine barge operations) should be considered under this design element due to the amount of associated emissions.

2. Emissions and Entity Data

Data collection and analysis are underway to estimate the number of fleets at various threshold levels and the portion of emissions that the fleets may represent. Initial indications are that there may be on the order of 10,000 vehicle fleets in the WCI partner states and provinces that each have 10 or more vehicles. However, this is a very preliminary figure.

3. Emissions at the Entity Level

Most fleet management systems would capture the relevant data necessary for estimating emissions from fleet vehicles. Emissions could be estimated from odometer readings, fuel use, and other factors. Protocols for estimating these emissions exist. However, fleet data have been suspect in terms of data reliability and verifiability. The margins of error associated with these data should be considered.

Currently, the fossil carbon content of liquid transportation fuels is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.

If N_2O and CH_4 were included in the cap and trade program for this sector then estimating emissions for these gases may be subject to a wide margin of uncertainty because emission rates depend on vehicle characteristics and maintenance conditions. National and international standard N_2O and CH_4 emission factors for different fuels could be used as a proxy for more precise estimations.

4. Administration

The ability to administer a cap and trade program in the fleet sector is largely a function of how fleets are defined. If the threshold for inclusion (by whatever metric) is low enough to include the numerous family-run or other similar small business operations in trucking, retail, and urban delivery, then the ability for these entities to understand and administer their obligations is questionable. Conversely, the largest fleet operations – especially in trucking, ferries and businesses like rental fleets – are likely well positioned from both an administrative and data perspective to deal with the regulatory burden. Steps may need to be taken, however, to ensure that fleets do not sub-divide their structures to potentially avoid regulation by falling under whatever threshold is put in place.

5. Leakage Issues

There are components of the large fleet sector for which there may be a high level of leakage from any attempt to regulate the large fleet sector. Medium- to large-scale fleets in the goods delivery sector have the ability to locate themselves in any number of locations so long as they have at least some reasonable level of proximity to the markets they operate in. Thus it is possible that in response to any cap-and-trade regime in WCI states and provinces that trucking fleets (in particular) may relocate to the borders of adjoining states and provinces not subject to the cap-and-trade regime.

However, the International Fuel Tax Agreement (IFTA) requires diesel trucks operating in multiple jurisdictions to calculate fuels consumed in each state and province based on the miles traveled in each state/province. All the WCI partners are parties to the IFTA.[15] Consequently, the IFTA data could be used to compute a compliance obligation for fleet operators of diesel trucks that operate in multiple jurisdictions, thereby avoiding leakage.[16]

Leakage is less of an issue for fleets that must serve specific areas. These fleets may include municipal and state/province government vehicles, as well as electric and gas utility trucks. Similarly, leakage would not apply to ferry fleets, and likely not to marine barge and other localized marine fleets.

---

[15] The 48 contiguous states of the United States and 10 Canadian provinces are parties to IFTA. Yukon Territory, Northwest Territory, Nunavut, and the District of Columbia are not parties to IFTA.

[16] IFTA covers diesel trucks with the following characteristics: (a) has three or more axles; or (b) has two axles and a gross vehicle or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms; or (c) is used in a combination that has a combined or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms. Recreational vehicles are not covered.

Smaller fleets serving specific urban markets are less likely to be able to relocate to avoid regulation. However, as previously noted, the administrative feasibility of regulating the smaller fleets is in question.

I. Agriculture Emissions

1. Description

1.1 Sectors

This design element covers the agricultural sector, which includes a diverse set of production activities, including: crop production; livestock production; grazing lands; and other activities. Agriculture can serve as a sink (i.e., can remove carbon dioxide from the atmosphere) or as a source of emissions. Not included in this design element is forestry, although agriculture and forestry are often interrelated because land can change from one use to the other and back.

1.2 Emissions Sources

Given the diversity of agricultural activities, there are a large number of sources of emissions, including:

- methane and nitrous oxide (N_2O) emissions from livestock manure management;
- N_2O emissions from soils due to fertilizer use, legume production, and increased microbial activity associated with liming;
- methane emissions from livestock digestive processes, rice cultivation; and cultivation of other wetland crops;
- methane emissions from the conversion of lands from trees or grasses to annual cropland; and
- carbon dioxide (CO_2) emissions from the use of lime.

In addition to these sources, agricultural lands can emit CO_2 or act as a sink for CO_2 in a given year by changing the carbon stock on the agricultural land. Carbon stock is the carbon contained in biomass, including above and below ground biomass, at a specific point in time. If the carbon stock increases from one year to the next, the agricultural land acted as a sink, and accumulated carbon by removing it from the atmosphere. If the carbon stock decreases, the land released carbon.

Practices that can increase carbon stock (i.e., remove CO_2 from the atmosphere) include reduced tillage, use of cover crops, favorable crop rotations, changing from row crops to permanent pasture or other perennial crops, and increasing productivity of plants on pasturelands.

Emissions due to fertilizer production and fuel use in farm equipment are not included as sources in this sector.

1.3 Greenhouse Gases

N_2O and methane are the primary GHG emitted in the agriculture sector. CO_2 emissions and sinks also occur.

1.4 Point of Regulation

The point of regulation for agriculture is the land owner. The land owner typically has control over how the lands are managed, including the type and level of agricultural production that takes place. Consequently, the land owner has the most influence over the activities that lead to emissions (or sinks) on his/her agricultural lands.

Notably, some agriculture lands are leased to others who use the land for production purposes. For example, grazing lands are often leased to livestock owners, so that the land owner does not necessarily have a comprehensive inventory of the livestock grazing taking place. Federal and state governments are significant leasers of grazing lands, for example accounting for approximately 33% of grazing and range lands in the United States.

2. Emissions and Entity Data

Among the WCI partner states and provinces, agriculture emissions accounted for about 58 MMT of CO_2e in 2005, or about 6% of total gross emissions. This percentage is less than 10% for all the partners, with the exception of Manitoba, which reports agriculture emissions accounting for 30% of gross emissions in 2005. Table 12 summarizes the emissions for the WCI partners.

The total number of entities that would be covered in this sector depends on whether, and at what level, an annual emissions threshold is set. In the livestock sector, confined animal operations (CAOs) typically have the highest concentration of animals and manure that can lead to emissions. As shown in Table 12, the number of CAOs totals more than 18,000 among the WCI partners. Also shown in the table is the number of farms with harvested cropland, an indication that nitrogen fertilizers may be used. The total number of farms with harvested cropland is on the order of 150,000 among the WCI partners.

3. Emissions at the Entity Level

Precise direct measurement of agriculture GHG emissions at the entity level is not currently practical. Emissions estimates are typically made using emissions factors associated with various types of management practices. However, site-specific conditions and individual management practices can have a significant impact on emissions so that actual entity-level emissions can vary substantially from the estimates based on representative emissions factors.

For example, N_2O emissions from soils are the largest component of agriculture GHG emissions. Emission factors for N_2O from soils have very large ranges and uncertainties due to the highly variable rate of emissions spatially and temporally across soil conditions and seasons. Perhaps most importantly, the N_2O emissions factors cannot currently estimate with precision the changes in emissions that may result from changes in practices at the entity level.

Similarly, although emissions factors for livestock emissions, manure management emissions, and rice cultivation emissions are available, they do not easily incorporate site-specific practices that can affect emissions rates.

Emissions or removals of CO_2 can be inferred from changes in carbon stocks. For example, soil carbon stocks can be measured by using soil samples. Together with a properly designed survey, such samples can result in estimates of soil carbon content with high levels of accuracy and precision. However, because the increases or decreases in carbon stocks are small relative to the amount of carbon in the soil, changes can best be estimated by performing surveys spaced a number of years apart. In most circumstances, a five year interval between measurements is likely to be the shortest interval that would result in reliable estimates of changes in soil carbon.

Emissions modeling, combined with field measurements, can be used to better estimate emissions and sinks from agricultural activities. However, the use of these models is generally beyond what can reasonably be expected from most producers.

4. Administration

If individual agricultural land owners are required to hold allowances or report on emissions and emission reductions, a very large number of entities would be involved. As shown in Table 12, many thousands of entities would have compliance obligations. Moreover, as suggested above, tools to measure many agricultural emissions are in early stages of development, and current estimates can have large uncertainties. The wide variety of mechanisms that result in emissions or emission reductions, together with the difficulties of obtaining reliable estimates in many cases would pose a significant challenge. Additionally, as mentioned above, many land owners lease their land to others for grazing or other agricultural purposes. Consequently, the land owner may not have adequate information to perform a reasonable emissions calculation. When combined, these factors pose very significant administrative challenges.

5. Leakage Issues

The agriculture sector is highly vulnerable to emission leakage. The market for agriculture products is international in scope, and highly competitive. If compliance requirements in the WCI region reduce production, production could increase in another region. The shift in production location may result in no net change in emissions overall. Consequently, particular care must be taken as it relates to imposing reporting or other compliance requirements within this sector.

Table 12: Summary of Agriculture Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	CAO Operations[a]	Harvested Cropland[b]
Arizona	4.7	5%	547	3,139
California (2004)	23.5	5%	4,815	54,115
New Mexico	6.2	9%	857	7,204
Oregon (2004)	4.9	7%	3,682	23,013
Utah	4.2	6%	1,862	9,661
Washington	5.6	6%	3,043	21,802
British Columbia	2.6	4%	2,000[c]	14,484
Manitoba	6.1	30%	1,439[c]	16,660
Total WCI Partners	**57.7**	**6%**	**18,245**	**150,078**

a. Confined animal operations, including dairy operations, beef cattle operations, and hog farms. Does not including grazing operations (i.e., non-confined).

b. Entities reporting harvested cropland.

c. Does not include beef cattle operations.

MMT = million metric tons

Percent of gross emissions calculated for each state/province.

Preliminary estimates, subject to review and revision.

J. Forestry and Land-Use Change

1. Description

Forestry and land-use change encompass the suite of human activities and naturally occurring processes and events that result in changes in forest cover and/or changes to the amount of carbon stocks on forest lands. Forestry can serve as a sink (i.e., can remove carbon dioxide from the atmosphere) or as a source of emissions.

1.1 Sectors

The forestry sector refers to lands that support, or can support, a given tree canopy cover and that allow for management of one or more forest resources, including timber, fish and wildlife, biodiversity, water quality, recreation, aesthetics and other public benefits.[17] Forest lands are owned by federal, state, provincial, and municipal governments, companies, individuals, and non-governmental organizations. Forest lands can serve multiple purposes, including supply of wood and fiber, recreation, habitat, scenic enhancement, water quality, preservation of carbon stocks, and other purposes.

Land-use change refers to the conversion of land from one purpose to another. Forest land may be converted to other uses through deforestation or, for example, to residential use. Land that was not in forest cover may become forest land (i.e., through reforestation or afforestation). Agriculture and forestry are often interrelated because land frequently changes from one use to the other and back.

This design element does not include the processing of timber into products, or the use of forest biomass for energy production. The long-term fate of harvested wood products could be included as part of this design element, but doing so is challenging, particularly at the land owner level.

1.2 Emissions Sources and Sinks

The extent to which forest lands emit greenhouse gases (primarily CO_2) or act as a sink for CO_2 in a given year is measured in terms of the change in carbon stock on the forest land. Carbon stock is the carbon contained in forest biomass, including above and below ground biomass, at a specific point in time. If the carbon stock increases from one year to the next, the forest land acted as a sink, and accumulated carbon by removing it from the atmosphere. If the carbon stock decreases, the forest land released carbon.

Carbon stocks on forest lands can increase or decrease through both natural events and human intervention. Natural fire cycles affect the carbon stock on forest lands. Human activities can affect the fire cycle, however. Forest management for commercial or noncommercial harvest of biomass can also affect carbon stocks. If the amount of biomass that grows is the same as the amount of biomass removed for products or energy, the managed forest is presumed to result in no net emissions from changes in carbon stocks. In the event of forest fires, insect and disease, or unsustainable harvesting practices, forests can act as significant carbon sources.

Land-use change can also result in emissions or a sink. Land that changes from non-forest cover to forest cover will show an increase in carbon stock, and consequently is a sink over the

[17] A tree canopy cover of 10% is used to define forest land by the California Climate Action Registry (see *Forest Sector Protocol*, Version 2.1, The California Climate Action Registry, September 2007, available at: http://www.climateregistry.org/PROTOCOLS/FP/). Other percentages are also used, such as 25% in British Columbia and other Canadian provinces.

long term. Land that is converted from forest cover to another use, such as agriculture, will show a reduction in carbon stock, and consequently is an emission source.

While the overall impact of human activities and natural events and processes can be assessed as changes in carbon stock, the specific activities and events that result in emissions include:

- immediate release from burning of biomass (including in forest fires);
- residual release from biomass decay;
- soil carbon releases due to soil disturbance;
- decay of harvested wood products; and
- decay of standing timber (from insect and disease or general decline).

Finally, it should be noted that long-lived wood products, such as furniture and building materials, also represent a carbon pool. The carbon in these products was removed from the atmosphere through forest management. Methods for accounting for the wood product carbon pool have been developed for national and state/province level inventories. However, accounting methods are not available for application at the land owner level. Consequently, incorporating the carbon pool from long-lived wood products into a cap-and-trade program at the land-owner level would be very challenging at this time.

1.3 Greenhouse Gases

The predominant greenhouse gas affected by forestry and land-use change is CO_2. However, biomass combustion (e.g., due to forest fires) also results in nitrous oxide (N_2O) emissions. Forests can also act as either sources or sinks for methane. The N_2O and methane emissions are very small compared to the CO_2 emissions and sinks.

1.4 Point of Regulation

The point of regulation for forestry and land-use change is the land owner. The land owner typically has control over how the forest lands are managed, within the applicable regulatory framework of the jurisdiction in which the lands are located. Consequently, the land owner has the most influence over changes in carbon stock on his/her forest lands.

As discussed below, governments are large owners of forest lands. Companies and individuals own smaller parcels, although some individual private holdings are significant. A threshold of parcel size may be used to limit the coverage of the large numbers of owners of small amounts of forest lands.

2. Emissions and Entity Data

Among the WCI partners and provinces, forestry and land use change have been estimated to be an overall sink for GHG emissions. As shown in Table 13, the sink was on the order of 11% of gross emissions in 2005. The size of the sink varies significantly across states and provinces, with the forestry sink being sizable compared to gross emissions from some jurisdictions. Of note is that although forestry and land use currently are a sink, some analysts have estimated that the forest sector could be a much larger sink than is currently the case. Consequently, forestry provides an opportunity to increase the sequestration of carbon.

Governments are significant owners of forest lands in the WCI states and provinces. For example, the provincial government of British Columbia owns 95% of forested land in the province. Most of remainder of the forest land is owned by a small number of forestry companies, and many small land owners. In California, the federal government owns approximately 52% of forest lands, and provincial/local governments own about 3%. The remainder of the forest land (45%) is privately owned. Similarly, in Washington, approximately 57% of forest lands are publicly owned, with 43% privately owned. Table 13 lists the portion of forest land that is publicly owned in each WCI partner jurisdiction.

The land owners that convert forest lands to other uses (such as urban development) are not typically the large government land owners. Rather, owners of smaller parcels are involved in converting forest land to other uses, an activity that typically results in net emissions. Many thousands of land owners in the WCI region play a role in conversion of forest lands to other uses.

3. Emissions at the Entity Level

Protocols on how to perform forest carbon modeling are well established (IPCC Good Practice Guidance[18], 2006 IPCC Inventory Guidelines[19]) as are international reporting mechanisms (UNFCCC, Kyoto Protocol[20]). While the models have degrees of uncertainty (particularly due to the quality and consistency of input inventory data and growth and yield curves), they are internationally accepted and used. These approaches are typically used at the government level for national and state/province inventories.

Protocols have also been developed for measuring changes in carbon stock at the land owner or entity level.[21] To apply these methods, landowners would be required to conduct periodic inventories to determine their carbon stock over time. As these methods typically rely on characterizations of samples of areas within forest lands, and are measuring biological activities, the resulting emission/sink estimates are generally considered to be less precise than emissions calculations for fossil fuel combustion emissions.

Notably, the extent to which a given parcel of forest land is a source or a sink in a given year depends, in part, on previous years and future years. For example, the natural fire cycle may reduce the carbon stock on certain forest lands in a given year. In that year, the land is an emissions source. In subsequent years, the carbon stock may increase, indicating that the forest is a sink. Over time, the forest may be carbon neutral, so that it is neither a source nor a sink. This time-dependent nature of carbon stocks on forest lands would need to be addressed in the estimating procedure at the individual land owner level under a cap-and-trade program.

4. Administration

As described above, governments typically own a large portion of forest lands. Nevertheless, there are many owners of large land holdings (including those engaged in commercial harvesting) and a very large number of owners of smaller land parcels. Many of the forest land owners are not typically covered by existing air quality regulations, although those involved in commercial harvesting may be regulated under other programs. Identifying all the relevant land owners could be a significant administrative challenge unless smaller parcels were excluded from the program.

The ability to measure emissions from all relevant land owners also presents a challenge. Specialized expertise is required to measure carbon stock changes at the entity level using

[18] http://www.ipcc-nggip.iges.or.jp/public/gpglulucf/gpglulucf.htm

[19] http://www.ipcc-nggip.iges.or.jp/public/2006gl/index.htm

[20] http://unfccc.int/kyoto_protocol/items/2830.php

[21] See, for example, *Forest Sector Protocol*, Version 2.1, The California Climate Action Registry, September 2007, available at: http://www.climateregistry.org/PROTOCOLS/FP/.

existing protocols. Ensuring the availability of this expertise to all relevant land owners could also present a significant challenge.

Given these administrative challenges, a less than fully comprehensive approach to covering forestry and land-use change within a cap-and-trade program may need to be considered. For example, the cap-and-trade program could focus solely on land conversion, from forest cover to other uses, and from other uses to forest cover. Other policy measures and approaches (outside of the cap-and-trade program) could be used to address the other aspects of the forestry and land-use change sector. The portion of emissions/sinks that could be addressed with a cap-and-trade program by such an approach remains to be assessed.

5. Leakage Issues

Important components of the forestry sector are highly vulnerable to emission leakage. The market for wood products is international in scope, and highly competitive. In response to reduced commercial forest production in one region, production could increase in another region. The shift in harvest location may result in no net change in emissions overall. Consequently, particular care must be taken as it relates to requirements for emission measurement or other requirements for the commercial forest products portion of the sector.

Land conversion, from forest lands to urban development for example, may be vulnerable to leakage if alternative locations for development are available. However, given the size of WCI jurisdictions, such leakage has the potential to be small. Perhaps more important is the potential for increased costs to affect the rate of forest conversion. If significant costs are imposed to prepare emission inventories for forest lands, owners of small parcels may find it advantageous to convert their land to other uses so as to avoid the emission inventory requirement. This potential impact must be considered carefully to assess potential negative impacts of including forest lands under a cap-and-trade program.

Table 13: Summary of Forestry Emissions (Sinks)

State/Province	**2005 Emissions (MMT CO_2e)**	**Percent of 2005 Gross Emissions**	**Portion of Forest Land Publicly Owned**

K. High GWP Gases

1. Description

Hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6) are potent greenhouse gases, some of which persist in the atmosphere for thousands of years. These gases, referred to as high global warming potential (GWP) gases are from 650-23,900 times more potent than CO_2 in terms of their capabilities to trap heat in the atmosphere over a 100-year period. Also, because they remain in the atmosphere almost indefinitely, atmospheric concentrations of these gases will increase as long as emissions continue.

1.1 Sectors

High GWP gases are used by and emitted from a wide variety of activities and equipment. The overwhelming majority of the use and emissions of these gases are associated with their use as substitutes for ozone depleting substances that have been phased out. Consequently, these gases are used are as refrigerants in residential, commercial and industrial equipment, as well as aerosol propellants and solvents.[22] High GWP gases are also used in semiconductor manufacturing, magnesium production, and other miscellaneous applications. SF_6 is used in electric power transmission and distribution systems. Emissions of SF_6 from these sources are included in the electric sector, and are not included here.

In some cases, high GWP gases are produced as byproducts of industrial processes. For example, CF_4 and C_2F_6 are produced during aluminum smelting. These process-related emissions are not included in this design element, but rather are included under industrial process emissions.

1.2 Emissions Sources

High GWP gases are emitted in several ways. When used as refrigerants, these gases may leak during normal equipment operation, or may be released as a result of equipment failure. Additionally, during equipment servicing or disposal the refrigerants may be deliberately or inadvertently released. It is currently best practice to collect and recover refrigerants during servicing and disposal so as to prevent emissions (capture and recycling is required in some jurisdictions). However, consumers can purchase cans of refrigerant to recharge their automobile air conditioners. Emissions may result from these consumer maintenance activities, and residual amounts of refrigerant in the cans are also typically emitted.

The semiconductor manufacturing industry uses high GWP gases in plasma etching and in cleaning chemical vapor deposition tool chambers. These processes use the gases to selectively create circuitry patterns and remove deposited materials.[23] The high GWP gases are vented as part of this process. In some cases, the gases may be captured and recycled to prevent emissions. The magnesium metal production and casting industry uses sulfur hexafluoride (SF_6) as a cover gas to prevent the rapid oxidation of molten magnesium in the presence of air. The SF_6 is emitted as part of this process.

1.3 Greenhouse Gases

The high GWP gases include hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6).

---

[22] For more information see: *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990 –2005*, U.S. Environmental Protection Agency, Washington, D.C., 2007, p. 4-44, available at: http://epa.gov/climatechange/emissions/usinventoryreport.html.

[23] For more information, see: http://www.epa.gov/highgwp/sources.html.

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for high GWP gases as the point of emission for the majority of the high GWP emissions sources. In particular, emissions from leaks and servicing of residential, commercial, and industrial refrigeration and air conditioning equipment would be the responsibility of the equipment owners and servicing companies. In most cases these emissions cannot be measured directly, and the equipment owners and service personnel are not in a position to calculate and report the emissions as part of a cap and trade system. Similarly, the users of aerosol products are not in a position to calculate and be responsible for the emissions associated with their product usage.

Consequently, the approach under consideration is to hold the manufacturers of the high GWP gases responsible for the emissions. In nearly all cases, all the gases produced will eventually be emitted. The gases are rarely converted to other substances or destroyed. Consequently, the quantity of gas manufactured is a reasonable estimate of the expected emissions. The gas manufacturer would be required to hold allowances to cover the total production and sale of high GWP gases each year.

In taking this approach, the program would cover the emission of newly manufactured high GWP gases. This approach does not cover the high GWP gases that are already stored in equipment, and are vulnerable to release.

As an alternative to placing the point of regulation on the manufacturers, it could be placed at the point where the gases enter into commerce in each state or province. This approach would require comprehensive tracking of the distribution and sale of these gases within each jurisdiction, for example through the licensing of dealers.

The use of high GWP gases in industrial applications, such as semiconductor manufacturing and magnesium manufacturing, could be addressed differently. The entity responsible for the emissions (i.e., the facility) could be defined as the point of regulation. The quantity of gas used and emitted could be tracked, and the entity would be required to hold emission allowances.

2. Emissions and Entity Data

Among the WCI partner jurisdictions, the high GWP gases are a relatively minor portion of total gross emissions, accounting for about 3% of total emissions in 2005. However, these emissions are expected to grow faster than total emissions through 2020. Table 14 summarizes the emissions estimates for 2005.

High GWP gases are produced by a small number of chemical manufacturing companies internationally. For example, *Chemical Market Reporter* identifies nine companies producing fluorocarbon gases (HFCs) in the United States at 14 plants. Only one plant is located in a WCI partner state, accounting for less than 10% of total production capacity.

3. Emissions at the Entity Level

As described above, one point of regulation under consideration is at the gas manufacturer. At this point, the regulated entity (the manufacturer) cannot measure or calculate actual GHG emissions. Rather, the entity can calculate potential emissions based on the expected release over time of the total amount of the gas produced. The manufacturer would calculate its emissions responsibility as the quantity of gas produced times the appropriate GWP for the gas.

If the point of regulation is at the industrial facility that uses and emits the gas, the calculation would be similar. The total amount of gas used and emitted would be multiplied by the appropriate GWP. Any destruction or conversion of the gas in the industrial process could be accounted for at the facility level.

4. Administration

The relatively small number of manufacturers of high GWP gases would make administration at the manufacturer level tractable. However, as discussed above, nearly all the manufacturers and their plants are not located in WCI jurisdictions. Consequently, WCI states and provinces would not be in a position to regulate their production or sales of these gases.

The alternative approach of setting the point of regulation at the point where the gases enter into commerce in each state and province would be more administratively challenging. A system of licensing and tracking of the sales of the gases does not currently exist, and would need to be created.

Assigning the point of regulation to industrial facilities that use the gases, such as semiconductor manufacturing and magnesium manufacturing, is administratively feasible. There are a relatively small number of facilities, each of which could be tracked. The covered entities should have the capability to know their compliance obligations and understand the applicable requirements. However, it should be noted that these facilities account for a very small portion of the total emissions from this sector.

5. Leakage Issues

Vulnerability to emissions leakage is an important consideration for this design element. High GWP gases are produced and traded internationally. Actions that increase production costs in the U.S. and Canada could shift production elsewhere, resulting in no change in actual emissions. To address this leakage potential, imports of the gases would also need to be covered, which is beyond the jurisdiction of states and provinces. The potential impacts associated with covering industrial facilities should also be examined. For example, semiconductor production could also shift elsewhere, resulting in no change in actual emissions.

Table 14: Summary of High GWP Gas Emissions

State/Province	**2005 Emissions (MMT CO_2e)**	**Percent of 2005 Gross Emissions**
Arizona	3.7	4%
California (2004)	14.8	3%
New Mexico	1.1	1%
Oregon (2004)	2.1	3%
Utah	2.0	3%
Washington	2.1	2%
British Columbia	0.0	0%
Manitoba	0.0	0%
Total WCI Partners	**25.8**	**3%**

NA = Data not available. Data currently being developed.
MMT = million metric tons
Percent of gross emissions calculated for each state/province.
Preliminary estimates, subject to review and revision.

Scope Subcommittee
Stakeholder Conference Call
8:30 AM Pacific Time   February 12, 2008

Call in Number: 1.800.868.1837; Participant Code: 659 537#
To ask a question, press *1

8:30 Introductions

8:40 Transportation Fuels

The subcommittee would like to understand the comments received regarding the inclusion of transportation fuels in the scope of the WCI cap-and-trade program. Many comments were received supporting the inclusion of transportation fuels. We would like to discuss the following issues:

1. How does the inclusion of transportation fuels affect other sources in the cap-and-trade program, and the development of a market for allowances?
2. Should alternate strategies be used to reduce emissions from transportation through 2020 rather than including transportation fuels in a cap-and-trade program? How do the alternate strategies compare in terms of cost and environmental effectiveness? Are some strategies complementary to including transportation fuels in a cap-and-trade program?
3. Comments were received suggesting that transportation fuels be phased in to a cap-and-trade program in the future. Does phasing create risks, such as increasing uncertainty or volatility in the allowance market? What are the benefits of phasing?
4. What are the pros and cons of allowing flexibility among the WCI states and provinces regarding the inclusion of transportation fuels in the cap-and-trade program?
5. If transportation fuels are included in the scope, how will the transportation fuels industry comply with the cap? What are the implications of the cost of carbon allowances being substantially passed through to consumers? Should the potential impacts on low income consumers be addressed, and if so how?

9:20 Natural Gas

The subcommittee would like to understand the comments received regarding the inclusion of residential and commercial natural gas combustion by placing the regulatory obligation at the local distribution company. We would like to discuss the following issues:

1. Should alternate strategies be used to reduce emissions from residential and commercial natural gas combustion through 2020 rather than including them in a cap-and-trade program? How do the alternate strategies compare in terms of cost and environmental effectiveness? Are some strategies complementary to including these emissions in a cap-and-trade program?
2. If these emissions are included in the scope, how will the LDCs comply with the cap? What are the implications of the cost of carbon allowances being substantially passed

through to consumers? Should the potential impacts on low income consumers be addressed, and if so how?

9:40 Open Discussion on All Scope Topics

The subcommittee invites participants to ask questions and make additional comments.

WCI Reporting Subcommittee
1/3/08

Summary of Major Options for a GHG Reporting System to Support the WCI Program

Background

A robust and credible reporting system will be the backbone of the WCI program. This system will need to ensure that emissions are quantified and reported in an accurate and transparent manner. It will allow regulators in the participating jurisdictions to assess compliance of regulated sources, measure progress against state, provincial and regional targets and generate public trust in this progress. Additionally, market participants of all stripes will rely on the reporting system and the data it generates to make decisions on which significant transactions will be based. Confidence in the reporting system will be critical to the success of the WCI program.

Starting Assumptions

The WCI is fortunate in that several GHG reporting systems exist that can inform the design of and perhaps even underpin the reporting system it will require. The Reporting Subcommittee has assessed many of these systems and anticipates that the reporting system it ultimately recommends will attempt to establish as much consistency with as many of them as the details and rigor of the WCI program allow. Many of the details of the WCI reporting system however will necessarily depend on decisions currently being considered by other Subcommittees.

This reality aside, the WCI partners are unanimous in their view that the reporting component of the program should rely as heavily as possible upon the infrastructure currently under design by The Climate Registry (the TCR). The TCR is a nonprofit corporation that is a collaborative effort between U.S. states, Canadian provinces and Mexican states to establish a common infrastructure for measuring and reporting GHG emissions. All of the WCI partners are members of the governing board of the TCR. The objective of the TCR is to provide a common set of tools for the measurement and reporting of GHG emissions that can support a broad range of state or provincial policies.

In the first phase of its development, the TCR is designing a voluntary entity wide GHG reporting program. This program can be conceptualized of as consisting of three major components: 1) entity reporting specifications, 2) quantification methodologies and 3) reporting services and systems. The reporting specifications dictate all parameters specific to the TCR program--what must be reported, how an entity is defined for reporting purposes, the sources and gases it must report, the frequency of reporting and verification, etc. The quantification methodologies dictate how emissions from specific sources are measured or calculated. Finally, the TCR's services and systems will provide assistance to reporters, support verification, and collect, store and make data available to the public.

A WCI reporting system could rely heavily on the TCR's quantification methodologies and its services and systems. Doing so should reduce the costs of implementation for partners, ease the reporting burden on regulated entities, and ensure the basic consistency both between data collected within the WCI region and data collected in other regions that also rely on the TCR. However, the WCI will necessarily need to develop its own reporting specifications, consistent with the scope of the sources and gases it regulates and other program parameters. Figure 1 and Table 1 illustrate how the WCI could rely on the TCR to provide major components of its reporting system.

<u>Major Options for a Reporting System</u>

Beyond the WCI's intention to rely on TCR infrastructure to the maximum extent possible, the Reporting Subcommittee has identified several major options for the design and implementation of a reporting system that it is actively considering. These are summarized below.

The WCI Reporting Subcommittee welcomes partner, observer, and stakeholder input regarding these options. Specifically, the Subcommittee seeks input regarding additional advantages or disadvantages concerning the options below and any recommendation that the commenting party may have for choosing between the options. In addition, the Subcommittee welcomes any suggestions parties may as to whether additional major options should be considered, and if so what they are.

1. Breadth/Scope of Reporting

a. Should reporting be required only for sectors/sources included within the cap?

Advantages
▪ Ease of start up, could be put in place relatively quickly
▪ Necessary reporting methodologies likely available "off the shelf"

Disadvantages
▪ Limited data utility: supports compliance only

b. Or, should reporting be required for sectors/sources not included in the cap-and-trade program (e.g., ones that are likely to be phased in over time)?

Advantages	Disadvantages
▪ Could support expansion of cap to additional sectors/sources (both by collecting data that could inform decisions about expansion and through regulatory assimilation of reporters)	▪ Increased reporting burden
▪ Potential to stimulate voluntary reductions outside of cap through measurement and public reporting	▪ May require development or refinement of reporting approaches that do not yet exist or are not yet robust enough
▪ Data collection could support development of sectoral baselines for offsets	
▪ System could serve to aggregate top down inventories of partner jurisdictions for a regional top down inventory	

2. Initiation of Reporting

a. Should mandatory reporting begin before cap and trade commences?

Advantages	Disadvantages
▪ Bottom-up data could be used to "true-up" baselines otherwise established with top-down data only	▪ Likely to delay start of cap
▪ Sector/source data could inform allocation decisions (minimizing initial risk of over-allocating sources)	
▪ Would allow reporters time to put measurement and management systems in place	
▪ Could promote voluntary early reductions (especially if coupled with a mechanism for incentivizing early action)	

b. Or should mandatory reporting begin only with the start of the cap's first compliance period?

Advantages	Disadvantages
▪ Could initiate cap more quickly	▪ First compliance period of cap may be a de facto "training wheels" period that may be accompanied by greater market volatility
▪ Minimizes pre-cap compliance burden	

3. Coordination Among Partner Jurisdictions on Reporting

a. Should WCI develop a single WCI reporting rule that stipulates all reporting specifications?

Advantages	Disadvantages
▪ Maximizes harmonization of reporting systems across WCI jurisdictions and consistency of data collected there from	▪ Adoption of a single reporting rule in all WCI jurisdictions, without significant modification may prove difficult
▪ Easy adoption of reporting rules for jurisdictions that do not already have reporting rules in place	▪ Could create challenges for WCI jurisdictions that already have reporting rules in place
▪ Easier to update or modify reporting rules through a unitary reporting rule	
▪ Minimizes compliance burden for entities operating sources in multiple WCI jurisdictions	

b. Or should individual WCI jurisdictions have loosely coordinated rules possessing common core elements? If so, what aspects should the common core elements cover or include?

Advantages	Disadvantages
▪ Would require less modification of existing rules in WCI jurisdictions that have adopted or are developing reporting systems	▪ Partners put in position of assessing whether one another's reporting rules comply with minimum standards
▪ Identifying the minimum required common elements for reporting rules for partner jurisdictions would require less time and resources than development of a detailed model reporting rule	▪ Partners might be need to develop quantification methods for sources and sectors for which methods do not yet exist (either in TCR guidance or in other existing mandatory reporting systems)

4. Data Management and TCR Interaction

a. Should WCI require that all capped sources report directly to and verify through the TCR?

Advantages
▪ Maintaining a single central data collection system and database through the TCR more efficient and less resource intensive than maintaining multiple partner-specific systems
▪ Minimizes the reporting burden on entities that operate regulated sources within multiple jurisdictions (i.e. reporting to a single system)
▪ Would ensure consistency across jurisdictions in the way that data quality is verified
▪ Greater ease of start-up as TCR is already in process of developing a data collection system and verification system

Disadvantages
▪ May present a legal question for some jurisdiction as to whether sources can be mandated to report to a non-profit third party
▪ Could create the appearance that partner jurisdictions are ceding compliance authority (though could be mitigated by allowing partners "first touch" such that data is not released by TCR until partner provides approval)

b. Or should sources report to and verify at the level of the individual jurisdiction (with data then uploaded to the TCR or otherwise shared centrally)

Advantages
▪ Would allow jurisdictions that have already have data collection and verification systems in place to continue to rely on those systems
▪ GHG reporting and verification in some jurisdictions might simply be "piggy-backed" on existing air pollution data collection efforts

Disadvantages
▪ WCI would have to articulate minimum data handling and verification standards
▪ Partners and TCR would have to invest significant resources in data exchange capabilities
▪ "Versioning" problem would be significant where updates to partner data collection systems would create ongoing data exchange challenges
▪ Standards for data verification could vary significantly

5. *Verification*

a. Should WCI require third party verification?

Advantages	Disadvantages
▪ Consistent with international practice	▪ Might require additional layer of data quality assurance than is already required by some jurisdictions
▪ Could rely on TCR third party verification system that is already under development	▪ Stakeholder perception that costs of verification high
▪ Efficient approach for large number of diverse source types	
▪ Could allow entities that operate regulated sources in multiple WCI jurisdictions to use a single verifier, reducing costs	

b. Or should WCI allow multiple approaches to ensuring data quality (other than third party verification)?

Advantages	Disadvantages
▪ Greater flexibility for partners to rely on existing data quality assurance approaches	▪ Nearly impossible to maintain and implement consistent standards for data quality
▪ Could streamline quality assurance process for sources reporting both GHG and other air pollution data	▪ Increased costs for entities operating regulated sources in more than one WCI jurisdiction

6. *Administrative Costs & Fees*

a. Should states and provinces mandate that fees go directly to TCR and TCR administers the reporting database?

Advantages	Disadvantages
▪ Consistent fee structure across states and provinces.	▪ States and provinces may not have authority to require fees to be paid to a third party without new legislation.
▪ Fewer transaction steps should allow lower transaction costs.	▪ States and provinces will not have fee revenue to support their reporting efforts.
▪ TCR would more directly manage its own financial health.	

Advantages	Disadvantages
	▪ There may need to be a different fee structure for entities that report only within partner jurisdictions instead of entity-wide with TCR.

b. Or should states and provinces collect fees and contract with TCR to administer the reporting database?

Advantages	Disadvantages
▪ States and provinces could use a portion of the fees to administer their reporting efforts	▪ TCR may not be assured of adequate funding to administer the database.
	▪ More transaction steps may result in higher transaction costs.

7. *Mandatory Federal Greenhouse Gas Reporting*

On December 18, 2007, Congress adopted an omnibus appropriations bill that directed the U.S. Environmental Protection Agency to develop and publish a rule requiring mandatory reporting of greenhouse gas emissions above appropriate thresholds in all sectors of the economy. The Agency is publish a draft rule within nine months, and a final rule within 18 months, and is to determine appropriate thresholds, frequency of reporting, and reporting of emissions resulting from upstream production and downstream sources to the extent it deems appropriate. Similarly on December 8, 2007, Canadian Environment Minister John Baird announced that firms in Canada's major industrial sectors (emitting above set thresholds) will be required to report their 2006 greenhouse gas emissions by May 31, 2008 to enable the Government to develop its industrial air emissions regulations.

How should WCI states/provinces and The Climate Registry incorporate and interface with this development and new Canadian Federal GHG reporting requirements in designing and implementing their GHG reporting program?

WCI Offsets Subcommittee

Summary of Major Options for a GHG Offsets System to Support the WCI Program

January 3, 2008

Background

The Western Climate Initiative Offsets Subcommittee is examining the potential design, scope and operation of a greenhouse gas offset mechanism as an element of the WCI cap-and-trade system. The Subcommittee will develop recommendations within each of the four task areas in its workplan[1]: the role and objectives of a WCI offset mechanism, the core design elements of a WCI offset mechanism, offset eligibility and fungibility, and offset program structure and authority. While work on each of these tasks continues, the Offsets Subcommittee has identified a set of critical path questions – the Major Options listed below -- that will inform the extent and direction of further analysis and recommendations.

The Offsets Subcommittee seeks Partner, observer, stakeholder and public input on these options. This document identifies several advantages and disadvantages for each option. The Subcommittee recognizes that this list is not exhaustive, and that many of the pros and cons may be lessened – or enhanced – depending on how an offset mechanism is designed and implemented in practice. Therefore, the Subcommittee welcomes input on additional advantages and disadvantages, and on how some of the advantages shown can be maximized, or disadvantages minimized, in the design of an effective offsets mechanism.
Commenters are encouraged to fully discuss the reasoning behind each response.

[1] The Workplan for the WCI subcommittees was released to the public on October 29th, 2007 and is available at: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F13792.pdf

1. Should the WCI allow offsets as a compliance mechanism?

Advantages	Disadvantages
▪ Achieves a given emissions goal at lower overall cost (economic efficiency); provides lower cost compliance options for capped sources ▪ By reducing program costs, can enable establishment of a lower cap than might otherwise be possible	▪ Poses a risk to environmental integrity of the cap, if issues surrounding additionality, permanence, leakage, quantification or verification are not adequately dealt with.
▪ Can spur technology development and innovation in sectors, sources, and locations not included in the cap-and-trade program ▪ Can provide environmental and social co-benefits, such as reduced air pollution, habitat preservation, or job creation, in sectors/sources not included in the cap-and-trade program	▪ Reduces incentive for investment and innovation in lower-emitting technologies by sources and sectors included in the cap-and-trade program ▪ Reduces any associated co-benefits in these sources and sectors
▪ Sends a carbon market signal to emissions sources or sectors that might be otherwise difficult – with emissions too small, disperse, uncertain, or episodic -- to include in a cap-and-trade program ▪ Enables participation of, and new revenues sources and business opportunities for, sectors/sources and locations not included in the cap-and-trade program	▪ May create a barrier to later inclusion of sectors/sources in cap-and-trade systems or conflict with alternative policy instruments (e.g. standards or incentives) in sectors/sources where offsets are allowed, if these issues are not adequately addressed in program design ▪ May be perceived as inequitable to the extent that some emission sources benefit from offset revenue while sources covered by the cap-and-trade system face compliance costs
▪ May be less costly per ton of GHG reduced than other mechanisms (e.g. regulation or incentives) for achieving reductions at sources/sectors not included in the cap-and-trade program, as a result of market forces	▪ May be more costly per ton of GHG reduced than other mechanisms where the cost of implementing offset projects is significantly lower than the market price of offsets
▪ Builds capacity and expertise within the region	▪ Can create administrative complexity and costs, and decisions would be needed on rules and procedures
	▪ May create challenges in sectors/sources not included in the cap-and-trade program where existing incentives and regulations differ significantly between jurisdictions, if these issues are not adequately addressed in program design

2. Location

The WCI is considering the implications of restricting the eligibility of offsets on a geographical basis. Such restrictions could limit some of the disadvantages noted above. At the same time, the WCI recognizes that such restrictions may affect the liquidity of the market and increase compliance costs.

a. Should the WCI allow offsets (only)* from projects located within its Partner jurisdictions?

Advantages	Disadvantages
▪ Enables financial flows and reductions/removals to remain within the region; concentrates other benefits of offset market to the region listed above (co-benefits, innovation); may be easier to ensure credibility and environmental integrity of offsets outside the WCI region (see list of potential disadvantages of allowing offsets from outside the WCI under question 2b below)	▪ Could lead to increased compliance costs, less stringent cap for sources/sectors in the cap-and-trade system, greater price uncertainty, reduced prospects for linkage (see list of potential advantages of allowing offsets from outside the WCI under 2b below)
▪ Could provide a competitive edge for the region, assuming other jurisdictions eventually adopt cap-and-trade programs with a role for offsets	▪ May be questioned by industry (with operations both within and outside the WCI) or by other jurisdictions
▪ May provide leverage to encourage other jurisdictions to join	

* - Note that all options are still under consideration, including the possibility of not allowing offsets from within the region, thus "only" is shown in parenthesis. The subcommittee recognizes that questions 1, 2a, and 2b are somewhat overlapping.

b. Should the WCI allow offsets from projects located outside the WCI (either in the rest of North America or internationally)?

Advantages	Disadvantages
▪ Enables access to a much larger and well established offset market, providing liquidity and offset availability, which may be important in achieving economic efficiency benefits or setting a more ambitious cap level ▪ Could reduce price uncertainty due to the magnitude of potential supply	▪ Could lead to financial flows out of the region and foregone benefits to local projects ▪ May be more difficult to ensure credibility and environmental integrity of offsets outside the WCI region
▪ Can provide support to, and increase prospects for linkage with, other regional or international climate agreements	▪ May raise concerns about consistency or rules and procedures with a WCI offsets program if created
▪ May require less administrative effort for offsets that have undergone adequately rigorous certification processes	▪ May increase complexity and costs of administration, or risk environmental integrity, for offsets that have not undergone certification processes that are adequately rigorous
▪ Can support adoption of low-carbon technologies, technology transfer, and sustainable development benefits to developing countries	▪ May not yield anticipated technology transfer and sustainable development benefits unless additional criteria are applied

3. *Quantitative Limits on the Use of Offsets.*

a. Should there be quantitative limits on the use of offsets (perhaps based on their location) to meet compliance obligations?

Advantages	Disadvantages
▪ Moderates some of the potential disadvantages of offsets (see section 1) ▪ May increase the extent of emission-reducing investments made by sources/sectors included in the cap-and-trade program	▪ Reduces ability to utilize lower-cost compliance options, and thereby could increase compliance costs ▪ Reduces the market signal to, and potential ancillary benefits from sectors, sources and locations not included in the cap-and-trade program. ▪ May result in setting a less stringent cap for the cap-and-trade program, given the higher overall program costs that offset limits might imply
▪ Can be relaxed if compliance costs are considered to be too burdensome	▪ May constrain development of a robust offset market (e.g., due to investment uncertainties) and create liquidity concerns
▪	▪ Differing limits based on location would increase administrative complexity

In relation to the quantitative limits, the WCI is also considering: how such limits might change over time; how such limits might vary based on the price of allowances; and whether offsets might be discounted (such that a ton of emission reductions from an offset might count as less than a ton towards compliance obligations, based on their location, project type, or other factors), among other possibilities.

4. *Eligible offset project types within WCI*

a. ***Should the WCI decide by August 2008 upon an initial list of approved project types, possibly including approved baseline and monitoring methodologies, prior cap-and-trade design?*** If offsets are allowed (see question 1 above), the WCI would likely establish a process and criteria for approving project types and methodologies on an ongoing basis. The question here is whether time is sufficient and benefits are significant enough to warrant establishing an initial set of approved project types (and perhaps including methodologies) prior to the WCI design to be issued in August 2008.

Advantages	Disadvantages
▪ Quantification methods exist for a number of project types, and have been approved for use in a number of systems (e.g., RGGI, CDM)	▪ Requires assessment of the availability of sufficiently robust quantification methods to ensure that offsets from a given project type are real surplus/additional, verifiable, permanent, and enforceable
▪ Sends an early signal and provides added certainty to potential offset sources and investors	

b. Should the WCI allow offsets from sources capped and regulated by the cap-and-trade system or from indirect emission reductions in sectors covered by the cap-and-trade system?

Advantages	Disadvantages
▪ Increases liquidity	▪ More administratively burdensome than treatment under the cap
▪ To maintain environmental integrity (and avoid double counting) allowances can be set aside or retired for offsets from capped sources	▪ Requires maintaining set asides or determining which allowances to retire, which can increase complexity of the system
▪ Enables additional (double) crediting for specific project types, where an added incentive for specific project types or technologies is desired	▪ Creates potential for double counting from simultaneously generating both an offset and a freed up allowance
▪ Can be allowed (as early action credit) until caps take effect	▪ Offsets from sources/sectors included in the cap-and-trade system are excluded by some other trading systems (e.g. RGGI)
▪ Indirect emissions reduction projects represent a potentially significant area of interest and potential (demand-side electricity efficiency, renewable electricity, biofuels, transit, cement use, etc.)	▪ Other mechanisms such as allowance allocation can be used to support indirect emission reduction opportunities

.

5. Linkage with, and use of allowances from, other emission trading systems

The WCI is initially discussing the question of linkage within the Offset Subcommittee, with the recognition that it raises a number of questions distinct from the offsets-specific issues noted above. Input from multiple subcommittees is anticipated. Potential linkage with other systems will have implications with respect to offsets, both directly (by enabling access to offset commodities within other systems) and indirectly (since allowances may be internally fungible with offsets in other systems).

a. Bilateral linkage: Should the WCI link directly with other, rigorous cap-and-trade programs and allow fungibility of allowances among the two (or more) systems?

Advantages	Disadvantages
▪ Encourages harmonization among regional, national, and/or international systems and prepares for a potential future global market	▪ May limit or complicate WCI design choices; linkage will be challenging where cap-and-trade systems differ significantly in terms of cap stringency and basis (e.g., absolute vs. intensity-based), borrowing, penalties for non-compliance, offset limitations, monitoring protocols, and other key features. ▪ Would be undermined by price caps or floors unless harmonized
▪ Increases market liquidity and overall cost-effectiveness across the linked systems ▪ Affords a highly credible, low-transaction cost alternative to project-based offsets, where allowances are not over-allocated in other programs, ▪ May reduce WCI compliance costs if allowances in other systems trade at a lower price	▪ Could position WCI as a "price-taker", subject to prices based on other systems' supply-demand relationships, especially if linked systems are larger (e.g. EU Emissions Trading System); ▪ May increase WCI compliance costs if allowances in other systems trade at a higher price
	▪ Differences in allocation levels and modes among systems may create equity and competitiveness concerns

b. Unilateral linkage: Should the WCI allow the use of allowances from other, similarly rigorous cap-and-trade programs to be used as a compliance mechanism by capped sources in the WCI?

Advantages	Disadvantages
▪ May reduce WCI compliance costs if allowances in other systems trade at a lower price ▪ Increases liquidity; enables access to larger market	▪ Requires assessment to establish that allowances from other systems have sufficient rigor

Approaches to Covering Electricity Emissions

Electricity Subcommittee
David Van’t Hof, Chair

Regional Stakeholders’ Meeting
January 10, 2008

Electricity Subcommittee Tasks

- Recommend emissions scope (CO_2, N_2O, SF_6)
- Gather data on electricity sales, emissions, imports, etc.
- Evaluate options for point of compliance--maximize coverage, energy efficiency and meet other criteria determined important.
- Recommend point of regulation.
- Recommend method for establishing baseline emissions.

Stakeholder Input on Work Plan

- More than 85 sets of written comments were received on the work plan; on website
- Comments ranged from principles for the design of a regional program, to specific design choices for the electricity sector

Stakeholder Input on Work Plan

Commenters included:

- Coalition of 34 Environmental and Energy NGOs
- Avista Corporation
- Business Council for Sustainable Energy (BSCE)
- Center for Resource Solutions
- Citizens Utility Board of Oregon
- Energy Producers and Users Coalition of CA
- Industrial Customers of Northwest Utilities
- Morgan Stanley
- The Nature Conservancy
- Pacificorp
- Puget Sound Energy
- Renewable Energy Marketing Association
- Sightline
- Washington Public Utilities Association

Stakeholder Input on Work Plan

- Last week, released table of possible approaches to covering the sector
- Subcommittee seeks comments on advantages and disadvantages of each approach today, and in writing by January 22nd.

Options for Covering Electricity

- Load-based--
  - *Option 1: Load-based Cap Approach*. Retail electricity providers are required to surrender enough allowances to cover emissions attributable to electricity delivered from whatever source.
  - *Option 2: CO_2 Reduction Credits Approach*. Establish baselines for all generators in the western grid; issue CO_2RCs for reductions from baselines. Require retail providers to hold and retire CO_2RCs to accomplish reductions from sector.

Options for Covering Electricity

- Generator-based--fossil-fuel burning electricity generators surrender allowances to cover emissions.

Options for Covering Electricity

- Hybrid load-generator approaches--
  - “First seller” approach: compliance obligation on the entity that “first sells” electricity in the jurisdiction, i.e., the in-state generators and in-state sellers of electricity.
  - Other “Hybrid”: Generators as to in-state generation and retail providers as to imported electricity.

Emissions Coverage Under Options

Load-based Cap	Load-based CO2RCs	Generator-based	Hybrid of load & generator	"First Seller" Hybrid
Covers all electricity delivered in-jurisdiction through retail provider.	Covers all electricity consumed by achieving reductions anywhere in western grid.	Covers all in-jurisdiction emissions from electricity generation.	Cover in-jurisdiction generators; cover imports through retail providers	Covers all electricity at point of first sale (generators & first importer)
Not exports; may not cover self-generation. Contract shuffling.	Not exports; may not cover self-generation.	Not imports; not tribal or federal generators. "Leakage"	Covers imports, exports, generation	May not cover where federal gov't is first seller

Advantages

<table>
<tr><th>Load-based Cap</th><th>Load-based CO_2RCs</th><th>Generator-based</th><th>Hybrid of load & generator</th><th>“First Seller”</th></tr>
<tr><td colspan="2">• Covers all power through retail provider
• RP in best position to invest in EE
• Regulatory structure exists
• Successful load-based program could influence future federal program</td><td>• Well proven through experience
• Emissions monitoring and reporting structure in place
• Generators in best position to make plant upgrades & add technology
• Easily linked to other existing source-based programs
• Establishes clear emissions baselines for future federal program</td><td colspan="2">• Hybrid options have the broadest emissions coverage of the options.
• Advantage over load-based system is that it covers in-state generation more completely & covers exports
• Advantage over generator-based system is that it covers imports.
• Provisions for generator-based component could ease transition to national generator-based program.</td></tr>
</table>

Disadvantages

<table>
<tr><th>Load-based</th><th>Load-based CO_2RCs</th><th>Generator</th><th>Hybrid of load & generator</th><th>“First Seller”</th></tr>
<tr><td colspan="2" rowspan="2">

- Difficult to track power from outside jurisdiction, from power pools & short-term transactions (May not need tracking with CO_2RCs)
- Does not cover in-jurisdiction power sold & delivered outside (Exports).
- Not proposed in any national legislation, making transition to national program an issue
- International systems may not recognize load-based reductions

</td><td rowspan="2">

- Only covers in-jurisdiction emissions from power generation; imports not covered, including “imports” from tribal lands.
- If not auctioned, free allowances to the generator may not stimulate end-use energy efficiency and may also create windfall profit opportunities.

</td><td colspan="2">

- Complexity: design of the program requires both a generator-based component and an imports component.
- In regional context, special care is needed to avoid double-counting of emissions from capped jurisdictions

</td></tr>
<tr><td></td><td>

- May not cover federal first sellers

</td></tr>
</table>

Key Practical Challenges

Load-based Cap	Load-based CO_2RCs	Generator-based	Hybrid of load & generator	"First Seller"
• Tracking emissions with power sales • Assigning default emission rates • New system required to track emissions and trades • Need to distinguish cogen emissions between steam and electricity	• May need to track emissions and sales • New system required to issue and track CO_2RCs	• Most implementation issues have been addressed in existing programs • Emissions associated with imports and leakage are still being addressed by RGGI.	• Same challenges as load-based. • Need to integrate generator and load-based components. • Need to treat imports and in-jurisdiction generation similarly • New system needed to track on load-side	• Need to identify first sellers • Need to address any gaps in jurisdiction over some first sellers • Need to consider legal authority to regulate first sellers • Need to develop first-seller based tracking system

Stakeholder Feedback Needed

- Are we considering the right set of options?
- Are there additional advantages and disadvantages that should be considered for the approaches outlined?
- What approach will best serve the WCI region, and why?

Subcommittee's Next Steps

- Review and Consider Stakeholder Comments
- Subcommittee Deliberation
- Recommendation to Partners
- Incorporation in the Overall Proposals

Western Climate Initiative

Offset Mechanism Design Issues

Offsets Subcommittee
Tim Lesiuk, Province of British Columbia

January 10, 2008

Portland, Oregon

Colorado	Kate Fay	Washington	Greg Nothstein
Manitoba	Jane Gray	Wyoming	Kelly Bott

Workplan

- Task 1: Role of an offset mechanism
  - Identified in workplan
  - Comments received
- Task 2: Core design elements
  - Identified in workplan
  - Comments received
- Task 3: Project eligibility and fungibility
  - Released prior to workshop
  - Comments requested
- Task 4: Mechanism structure and authority
  - Pending outcome of Tasks 1, 2, and 3

Workplan Comments

- Support for offsets as a compliance mechanism
  - suggestion of a limited or short-term role
- Broad support for a wide variety of project types
- General interest in limiting transaction costs
- No clear opinion on quantitative limits for offsets
- Simple and robust approach to determining “real” and “surplus / additional”
- Mixed support for offsets from outside the WCI jurisdictions
- Suggestions of specific models and resources for how WCI could administer an offset mechanism

Major Options

- Offset Mechanism
- Location
- Quantitative limits
- Project Types
- Linkages

Offset Mechanism

- Should the WCI allow offsets as a compliance mechanism?

Location

- Should the WCI only allow offsets from projects located within the Partners' jurisdictions?
- Should the WCI allow offsets from projects located outside the Partners' jurisdictions?

Quantitative Limits

- Should there be quantitative limits on the use of offsets to meet compliance obligations?

Project Types

- Should the WCI decide upon an initial list of approved project types prior to cap-and-trade design?
- Should the WCI allow offsets from sources capped and regulated by the cap-and-trade system or from indirect emission reductions in sectors covered by the cap-and-trade system?

Linkages

- Should the WCI link directly with other, similarly rigorous cap-and-trade programs and allow fungibility of allowances among the systems?
- Should the WCI allow the use of allowances from other, similarly rigorous cap-and-trade programs to be used as a compliance mechanism by capped sources in the WCI?

Western Climate Initiative

Regional Stakeholder's Workshop

January 10, 2008

Portland, Oregon

Overview

Western Regional Climate Action Initiative (WCI)

- Collaboration of Western states, provinces and Mexican states to reduce greenhouse gas emissions in our region
- Partners include
  - Washington, Oregon, California, Arizona, New Mexico, Utah, Manitoba, British Columbia, and as of today, Montana
- Observers include
  - Kansas, Wyoming, Nevada, Colorado, Alaska, Idaho, Quebec, Saskatchewan, Ontario and the Mexican states of Sonora and Tamaulipas

Collaboration is to include

- Setting a regional goal consistent with each partner's reduction goal
- Joining a multi-state registry to track, manage and credit entities with reductions
- Developing a design for a regional market-based multi-sector mechanism, such as a load-based cap and trade program.

Western Climate Initiative Status

Achieved two of the three directives:

- A regional goal has been established
  - 15% below 2005 by 2020
- All partners and observers have joined The Climate Registry
  - Consistent, verifiable reporting of emissions

Progress on design work

- 5 subcommittees underway
  - Scope
  - Allocations
  - Electricity
  - Offsets
  - Reporting
- Preliminary design anticipated Spring, 2008
- Completed design by August 26, 2008

How WCI Works

- Monthly all-partner staff working sessions in person
- Bi-weekly teleconferences of partners/observers and of subcommittee chairs
- Subcommittees engage in technical details to generate recommendations for partners
- Consensus decision making
- Technical support provided by partner agency staff, Pew Center on Climate Change, World Resources Institute, New America Foundation and The Center for Climate Strategies
- Western Governors Association provides project management support

What we expect to deliver

- Memorandum of Agreement
  – Recommended design elements
    - Substantive Agreement
    - Process to get rest of agreement
    - States/provinces will use results for legislative authority to implement
  – Further regional collaboration for ghg reductions

Western Climate Initiative (WCI) Stakeholder Outreach – Initial Plans

- Regional outreach and communication
  - Work plan and other documents submitted for public review and comment
  - Regional teleconferences after each WCI work session
  - Regional face-to-face workshops scheduled *to date*
    - January 10, 2008 (Portland): Discuss major options under consideration (350+ registered attendees)
    - May 2008: Discuss initial subcommittee recommendations
    - July 2008: Discuss proposed design
  - WCI list serve
  - Website

- State/Provincial outreach and communication

Questions?

Western Climate Initiative

Scope Design Issues

Scope Subcommittee
Michael Gibbs, Cal/EPA

January 10, 2008
Portland, Oregon

Overview

- Scope Subcommittee
  - Mission
  - Members
  - Work Plan
  - Work Plan Comments
- Major Options
  - Design Elements
  - Major Options
  - Questions

Mission

- Recommend the scope of a proposed cap and trade program:
  - The sectors that fall under the cap.
  - The emissions sources that fall under the cap.
  - The greenhouses gases that fall under the cap.
  - The point(s) of regulation where the cap would be enforced.
- Electric Sector evaluated by the Electricity Subcommittee.

Mission (Continued)

- The Subcommittee must balance multiple objectives, consistent with the WCI design principles.
  - …administratively simple …
  - …minimizes administrative costs…
  - …covers as many sources as is practical…
  - …minimizes the potential for leakage…
  - …facilitates linkage…

  - Combinations of Design Elements
- Questions

Design Elements

- Design Elements A through K
  - Description
  - Emissions and Entity Data
  - Emissions at the Entity Level
  - Administration
  - Leakage Issues
- Working Draft – solicit comments

Design Elements

A. Large stationary combustion sources

B. Liquid transportation fuels

C. Residential and commercial natural gas combustion

C1. Residential and commercial fuel oil and other fuel combustion

D. Industrial process and waste management emissions

E. Fossil fuel industry

F. Fossil carbon content of fuels

G. Passenger cars and light duty trucks

H. Large transportation fleets

I. Agriculture emissions

J. Forestry and land use change

K. Production of high GWP gases

Major Options

	Options				
Design Elements	**1**	**2**	**3**	**4**	**5**
Electric Sector	X	X	X	X	
A. Large stationary combustion sources	X	X	X	X	
B. Liquid transportation fuels			X	X	
C. Residential and commercial natural gas combustion		X	X		
C1. Residential and commercial stationary combustion of fuel oil and other liquid fuels		X	X		
D. Industrial process and waste management emissions	X	X	X	X	X
F. Fossil carbon content of fuels					X

Major Options (Continued)

- Design Elements not in the options:
  E. Fossil Fuel Industry (oil and natural gas production; natural gas processing)
  G. Passenger Cars, Light Duty Trucks and Medium Duty Vehicles (manufacturers)
  H. Large Transportation Fleets
  I. Agriculture Emissions
  J. Forestry and Land Use Change
  K. Production of High GWP Gases

Questions

- Feasibility: Subcommittee’s assessment of the design elements that are feasible.
- Options: The range of options presented.
- Thresholds: What thresholds (e.g., tons of emissions per year) are appropriate to use.
- Phasing: Which design elements, if any, should be phased in over time.

Questions?

Short Break

Western Climate Initiative

Allocations Design Issues

Allocations Subcommittee
Steve Owens, Chair

January 10, 2008
Portland, Oregon

Mission

The mission of the WCI Allocation Subcommittee is:

- To recommend a methodology for determining the number of allowances to be apportioned, either individually to each WCI partner and thereby establishing each Partner's overall emissions allowance budget for the WCI program, or regionally for the WCI region overall; and

- To determine whether to recommend that the Partners establish a common method for distributing the budgeted emissions allowances (a) among covered sectors; and (b) within each sector to covered entities.

  If a common allowance distribution method is recommended, the Subcommittee will recommend a distribution method or methods for consideration by the WCI Partners.

- WCI Work Plan, 10/29/07

Subcommittee Members

- **<u>Arizona</u>**: Steve Owens, Patrick Cunningham, Ira Domsky, Lee Alter

Summary of Comments Received as of November 30, 2007

The following is a brief summary of the responses to allocation-related questions in the work plan released on October 31, 2007.

- Distribution: Eight commenters recommend that allowances should be distributed free of charge while four supported their sale by auction. Several comments supported use of both methods.
- Early Action Incentives: Five commenters supported the use of rewards or incentives to recognize or encourage GHG reduction investments before the program starts. One commenter opposed the use of incentives and one expressed limited support.
- Banking and Borrowing: Seven commenters supported the use of allowance banking while two supported limits on banking. No commenters opposed banking of allowances. Support for borrowing was less strong with four in favor, one opposed and four supporting limited borrowing.
- Safety Valve: Five commenters supported the use of some form of safety valve mechanism, and two were opposed.
- Other Issues: A handful of other comments were received on issues such as regional apportionment and point of regulation. Three commenters supported the use of new source allowance set-asides.

Question #1

Apportionment of Allowances

- Apportionment means the subdivision of the regional cap and trade emissions cap among the participating jurisdictions.
- Should each Partner should be authorized to distribute allowances equal to that Partner's share of the regional cap, or, should a regional entity distribute allowances on behalf of all the Partners without apportioning the regional cap among them?

Question #1

a. Should allowances be distributed centrally, without apportionment to Partners?

Advantages
• Reduces the need for a framework to prevent "over allocation" by Partners
• Reduces disputes between Partners over apportionment 'amounts'
• Partners establish regional and possibly sector 'cap(s)', but individual Partner 'caps' are not required
• Centralized distribution increases administrative efficiency
• Ensures equity among same-industry competitors throughout region

Disadvantages
• All Partners must agree on distribution method(s), including allocation among sectors (if required)
• Could require 'regional entity' to assume greater authority
• If allowances are sold, Partners would not have unilateral authority over the sale, and sale proceeds would go to Partners indirectly

Question #1

b. Or, should allowances be apportioned to, and distributed by Partners individually?

Advantages
• Partners are free to choose the degree of distribution consistency across the region
• Allows a more conventional role for the regional organization
• Partners receive allowance sale proceeds directly

Disadvantages
• Increases the risk that inconsistent distribution methods create an unfair competitive situation among covered entities across the region
• Decentralized distribution is administratively inefficient
• Partners must agree on the basis of apportionment and potentially individual Partner 'caps'

Question #1

c. Or, should some combination of centralized distribution and apportionment be pursued?

d. ISSUE: The Allocations Subcommittee recognizes that centralized distribution will require more intensive cooperation and a different approach to the exercise of provincial, state and tribal authority. Comments, observations and recommendations are being sought to assist the committee with mechanisms for design and implementation of a regional allocation system.

Question #2

Distribution of Allowances

- Distribution or allocation of allowances means the process by which emissions allowances are distributed for use by covered sources under an emissions cap and trade system.

- To what degree should distribution by the Partners be made uniform, or standardized, among participating jurisdictions?

Allocations Subcommittee Question #2

a. Assuming allowances are distributed by Partners, should distribution methods be standardized?

Advantages
• Reduces the need for a framework to prevent "over allocation" by Partners
• Promotes equity among same-industry competitors throughout region
• Promotes consistency among sectors throughout the region
• Promotes greater consistency among the standards and rules applied across the region

Disadvantages
• Partners must agree on distribution methods
• Partners will find it more difficult to tailor distribution methods to accommodate unique circumstances within their internal sectors
• Standardized distribution requires all Partners to secure legislative or other approvals without allowance for dissimilar results

Question #2

b. Assuming allowances are distributed by Partners, should distribution methods be left to each jurisdiction to decide?

Advantages
• Partners are free to establish individual distribution methods, allowing legislatures to adopt dissimilar programs and allowing state or province-specific issues to be individually addressed
• The regional program can be enacted without the Partners agreeing on distribution methods

Disadvantages
• Increases the risk that inconsistent distribution methods create an unfair competitive situation among covered entities across the region
• Increases the risk that individual Partner distribution decisions will seek a competitive advantage for particular industries or sectors
• May require creation of regional entity with authority to approve or deny Partner distribution plans to enforce minimum standards of consistency or as a check against the concern raised immediately above

Question #2

c. ***Or, should some flexibility be allowed within prescribed limits beyond which all Partners must adopt the same distribution system?***

d. ISSUE: The Allocations Subcommittee recognizes that there are many more detailed questions concerning the distribution of allowances than are asked here. The subcommittee anticipates seeking comment on these questions at a later time.

e. ISSUE: The Allocations Subcommittee recognizes the special challenges associated with the development of a regional system that could successfully merge into a future national program, and the additional complications of developing a single regional program that can accomplish this in two nations. The subcommittee seeks comments on how to ensure that the proposed and potential future programs will function well together.

Question #3

Allocation Methods

- There are multiple ways allowances can be distributed or allocated for use by covered sources.

- Whether and to what degree should allowances be distributed directly to covered sources free of charge?

Question #3

a. Assuming there is centralized distribution or at least partial standardization of decentralized distribution, should some of the allowances be distributed directly to covered entities free-of-charge?

Advantages
• Covered entities with fixed contracts or which are otherwise unable to pass-through the allowance cost would be protected from economic hardship
• Covered entities that are price-regulated would be able to comply without seeking to pass the allowance cost along to the consumer

Disadvantages
• Partners need to develop a basis for free distribution, i.e. 'grandfathering', 'benchmarking', etc.
• Partners may need to provide some reserve or other mechanism to accommodate free distribution for new sources to avoid discouraging investment in new plants
• Many existing covered entities may reap a financial benefit without an associated benefit to consumers or GHG reductions

Question #3

b. Assuming there is centralized distribution or at least partial standardization of decentralized distribution, should some or all of the allowances be auctioned or otherwise sold?

Advantages
• All covered entities compete equally for allowances
• Reduced risk of financial windfall for covered entities
• Program design is simplified
• Revenues from the auction or sale are controlled by the state or province and can be used to mitigate any financial impact of the program on consumers. Revenues can also finance investment in complementary GHG reduction measures, research and development of promising technologies or fund other GHG mitigation or adaptation measures.

Disadvantages
• Covered entities with fixed contracts or which are otherwise unable to pass-through the allowance cost may be exposed to economic hardship

Question #3

c. Should the allowance distribution system have the capacity to change over the life of the program through phasing in particular distribution methods or using different distribution bases?

d. Should the Partners place restrictions on the use of revenues from auctioned allowances?

Question #4

Early Actions

- **WCI cap and trade design principle:**

  "Provide appropriate recognition and incentives for early emissions reductions"

- **How should the cap and trade program either encourage or hold-harmless emission reductions efforts that occur prior to the start of the program?**

  Qualifying early actions would have to be quantifiable, verifiable, enforceable and permanent.

Question #4

a. ***The WCI Design Principles state that the program will "provide appropriate recognition and incentives for early emissions reductions." Should the program accomplish this:***

   i. ***Through the selection of benchmarking and program start dates?***

Selection of benchmarking and program start dates
• Careful selection of these dates could hold those undertaking early actions harmless, and could offer incentives to undertake these reductions in advance of the program start.

Question #4

ii. Through special allocations of allowances?

1. ***Drawn from within the cap?***

2. ***Drawn from outside the cap?***

Special allocations of allowances
• Special allocations of allowances can create a financial incentive if the distribution to those undertaking early reductions occurs over and above that which otherwise occurs after the program begins. • Such special allocations can be created through an allowance set-aside under the cap, or allowances can be made available to early actors over and above the cap (as has been done by RGGI).

Question #4

iii. Through auctioning of allowances?

Auctioning of allowances
• If all covered entities are required to purchase allowances from the market, those undertaking early emissions reductions will avoid the need to purchase those allowances. The avoidance of this cost is an economic incentive equal to the one that exists after the program begins.

iv. By other means?

GHG Reporting Design Options

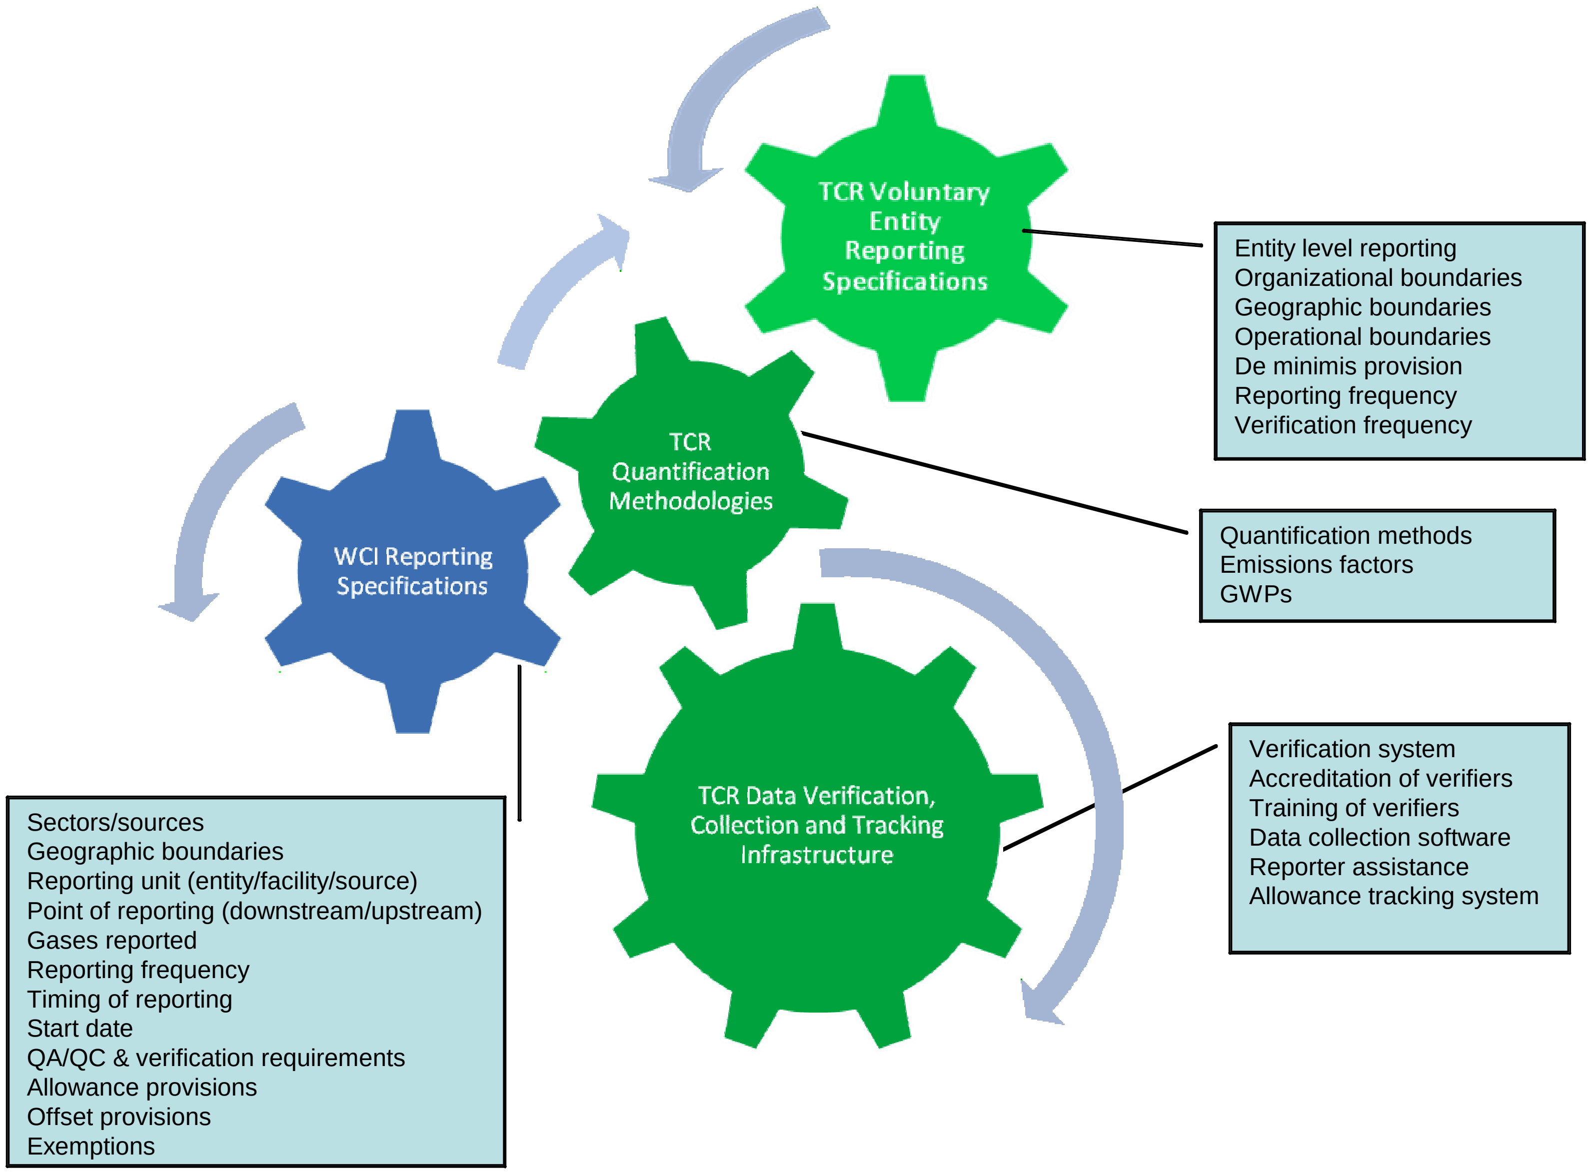
Reporting Subcommittee
Jim Norton, Chair

January 10, 2008
Portland, Oregon

Key Points

- Key Principles
  - Maximum consistency in quantification and reporting, for sources and for states/provinces
  - Maximum reliance on The Climate Registry (TCR)
- WCI & TCR - Form will follow function…
  - Key WCI decisions impacting reporting remain TBD
  - Anticipate a set of WCI Reporting Specifications
  - Expect to employ TCR quantification protocols and reporting systems and services
- A Moving Target
  - From multiple registry efforts to a unified effort – The Climate Registry
  - From little federal activity to recent federal actions regarding GHG reporting in US and Canada

WCI Interaction with TCR Reporting System Components



Reporting Design Option Issues

1. Breadth/Scope of Coverage
2. Initiation of Reporting
3. Coordination Among Partner Jurisdictions on Reporting
4. Data Management and TCR Interaction
5. Verification
6. Administrative Costs & Fees
7. Mandatory Federal GHG Reporting

1. Breadth/Scope of Coverage

a. Should reporting be required only for sectors/sources included within the cap?

b. Or should reporting be required for sectors/sources not included in the cap-and-trade program (e.g., ones that are likely to be phased in over time)?

2. Initiation of Reporting

a. Should mandatory reporting begin before cap-and-trade commences?

b. Or begin only with the start of the cap’s first compliance period?

3. Coordination Among Partner Jurisdictions

a. Should WCI develop a single WCI reporting rule that stipulates all reporting specifications?

b. Or should individual WCI jurisdictions have loosely coordinated rules possessing common core elements? If so, what aspects should the common core elements cover or include?

4. Data Management and TCR Interaction

a. Should WCI require that all capped sources report directly to and verify through the TCR?

b. Or should sources report to and verify at the level of the individual jurisdiction (with data then uploaded to the TCR or otherwise shared centrally)?

5. Verification

a. Should WCI require third party verification?

b. Or should WCI allow multiple approaches to ensuring data quality (other than third party verification)?

6. Administrative Costs & Fees

a. Should states and provinces mandate that fees go directly to TCR, and TCR administers the reporting database?

b. Or should states and provinces collect fees and contract with TCR to administer the reporting database?

7. Mandatory Federal GHG Reporting

In December, Congress directed EPA to adopt a mandatory GHG reporting rule within 18 months, and Canada's federal government required firms in major industrial sectors to report 2006 GHG emissions by May 31, 2008.

a. How should WCI states/provinces and TCR incorporate and interface with these developments in designing and implementing their GHG reporting program?

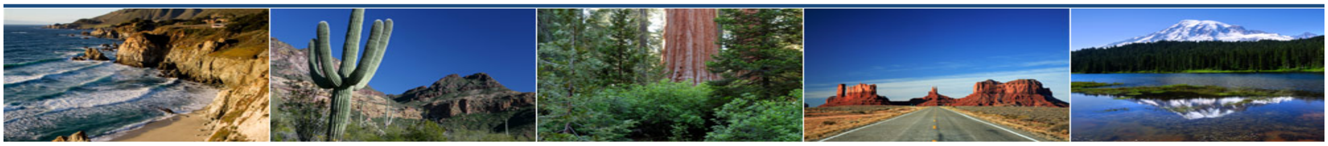
Overview of Comments to Date

- Mandatory reporting before baseline establishment
  - Divided opinion
  - Possibly for sectors where good historical data not available
- Tracking of allowances and offsets
  - TCR would need system for issuing certificates, tracking transactions, RECs, etc.
  - Western Regional Energy Generator Information System (WREGIS) suggested for electric power sector, possibly expand to other sectors
- Integration of WCI reporting with TCR
  - Several opposed to use of TCR
  - Protocols lacking and/or undesirable for land use, ag, forestry (esp. managed forests)
  - Some felt there was Insufficient stakeholder input to TCR design
  - Some complaints based on assumption WCI reporting will follow all of TCR voluntary reporting protocol

Possible Next Steps

- Receive and digest stakeholder comments on options questions.
- Written comments requested by Feb 1
- WCI determines key precursor elements including the scope by end of February 08
- Subcommittee recommends reporting options to WCI partners in March 08
- Input from stakeholders at meeting in May 08 or earlier
- Proceed to develop draft GHG Reporting program per WCI partners direction.
- Input from stakeholders at meeting in July 08
- Final mandatory reporting program released in August 08

Western Climate Initiative



January 24, 2008

Dear WCI Stakeholders:

On behalf of all the WCI partners, we'd like to thank those of you who were able to participate in our first regional face-to-face stakeholder meeting in Portland on January 10. We had about 300 people attend in person and almost 200 participate via the webinar.

At the end of the meeting, we committed to let you know about future opportunities for stakeholder involvement in WCI. Attached you will find a detailed schedule of future calls and meetings. In addition, each state and province will continue their own stakeholder processes.

As you will see in the schedule, the WCI will continue to post draft documents on our website for public review and comment. Currently, each subcommittee has posted its Major Options paper, which outlines the various options they are considering. Please provide comments on the options papers through the website by February 1.

In March, the subcommittees will post for public review and comment their initial draft design recommendation(s). Each subcommittee will then schedule a stakeholder call to discuss their initial draft. The Offsets Subcommittee will use a stakeholder workshop in Vancouver on March 26 as the primary opportunity for input on its preliminary recommendations. The Offsets Subcommittee plans to release discussion drafts prior to the workshop.

In May, we will release the final draft recommendations from each subcommittee and the results of our economic analysis. There will be a face to face stakeholder meeting to discuss these documents in Salt Lake City on May 21.

The WCI partners will take the comments received on the final drafts and work on final recommendations in June and July. Draft final recommendations for the design of a regional cap-and-trade program will be made available in mid-July and a face-to-face stakeholder meeting will be scheduled in late-July. Comments on the final draft will be incorporated into the design recommendations to be released in August 2008.

We look forward to your continued involvement in this important project. Please do not hesitate to contact any of the WCI Partners with questions about our work or the stakeholder involvement process.

Sincerely,

Janice Adair, Washington	Steve Owens, Arizona
WCI Chair	WCI Co-Chair

Draft Electricity Point of Regulation Recommendations for Public Review and Comment

March 3, 2008

To: All Interested Parties

This memorandum presents the WCI draft recommendation for the electricity point of regulation for the WCI cap-and-trade program. The recommendation is based on the WCI's analysis and assessment of the various approaches to covering the electricity sector released in table format in January 2008.[1] The WCI has taken into account all stakeholder comments received in writing, as well as the oral comments received at the January 10, 2008 stakeholder meeting and the February 11, 2008 stakeholder conference call.

Background

As set out in the "Update on Subcommittee Activities and Request for Stakeholder Input" released by the Electricity Subcommittee on January 2, 2008, the Electricity Subcommittee has considered several potential approaches to covering the electricity sector, including:

(1) Pure load-based approach that places the point of compliance on retail providers within WCI and requires tracking of emissions attributes;

(2) Pure generator-based approach that places the compliance obligation on fossil-fuel-fired generators in WCI;

(3) The CO_2 Reduction Credits (CO_2RCs) approach to reducing emissions in the western interconnect area by placing a requirement to purchase and retire CO_2RCs on retail electricity providers in WCI;

(4) A load-generator hybrid approach that combines the generator-based and load-based approaches to cover both emissions attributable to electricity delivered inside and outside of WCI; and

[1] The approaches table is available online at: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F14577.PDF

(5) A “deliverer” or “first seller” approach that places the point of regulation on the first entity to deliver electricity in a WCI jurisdiction.

The benefits and challenges associated with each approach are detailed in the Subcommittee’s “Summary Table Comparing Different Approaches to Electric Sector Cap-and-Trade”.

<u>The Preliminary Draft Approach</u>

After careful consideration of the Subcommittee’s recommendation, as well as the many stakeholder comments received by the Electricity Subcommittee, the Partners reached the following preliminary points of agreement:

The Partners agree:

- The point of regulation for the electricity sector should maximize coverage and minimize emissions leakage.
- A generator-based approach to covering the electricity sector is the preferable option.
- The generator-based option will be most effective with universal participation throughout WECC.[2]
- A proposal to bring in additional generators serving the western interconnect will be developed with a date certain by which those other jurisdictions will join the WCI. If the additional WECC jurisdictions do not join by that date, then the WCI will continue to develop the first-jurisdictional deliverer approach described below.
- That because not all generators serving the western interconnect are currently within the WCI, additional measures are needed to maximize coverage and minimize leakage.
- That the first jurisdictional deliverer approach should address the coverage and leakage issues during the transition to full WECC participation in the WCI:
    - The first jurisdictional deliverer approach covers all emissions generated in WCI; and,
    - All emissions attributable to electricity delivered in WCI but generated outside WCI.

[2] The Western Electricity Coordinating Council (WECC) region encompasses the interconnected power grid of the Western states, provinces, tribes, and a small part of Mexico (i.e., the “western interconnect”).

- To explore additional complementary measures to reduce leakage.

- That the point of regulation does not dictate the method of allocation and the partners are continuing to work on the allocation issue.

The Electricity Subcommittee is now in the process of working through questions raised by the Partners, including how additional generation in the WECC can be brought into the WCI, and how the first jurisdictional deliverer approach would actually be implemented in Partner jurisdictions. The Partners are eager to get stakeholder input on this draft point of regulation for the electricity sector.

Descriptions of the Approaches

The "first jurisdictional deliverer" and "generator-based" approaches are described below. The Electricity Subcommittee will work to provide more detail on these approaches, and to address any concerns or issues raised by individual partners and stakeholders.

The "Generator-based" Approach

- Each WCI partner would implement a set of requirements that apply to fossil-fuel electric generators (i.e. sources) in their jurisdiction.

- Generators would be required to measure, monitor and report emissions.

- At the end of each compliance period, generators would be required to "cover" all of their emissions with emissions allowances issued by the state or province.

- Leakage and coverage issues would be addressed if all jurisdictions in the WECC became trading partners in the WCI.

- Leakage and coverage challenges could be overcome through a "Generator-Plus" model in which imports are addressed through complementary measures.

The "First Jurisdictional Deliverer" Approach

- The point of regulation is on the first entity that the WCI partner has jurisdiction over that delivers power onto the WCI grid at a designated point of delivery

- First jurisdictional deliverers are (a) the fossil-fuel generators in the WCI jurisdictions and (b) the first party to deliver electricity generated outside the WCI region over whom the WCI Partner may assert jurisdiction.

- An importing deliverer could be an independent energy producer, a retail provider, a power marketer, or a power broker.

- For multi-jurisdictional utilities (spanning in and out of the WCI region) a load-based approach to cover non-WCI power imported over their power lines into their WCI service areas could be used.

- In the case of deliveries by Federal entities -- such as the Bonneville Power Administration (BPA) and the Western Area Power Administration (WAPA) -- the first jurisdictional entity may be a retail provider.

- WCI partners would have the option of phasing-in this approach over time, beginning with the fossil-fuel generators in the WCI jurisdiction.

- Tracking will be needed to account for greenhouse gas emissions resulting from power imports and exports among WCI jurisdictions and imports from non-WCI areas.

- Power generated outside WCI states and provinces that is "wheeled through," but not delivered, to the WCI would be exempt from coverage.

The Other Approaches

In reaching the preliminary draft electricity point of regulation, the Partners necessarily had to set aside consideration of the other approaches to the electricity sector. Each of these approaches is listed below, together with some of the reasons given by one or more of the Partners for not selecting the approach:

(1) A pure load-based approach was removed for consideration because, among other reasons, it would require a complex emissions attribute tracking system, would not cover exported electricity; presented potential jurisdictional hurdles, and could be difficult to harmonize with a potential generator-based national cap-and-trade program.

(2) A load-generator hybrid approach was removed from consideration after, the Subcommittee determined it could modify the original "deliverer" or "first seller" approach into the first jurisdictional deliverer approach and meet WCI's needs with a less-complicated administrative structure than that of the load-generator hybrid.

(3) The CO_2 Reduction Credits (CO_2RCs) approach was removed from consideration because it requires the periodic adjustment of the reduction requirement imposed on retail providers depending on load growth in the West; it is complex and difficult to understand; and because it presented issues with harmonizing to a potential generator-national program.

It bears noting that this discussion is meant to give you a sense of the chief reasons for not recommending each approach. The explanations are not complete and are not all shared by all Partners.

Next Steps

The Partners have directed the Electricity Subcommittee to gather stakeholder input on the draft electricity point of regulation, and to develop more detailed assessment of how to add more generation from the WECC into the WCI as well as how the first jurisdictional deliverer approach would be implemented in individual jurisdictions.

To that end, there will be a stakeholder conference call on Tuesday, March 11, 2008 from 10:30 to 12:00 noon Pacific Standard Time. During that call, questions will be taken on the draft point of regulation. Written comments are also encouraged, and the Partners are suggesting that these comments be forwarded via the website no later than Monday, March 17, 2008.

On behalf of the WCI Electricity Subcommittee and all of the WCI Partners, I thank you for your continued interest in the Western Climate Initiative and the Electricity Subcommittee's work.

Sincerely,

/s/

David Van't Hof

Scope Subcommittee

March 3, 2008[1]

Summary of Major Design Options Under Consideration

This paper presents the major design options under consideration by the Scope Subcommittee. The mission of the Scope Subcommittee is to recommend the scope of a proposed cap-and-trade program, defining:

- The sectors that fall under the cap-and-trade program.
- The emissions sources that fall under the cap-and-trade program.
- The greenhouse gases that fall under the cap-and-trade program.
- The point(s) of regulation where the cap-and-trade program would be enforced.

To develop options for the program scope, the Scope Subcommittee defined individual design elements for consideration. The list of the design elements was released for public review and comment as part of the WCI work plan (see www.westernclimateinitiative.org).

The Scope Subcommittee is assessing the feasibility of including the design elements as part of the program scope. A brief description of each of the design elements is presented below, starting on page 4. While each of the design elements remains under consideration, the subcommittee's preliminary analysis has been used to identify design elements that appear to be feasible to include in a cap-and-trade program in the near term. These design elements include:

- Electric sector, as defined by the Electricity Subcommittee;[2]
- Large stationary combustion sources;
- Liquid transportation fuels;
- Residential and commercial natural gas combustion;
- Residential and commercial stationary combustion of fuel oil and other liquid fuels;
- Industrial process and waste management emissions; and
- Fossil carbon content of fuels.

---

[1] The paper was originally released on January 2, 2008. This revised version incorporates updated emissions data and data for Montana. The discussion of the options remains unchanged.

[2] The Electric Subcommittee is assessing how best to include the electric sector in the program. The major options under consideration by the Electric Subcommittee are reported separately.

While the subcommittee's preliminary analysis indicates that these elements are feasible to include in the program, we note that significant administrative and potential emissions leakage issues remain to be assessed. Additionally, options for phasing in and combining the elements must be considered. These issues are being examined through the subcommittee's continuing analysis and assessment.

Combinations of the feasible design elements are presented as five major design options below. These options indicate how the elements could be combined to create a cap-and-trade program with varying levels of coverage. Option 1, with the narrowest scope, would cover the electric sector, large fossil fuel stationary combustion sources, and large industrial process emissions. Option 3 has a significantly broader scope by also including liquid transportation fuels and fossil fuel stationary combustion in the residential and commercial sectors. Option 5 represents an alternative approach, focusing on the fossil carbon content of all fuels.

The subcommittee's preliminary analysis has indicated that several design elements are not likely to be feasible to be included under the cap in a cap-and-trade program in the near term. The factors indicating that these elements are not good candidates for inclusion under the cap-and-trade program are: inability to measure or calculate emissions reliably at the entity level; administrative challenges due to the large number of regulated entities; and significant vulnerability to emissions leakage. These design elements include:

- emission sources at fossil fuel production facilities for which it is difficult to measure or calculate emissions at the entity level;
- passenger cars, light duty trucks and medium duty vehicles regulated at the manufacturer;
- large transportation fleets;
- agriculture emissions and sinks;
- forestry emissions and sinks; and
- high-GWP gases regulated at the point of manufacture.

While the sectors and sources included in these design elements may ultimately not be recommended for inclusion under the cap of a cap-and-trade program, these sectors and sources may be appropriate for inclusion in an offset program, or may be addressed through other policies or measures.

By releasing this preliminary list of major design options, the Scope Subcommittee solicits public comments on these materials. Comments would be particularly appreciated on the following:

1. Feasibility: Do you agree with the subcommittee's assessment of the design elements that are feasible for inclusion in a cap-and-trade program? If not, what would you change?
2. Options: Do you agree with the range of options presented by the subcommittee? If not, what options would you add or delete?
3. Thresholds: What thresholds (e.g., tons of emissions per year) are appropriate to use to define the entities with regulatory obligations under each of the design elements?
4. Phasing: Which design elements, if any, should be phased in over time?

Major Scope Options Under Consideration as of December 2007 – For Public Review and Comment

A. Large Stationary Combustion Sources

1. Description

1.1 Sectors

This sector includes all large stationary combustion sources, including oil refining, cement manufacturing (including clinker production), pulp and paper manufacturing, hydrogen production, and other large combustion sources. Electric power generation is included in the Electric Sector, and is not included in this design element. An annual emissions threshold may be used to define the combustion sources considered “large.” Various thresholds have been defined in other programs (such as mandatory greenhouse gas reporting programs). A threshold has not yet been selected for this design element, and is under consideration.

1.2 Emissions Sources

Fossil fuel combustion in stationary equipment only.

1.3 Greenhouse Gases

All six Kyoto gases are included. However, CO_2 comprises the overwhelming majority of the total emissions in this sector (close to 100%).

1.4 Point of Regulation

The point of regulation is the facility where the combustion emissions occur.

2. Emissions and Entity Data

Among the WCI partner states and provinces, fossil fuel combustion at industrial facilities (not including electric power generation) accounted for about 130 MMT of CO_2e in 2005, or about 13% of total gross emissions. This percentage varies from about 4% to 23% across the states and provinces.

The total number of entities that would be covered in this sector depends on whether, and at what level, an annual emissions threshold is set. Table 1 summarizes the emissions for the WCI partners.

3. Emissions at the Entity Level

Greenhouse gas emissions from fossil fuel combustion at large stationary sources can be measured or calculated with an adequate level of precision to support inclusion in a cap-and-trade program. Fuel-based calculations can generally be used to quantify CO_2 emissions, which comprise nearly 100% of the emissions for this sector. Alternatively, continuous emissions monitors (CEMs) can be used to measure emissions.

4. Administration

This sector does not pose significant administrative challenges. Regulatory agencies are able to identify most if not all the entities in this sector with compliance obligations because the facilities typically have other air emission compliance requirements. The covered entities should also have the capability to know their compliance obligations and understand the applicable requirements. The emissions from this sector are reasonably well known, so that an acceptable emission baseline can be developed.

5. Leakage Issues

Vulnerability to significant leakage varies among the facilities that would be covered under this sector. Some facilities require close proximity to their markets, so that significant leakage to locations outside the WCI region is not expected. However, others (such as the cement industry and the pulp and paper industry), may be vulnerable to leakage as their products are traded as commodities internationally. The vulnerability to leakage needs to be assessed individually for each industry.

Table 1: Summary of Stationary Combustion Source Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	5.2	5%
California (2004)	79.0	16%
Montana	2.8	8%
New Mexico	3.2	4%
Oregon (2004)	6.2	9%
Utah	6.5	9%
Washington	11.0	12%
British Columbia	14.9	23%
Manitoba	1.4	7%
Total WCI Partners	**130.2**	**13%**

MMT = million metric tons

Percent of gross emissions calculated for each state/province. Estimates do not apply an emissions threshold for potentially covered entities.

Preliminary estimates, subject to review and revision.

B. Liquid Transportation Fuels

1. Description

This design element covers CO_2 emissions from the combustion of liquid transportation fuels. The point of regulation being examined is the point at which the fuels enter into commerce in the individual WCI states and provinces. As described below, this point may vary among the states and provinces.

1.1 Sectors

This design element focuses on liquid fossil fuels used in the transportation sector, including but not limited to gasoline, distillate fuels (diesel, etc.), jet fuel, aviation gas, and LPG. The liquid fuels used for stationary combustion by residential, commercial, and industrial customers are described separately. Nevertheless, the manner in which liquid fuels could be covered for these other customers is closely related to how they could be covered for transportation uses. Fuel use in the electricity sector is also not covered in this design element.

1.2 Emissions Sources

The emission source is the combustion of liquid fossil fuels in mobile sources. These sources include on-road and off-road vehicles, including: passenger cars; trucks; rail; marine vessels; and aircraft. Off-road equipment, such as farm equipment and construction equipment could also be included.

1.3 Greenhouse Gases

Carbon dioxide is the dominant GHG produced in this element, accounting for on the order of 97% of emissions from these sources. Nitrous oxide (N_2O) and methane (CH_4) are also emitted.

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for transportation emissions at the point of emission, which would be the individual vehicle owner. Rather, the point of regulation under consideration for this element is the point at which transportation fuels enter into commerce in the individual states and provinces. In selecting this point of regulation, consideration is being given to the fact that most jurisdictions have a mechanism for tracking the sale of transportation fuels for other purposes. Building on the existing fuel tracking procedures in each jurisdiction is expected to simplify program design and implementation requirements.

For some jurisdictions, the point at which liquid fuels are tracked is the fuel distribution terminal, often referred to as the terminal rack. For example, in the United States, federal excise taxes on transportation fuels are collected at the terminal rack. Some states rely on this terminal-rack based tracking system to collect state taxes, thereby providing the capability to track fuel flows into the state.

Some jurisdictions (e.g., Oregon) track gasoline deliveries to retailers for tax purposes. For these jurisdictions, the preferred point of regulation may be the licensed fuel wholesalers that are already required to report the quantity of fuel delivered.

Using this approach, the compliance obligation would be to hold emission allowances to cover the fossil carbon content of the fuel that is entering into commerce in the individual states and provinces. The regulated entity would be the party that enters the fuel into commerce in the state or province, such as the owner of the fuel dispensed at the terminal rack, or the licensed fuel wholesaler that dispenses fuel to retail locations.

2. Emissions and Entity Data

The transportation sector is one of the largest sources of GHG emissions for each of the WCI partners. The emissions estimate for 2005 is about 353 MMT CO_2e, accounting for about 35% of total gross emissions among the WCI partners. The percentage of total gross emissions varies among the partners from about 21% to 45%. Table 2 summarizes the emissions estimates for the WCI partners.

The total number of entities with a compliance obligation depends on the point of regulation. If terminal racks are the point of regulation for most jurisdictions, the total number of terminals and refineries (where the racks are located) is on the order of about 210 for the WCI partners (see Table 2). If wholesalers are the point of regulation, the number of entities will be larger. For example, Oregon licenses about 160 motor vehicle fuel dealers. The appropriate point of regulation and the number of entities is under investigation.

3. Emissions at the Entity Level

As described above, the point of regulation under consideration is the point at which liquid transportation fuels enter into commerce in the individual states and provinces. At this point, the regulated entity cannot measure or calculate actual GHG emissions from fuel combustion. Rather, the entity can calculate potential CO_2 emissions based on the fossil carbon content of the fuel and the quantity of the fuel. Virtually all the carbon in the fuel is converted to CO_2, so that the carbon content of the fuel is an accurate predictor of CO_2 emissions.

Several issues need to be addressed in order to use this calculation of potential emissions:

- Variations in fossil carbon content: Currently, the fossil carbon content of liquid transportation fuels is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.
- Fuel use for non-combustion purposes: The emission calculation presumes that all the fuel delivered will be combusted. Some fuels may be used to produce products (such as plastics) that sequester carbon. While this eventuality may be unlikely for transportation fuels, the issue remains to be assessed.

Notably, this method of calculating emissions is a proxy only for the CO_2 emissions that occur when the fuel is combusted. The calculation does not include N_2O and CH_4 emissions, although those emissions would also be expected to occur during combustion along with the CO_2 emissions. Additionally, the method does not include the GHG emissions associated with producing the fuel. Rather, this method covers emissions associated with fuel use, but not fuel production. Emissions associated with fuel production (e.g., emissions at the refinery) would be covered separately as stationary combustion or process emissions from the facilities involved in producing the fuel in the WCI states and provinces.

4. Administration

By leveraging existing fuel tracking procedures in states and provinces, the administrative challenges for this design element can be minimized. However, the tracking capabilities of each state and province remain to be examined in detail to assess the comprehensiveness of the existing tracking capabilities. Insofar as the existing procedures provide incomplete coverage of the fuels, additional tracking capabilities may be required.

The potential challenges associated with verifying the fossil and non-fossil carbon components of transportation fuels at the proposed point of regulation remain to be examined.

5. Leakage Issues

The potential for emission leakage is significant for components of the transportation sector:

- Marine: Ocean-going vessels can obtain fuel outside the WCI partner jurisdictions.
- Aviation: Airline operations are particularly sensitive to fuel costs. Opportunities to obtain fuel outside the WCI partner jurisdictions may be significant.

Gasoline use in passenger cars, light duty trucks, and medium duty vehicles is less vulnerable to leakage, as motorists typically obtain fuel in close proximity to their residences and places of employment. On-road gasoline use accounts for about two-thirds of the total emissions from this sector, making it the largest portion of emissions.

Long-haul trucking may also be vulnerable to leakage if trucks can operate within WCI jurisdictions with fuel obtained from outside the WCI jurisdictions. However, the International Fuel Tax Agreement (IFTA) requires diesel trucks operating in multiple jurisdictions to calculate fuels consumed in each state and province based on the miles traveled in each state/province. All the WCI partners are parties to the IFTA.[3] Consequently, the IFTA data could be used to compute a compliance obligation for diesel trucks that operate in multiple jurisdictions, thereby avoiding leakage.[4]

These differences in leakage potential may indicate that the program should consider focusing coverage on the portion of transportation fuels that are least subject to leakage.

[3] The 48 contiguous states of the United States and 10 Canadian provinces are parties to IFTA. Yukon Territory, Northwest Territory, Nunavut, and the District of Columbia are not parties to IFTA.

[4] IFTA covers diesel trucks with the following characteristics: (a) has three or more axles; or (b) has two axles and a gross vehicle or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms; or (c) is used in a combination that has a combined or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms. Recreational vehicles are not covered.

Table 2: Summary of Liquid Transportation Fuel CO_2 Emissions and Entity Counts

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	# Entities	
			Terminals	Refineries
Arizona	38.2	38%	13	--
California (2004)	177.7	37%	84	20
Montana	7.7	21%	13	4
New Mexico	15.1	21%	16	3

C. Residential and Commercial Natural Gas Consumption

1. Description

Under this element, the carbon dioxide emissions associated with residential and commercial combustion of natural gas would be covered. The point of regulation is the local natural gas distribution company (LDC). The LDCs would be required to hold allowances to cover the carbon dioxide emissions associated with the ultimate combustion of the natural gas they sell to their residential and commercial customers, based on the carbon content and volume of the fuel they sell.

LDCs also deliver gas to large industrial and electric utility customers. They would not be required to hold allowances for emissions associated with those deliveries. The expectation is that those emissions would be covered at the source, as described in separate design elements.

1.1 Sectors

The sector covered is part of residential and commercial stationary combustion.

1.2 Emissions Sources

The emissions sources are residential and commercial natural gas combustors, such as boilers and furnaces.

1.3 Greenhouse Gases

The greenhouse gas covered is carbon dioxide. Other combustion-related greenhouse gases would also be affected (e.g., nitrous oxide and methane). However, the other emissions are not addressed explicitly through this design element.

1.4 Point of Regulation

The entities with compliance obligations are local natural gas distribution companies (LDCs). LDCs are typically private companies regulated by state and provincial utility commissions or similar boards. Some LDCs may be municipal utilities. All LDCs, regardless of size or volume of gas delivered, could be included in this program element.

2. Emissions and Entity Data

Based on the information collected to date, there are about 60 LDCs in the WCI partner states and provinces; and about 155 total if WCI observers are included. The CO_2 emissions associated with the natural gas these LDCs distributed in 2005 to residential and commercial customers is 72 MMT for the U.S. partners. Table 3 summarizes this data and the data on the numbers of LDCs.

3. Emissions at the Entity Level

Calculating emissions associated with residential and commercial combustion would be straightforward for LDCs. LDCs already account for the volumes of natural gas they sell by customer class. The LDCs would need to apply the appropriate carbon content factor to these gas volumes to calculate their compliance obligation. The LDC would exclude from this calculation any natural gas that is sold to an entity that has a separate compliance obligation under the program, such as an industrial source that is regulated directly.

4. Administration

Covering LDCs in a cap-and-trade program does not pose unusually significant administrative challenges. LDCs are already subject to economic regulation by the state public utilities commissions in the United States and by provincial authorities in Canada. Thus, a state or provincial regulatory agency can identify all the entities with compliance obligations. The LDCs would have the capability to know that they have compliance obligations and understand their compliance requirements. The number of entities appears manageable. However, there are a number of small LDCs in Kansas (a WCI observer state). An annual emissions threshold, for example 10,000 tons of CO_2, could be used to exclude small LDCs.

5. Leakage Issues

LDCs themselves would not be subject to emission leakage issues. The LDCs are regulated monopolies with defined service territories. LDC customers may vary with regard to leakage vulnerabilities. Most residential and commercial natural gas customers do not have high greenhouse gas emissions intensities. Consequently internalizing the cost of the carbon content of natural gas into natural gas prices (as would be expected) would not significantly affect the competitiveness of most customers.

However, there are two circumstances of note. First, increased natural gas prices could adversely affect low income residential customers. Assistance programs for low income customers, provided by many LDCs in the United States, could be a mechanism for addressing this impact. Second, there may be some individual large volume gas customers for which carbon emissions are significant. If these customers face competition from regions that do not limit greenhouse gas emissions, they may vulnerable to emissions leakage. The circumstances of these customers would be similar to large stationary source emissions sources that would be covered directly. The number of customers for which this is an issue, and the potential impacts on these customers, remain to be identified.

Table 3: Summary of Residential and Commercial Natural Gas CO_2 Emissions and Number of LDCs

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	# LDCs
Arizona	3.8	4%	8
California (2004)	38.9	8%	11
Montana	1.8	5%	5
New Mexico	3.1	4%	19
Oregon (2004)	3.5	5%	3

Washington	6.7	7%	7
British Columbia	6.5	10%	4
Manitoba	2.3	11%	1
Total WCI Partners	**71.7**	**7%**	**60**
MMT = million metric tons Percent of gross emissions calculated for each state/province. Emissions data currently being developed for provinces. Preliminary estimates, subject to review and revision.			

C1: Residential and Commercial Stationary Combustion of Fuel Oil and Other Liquid Fuels

1. Description

This design element covers CO_2 emissions from the stationary combustion of fuel oil and other liquid fuels in the residential and commercial sector. The point of regulation being examined is the point at which the fuels enter into commerce in the individual WCI states and provinces. As described below, this point may vary among the states and provinces.

1.1 Sectors

This design element focuses on liquid fossil fuels used for stationary combustion by residential and commercial customers. The fuels include heating oil, propane and liquefied petroleum gas (LPG). The liquid fuels used in the transportation sector are described separately. Nevertheless, the manner in which liquid fuels could be covered for transportation uses is closely related to how they could be covered for these residential and commercial uses. Fuel use in the electricity sector is also not covered in this design element.

1.2 Emissions Sources

The emission source is the combustion of liquid fossil fuels in stationary source equipment, such as furnaces and boilers.

1.3 Greenhouse Gases

Carbon dioxide is the dominant GHG produced in this element, accounting for on the order of 99% of emissions from these sources. Nitrous oxide (N_2O) and methane (CH_4) are also emitted.

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for residential and commercial stationary fuel combustion emissions at the point of emission, which would be the individual building owner. Rather, the point of regulation under consideration for this element is the point at which the relevant fuels enter into commerce in the individual states and provinces. In selecting this point of regulation, consideration is being given to the fact that some jurisdictions have a mechanism for tracking the sale of these fuels for other purposes. Building on the existing fuel tracking procedures in each jurisdiction is expected to simplify program design and implementation requirements.

For some jurisdictions, the point at which liquid fuels are tracked is the fuel distribution terminal, often referred to as the terminal rack. For example, in the United States, federal excise taxes on liquid fuels are collected at the terminal rack. Some states rely on this terminal-rack based tracking system to collect state taxes, thereby providing the capability to track fuel flows into the state.

Some jurisdictions track fuel deliveries to retailers for tax purposes. For these jurisdictions, the preferred point of regulation may be the licensed fuel wholesalers that are already required to report the quantity of fuel delivered.

Using this approach, the compliance obligation would be to hold emission allowances to cover the fossil carbon content of the fuel that is entering into commerce in the individual states and provinces. The regulated entity would be the party that enters the fuel into commerce in the state or province, such as the owner of the fuel dispensed at the terminal rack, or the licensed fuel wholesaler that dispenses fuel to retail locations.

2. Emissions and Entity Data

The stationary combustion of liquid fossil fuels in the residential and commercial sectors accounts for a small portion of overall GHG emissions within the WCI partners jurisdictions. Although incomplete data are currently available, these sources appear to account for less than 1% of total emissions in 2005 (see Table 4).

The total number of entities with a compliance obligation depends on the point of regulation. If terminal racks are the point of regulation for most jurisdictions, the total number of terminals and refineries (where the racks are located) is on the order of about 210 for the WCI partners (see Table 4). If wholesalers are the point of regulation, the number of entities will be larger. The compliance obligation for these fuels would likely be closely coordinated with the compliance obligation for the carbon content of liquid transportation fuels, which is described separately.

3. Emissions at the Entity Level

As described above, the point of regulation under consideration is the point at which liquid fuels enter into commerce in the individual states and provinces. At this point, the regulated entity cannot measure or calculate actual GHG emissions from fuel combustion. Rather, the entity can calculate potential CO_2 emissions based on the fossil carbon content of the fuel and the quantity of the fuel. Virtually all the carbon in the fuel is converted to CO_2, so that the carbon content of the fuel is an accurate predictor of CO_2 emissions.

Several issues need to be addressed in order to use this calculation of potential emissions:

- <u>Variations in fossil carbon content</u>: Currently, the fossil carbon content of liquid fuels is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.

- <u>Fuel use for non-combustion purposes</u>: The emission calculation presumes that all the fuel delivered will be combusted. Some fuels may be used to produce products (such as plastics) that sequester carbon. While this eventuality may be unlikely for these fuels, the issue remains to be assessed.

Notably, this method of calculating emissions is a proxy only for the CO_2 emissions that occur when the fuel is combusted. The calculation does not include N_2O and CH_4 emissions, although those emissions would also be expected to occur during combustion along with the CO_2 emissions. Additionally, the method does not include the GHG emissions associated with producing the fuel. Rather, this method covers emissions associated with fuel use, but not fuel production. Emissions associated with fuel production (e.g., emissions at the refinery) would be covered separately as stationary combustion or process emissions from the facilities involved in producing the fuel in the WCI states and provinces.

4. Administration

By leveraging existing fuel tracking procedures in states and provinces, the administrative challenges for this design element can be minimized. However, the tracking capabilities of each state and province remain to be examined in detail to assess the comprehensiveness of the existing tracking capabilities. Insofar as the existing procedures provide incomplete coverage of the fuels, additional tracking capabilities may be required. As discussed above, the tracking of these fuels would be coordinated closely with the tracking of transportation fuels.

The potential challenges associated with verifying the fossil and non-fossil carbon components of fuels at the proposed point of regulation remain to be examined.

5. Leakage Issues

Fuel oil customers may vary with regard to leakage vulnerabilities. Most residential and commercial fuel oil customers do not have high greenhouse gas emissions intensities. Consequently internalizing the cost of the carbon content of fuel oil into fuel oil prices (as would be expected) would not significantly affect the competitiveness of most customers.

However, there are two circumstances of note. First, increased fuel prices could adversely affect low-income residential customers. Assistance programs for low-income customers could be a mechanism for addressing this impact. Second, there may be some individual commercial customers for which carbon emissions are significant. If these customers face competition from regions that do not limit greenhouse gas emissions, they may vulnerable to emissions leakage. The circumstances of these customers would be similar to large stationary source emissions sources that would be covered directly. The number of customers for which this may be an issue, and the potential impacts on these customers, remain to be identified.

Table 4: Summary of CO_2 Emissions from Residential and Commercial Stationary Combustion of Fuel Oil and Other Liquid Fuels

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	# Entities	
			Terminals	Refineries

D. Industrial and Waste Management Process and Fugitive Emissions

1. Description

This element includes industrial and waste management process and fugitive emissions regulated at the point of emission.

1.1 Sectors

This sector includes specifically identified industrial processes and waste management activities, such as oil refining, cement production, aluminum smelting, iron and steel production, adipic acid production, nitric acid production, lime production, pulp and paper manufacturing, sawmill kilns, agricultural chemical manufacturing, plastics manufacturing, natural gas transmission and distribution, magnesium smelters and casters, mineral production, silicon chip manufacturing, ammonia production, wastewater treatment facilities; landfill operations, wastewater treatment from food processing; and others. An annual emissions threshold may be used to define the facilities included in the program. This threshold has not been established, and is under consideration. Process emissions from the Electric Sector are included in the Electric Sector, and are not included here.

1.2 Emissions Sources

The emission sources included are process emissions from stationary sources. Process emissions include emissions from chemical, biological, and other non-combustion processes. The emissions may be deliberate (e.g., vented), fugitive (e.g., leaked), or accidental. Fossil fuel combustion emissions are not included in this design element, and are covered in a separate description.

1.3 Greenhouse Gases

All six Kyoto greenhouse gases are included.

1.4 Point of Regulation

The point of regulation is the facility where the emissions occur.

2. Emissions and Entity Data

Among the WCI partner states and provinces, process emissions accounted for about 70 MMT of CO_2e in 2005, or about 7% of total gross emissions. This percentage varies from about 4% to 12% across the states and provinces.

The total number of entities that would be covered in this sector depends on whether, and at what level, an annual emissions threshold is set. The potential number of entities with compliance obligations is currently being assessed. Table 5 summarizes the emissions for the WCI partners.

3. Emissions at the Entity Level

The ability to measure or calculate emissions reliably and precisely at the entity level must be assessed for each of the industrial process and waste management sources in the WCI region. This assessment must examine:

- Is there an existing measurement or calculation protocol or method for the source?
- Is a new protocol or method required?

- What greenhouse gases can be measured or calculated reliably and precisely?
- Are there technical barriers to the entities being able to measure/calculate their emissions with sufficient precision to be covered by the cap-and-trade program? If there are barriers, which sources cannot be included, and how does their exclusion affect the emissions covered?

There are numerous industrial processes that emit greenhouse gases, and the answers to these questions will vary widely among the processes. For example, a protocol has been developed to calculate process emissions from cement manufacturing. Also, emissions of N_2O from nitric acid production can be monitored accurately using measurement devices in the process vent. Alternatively, process emissions at refineries are themselves diverse. Some refinery process emissions may be amenable to measurement or calculation, while others (such as fugitive emissions) may not be suitable for inclusion. This element could cover only those emissions that can be measured or calculated adequately. If needed, processes could be added to the program as methods or protocols are developed over time.

4. Administration

The primary administrative challenge associated with this sector is the inability to measure or calculate emissions precisely from some sources. Most of the large facilities that fall under this design element would already have compliance obligations under other regulatory programs. Consequently, the entities are well known and would be in a position to understand their compliance obligations under a cap-and-trade program. As discussed above, the use of an annual emissions threshold would reduce the number of entities with compliance obligations.

5. Leakage Issues

Vulnerability to leakage varies among the facilities that would be covered under this sector. Some facilities require close proximity to their markets, so that significant leakage to locations outside the WCI region is not expected. However, others (such as the cement industry), may be vulnerable to leakage as their products are traded as commodities internationally. The vulnerability to leakage needs to be assessed individually for each industry.

Table 5: Summary of Industrial and Waste Management Emissions Process and Fugitive Emissions

State/Province	2005 Emissions (MMT CO_2e) Industrial Processes	Waste Management	Percent of 2005 Gross Emissions	Entity Count Industrial Facilities	Landfills
Arizona	4.5	2.1	7%	53	32
California (2004)	24.1	9.4	7%	451	372
Montana	0.9	0.3	3%	12	5
New Mexico	1.6	1.4	4%	17	9
Oregon (2004)	3.4	1.9	8%	37	117
Utah	3.7	2.0	8%	26	31
Washington	3.3	2.4	6%	39	11

Preliminary estimates, subject to review and revision.

E. Fossil Fuel Production and Processing

1. Description

Fossil Fuel Production and Processing encompasses oil and gas exploration, production, and processing, and coal mining. This design element includes a broad set of facilities and activities with diverse emissions sources. Some of the emissions sources included here are also part of other design elements (e.g., stationary combustion sources and process emissions). However, the sources are described here to provide a comprehensive description of emissions from this industry.

1.1 Sectors

The Fossil Fuel Production and Processing Sector can be categorized into the following components:

- Oil Production: Oil production covers exploration, drilling, production, and transportation of crude oil by pipeline to terminals or refineries. Facilities include well fields, pipelines, and tank batteries. Ships used to transport crude oil are included in the transportation sector. The output of this process is crude oil.
- Natural Gas Production and Processing: Natural gas production and processing covers exploration, production, and treatment of natural gas. Facilities include well fields, pipelines, and processing equipment. The output of this process is natural gas that meets specifications required for injection into natural gas transmission and distribution pipelines.
- Coal Mining: Coal mining covers mine development and operations, including surface mining (i.e., open pit mining) and underground mining. Coal processing facilities are considered a stationary source, and coal transport (e.g., by train) is considered part of the transportation sector.

Oil and gas are often produced from the same wells. In these cases, the distinction between oil production facilities and natural gas production facilities is not meaningful. Additionally, condensate and other liquids are often produced with oil and/or natural gas. The oil and natural gas production and processing facilities listed above encompass the production and processing of these liquids.

Methane recovered from coal seams (often referred to as "coalbed methane") can also be used to produce pipeline quality natural gas. Coalbed methane production and treatment is included in this design element as part of natural gas production.

Pipelines of various types are also used to transport crude oil, liquid products, and gas. Pipelines are included in this design element, including: gathering lines; crude oil and liquid products pipelines that run to refineries, terminals, and tanks; and gas pipelines that connect to transmission lines. Natural gas transmission and distribution pipelines are not included in this design element.[5] Similarly, refineries and the transport of refined products to market are not included in this design element.[6]

[5] Natural gas transmission and distribution pipelines are considered stationary sources with combustion emissions (i.e., from compressors) and process emissions (i.e., gas venting and fugitive emissions).

[6] Refineries are considered a stationary source with combustion emissions and process emissions. The transport of refined products to market is considered part of the transportation sector.

1.2 Emissions Sources

The Fossil Fuel Production and Processing Sector includes a diverse set of greenhouse gas emissions sources. Many of the sources are specialized pieces of equipment found only in this industry. The major emission sources in oil and gas production and processing are listed in Table 6. As shown in the table, the emissions sources can be categorized into six types:

- Stationary combustion includes all types of fossil fuel combustion, including flaring.
- Process vents include equipment that is designed to vent emissions as part of its normal operation. Amine treatment as part of acid gas removal is an example of a process with this type of venting.
- Maintenance venting includes emissions that occur during scheduled maintenance activities.
- Non-routine venting occurs periodically, often for safety reasons.
- Other venting is associated with specific activities or pieces of equipment, some of which are designed to vent as part of normal operation (e.g., pneumatic devices and chemical injection pumps).
- Fugitive emissions occur from unintended leaks from equipment components.

The relative importance of each of the sources depends on site-specific equipment requirements, operations, and configurations.

The source of coal mining emissions is primarily due to the release of methane from the coal and surrounding strata due to mining activities. In underground mines, methane can create an explosive hazard, so it is removed through a ventilation system. Methane concentrations in ventilation system emissions are typically less than 1%, and consequently the methane is nearly always emitted to the atmosphere. In some mines, a degasification system is used to withdraw methane prior to mining due to large quantities of methane occurring in the coal and surrounding strata. The methane collected by the degasification system may be recovered and used for fuel in some cases.

In surface mining, the methane associated with the coal is emitted directly to the atmosphere as the coal is uncovered. For both underground coal and surface-mined coal, some methane remains in the coal after it is mined. This methane is released subsequently during processing, transport, and storage.

Finally, methane is also emitted from closed or abandoned underground mines. Although mining is no longer active, closed mines can release methane from vents, fissures, or boreholes.

This list of emissions sources for Fossil Fuel Production and Processing includes only those sources that produce emissions during the production and processing of the fuel (oil, gas, and coal). When the resulting products are combusted (i.e., when refined oil products and natural gas are used as fuel by others), they also produce emissions (primarily carbon dioxide). The emissions from fuel combusted by others are not included in this design element.

1.3 Greenhouse Gases

The predominant GHGs emitted from Fossil Fuel Production and Processing are:

- Carbon dioxide (CO_2): CO_2 is released from fossil fuel combustion at oil and gas production and processing facilities. This combustion includes emissions from flaring (see Table 6). Also, CO_2 is often mixed with natural gas as it is produced from underground formations, particularly from coalbed methane sources. During gas processing, this CO_2 is typically separated from the natural gas and vented.[7]

- Methane (CH_4): Methane is typically released due to venting and leaks during oil and natural gas production and processing (methane is the primary component of natural gas). Methane is also released from coal mines.
- Nitrous oxide (N_2O): N_2O emissions are primarily associated with fuel combustion. N_2O emissions are typically a very small portion of total GHG emissions from Fossil Fuel Production and Processing.

The largest GHG emissions from Fossil Fuel Production and Processing are CO_2 from combustion of fuel and CO_2 separated from the raw gas stream.

1.4 Point of Regulation

The point of regulation currently under consideration is the facility where the emissions occur. As discussed above, oil and gas production facilities include a diverse set of equipment, processes, and activities. These facilities may also cover large geographic areas, encompassing well fields, pipelines, and tank batteries. Ownership and operational control may be divided among multiple entities as the oil and gas is produced and processed.

2. Emissions and Entity Data

Among the WCI partner states and provinces, Fossil Fuel Production and Processing emissions accounted for nearly 45 million metric tons (MMT) of CO_2e in 2005, or about 4% of total gross emissions from the WCI partners. However, for New Mexico and British Columbia, emissions from the Fossil Fuel Production and Processing Sector are a larger portion of total gross emissions, accounting for about 27% and 22% respectively of their gross emissions in 2005. Table 7 summarizes the emissions estimates for each province and state.

Although significant improvements have been made in the ability to calculate GHG emissions from Fossil Fuel Production and Processing, considerable uncertainty remains in national and state/provincial emission inventory estimates. Emissions factors for some types of emissions, such as fugitive emissions, continue to have broad ranges of uncertainty. Additionally, some activity data, such as the quantities of gas flared or vented, are not well measured or reported in some circumstances. Various efforts are ongoing to continue to improve emissions estimates for this industry.

The number of operating oil and gas wells is on the order of 70,000 and 50,000 respectively for the WCI partners (see Table 8). Typically, a small number of well field operators account for a large portion of operating wells and oil and gas production. For example, within the United States in 2005, the top 50 operators account for 77% of oil production and 72% of natural gas production.[8] In British Columbia, five operators account for about 80% of natural gas production, and in New Mexico 20 operators account for about 80% of natural gas production. Similarly, in California, 30 operators account for more than 90% of oil and gas production. Consequently, if a size threshold were adopted for participation in a cap-and-trade program, a large portion of total production could be covered while keeping the number of oil and gas field operators with a regulatory obligation manageable. Assessments of size threshold options and the number of entities covered remains ongoing.

[7] In some cases, CO_2 separated from natural gas is captured and re-injected or used for other purposes.

[8] U.S. Energy Information Agency, “Operator Information by Size Class” available at: http://tonto.eia.doe.gov/dnav/pet/pet_crd_crpdn_adc_mbbl_m.htm.

The number of coal mines operating in the WCI jurisdictions is on the order of 35, including 19 underground and 16 surface mines (see Table 8).

3. Emissions at the Entity Level

The ability to measure or calculate emissions reliably and precisely at the facility or entity level varies depending on the activities performed and equipment used at the facility and the manner in which data are collected and verified. For oil and gas production and processing emissions, several resources have been developed to assist in estimating emissions:

- The American Petroleum Institute's *Compendium of Greenhouse Gas Emissions Estimation Methodologies for the Oil & Gas Industry*[9] promotes consistency in estimating petroleum company's GHG emissions and provides recommendations on ways to improve and streamline GHG emissions estimates among existing methodologies.
- The International Petroleum Industry Environmental Conservation Association (IPIECA), International Association of Oil and Gas Producers (OGP) and API also prepared the *Petroleum Industry Guidelines for Reporting Greenhouse Gas Emissions*[10], a consistent global framework for accounting and reporting of GHG emissions by the industry sector.
- The World Business Council for Sustainable Development (WBCSD) and World Resources Institute (WRI) have developed *The Greenhouse Gas Protocol: a Corporate Accounting and Reporting Standard*[11], a common framework for defining the boundaries of reporting emissions.
- The New Mexico Environment Department, California Air Resources Board, and California Climate Action Registry, in cooperation with the Western Regional Air Partnership, have begun a joint initiative to develop a registry reporting protocol specific to the upstream oil and gas industry sector (i.e., production) and natural gas processing. This protocol, in combination with protocols already developed or soon to be completed for petroleum refining and natural gas transmission and distribution, will provide a basis for accelerated adoption of a complete oil and gas sector protocol by The Climate Registry. The protocol will not be likely to be completed until mid 2009.

While these resources have improved (and are continuing to work to improve) the consistency of emissions calculations and methods, the accuracy of entity-specific emissions calculations remains an issue of concern for certain sources at oil and gas production and processing facilities. Emissions calculations for metered fuel use and process vents amenable to measurement are expected to be as precise as the estimates performed for similar emissions from other stationary sources. However, emissions calculations for unmetered gas use (either flared or vented) and leaks pose challenges. The use of average or representative emissions factors for some sources (such as fugitive emissions) does not enable site-specific conditions to be reflected, and does not allow for improved operation and maintenance to be reflected in reduced emissions estimates.

---

[9] *Compendium of Greenhouse Gas Emissions Estimation Methodologies for the Oil & Gas Industry,* American Petroleum Institute (API), Washington, DC, February 2004, available at http://ghg.api.org.

[10] *Petroleum Industry Guidelines for Reporting Greenhouse Gas Emissions*, International Petroleum Industry Environmental Conservation Association (IPIECA), London, United Kingdom, December 2003.

[11] *The Greenhouse Gas Protocol: a corporate accounting and reporting standard*, World Business Council for Sustainable Development (WBCSD) and World Resources Institute (WRI), Washington, DC, January 2004, available at http://www.ipieca.org/reporting/ghg.html.

Based on the information reviewed to date, only a portion of the sources at oil and gas production and processing facilities will likely be feasible to include in a cap-and-trade program at this time. Improved methodologies may enable additional sources to be included in the future. The identification and assessment of those sources remains ongoing.

The ability of individual coal mines to calculate or measure emissions accurately varies. Surface mined coal does not provide an opportunity to measure emissions, although those emissions are typically low. Emissions from underground coal mining can be estimated from methane concentrations in ventilation air. Additionally, methane collected in degasification systems (prior to mining) is typically quantified.

Emissions from coal mines emitting over 100,000 metric tons CO_2e in Canada report their emissions federally.[12] The Environment Canada National Inventory Report contains data on fugitive emissions from coal mining, but the data for British Columbia is confidential due to the low number of market participants in the province (four).[13]

The ability to calculate emissions precisely from underground coal mining remains under review.

4. Administration

The primary administrative challenge associated with this sector is the inability of entities to measure or calculate emissions precisely from some sources. The entities that own or operate facilities that fall under this design element would already have compliance obligations under other regulatory programs. Consequently, the entities are well known and would be in a position to understand their compliance obligations under a cap-and-trade program.

The number of entities in the oil and gas production and processing industry could be large. Complex ownership and operating arrangements are also typically encountered. As discussed above, the use of a size or annual emissions threshold would reduce the number of entities with compliance obligations.

5. Leakage Issues

Oil, gas, and coal mining activities are undertaken at the locations of the resources themselves. Consequently, the operations cannot relocate to avoid participation in a cap-and-trade program. However, the companies that operate these facilities compete for investment resources. Increased cost or regulatory burdens have the potential to shift investment and production from WCI jurisdictions to other regions. Over time, therefore, production activities could shift to locations without GHG emissions limits, so that no net emission reduction is achieved. The significance of this vulnerability to emissions leakage remains under review.

[13] *National Inventory Report, 1990-2005: Greenhouse Gas Sources and Sinks in Canada*, Table A11-20: 1990-2005 GHG Emission Summary for British Columbia, Environment Canada, Ottawa, Canada, April 2007, available at http://www.ec.gc.ca/pdb/ghg/.

Table 6: Major Greenhouse Gas Emissions Sources from Oil and Gas Production and Processing

Equipment*	Emissions Type
Boilers/steam generators	Stationary combustion
Heaters/treaters	Stationary combustion
Compressors (internal combustion engines and turbines)	Stationary combustion
Flares	Stationary combustion
Incinerators	Stationary combustion
Gas sweetening processes	Process vent
Gas dehydration	Process vent
Vessel blowdowns	Maintenance venting
Well workovers	Maintenance venting
Compressor starts	Maintenance venting
Compressor blowdowns	Maintenance venting
Gathering pipeline blowdowns	Maintenance venting
Pressure relief valves	Non-routine venting
Well tests and blowdowns (when not flared)	Non-routine venting
Emergency shutdown/emergency safety blowdown	Non-routine venting
Tanks	Other venting
Pneumatic devices	Other venting
Chemical injection pumps	Other venting
Well drilling and testing	Other venting
Leaks from equipment components	Fugitive emissions
* Mobil sources are also used in oil and gas production fields (e.g., supply boats, barges, trucks, and aircraft). Mobil sources are not included in this design element.	

Table 7: Summary of Fossil Fuel Production and Processing Greenhouse Gas Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	0.6	1%
California (2004)	5.6	1%
Montana	5.0	13%
New Mexico	19.5	27%
Oregon (2004)	0.7	1%
Utah	4.1	6%
Washington	0.9	1%
British Columbia	6.1[a]	22%
Manitoba	0.6	3%
Total WCI Partners	**43.1**	**4%**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
Preliminary estimates, subject to review and revision.
a. This figure for British Columbia is under joint review by provincial and federal officials and may be revised.

Table 8: Oil Wells, Gas Wells, and Coal Mines

State/Province	Oil Wells (2004)	Gas Wells (2004)	Coal Mines (2005)	
			Surface	Underground
Arizona	20	8	2	0
California	45,515	3,362	0	0
Montana	3,765	5,356	5	1
New Mexico	14,928	33,029	3	1
Oregon	0	16	0	0
Utah	2,180	3,936	0	13

F. Fossil Carbon Content of Fuels

1. Description

1.1 Sectors

This design element covers CO_2 emissions from fossil fuel combustion throughout the economy, including: the electricity sector, transportation fuels, residential and commercial stationary combustion, and industrial stationary combustion.

1.2 Emissions Sources

This design element covers fossil fuel combustion throughout the economy. The fuels include coal, oil, natural gas, and other fossil fuels (such as propane).

1.3 Greenhouse Gases

This design element would cover CO_2 emissions. Other greenhouse gases associated with fuel combustion (nitrous oxide and methane) would be affected, but not covered explicitly. CO_2 emissions are estimated to account for more than 98% of the GHG emissions from fossil fuel combustion.

1.4 Point of Regulation

For some sectors, such as large industrial sources, GHG emissions can be tracked at the point of combustion. For other sectors, such as transportation, it is generally considered impractical to define the point of regulation at the point of emission, which would be the individual vehicle owner. The point of regulation under consideration for this element is to cover all fossil fuels at an appropriate point in their distribution and use. The appropriate point will vary depending on the fuel:

- Liquid Fuels: The preferred point of regulation for liquid fuels (gasoline, diesel, propane) will likely be the point at which these fuels enter into commerce in the individual states and provinces. In examining this point of regulation, consideration is being given to the fact that most jurisdictions have an existing mechanism for tracking the sale of liquid fuels. The manner in which jurisdictions track fuel distribution and sales varies, so that the preferred point of regulation may also vary among jurisdictions. Some states track fuel deliveries through licensed wholesalers. Other states track fuel dispensed from terminals and refineries. Care is needed to ensure that the tracking systems are comprehensive and compatible. Because these tracking systems have generally been developed to support tax collection, building on the existing fuel tracking procedures in each jurisdiction is expected to simplify program design and implementation requirements.
- Natural Gas: The preferred point of regulation for natural gas will likely be a combination of entities. For residential and commercial customers (and some industrial customers), natural gas is delivered by local distribution companies (LDCs). The LDCs are in a position to track and report natural gas delivered to these customers. Some large natural gas users (e.g., some industrial customers) purchase natural gas directly, bypassing the LDCs. The point of regulation for direct purchasers of natural gas would be the direct purchasers themselves. Coordination would be required to ensure the combined set of entities cover natural gas use comprehensively, and without duplication, in each jurisdiction. Another option for covering natural gas would be at the pipeline.
- Coal: In most jurisdictions, coal is typically combusted in facilities that are known to regulatory agencies for other environmental control purposes. The preferred point of regulation would likely be the individual facilities that combust coal.

2. Emissions and Entity Data

CO_2 emissions from fossil fuel combustion are the largest component of GHG emissions for each of the WCI partners. The emissions estimate for 2005 is about 820 MMT CO_2e, accounting for about 81% of total gross emissions among the WCI partners. The percentage of total gross emissions varies among the partners from about 55% to 87%. Table 9 summarizes the emissions estimates for the WCI partners.

The number of entities with regulatory obligations under this design element is being assessed. The number of pipelines and LDCs in the WCI partner states is shown in Table 10, along with the number of refineries and liquid fuel terminals. The number of licensed fuel wholesalers is expected to be larger than the number of terminals. For example, Oregon licenses about 160 motor vehicle fuel dealers. The number of entities that purchase natural gas directly or combust coal remains to be identified, but is expected to be a manageable number for administrative purposes.

3. Emissions at the Entity Level

As described above, the points of regulation under consideration for natural gas and liquid fuels do not coincide with their emissions points. LDCs and fuel distributors (whether at terminals or wholesalers) cannot measure or calculate actual GHG emissions from fuel combustion. Rather, the entity can calculate potential CO_2 emissions based on the fossil carbon content of the fuel and the quantity of the fuel. Virtually all the carbon in the fuel is converted to CO_2, so that the carbon content of the fuel is an accurate predictor of CO_2 emissions.

Several issues need to be addressed in order to use this calculation of potential emissions:

- Variations in fossil carbon content: Currently, the fossil carbon content of liquid fuels and natural gas is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.
- Fuel use for non-combustion purposes: The emission calculation presumes that all the fuel delivered will be combusted. Some fuels may be used to produce products (such as plastics) that sequester carbon. A mechanism is needed to account for this carbon sequestration at the point of use of the fuel.

Notably, this method of calculating emissions is a proxy only for the CO_2 emissions that occur when the fuel is combusted. The calculation does not include N_2O and CH_4 emissions, although those emissions would also be expected to occur during combustion along with the CO_2 emissions. Additionally, the method does not include the GHG emissions associated with producing the fuel. Rather, this method covers emissions associated with fuel use, but not fuel production. Emissions associated with fuel production would be covered separately as emissions from the facilities involved in producing the fuel.

For direct purchasers of natural gas and for coal combustion facilities, the entity would also be capable of measuring or calculating CO_2 emissions. Facilities could use fuel consumption data along with the carbon content of the fuel. Alternatively, some facilities may find it advantageous to measure emissions directly.

4. Administration

This sector does not pose significant administrative challenges. Regulatory agencies are able to identify most if not all the entities in this sector with compliance obligations because the entities typically have other regulatory requirements. LDCs are already subject to economic regulation by the state public utilities commissions in the United States and by provincial authorities in Canada. Thus, a state or provincial regulatory agency can identify all the entities with compliance obligations. Large industrial purchasers of natural gas and coal combustors typically have other air emission compliance requirements, and consequently are known to regulators.

By leveraging existing liquid fuel tracking procedures in states and provinces, the administrative challenges for these fuels can be minimized. However, the tracking capabilities of each state and province remain to be examined in detail to assess the comprehensiveness of the existing tracking capabilities. Insofar as the existing procedures provide incomplete coverage of the fuels, additional tracking capabilities may be required.

The covered entities should also have the capability to know their compliance obligations and understand the applicable requirements. The emissions from this sector are reasonably well known, so that an acceptable emission baseline can be developed.

5. Leakage Issues

This design element covers a very broad set of sectors throughout the economy. Significant vulnerabilities to leakage exist in specific components of fossil fuel use.

- Electric Sector: This design element covers the combustion at fossil fuel power plants either directly (e.g., as direct natural gas purchasers and coal combustion facilities) or indirectly through the inclusion of natural gas LDCs and oil distributors. Because emissions leakage associated with electricity imports from jurisdictions without GHG emissions caps can be significant, such leakage would need to be addressed as part of this approach.

- Transportation fuels: The potential for emission leakage is significant for components of the transportation sector:

    - *Marine:* Ocean-going vessels can easily obtain fuel outside the WCI partner jurisdictions.

    - *Aviation:* Airline operations are particularly sensitive to fuel costs. Opportunities to obtain fuel outside the WCI partner jurisdictions may be significant.

    Gasoline use in passenger cars, light duty trucks, and medium duty vehicles is less vulnerable to leakage, as motorists typically obtain fuel in close proximity to their residences and places of employment.

    Long-haul trucking may also be vulnerable to leakage if trucks can operate within WCI jurisdictions with fuel obtained from outside the WCI jurisdictions. However, the International Fuel Tax Agreement (IFTA) requires diesel trucks operating in multiple jurisdictions to calculate fuels consumed in each state and province based on the miles traveled in each state/province. All the WCI partners are parties to the IFTA.[14]

[14] The 48 contiguous states of the United States and 10 Canadian provinces are parties to IFTA. Yukon Territory, Northwest Territory, Nunavut, and the District of Columbia are not parties to IFTA.

Consequently, the IFTA data could be used to compute a compliance obligation for diesel trucks that operate in multiple jurisdictions, thereby avoiding leakage.[15]

- Industrial Facilities: Vulnerability to leakage varies among the industrial facilities that would be covered under this sector. Some facilities require close proximity to their markets, so that significant leakage to locations outside the WCI region is not expected. However, others (such as the cement industry and the pulp and paper industry), may be vulnerable to leakage as their products are traded as commodities internationally. The vulnerability to leakage needs to be assessed individually for each industry.

Table 9: Summary of CO_2 Emissions from Fossil Fuel Combustion

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	86.6	87%
California (2004)	416.2	86%
Montana	22.6	61%
New Mexico	43.9	60%
Oregon (2004)	57.7	83%
Utah	54.0	78%
Washington	81.0	85%
British Columbia	46.9	71%
Manitoba	11.4	55%
Total WCI Partners	**820.1**	**81%**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
Preliminary estimates, subject to review and revision.

[15] IFTA covers diesel trucks with the following characteristics: (a) has three or more axles; or (b) has two axles and a gross vehicle or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms; or (c) is used in a combination that has a combined or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms. Recreational vehicles are not covered.

Table 10: Summary of Number of Potentially Regulated Entities for Fossil Fuels

	Natural Gas			Petroleum

Data for direct purchasers of natural gas and for coal combustors are under development. Preliminary estimates, subject to review and revision.					

G. Passenger Cars, Light Duty Trucks and Medium Duty Vehicles

1. Description

This design element covers emissions from passenger cars, light duty trucks and medium duty vehicles. These emissions could be covered through several different approaches. This design element focuses on vehicle manufacturers as one option for covering these emissions.

1.1 Sectors

The sector covered is the light and medium duty vehicle portion of the transportation sector (cars and trucks less than 14,000 pounds gross vehicle weight rating).

1.2 Emissions Sources

Emission sources include all emissions during the operation of passenger cars, light duty trucks and medium duty vehicles, including: fuel combustion; refrigerant emissions; and evaporative emissions. Emissions associated with producing the vehicles or producing the fuel used by the vehicles are not included in this design element.

1.3 Greenhouse Gases

All six Kyoto gases are included. The primary gases associated with vehicle operations are CO_2, CH_4, N_2O, and high GWP gases (refrigerants).

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for passenger cars, light duty trucks and medium duty vehicles at the point of emission, which would be the individual vehicle owner. Rather, the point of regulation under consideration for this element is the vehicle manufacturer. In considering this point of regulation, the vehicle manufacturer would be assigned responsibility for the expected emissions associated with their new vehicles that are sold in each jurisdiction, or alternatively, for vehicles *delivered for sale* in a jurisdiction. This regulatory obligation could take various forms, including:

- <u>Fleet Requirement</u>: Under this approach, a maximum fleet average emission rate would be defined for each year. The actual fleet average for each manufacturer would be calculated each year based on the new vehicles sold (or delivered for sale) by that manufacturer in that year. Manufacturers would be required to hold allowances for emissions that exceed the fleet average maximum, and could earn credits for attaining average fleet emissions below the maximum. Whether and how these emission allowances and credits could be traded with other components within of a cap-and-trade system remain to be assessed.
- <u>Lifetime Emissions</u>: Under this approach, each manufacturer would be responsible for the expected lifetime emissions associated with its new vehicles sold (or delivered for sale) each year. The manufacturer would be required to hold emission allowances equal to the expected lifetime emissions from the new cars sold in that year.

2. Emissions and Entity Data

The transportation sector is one of the largest sources of GHG emissions for each of the WCI partners. Table 11 summarizes the emissions estimates for the WCI partners. The total number of entities with compliance obligations is the number of vehicle manufacturers that sell vehicles in the WCI states and provinces. There are approximately 40 manufacturers that sell vehicles in these jurisdictions.

3. Emissions at the Entity Level

As described above, the point of regulation under consideration is the sale of new passenger cars, light duty trucks and medium duty vehicles by manufacturers. At this point, the regulated entity (the manufacturer) cannot measure or calculate actual GHG emissions from vehicle use. Rather, the entity can calculate potential emissions based on the expected operating characteristics of the vehicles sold, including the number of years the vehicles remain in use. These emissions estimates depend, in part, on how owners maintain and use their vehicles (e.g., vehicle miles traveled annually). Additionally, actual emissions will depend on fuel characteristics, including the availability and use of fuels with non-fossil carbon components.

To carry out the necessary emission calculations, the emissions rate associated with each model sold would need to be certified (e.g., emissions per mile traveled). Vehicle testing procedures have been developed to support requirements such as the California vehicle emissions regulations that focus on fleet average emissions. Additional data are required to calculate expected lifetime emissions. Consequently, lifetime emission estimates made at the time of sale by the manufacturers will necessarily have additional uncertainty, which may be a barrier to using the lifetime emissions approach.

4. Administration

There are roughly 40 manufacturers of passenger cars and light duty trucks worldwide. Therefore, the number of entities does not pose an administrative challenge. The manufacturers have the capability to know their compliance obligations and understand the applicable requirements. The potential need to track nearly new vehicles that are registered in the state or province needs to be assessed. For example, to avoid the program requirements, a new vehicle could be sold and registered in a non-WCI jurisdiction and then moved to a WCI jurisdiction and registered. Vehicles with fewer than 15,000 miles (for example) that are registered for the first time in a WCI jurisdiction could be counted as a newly sold vehicle for purposes of the program. Whether this tracking of nearly new vehicles would be needed, and how it would be administered remains to be considered.

In addition to administrative issues, potential legal issues also remain to be examined. The WCI jurisdictions must assess whether they have an adequate regulatory basis for requiring reporting and participation by vehicle manufacturers. If needed, jurisdictions could consider regulating (via permit) automobile manufacturers as “Indirect Sources” of air pollution (for example, Oregon’s regulations at OAR 340-254-0030).

5. Leakage Issues

The sale of new passenger cars and light duty trucks is not particularly vulnerable to leakage because consumers purchase vehicles primarily for local transportation purposes. Concerns have been raised regarding impacts on the rate of turnover of the vehicle fleet. Higher vehicle prices may slow the rate of vehicle replacement, leading to vehicles with higher emissions remaining on the road longer than would otherwise be the case. This impact can be assessed for alternative program designs.

Table 11: Summary of CO_2 Emissions from On-Road Gasoline Combustion

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions
Arizona	24.4	24%
California (2004)	138.1	28%
Montana	4.1	11%
New Mexico	8.9	12%
Oregon (2004)	13.1	19%
Utah	8.8	13%
Washington	23.5	25%
British Columbia	10.5	16%
Manitoba	2.9	14%
Total WCI Partners	**234.2**	**23%**

MMT = million metric tons
Percent of gross emissions calculated for each state/province.
NA = Not Available. Emissions data currently being developed.
Preliminary estimates, subject to review and revision.

H. Large Transportation Fleets

1. Description

This design element covers large transportation fleets. The point of regulation would be entities (e.g., companies, local governments, transit agencies, etc.) that operate fleets of motor vehicles or boats. A key issue in this sector is what constitutes a "fleet" of vehicles or boats. Thresholds in both quantitative (e.g., number of vehicles or boats) and qualitative (e.g. types of vehicles or boats) terms may be applied to limit the scope of regulation within this sector.

1.1 Sectors

Large Transportation Fleets regulated at the fleet management level.

1.2 Emissions Sources

Fossil fuel combustion from fleet vehicles and boats.

1.3 Greenhouse Gases

Carbon dioxide is the dominant GHG produced in this element, accounting for on the order of 97% of emissions from these sources. Nitrous oxide (N_2O) and methane (CH_4) are also emitted.

1.4 Point of Regulation

The point of regulation for this option would be the entity that owns and operates the vehicles that are to be regulated. This entity would be required to hold allowances equal to the emissions of the fleet vehicles. Issues around leased vehicles would need to be clarified.

A threshold for inclusion in the sector would seem to be a practical necessity. Possible thresholds include number of vehicles or boats, combined fleet vehicle miles traveled, total fuel use, or other metrics. However, it may be most appropriate to set an emissions threshold for including fleets in the cap-and-trade program.

Other factors may play into the definition of a "fleet" for the purposes of compliance. Types of vehicles (commercial, off-road, on-road, marine, weights of vehicles, etc.) may be one factor. Geographic range, or the geographic location of a centralized operations base, may also play into a definition of what constitutes a fleet for inclusion in such a program. Inclusion of ferry and other boat fleets (such as those operated by Washington State Ferries, the BC Ferry Corporation and marine barge operations) should be considered under this design element due to the amount of associated emissions.

2. Emissions and Entity Data

Data collection and analysis are underway to estimate the number of fleets at various threshold levels and the portion of emissions that the fleets may represent. Initial indications are that there may be on the order of 10,000 vehicle fleets in the WCI partner states and provinces that each have 10 or more vehicles. However, this is a very preliminary figure.

3. Emissions at the Entity Level

Most fleet management systems would capture the relevant data necessary for estimating emissions from fleet vehicles. Emissions could be estimated from odometer readings, fuel use, and other factors. Protocols for estimating these emissions exist. However, fleet data have been suspect in terms of data reliability and verifiability. The margins of error associated with these data should be considered.

Currently, the fossil carbon content of liquid transportation fuels is well known. However, in the future, fuels may include varying levels of non-fossil carbon components (e.g., in response to low carbon fuel standards). Consequently, the fossil carbon component of the fuel may need to be verified at the point of regulation, or may need to be provided to the point of regulation by the fuel producer. The mechanism required to make this fossil carbon content determination remains to be determined.

If N_2O and CH_4 were included in the cap and trade program for this sector then estimating emissions for these gases may be subject to a wide margin of uncertainty because emission rates depend on vehicle characteristics and maintenance conditions. National and international standard N_2O and CH_4 emission factors for different fuels could be used as a proxy for more precise estimations.

4. Administration

The ability to administer a cap and trade program in the fleet sector is largely a function of how fleets are defined. If the threshold for inclusion (by whatever metric) is low enough to include the numerous family-run or other similar small business operations in trucking, retail, and urban delivery, then the ability for these entities to understand and administer their obligations is questionable. Conversely, the largest fleet operations – especially in trucking, ferries and businesses like rental fleets – are likely well positioned from both an administrative and data perspective to deal with the regulatory burden. Steps may need to be taken, however, to ensure that fleets do not sub-divide their structures to potentially avoid regulation by falling under whatever threshold is put in place.

5. Leakage Issues

There are components of the large fleet sector for which there may be a high level of leakage from any attempt to regulate the large fleet sector. Medium- to large-scale fleets in the goods delivery sector have the ability to locate themselves in any number of locations so long as they have at least some reasonable level of proximity to the markets they operate in. Thus it is possible that in response to any cap-and-trade regime in WCI states and provinces that trucking fleets (in particular) may relocate to the borders of adjoining states and provinces not subject to the cap-and-trade regime.

However, the International Fuel Tax Agreement (IFTA) requires diesel trucks operating in multiple jurisdictions to calculate fuels consumed in each state and province based on the miles traveled in each state/province. All the WCI partners are parties to the IFTA.[16] Consequently, the IFTA data could be used to compute a compliance obligation for fleet operators of diesel trucks that operate in multiple jurisdictions, thereby avoiding leakage.[17]

Leakage is less of an issue for fleets that must serve specific areas. These fleets may include municipal and state/province government vehicles, as well as electric and gas utility trucks. Similarly, leakage would not apply to ferry fleets, and likely not to marine barge and other localized marine fleets.

---

[16] The 48 contiguous states of the United States and 10 Canadian provinces are parties to IFTA. Yukon Territory, Northwest Territory, Nunavut, and the District of Columbia are not parties to IFTA.

[17] IFTA covers diesel trucks with the following characteristics: (a) has three or more axles; or (b) has two axles and a gross vehicle or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms; or (c) is used in a combination that has a combined or registered gross vehicle weight of more than 26,000 pounds or 11,797 kilograms. Recreational vehicles are not covered.

Smaller fleets serving specific urban markets are less likely to be able to relocate to avoid regulation. However, as previously noted, the administrative feasibility of regulating the smaller fleets is in question.

I. Agriculture Emissions

1. Description

1.1 Sectors

This design element covers the agricultural sector, which includes a diverse set of production activities, including: crop production; livestock production; grazing lands; and other activities. Agriculture can serve as a sink (i.e., can remove carbon dioxide from the atmosphere) or as a source of emissions. Not included in this design element is forestry, although agriculture and forestry are often interrelated because land can change from one use to the other and back.

1.2 Emissions Sources

Given the diversity of agricultural activities, there are a large number of sources of emissions, including:

- methane and nitrous oxide (N_2O) emissions from livestock manure management;
- N_2O emissions from soils due to fertilizer use, legume production, and increased microbial activity associated with liming;
- methane emissions from livestock digestive processes, rice cultivation; and cultivation of other wetland crops;
- methane emissions from the conversion of lands from trees or grasses to annual cropland; and
- carbon dioxide (CO_2) emissions from the use of lime.

In addition to these sources, agricultural lands can emit CO_2 or act as a sink for CO_2 in a given year by changing the carbon stock on the agricultural land. Carbon stock is the carbon contained in biomass, including above and below ground biomass, at a specific point in time. If the carbon stock increases from one year to the next, the agricultural land acted as a sink, and accumulated carbon by removing it from the atmosphere. If the carbon stock decreases, the land released carbon.

Practices that can increase carbon stock (i.e., remove CO_2 from the atmosphere) include reduced tillage, use of cover crops, favorable crop rotations, changing from row crops to permanent pasture or other perennial crops, and increasing productivity of plants on pasturelands.

Emissions due to fertilizer production and fuel use in farm equipment are not included as sources in this sector.

1.3 Greenhouse Gases

N_2O and methane are the primary GHG emitted in the agriculture sector. CO_2 emissions and sinks also occur.

1.4 Point of Regulation

The point of regulation for agriculture is the land owner. The land owner typically has control over how the lands are managed, including the type and level of agricultural production that takes place. Consequently, the land owner has the most influence over the activities that lead to emissions (or sinks) on his/her agricultural lands.

Notably, some agriculture lands are leased to others who use the land for production purposes. For example, grazing lands are often leased to livestock owners, so that the land owner does not necessarily have a comprehensive inventory of the livestock grazing taking place. Federal and state governments are significant leasers of grazing lands, for example accounting for approximately 33% of grazing and range lands in the United States.

2. Emissions and Entity Data

Among the WCI partner states and provinces, agriculture emissions accounted for about 65 MMT of CO_2e in 2005, or about 6% of total gross emissions. This percentage is less than 10% for all the partners, with the exception of Montana and Manitoba, which report agriculture emissions accounting for 21% and 30% of gross emissions in 2005, respectively. Table 12 summarizes the emissions for the WCI partners.

The total number of entities that would be covered in this sector depends on whether, and at what level, an annual emissions threshold is set. In the livestock sector, confined animal operations (CAOs) typically have the highest concentration of animals and manure that can lead to emissions. As shown in Table 12, the number of CAOs totals nearly 20,000 among the WCI partners. Also shown in the table is the number of farms with harvested cropland, an indication that nitrogen fertilizers may be used. The total number of farms with harvested cropland is on the order of 150,000 among the WCI partners.

3. Emissions at the Entity Level

Precise direct measurement of agriculture GHG emissions at the entity level is not currently practical. Emissions estimates are typically made using emissions factors associated with various types of management practices. However, site-specific conditions and individual management practices can have a significant impact on emissions so that actual entity-level emissions can vary substantially from the estimates based on representative emissions factors.

For example, N_2O emissions from soils are the largest component of agriculture GHG emissions. Emission factors for N_2O from soils have very large ranges and uncertainties due to the highly variable rate of emissions spatially and temporally across soil conditions and seasons. Perhaps most importantly, the N_2O emissions factors cannot currently estimate with precision the changes in emissions that may result from changes in practices at the entity level.

Similarly, although emissions factors for livestock emissions, manure management emissions, and rice cultivation emissions are available, they do not easily incorporate site-specific practices that can affect emissions rates.

Emissions or removals of CO_2 can be inferred from changes in carbon stocks. For example, soil carbon stocks can be measured by using soil samples. Together with a properly designed survey, such samples can result in estimates of soil carbon content with high levels of accuracy and precision. However, because the increases or decreases in carbon stocks are small relative to the amount of carbon in the soil, changes can best be estimated by performing surveys spaced a number of years apart. In most circumstances, a five year interval between measurements is likely to be the shortest interval that would result in reliable estimates of changes in soil carbon.

Emissions modeling, combined with field measurements, can be used to better estimate emissions and sinks from agricultural activities. However, the use of these models is generally beyond what can reasonably be expected from most producers.

4. Administration

If individual agricultural land owners are required to hold allowances or report on emissions and emission reductions, a very large number of entities would be involved. As shown in Table 12, many thousands of entities would have compliance obligations. Moreover, as suggested above, tools to measure many agricultural emissions are in early stages of development, and current estimates can have large uncertainties. The wide variety of mechanisms that result in emissions or emission reductions, together with the difficulties of obtaining reliable estimates in many cases would pose a significant challenge. Additionally, as mentioned above, many land owners lease their land to others for grazing or other agricultural purposes. Consequently, the land owner may not have adequate information to perform a reasonable emissions calculation. When combined, these factors pose very significant administrative challenges.

5. Leakage Issues

The agriculture sector is highly vulnerable to emission leakage. The market for agriculture products is international in scope, and highly competitive. If compliance requirements in the WCI region reduce production, production could increase in another region. The shift in production location may result in no net change in emissions overall. Consequently, particular care must be taken as it relates to imposing reporting or other compliance requirements within this sector.

Table 12: Summary of Agriculture Emissions

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	CAO Operations[a]	Harvested Cropland[b]
Arizona	4.7	5%	547	3,139
California (2004)	23.3	5%	4,815	54,115
Montana	7.9	21%	1,554	16,543
New Mexico	6.2	8%	857	7,204
Oregon (2004)	5.1	7%	3,682	23,013
Utah	4.2	6%	1,862	9,661
Washington	5.4	6%	3,043	21,802
British Columbia	2.6	4%	2,000[c]	14,484
Manitoba	6.1	30%	1,439[c]	16,660
Total WCI Partners	**65.5**	**6%**	**19,799**	**166,621**

a. Confined animal operations, including dairy operations, beef cattle operations, and hog farms. Does not including grazing operations (i.e., non-confined).

b. Entities reporting harvested cropland.

c. Does not include beef cattle operations.

MMT = million metric tons

Percent of gross emissions calculated for each state/province.

Preliminary estimates, subject to review and revision.

J. Forestry and Land-Use Change

1. Description

Forestry and land-use change encompass the suite of human activities and naturally occurring processes and events that result in changes in forest cover and/or changes to the amount of carbon stocks on forest lands. Forestry can serve as a sink (i.e., can remove carbon dioxide from the atmosphere) or as a source of emissions.

1.1 Sectors

The forestry sector refers to lands that support, or can support, a given tree canopy cover and that allow for management of one or more forest resources, including timber, fish and wildlife, biodiversity, water quality, recreation, aesthetics and other public benefits.[18] Forest lands are owned by federal, state, provincial, and municipal governments, companies, individuals, and non-governmental organizations. Forest lands can serve multiple purposes, including supply of wood and fiber, recreation, habitat, scenic enhancement, water quality, preservation of carbon stocks, and other purposes.

Land-use change refers to the conversion of land from one purpose to another. Forest land may be converted to other uses through deforestation or, for example, to residential use. Land that was not in forest cover may become forest land (i.e., through reforestation or afforestation). Agriculture and forestry are often interrelated because land frequently changes from one use to the other and back.

This design element does not include the processing of timber into products, or the use of forest biomass for energy production. The long-term fate of harvested wood products could be included as part of this design element, but doing so is challenging, particularly at the land owner level.

1.2 Emissions Sources and Sinks

The extent to which forest lands emit greenhouse gases (primarily CO_2) or act as a sink for CO_2 in a given year is measured in terms of the change in carbon stock on the forest land. Carbon stock is the carbon contained in forest biomass, including above and below ground biomass, at a specific point in time. If the carbon stock increases from one year to the next, the forest land acted as a sink, and accumulated carbon by removing it from the atmosphere. If the carbon stock decreases, the forest land released carbon.

Carbon stocks on forest lands can increase or decrease through both natural events and human intervention. Natural fire cycles affect the carbon stock on forest lands. Human activities can affect the fire cycle, however. Forest management for commercial or noncommercial harvest of biomass can also affect carbon stocks. If the amount of biomass that grows is the same as the amount of biomass removed for products or energy, the managed forest is presumed to result in no net emissions from changes in carbon stocks. In the event of forest fires, insect and disease, or unsustainable harvesting practices, forests can act as significant carbon sources.

Land-use change can also result in emissions or a sink. Land that changes from non-forest cover to forest cover will show an increase in carbon stock, and consequently is a sink over the

[18] A tree canopy cover of 10% is used to define forest land by the California Climate Action Registry (see *Forest Sector Protocol*, Version 2.1, The California Climate Action Registry, September 2007, available at: http://www.climateregistry.org/PROTOCOLS/FP/). Other percentages are also used, such as 25% in British Columbia and other Canadian provinces.

long term. Land that is converted from forest cover to another use, such as agriculture, will show a reduction in carbon stock, and consequently is an emission source.

While the overall impact of human activities and natural events and processes can be assessed as changes in carbon stock, the specific activities and events that result in emissions include:

- immediate release from burning of biomass (including in forest fires);
- residual release from biomass decay;
- soil carbon releases due to soil disturbance;
- decay of harvested wood products; and
- decay of standing timber (from insect and disease or general decline).

Finally, it should be noted that long-lived wood products, such as furniture and building materials, also represent a carbon pool. The carbon in these products was removed from the atmosphere through forest management. Methods for accounting for the wood product carbon pool have been developed for national and state/province level inventories. However, accounting methods are not available for application at the land owner level. Consequently, incorporating the carbon pool from long-lived wood products into a cap-and-trade program at the land-owner level would be very challenging at this time.

1.3 Greenhouse Gases

The predominant greenhouse gas affected by forestry and land-use change is CO_2. However, biomass combustion (e.g., due to forest fires) also results in nitrous oxide (N_2O) emissions. Forests can also act as either sources or sinks for methane. The N_2O and methane emissions are very small compared to the CO_2 emissions and sinks.

1.4 Point of Regulation

The point of regulation for forestry and land-use change is the land owner. The land owner typically has control over how the forest lands are managed, within the applicable regulatory framework of the jurisdiction in which the lands are located. Consequently, the land owner has the most influence over changes in carbon stock on his/her forest lands.

As discussed below, governments are large owners of forest lands. Companies and individuals own smaller parcels, although some individual private holdings are significant. A threshold of parcel size may be used to limit the coverage of the large numbers of owners of small amounts of forest lands.

2. Emissions and Entity Data

Among the WCI partners and provinces, forestry and land use change have been estimated to be an overall sink for GHG emissions. As shown in Table 13, the sink was on the order of 11% of gross emissions in 2005. The size of the sink varies significantly across states and provinces, with the forestry sink being sizable compared to gross emissions from some jurisdictions. Of note is that although forestry and land use currently are a sink, some analysts have estimated that the forest sector could be a much larger sink than is currently the case. Consequently, forestry provides an opportunity to increase the sequestration of carbon.

Governments are significant owners of forest lands in the WCI states and provinces. For example, the provincial government of British Columbia owns 95% of forested land in the province. Most of remainder of the forest land is owned by a small number of forestry companies, and many small land owners. In California, the federal government owns approximately 52% of forest lands, and provincial/local governments own about 3%. The remainder of the forest land (45%) is privately owned. Similarly, in Washington, approximately 57% of forest lands are publicly owned, with 43% privately owned. Table 13lists the portion of forest land that is publicly owned in each WCI partner jurisdiction.

The land owners that convert forest lands to other uses (such as urban development) are not typically the large government land owners. Rather, owners of smaller parcels are involved in converting forest land to other uses, an activity that typically results in net emissions. Many thousands of land owners in the WCI region play a role in conversion of forest lands to other uses.

3. Emissions at the Entity Level

Protocols on how to perform forest carbon modeling are well established (IPCC Good Practice Guidance[19], 2006 IPCC Inventory Guidelines[20]) as are international reporting mechanisms (UNFCCC, Kyoto Protocol[21]). While the models have degrees of uncertainty (particularly due to the quality and consistency of input inventory data and growth and yield curves), they are internationally accepted and used. These approaches are typically used at the government level for national and state/province inventories.

Protocols have also been developed for measuring changes in carbon stock at the land owner or entity level.[22] To apply these methods, landowners would be required to conduct periodic inventories to determine their carbon stock over time. As these methods typically rely on characterizations of samples of areas within forest lands, and are measuring biological activities, the resulting emission/sink estimates are generally considered to be less precise than emissions calculations for fossil fuel combustion emissions.

Notably, the extent to which a given parcel of forest land is a source or a sink in a given year depends, in part, on previous years and future years. For example, the natural fire cycle may reduce the carbon stock on certain forest lands in a given year. In that year, the land is an emissions source. In subsequent years, the carbon stock may increase, indicating that the forest is a sink. Over time, the forest may be carbon neutral, so that it is neither a source nor a sink. This time-dependent nature of carbon stocks on forest lands would need to be addressed in the estimating procedure at the individual land owner level under a cap-and-trade program.

4. Administration

As described above, governments typically own a large portion of forest lands. Nevertheless, there are many owners of large land holdings (including those engaged in commercial harvesting) and a very large number of owners of smaller land parcels. Many of the forest land owners are not typically covered by existing air quality regulations, although those involved in commercial harvesting may be regulated under other programs. Identifying all the relevant land owners could be a significant administrative challenge unless smaller parcels were excluded from the program.

The ability to measure emissions from all relevant land owners also presents a challenge. Specialized expertise is required to measure carbon stock changes at the entity level using

[19] http://www.ipcc-nggip.iges.or.jp/public/gpglulucf/gpglulucf.htm

[20] http://www.ipcc-nggip.iges.or.jp/public/2006gl/index.htm

[21] http://unfccc.int/kyoto_protocol/items/2830.php

[22] See, for example, *Forest Sector Protocol*, Version 2.1, The California Climate Action Registry, September 2007, available at: http://www.climateregistry.org/PROTOCOLS/FP/.

existing protocols. Ensuring the availability of this expertise to all relevant land owners could also present a significant challenge.

Given these administrative challenges, a less than fully comprehensive approach to covering forestry and land-use change within a cap-and-trade program may need to be considered. For example, the cap-and-trade program could focus solely on land conversion, from forest cover to other uses, and from other uses to forest cover. Other policy measures and approaches (outside of the cap-and-trade program) could be used to address the other aspects of the forestry and land-use change sector. The portion of emissions/sinks that could be addressed with a cap-and-trade program by such an approach remains to be assessed.

5. Leakage Issues

Important components of the forestry sector are highly vulnerable to emission leakage. The market for wood products is international in scope, and highly competitive. In response to reduced commercial forest production in one region, production could increase in another region. The shift in harvest location may result in no net change in emissions overall. Consequently, particular care must be taken as it relates to requirements for emission measurement or other requirements for the commercial forest products portion of the sector.

Land conversion, from forest lands to urban development for example, may be vulnerable to leakage if alternative locations for development are available. However, given the size of WCI jurisdictions, such leakage has the potential to be small. Perhaps more important is the potential for increased costs to affect the rate of forest conversion. If significant costs are imposed to prepare emission inventories for forest lands, owners of small parcels may find it advantageous to convert their land to other uses so as to avoid the emission inventory requirement. This potential impact must be considered carefully to assess potential negative impacts of including forest lands under a cap-and-trade program.

Table 13: Summary of Forestry Emissions (Sinks)

State/Province	2005 Emissions (MMT CO_2e)	Percent of 2005 Gross Emissions	Portion of Forest Land Publicly Owned

K. High GWP Gases

1. Description

Hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6) are potent greenhouse gases, some of which persist in the atmosphere for thousands of years. These gases, referred to as high global warming potential (GWP) gases are from 650-23,900 times more potent than CO_2 in terms of their capabilities to trap heat in the atmosphere over a 100-year period. Also, because they remain in the atmosphere almost indefinitely, atmospheric concentrations of these gases will increase as long as emissions continue.

1.1 Sectors

High GWP gases are used by and emitted from a wide variety of activities and equipment. The overwhelming majority of the use and emissions of these gases are associated with their use as substitutes for ozone depleting substances that have been phased out. Consequently, these gases are used are as refrigerants in residential, commercial and industrial equipment, as well as aerosol propellants and solvents.[23] High GWP gases are also used in semiconductor manufacturing, magnesium production, and other miscellaneous applications. SF_6 is used in electric power transmission and distribution systems. Emissions of SF_6 from these sources are included in the electric sector, and are not included here.

In some cases, high GWP gases are produced as byproducts of industrial processes. For example, CF_4 and C_2F_6 are produced during aluminum smelting. These process-related emissions are not included in this design element, but rather are included under industrial process emissions.

1.2 Emissions Sources

High GWP gases are emitted in several ways. When used as refrigerants, these gases may leak during normal equipment operation, or may be released as a result of equipment failure. Additionally, during equipment servicing or disposal the refrigerants may be deliberately or inadvertently released. It is currently best practice to collect and recover refrigerants during servicing and disposal so as to prevent emissions (capture and recycling is required in some jurisdictions). However, consumers can purchase cans of refrigerant to recharge their automobile air conditioners. Emissions may result from these consumer maintenance activities, and residual amounts of refrigerant in the cans are also typically emitted.

The semiconductor manufacturing industry uses high GWP gases in plasma etching and in cleaning chemical vapor deposition tool chambers. These processes use the gases to selectively create circuitry patterns and remove deposited materials.[24] The high GWP gases are vented as part of this process. In some cases, the gases may be captured and recycled to prevent emissions. The magnesium metal production and casting industry uses sulfur hexafluoride (SF_6) as a cover gas to prevent the rapid oxidation of molten magnesium in the presence of air. The SF_6 is emitted as part of this process.

1.3 Greenhouse Gases

The high GWP gases include hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6).

---

[23] For more information see: *Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990 –2005*, U.S. Environmental Protection Agency, Washington, D.C., 2007, p. 4-44, available at: http://epa.gov/climatechange/emissions/usinventoryreport.html.

[24] For more information, see: http://www.epa.gov/highgwp/sources.html.

1.4 Point of Regulation

It is generally considered impractical to define the point of regulation for high GWP gases as the point of emission for the majority of the high GWP emissions sources. In particular, emissions from leaks and servicing of residential, commercial, and industrial refrigeration and air conditioning equipment would be the responsibility of the equipment owners and servicing companies. In most cases these emissions cannot be measured directly, and the equipment owners and service personnel are not in a position to calculate and report the emissions as part of a cap and trade system. Similarly, the users of aerosol products are not in a position to calculate and be responsible for the emissions associated with their product usage.

Consequently, the approach under consideration is to hold the manufacturers of the high GWP gases responsible for the emissions. In nearly all cases, all the gases produced will eventually be emitted. The gases are rarely converted to other substances or destroyed. Consequently, the quantity of gas manufactured is a reasonable estimate of the expected emissions. The gas manufacturer would be required to hold allowances to cover the total production and sale of high GWP gases each year.

In taking this approach, the program would cover the emission of newly manufactured high GWP gases. This approach does not cover the high GWP gases that are already stored in equipment, and are vulnerable to release.

As an alternative to placing the point of regulation on the manufacturers, it could be placed at the point where the gases enter into commerce in each state or province. This approach would require comprehensive tracking of the distribution and sale of these gases within each jurisdiction, for example through the licensing of dealers.

The use of high GWP gases in industrial applications, such as semiconductor manufacturing and magnesium manufacturing, could be addressed differently. The entity responsible for the emissions (i.e., the facility) could be defined as the point of regulation. The quantity of gas used and emitted could be tracked, and the entity would be required to hold emission allowances.

2. Emissions and Entity Data

Among the WCI partner jurisdictions, the high GWP gases are a relatively minor portion of total gross emissions, accounting for about 3% of total emissions in 2005. However, these emissions are expected to grow faster than total emissions through 2020. Table 14 summarizes the emissions estimates for 2005.

High GWP gases are produced by a small number of chemical manufacturing companies internationally. For example, *Chemical Market Reporter* identifies nine companies producing fluorocarbon gases (HFCs) in the United States at 14 plants. Only one plant is located in a WCI partner state, accounting for less than 10% of total production capacity.

3. Emissions at the Entity Level

As described above, one point of regulation under consideration is at the gas manufacturer. At this point, the regulated entity (the manufacturer) cannot measure or calculate actual GHG emissions. Rather, the entity can calculate potential emissions based on the expected release over time of the total amount of the gas produced. The manufacturer would calculate its emissions responsibility as the quantity of gas produced times the appropriate GWP for the gas.

If the point of regulation is at the industrial facility that uses and emits the gas, the calculation would be similar. The total amount of gas used and emitted would be multiplied by the appropriate GWP. Any destruction or conversion of the gas in the industrial process could be accounted for at the facility level.

4. Administration

The relatively small number of manufacturers of high GWP gases would make administration at the manufacturer level tractable. However, as discussed above, nearly all the manufacturers and their plants are not located in WCI jurisdictions. Consequently, WCI states and provinces would not be in a position to regulate their production or sales of these gases.

The alternative approach of setting the point of regulation at the point where the gases enter into commerce in each state and province would be more administratively challenging. A system of licensing and tracking of the sales of the gases does not currently exist, and would need to be created.

Assigning the point of regulation to industrial facilities that use the gases, such as semiconductor manufacturing and magnesium manufacturing, is administratively feasible. There are a relatively small number of facilities, each of which could be tracked. The covered entities should have the capability to know their compliance obligations and understand the applicable requirements. However, it should be noted that these facilities account for a very small portion of the total emissions from this sector.

5. Leakage Issues

Vulnerability to emissions leakage is an important consideration for this design element. High GWP gases are produced and traded internationally. Actions that increase production costs in the U.S. and Canada could shift production elsewhere, resulting in no change in actual emissions. To address this leakage potential, imports of the gases would also need to be covered, which is beyond the jurisdiction of states and provinces. The potential impacts associated with covering industrial facilities should also be examined. For example, semiconductor production could also shift elsewhere, resulting in no change in actual emissions.

Table 14: Summary of High GWP Gas Emissions

Western Climate Initiative
Draft Program Scope Recommendations

1. Introduction

This paper presents the WCI draft recommendation for the scope and point of regulation for the WCI cap-and-trade program. The recommendation is based on the WCI's analysis and assessment of the Major Options paper it released in January 2008. The WCI developed and applied evaluation criteria to these major options. It also took into account stakeholder comments received in writing by February 1, 2008, as well as comments at the January 10, 2008 stakeholder meeting and the February 12, 2008 stakeholder conference call on scope issues. Other key inputs include data collection and deliberations by the WCI, including: emissions inventory data; estimates of the potential number entities with regulatory obligations; an assessment of the feasibility of covering liquid fuels; a discussion of phasing; a review of emissions thresholds (including those used in other air emission programs); a review of non-combustion emissions sources; and briefings on two sectors--(a) oil and gas production and processing and (b) agriculture and forestry and land-use change.

This document is organized as follows.

- Section 2 defines scope and point of regulation.
- Section 3 summarizes the design elements that were considered for inclusion in the WCI cap and trade program.
- Section 4 evaluates the design elements, taking into account the WCI design principles and the Scope Subcommittee evaluation criteria, as well as consideration of phasing and thresholds. It describes the design elements that are recommended for inclusion, as well as those that are not.
- Section 5 defines and evaluates the major options, which are combinations of the design elements. It describes the evaluation criteria, linkage with the electricity sector recommendation, and the WCI scope recommendation.
- Section 6 discusses issues that remain under consideration, and how each has the potential to affect the final recommendation. These items include legal questions, economic impacts, and alternative policies that may be preferable or complementary to cap and trade for particular sectors or subsectors.

Appendix A is a summary of the Scope Subcommittee's current understanding of process emissions that can be calculated or measured at the entity level. Appendix B is a summary of information collected regarding potential points of regulation for liquid transportation fuels. Appendix C is the Major Options paper that the Scope Subcommittee released in early January 2008.

2. The Definition of Scope and Point of Regulation

The scope defines the GHG emissions that are included in the cap and trade program, including:

- The sectors that fall under the cap.
- The emissions sources that fall under the cap.
- The greenhouses gases that fall under the cap.
- The point(s) of regulation where the cap would be enforced.

From the scope definition, any entity or facility must be able to tell whether it has a compliance obligation under the cap, and which of its emissions are subject to the obligation.

The "point of regulation" is the portion of the scope definition that identifies the entities that have the obligation to surrender GHG emission allowances to cover GHG emissions. Several terms are used to describe the point of regulation:

- Downstream, at the point of emission: The point of regulation can be placed where the GHGs are emitted, such as where coal is combusted. This point of regulation is typically referred to as "downstream." Examples of downstream points of regulation include: (a) stationary source combustion of coal, natural gas, and oil; and (b) process and fugitive emissions from industrial facilities.
- Upstream, where carbon enters the economy: The point of regulation can be placed at the point where carbon enters into the economy. This point is typically referred to as "upstream." Examples of upstream points of regulation for fossil fuels include: (a) where natural gas is processed and upgraded to pipeline quality; (b) where oil products are refined or imported; and (c) where coal is mined. For some high global warming potential (GWP) gases (such as sulfur hexafluoride, SF_6), an upstream point of regulation may be the point at which the gas is manufactured.
- Midstream: The point of regulation can be placed at a point between the upstream and downstream. This point is typically referred to as midstream. Midstream points for fossil fuel may include where the fuel is distributed, examples including: (a) natural gas transmission pipelines; (b) natural gas local distribution companies (LDCs); and (c) gasoline and diesel terminal racks, fuel distributors or wholesalers.

Figure 1 illustrates the upstream-downstream continuum for points of regulation for the major fossil fuels. The left side of the figure shows the upstream portion of the continuum, where fuels are extracted. As you move to the right in the figure, you move toward the downstream point of emission. Not shown in the figure are two potential points of regulation that are outside the flow of fuels: load serving entities (LSEs) that deliver electricity to customers; and vehicle manufacturers. These two entities could also be considered as points of regulation.

As discussed below, considerations in selecting the points of regulation include the comprehensiveness of the coverage of the cap, the administrative feasibility of imposing the regulatory obligation, and the ability of the regulated entities to calculate or measure emissions.

Among the options that may be considered are combinations of upstream, downstream, and midstream points of regulation. For example, multiple points of regulation may be appropriate for covering emissions of natural gas combustion. For large stationary sources of natural gas combustion, such as power plants and industrial facilities, the preferred point of regulation may be at the point of emission. In this case, the regulatory obligation would be on the facility.

For residential and commercial buildings that use natural gas, it is generally considered infeasible to put the point of regulation on the homeowner or the building owner. Rather, the point of regulation could be moved toward the upstream to cover these emissions, such as to the local distribution company. A hybrid approach of downstream and midstream points of regulation would need to be coordinated carefully to ensure that natural gas emissions were not regulated twice. As shown in Figure 2, some large stationary sources purchase natural gas from LDCs. The point of regulation for the natural gas consumed by these sources would need to be either the facility, or the LDC, but not both.

Figure 1: The upstream/downstream continuum for fossil fuels

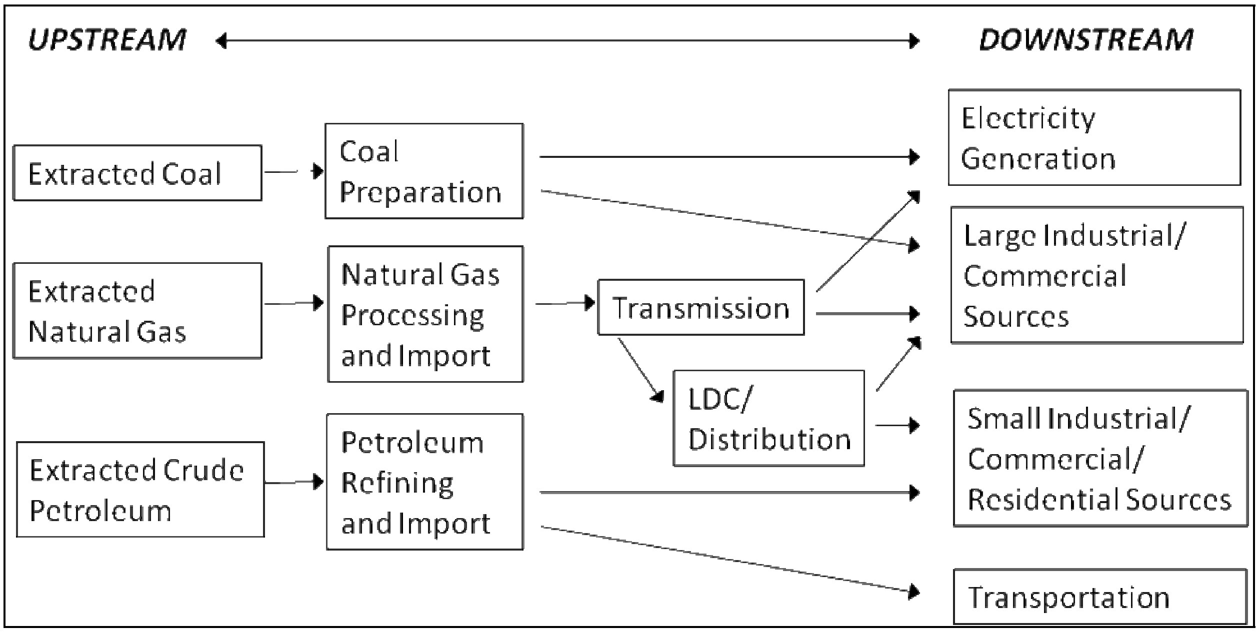

Figure 2: The movement of natural gas through the economy

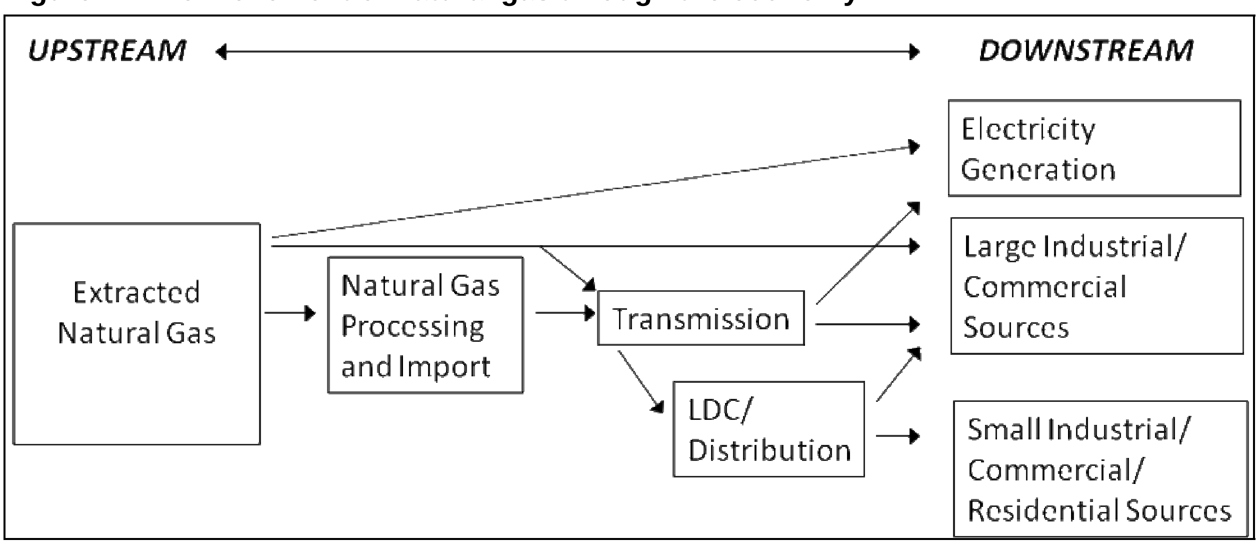

To define the scope and points of regulation for the WCI cap-and-trade program, particular attention is focused on identifying points of regulation that can be used by states and provinces.

In some cases, upstream points of regulation (e.g., natural gas processing facilities) fall outside the jurisdiction of the WCI states and provinces. Consequently, in some cases the furthest upstream point of regulation that may be considered is the point at which the fuel enters into the economy of the state or province. Within the framework of Figure 1, these points of regulation may be considered midstream.

3. The Scope Design Elements

To develop options for the program scope, the emissions inventory was divided into individual "design elements" for consideration. Each design element includes a specific set of sources, and a designation for the point of regulation. The options for the cap-and-trade program scope (discussed in Section 5) are then assembled from the individual design elements.

Table 1 presents a summary of the design elements considered. This list of the design elements was released for public review and comment as part of the WCI work plan (released October 2007). In response to comment and discussion, design element C was divided into two pieces, one for residential and commercial natural gas combustion and one for residential and commercial combustion of liquid fossil fuels. The electric sector is not included among the design elements, as that sector is being addressed by the Electricity Subcommittee.

As shown in the table, each design element covers a portion of the overall emissions inventory. As discussed below in Section 5, the emissions that would be included in a cap-and trade program would be less than the estimates in the table for two reasons. First, the WCI expects that thresholds will be applied to exempt small sources from some sectors. The amount by which thresholds will reduce coverage depends on the levels of the thresholds. Second, within design elements D and E, there are sources for which emissions cannot be measured or calculated with sufficient precision at the entity level. These sources will be excluded from coverage, further reducing the portion of total emissions covered by the options.

In addition to defining the emissions, the design element also identifies the point of regulation. The WCI recognizes that some of the design elements overlap, so that some emission sources can be covered by more than one design element. However, the recommended program scope combines the design elements so that no double counting or overlap occurs.

More detailed descriptions of the design elements were provided in the WCI Major Options paper for the Scope Subcommittee (released January 2008), and included as Appendix C. The descriptions in the appendix include the following for each design element:

- a description, including the sectors, sources, GHGs, and points of regulation;
- data on the emissions from the design element, and the number of entities that would be covered;
- an assessment of the ability to calculate or measure emissions at the entity level;
- the administrative feasibility of including the design element; and
- an examination of the potential risk of leakage.

Table 1: Summary of Design Elements

Design Element	Description	Estimated emissions (million metric tons) (% of WCI gross emissions)	Number of entities with a compliance obligation in the WCI region	Comments
A. Large Stationary Combustion Sources	Large combustion sources regulated at the industrial facilities.[1] All 6 Kyoto gases included, but mostly CO_2.	127 MMT CO_2e[2] 13% of WCI gross emissions	Number of entities depends on threshold adopted.	There are no significant administrative challenges. Vulnerability to leakage varies by industry.
B. Liquid Transportation Fuels	CO_2 emissions from the combustion of liquid transportation fuels regulated at the point where the fuels enter into commerce in each state or province. The point of regulation may vary among the states and provinces.	356 MMT CO_2e 36% of total WCI gross emissions	Depends on the point of regulation.	There are administrative challenges to identifying appropriate points of regulation by state and province. Gasoline use is generally not vulnerable to leakage, but any long-haul trucking that is not covered by the International Fuel Tax Agreement, aviation and marine transportation are.
C. Residential and Commercial Natural Gas Consumption	CO_2 emissions from with residential and commercial combustion of natural gas regulated at the Local Distribution Company (LDC).	70 MMT CO_2e 7% of total WCI gross emissions	There are about 60 LDCs.	There are no significant administrative challenges. Vulnerability to leakage may be an issue for some commercial customers.

[1] Electric power generation is included in the electric sector, being evaluated by the Electricity Subcommittee. Electric power generation is not included in this design element. Fuel combustion for cogeneration of heat and electricity may be covered in this design element, depending on emissions thresholds for coverage that are adopted.

[2] CO_2e - carbon dioxide equivalent

Design Element	Description	Estimated emissions (million metric tons) (% of WCI gross emissions)	Number of entities with a compliance obligation in the WCI region	Comments
C1: Residential and Commercial Stationary Combustion of Liquid Fuels	CO_2 emissions from the stationary combustion of heating oil and propane in the residential and commercial sector regulated at the point at which the fuels enter into commerce in each state or province.	Less than 1% of GHG emissions within the WCI region	As with B, the total number of entities with a compliance obligation depends on the point of regulation.	Though a small portion of emissions, coverage would help avoid creating inappropriate incentives for fuel switching to petroleum products. The administrative challenges for this element may be addressed as part of design element B. Leakage is not likely to be an issue for residential customers so long as competing heating fuels are covered, and may be an issue for some commercial customers.
D. Process and Fugitive Emissions from Industrial and Waste Management Sources	Process and fugitive emissions regulated at the point of emission.[3]	44 MMT of CO_2e 5% of total gross WCI emissions		The administrative challenge is being examined on a process-by-process basis. The primary need is to develop adequate protocols for certain sources prior to inclusion (see Appendix A). Vulnerability to leakage varies by industry.
E. Fossil Fuel Production and Processing	Oil and gas exploration, production, and processing, and coal mining and preparation, a broad set of facilities and activities with diverse emissions sources, including stationary combustion, venting and fugitive emissions. The point of regulation is at the facility where the emissions occur.	38 MMT CO_2e 4% of total gross WCI emissions	About 65,000 operating oil wells; 45,000 operating gas wells. A small number of operators account for 80-90% of oil and gas production. The number of operating coal mines is about 29.	Only a portion of the sources at oil and gas production and processing facilities will likely be feasible to include in a cap-and-trade program at this time. Leakage risk is relatively low because these activities are undertaken at the locations of the resources themselves, although the companies that operate these facilities do compete with entities outside the WCI region.

[3] Fugitive emissions include emissions from equipment leaks, pipeline leaks, and storage losses. Process emissions include planned and unplanned venting, accidental discharges, and related emissions. Together, process and fugitive emissions include all non-combustion emissions from industrial and waste management sources.

Design Element	Description	Estimated emissions (million metric tons) (% of WCI gross emissions)	Number of entities with a compliance obligation in the WCI region	Comments
F. Fossil carbon content of fuels regulated at the appropriate point for each fuel	CO_2 emissions from fossil fuel combustion throughout the economy. The fuels include coal, oil, natural gas, and other fossil fuels (such as propane). The points of regulation would be upstream or midstream for liquid fuels, downstream for coal, and at the pipelines or LDC/purchaser for natural gas.	797 MMT CO_2e 82% of total gross WCI emissions	There are 60 LDCs, 208 refineries and liquid fuel terminals, 109 natural gas pipelines.	This element does not pose significant administrative challenges. Significant vulnerabilities to leakage exist in specific components of fossil fuel use, especially marine transport, aviation, and energy-intensive industries.
G. Passenger cars and light duty trucks regulated at the manufacturer sales level.	Includes emissions during the operation of passenger cars, light duty trucks and medium duty vehicles, including: fuel combustion; refrigerant emissions; and evaporative emissions.	242 MMT CO_2e 25% of total gross WCI emissions	There are approximately 40 manufacturers that sell vehicles in the WCI region.	The potential need to track nearly new vehicles that are registered in the state or province needs to be assessed. Potential legal issues also remain to be examined. Light duty vehicle sales are not particularly vulnerable to leakage, but requirements can affect the rate of turnover of the vehicle fleet.
H. Large transportation fleets	Includes emissions from fuel used by entities (e.g., companies, local governments, transit agencies, etc.) that operate fleets of motor vehicles or boats.	Total emissions covered depend on the emissions threshold that may be adopted. Preliminary estimates show emissions are less than 4% of total WCI gross emissions.	About 10,000 vehicle fleets in the WCI partner states and provinces each have 10 or more vehicles.	Administrative feasibility is largely a function of how fleets are defined. The risk of leakage is significant for those fleets with flexibility as to their location; the risk is low for fleets that must serve specific areas.

Design Element	Description	Estimated emissions (million metric tons) (% of WCI gross emissions)	Number of entities with a compliance obligation in the WCI region	Comments
I. Agriculture emissions	Covers the agricultural sector, including a diverse set of production activities, including crop production; livestock production; and grazing lands. Agriculture can serve as a sink or as a source of emissions.	58 MMT CO_2e 6% of total WCI gross emissions.	>18,000 confined animal operations (CAOs) among the WCI partners. The total number of farms with harvested cropland is about 150,000.	Precise direct measurement of agriculture GHG emissions at the entity level is not currently practical, so that covering this sector poses very significant administrative challenges. The agriculture sector is highly vulnerable to emission leakage. The market for agriculture products is international in scope, and highly competitive.
J. Forestry and land-use change	Covers human activities and naturally occurring processes that result in changes in forest cover and/or carbon stocks on forest lands. Emissions would be regulated at the land owner level. Forestry and land-use change can serve as a sink or as a source of emissions.	Net sink: 10% of WCI gross emissions.	Governments are significant forest land owners in WCI. Most remaining forest land is owned by a small number of forestry companies, and tens of thousands of small land owners.	Identifying all the relevant land owners and measuring their net emissions or sequestration would be a significant administrative challenge. Important components of the forestry sector are highly vulnerable to emission leakage. Compliance and measurement costs could drive small landowners to convert their land to other uses. Land-use change could be handled separately from forestry, but still poses significant administrative challenges.

Design Element	Description	Estimated emissions (million metric tons) (% of WCI gross emissions)	Number of entities with a compliance obligation in the WCI region	Comments
K. Production of high-GWP gases	Covers HFCs, PFCs, SF_6 regulated at the point of production.	28 MMT 3% of gross WCI emissions	A small number of chemical companies produce these gases internationally. Nine companies produce HFCs in the U.S. at 14 plants. One plant is located in a WCI partner state, accounting for <10% of total U.S. production capacity.	Administration at the manufacturer would be tractable, but nearly all the manufacturers and their plants are not located in WCI jurisdictions. Administration at the point where the gases enter into commerce in each state and province would be more challenging. Regulating industrial facilities that use the gases is administratively feasible. Vulnerability to emissions leakage is significant as these gases are produced and traded internationally. Covering industrial facilities could also lead to leakage.

4. Evaluation of the Scope Design Elements

4.1 Design Principles and Criteria

The WCI recommendation for the scope of the cap-and-trade program is guided by the WCI Design Principles, listed below in Exhibit 1. Consistent with these design principles, the WCI has adopted the following additional criteria for evaluating whether individual design elements are appropriate for consideration within the program scope:

- The design element includes a meaningful portion of the GHG inventory within the WCI region.
- Emissions can be accurately and cost-effectively measured or calculated and reported by the entities.
- It is administratively feasible (considering the number of entities and other factors).
- There is an acceptable risk of leakage (taking into consideration alternative approaches for reducing emissions from the sources within the design element).

Table 2 presents the results of applying these criteria to the design elements, based on the information presented in Appendix C. As shown in the table, most of the design elements were found to have meaningful portions of the emissions inventory within the WCI region. For three design elements the WCI found that emissions cannot currently be accurately and cost-effectively measured or calculated at the entity level in a manner that is consistent with the implementation of a cap-and-trade program. These are: agriculture, forestry and land-use change, and passenger cars and light duty trucks (regulated at the manufacturer level). Additionally, the ability to measure or calculate emissions varies within two of the design elements: industrial and waste management process and fugitive emissions; and the fossil fuel production and processing industry. For these two design elements, Appendix A lists the emissions for which the WCI has identified emission calculation protocols that can be applied at the entity level.

The administrative feasibility of the design elements was evaluated primarily on the basis of (1) the number of entities that would have a regulatory obligation; and (2) the capacity of the regulated entities to undertake the steps needed to participate in the program. Two design elements (agriculture and forestry and land-use change) appear to have the potential to cover such a large number of entities so as to make it very challenging to administer a program that includes these design elements. Additionally, the number of transportation fleets that could be covered would also be very large, depending on the level of the emissions threshold adopted.[4] Indications are that covering transportation fuels at the point at which the fuels enter the economy is administratively feasible, although the precise approach remains under investigation.

Finally, the risk of emission leakage was assessed.[5] The WCI recognizes that varying levels of risk of leakage apply to many entities depending on the markets in which they operate. Table 2 identifies several design elements for which the WCI finds that there is substantial risk of leakage. Additionally, the risk varies within several design elements. Opportunities to mitigate

---

[4] Emission thresholds are discussion in Section 4.3.

[5] Emission leakage refers to emission sources relocating outside the region in order to avoid emissions regulations, such as a cap-and-trade program. The relocation of sources is called leakage because the emissions “leak” out of the region in response to efforts to reduce emissions.

these risks will be assessed, in part, through the design of allowance allocation mechanisms. Consequently, mitigating leakage is not discussed further in this paper.

Exhibit 1: WCI Design Principles for a Regional Cap-and-Trade Program

To attain the Western Climate Initiative's greenhouse gas reduction goal, the members are committed to designing a system that

1. Is equitable, administratively simple for government and private participants, minimizes administrative costs, and has a clear compliance path;
2. Maximizes total benefits throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts;
3. Requires all reductions to be real, surplus/additional, verifiable, permanent, and enforceable;
4. Stimulates investment, especially in low carbon technologies, and rewards innovations that will lead to long-term permanent greenhouse gas reductions;
5. Covers as many sources as is practical, while encouraging pollution reductions beyond the capped sources and sectors;
6. Provides appropriate recognition and incentives for early emissions reductions;
7. Assures a transparent and robust accounting system that will measure and report emissions rigorously and consistently across all sectors and throughout the region;
8. Minimizes the potential for leakage; and
9. Facilitates linkage to similarly rigorous regional and international greenhouse gas reduction markets and encourages other states, provinces, and countries to join the market.

Source: WCI Work Plan, October 29, 2007.

4.2 Considerations for Phasing

Phasing refers to adjusting the scope of the program over time to "phase in" some aspect of the program scope. Phasing could be applied to any aspect of the Scope definition, including: a design element; the sources included; the gases included; and the threshold(s) applied. Phasing would be defined in terms of:

- the specific aspect of the scope being phased in (e.g., a specific emissions source);
- the timing of the phase in (e.g., number of years); and
- any conditions associated with the phase in (e.g., the adoption of an emissions calculation protocol).

Table 2: Evaluation of Design Elements

Design Elements	Meaningful Portion of Emissions	Measure/Calculate Emissions by the Entity	Administratively Feasible	Acceptable Risk of Leakage
Electric Sector – Not Evaluated Here	--	--	--	--
A. Large stationary combustion sources at the point of combustion.	Yes	Yes	Yes	Generally Yes (some exceptions)
B. Liquid transportation fuels regulated where they enter into commerce in the state/province.	Yes	Yes	Yes, Method Under Evaluation	Generally Yes (some exceptions)
C. Residential and commercial natural gas combustion regulated at the LDC.	Yes	Yes	Yes	Yes
C1. Residential and commercial fuel oil and other fuel combustion regulated where they enter into commerce in the state/province.	No	Yes	Under Evaluation Probably Yes	Yes
D. Process and fugitive emissions from industrial and waste management sources regulated at the point of emission.	Yes	Varies, depending on source	Yes	Varies, depending on industry
E. Fossil fuel production and processing regulated at the facility level, such as the oil and gas field, gas processing plant, coal mine.	Yes	Varies, depending on source	Yes	Yes
F. Fossil carbon content of fuels regulated at an appropriate point for each fuel.	Yes	Yes	Under Evaluation Probably Yes	Generally Yes (some exceptions)
G. Passenger cars and light duty trucks regulated at the manufacturer level.	Yes	No	Yes	Yes
H. Large transportation fleets regulated at the fleet management level.	No	Yes	Probably No	Probably Yes
I. Agriculture emissions regulated at the producer or farm level.	Yes	No	No	Varies (mostly no)
J. Forestry and land-use change emissions regulated at the land owner level.	Yes	No (Possibly yes for some land-use change)	No	No (Possibly for some land-use change)
K. Production of high GWP gases regulated at the point of production.	Varies	Yes	Yes	No

The WCI identified several conditions that warrant the consideration of phasing:

1. Measurement/Calculation Protocol: No protocol currently exists for measuring or calculating emissions at the entity level. However, it is feasible to develop a protocol and the WCI can direct the development or recognition of a protocol in a timely manner. Phasing the coverage would enable the source to be included after the protocol becomes available.
2. Identification of Regulated Entities: The entities that will be regulated have not been well identified to date (e.g., they are not currently in other regulatory programs). It is expected that the regulated entities will be identified in the near future, for example through mandatory reporting requirements. Phasing the coverage would enable the source to be included after the regulated entities were well identified.
3. Emissions Data: Emissions data are not readily available for a source. It is expected that mandatory emissions reporting will provide emissions data in the near future. Phasing coverage would enable the source to be included after the emissions data become available.
4. Statutory Authority: Time is required to obtain statutory authority required to regulate certain sources. Phasing would enable the source to be included after the statutory authority was put in place.
5. Economic Impact: Phasing reduces costs and/or improves market development and price stability.

The WCI notes that the need for phasing depends, in part, on the start date for the program.

4.3 Considerations for Setting Emissions Thresholds

Emission thresholds can be used to define the minimum size of entities that would be covered under the cap-and-trade program. By using emissions thresholds the program can focus on those entities that have large emissions, while exempting small emitters that do not contribute significantly to total emissions in a sector or category. Also, with thresholds the program can reduce substantially the number of entities that would be regulated, thereby reducing the administrative cost of the program.

To assess potential emission thresholds, the WCI reviewed thresholds used in other GHG related programs, and assessed the sizes of entities that may be covered in the WCI region. Table 3 lists the thresholds used in the programs reviewed. As shown in the table, a variety of thresholds have been used. In several GHG emission reporting programs, reporting is triggered by a reporting requirement for conventional air pollutants.

The recently promulgated reporting rule in California uses several thresholds, including specific thresholds for electric power generators, and a separate threshold of 25,000 tons per year of CO_2e for other stationary combustion sources. Canada's and Wisconsin's reporting programs use a threshold of 100,000 tons per year of CO_2e. Canada's threshold is currently being revised to what may be a substantially lower limit.

The WCI reviewed the European Union Emissions Trading Scheme (EU ETS) and the Regional Greenhouse Gas Initiative (RGGI). RGGI covers the electricity sector only, and uses a single threshold for power plants. As shown in the table, the EU ETS uses industry-specific thresholds, generally linked to production capacity.

Table 3: Examples of Thresholds in GHG Related Programs

Program	Threshold
Mandatory GHG Emissions Reporting Programs	
California	Electricity: ≥2,500 Metric Tons of CO_2e and ≥1 MW nameplate capacity Stationary Combustion: ≥25,000 Metric Tons of CO_2e All cement plants and refineries
Connecticut	Title V Major Sources: Municipal Waste Combustors, capacity >35 Mg/day HAPs: 10 tons per year of one HAP or 25 tons per year combined 100 tons per year of any regulated air pollutant In serious ozone nonattainment areas: 50 tons per year VOCs or NO_x In severe ozone nonattainment areas: 25 tons per year VOCs or NO_x
Maine	Sources that emit or are licensed to emit: CO: 75 tons per year SO_2: 40 tons per year VOC or NO_x: 25 tons per year PM10 or PM2.5: 15 tons per year Pb: 0.1 tons per year NH3: 50 tons per year Any electric power & transmission facility emitting any amount SF_6 Any GHG-manufacturing facility emitting any amount of GHG
New Jersey	Title V major sources: 25 tons per year VOCs or NO_x 100 tons per year CO, SO_2, TSP, PM2.5, PM10, or NH_3 5 tons per year Pb
New Mexico	Electricity: 25 MW nameplate capacity Major Title V sources (as defined by the Agency) All cement plants and refineries
Wisconsin	100,000 tons per year of GHGs
Canada	100,000 tons per year of GHGs. Currently being revised – substantially lower thresholds may be adopted.
GHG Emissions Control Programs	
European Union Emissions Trading Scheme (EU ETS)	Electricity: 20 MW nameplate capacity All oil refineries, coke production, pulp production Pig iron or steel: >2.5 metric tons per hour capacity Cement: >500 metric tons per day of clinker production capacity Lime: >50 metric tons per day of production capacity Glass: >20 metric tons per day of production capacity Ceramic Products: >50 metric ton per day of capacity or kiln capacity >4 cubic meters with setting density >300 kg per cubic meter
Regional Greenhouse Gas Initiative (RGGI)	Electricity: 25 MW nameplate capacity

Based on this review, the WCI found that thresholds have been used in both reporting programs and emission control programs for GHGs. The WCI recommends that thresholds be considered for defining the scope of the cap-and-trade program. However, there is not yet a single threshold that has become widely accepted and criteria for selecting thresholds are to be developed. The thresholds need to be set based on the specific conditions found among the sources within the WCI region, discussed further in Section 5.

4.4 Design Elements Recommended for Consideration

Based on the application of the design principles and evaluation criteria presented above, the WCI has identified the following design elements as feasible for including in a cap-and-trade program within the timeframe contemplated for WCI: [6]

A. Large stationary combustion sources;

B. Liquid transportation fuels;

C. Residential and commercial natural gas combustion;

C1. Residential and commercial stationary combustion of fuel oil and other liquid fuels;

D. Process and fugitive emissions from industrial and waste management sources;

E. Fossil fuel production and processing; and

F. Fossil carbon content of fuels.

The WCI recognizes that the point of regulation for liquid fuels remains to be identified precisely. However, indications are that there are acceptable options for including this design element in an administratively feasible manner within each of the WCI jurisdictions. Appendix B presents the information reviewed on the potential points of regulation for liquid fuels.

Similarly, the WCI acknowledges that there is a subset of industrial, waste management, and fossil fuel industry emissions that may be challenging to develop adequate measurement protocols for use at the entity level. As presented in Appendix A, emissions protocols are not currently available for non-combustion emissions sources of emissions from oil and gas production, for example. The WCI recommends that those sources for which adequate protocols are available – or which can be developed in a timely manner – be considered for inclusion in the program at the outset, and that additional sources be phased in as emissions protocols are adopted. The WCI also recommends that high priority be placed on the development of suitable protocols for the fossil fuel production and processing sources, so that these sources can be included in the program from its initiation.

As described below in Section 5, these design elements were combined into major options for consideration.

4.5 Design Elements Not Recommended for Consideration

Based on the application of the design principles and evaluation criteria presented above, the WCI recommends against including for consideration the following design elements for a cap-and-trade program within the timeframe contemplated for WCI:

G. Passenger cars and light duty trucks regulated at the manufacturer level: Annual emissions cannot be calculated precisely by the manufacturer.

[6] The Electricity Subcommittee is assessing how best to include the electric sector in the program. The recommendations by the Electricity Subcommittee are reported separately.

H. Large transportation fleets regulated at the fleet management level: Not a meaningful portion of total emissions and likely to be administratively challenging due to the number of entities.

I. Agriculture emissions regulated at the producer or farm level: Emissions cannot be calculated or measured precisely and cost-effectively at the point of regulation, and likely to be administratively challenging due to the number of entities.

J. Forestry and land-use change emissions regulated at the land owner level: Emissions cannot be calculated or measured precisely and cost-effectively at the point of regulation, and likely to be administratively challenging due to the number of entities. Although land-use change emissions can be measured, incorporation would be administratively challenging due to the number of entities at the point of regulation.

K. Production of high GWP gases regulated at the point of production: Most of the points of regulation fall outside the jurisdiction of the WCI states and provinces.

These design elements are not considered in the major options discussed in the next section.

5. Evaluation of the Major Options

5.1 Definition of the Major Options

The WCI used the seven design elements considered feasible for inclusion in the cap-and-trade program to create five major options, shown in Table 4. These options indicate how the elements could be combined to create a cap-and-trade program with varying levels of coverage. Option 1, with the narrowest scope, would cover the electric sector, large fossil fuel stationary combustion sources, and large industrial process emissions. Option 3 has a significantly broader scope by also including liquid transportation fuels and fossil fuel stationary combustion in the residential and commercial sectors. Option 5 represents an alternative approach, focusing on the fossil carbon content of all fuels.

The coverage estimates shown in the table are likely to be biased upward for two reasons. First, the WCI expects that thresholds will be applied to exempt small sources from some sectors. The amount by which thresholds will reduce coverage depends on the levels of the thresholds. Second, within design elements D and E, there are sources for which emissions cannot be measured or calculated with sufficient precision at the entity level. These sources will be excluded from coverage, further reducing the portion of total emissions covered by the options.

As shown in the table, Option 1 covers less than 50% of the total emissions inventory in the WCI states and provinces. Because transportation fuels are a large portion of total emissions, their inclusion would increase coverage substantially. .

5.2 Evaluation Criteria and Recommendation

The criteria for evaluating among the major options include the design principles (above, in Exhibit 1), and the following:

- Breadth of coverage: Include as many sources as is practical to cover as much of the emissions inventory as possible.
- Market characteristics:
  - Include a sufficient number of market participants to create a vital and efficient market.
  - Include diverse market participants to create a vital and efficient market.

Table 4: Major Options Considered

Design Elements	Options 1	2	3	4	5
Electric Sector	X	X	X	X	
A. Large stationary combustion sources	X	X	X	X	
B. Liquid transportation fuels			X	X	
C. Residential and commercial natural gas combustion		X	X		
C1. Residential and commercial stationary combustion of fuel oil and other liquid fuels		X	X		
D. Industrial process and waste management emissions	X	X	X	X	X
E. Fossil fuel production and processing	X	X	X	X	X
F. Fossil carbon content of fuels					X
Portion of WCI Emissions Inventory Included*	~47%	~54%	~90%	~83%	~90%
* Portion of WCI Emissions Inventory calculated using the 2005 emissions inventory for the WCI partners. Estimates are approximate, and assume 100% coverage in each of the design elements. The use of emissions thresholds will reduce the portion of emissions covered. Additionally, some sources within design elements D and E cannot be measured or calculated adequately for inclusion in a cap-and-trade program at this time. These sources may need to be phased in over time as methods are developed.					

- Economic Impacts: Include those sources that benefit from the efficiencies of a cap-and-trade program so as to minimize economic impacts across the entire economy.

These criteria, along with the WCI Design Principles, generally indicate that a more comprehensive scope is preferred. This preference is balanced against potential opportunities to use alternative policy mechanisms to reduce emissions from sources with less overall economic impact than would be experienced using a cap-and-trade program. Given these considerations, the WCI recommends the following:

- Base Program: The WCI recommends that Option 1 be implemented by all WCI partners as a base program from the start of the cap-and-trade program. In making this recommendation, the WCI is separately recommending an approach for the electric sector that is consistent with the structure of Option 1. Additionally, as discussed above, WCI recommends that high priority be placed on developing emissions protocols for the fossil fuel production and processing sector so that as much of this sector as possible can be included in the cap-and-trade program from the start of the program.
- Transportation Fuels: Emissions from transportation fuels (design element B) are the single largest source in the region (about 36% of total emissions), and must be addressed through an effective combination of near-term and long-term policies. WCI members thus express strong interest in including transportation fuels within the cap and trade program. However, prior to recommending how best to reduce emissions in this sector, analyses of the economic impacts of various options for including transportation fuels in the program will be examined, including the potential effectiveness of alternative policies for reducing these emissions. Options to be considered include the potential to phase in transportation fuels in a later stage of the program, and special consideration for low-income populations and for rural communities most adversely impacted by consequent price change in the sector. It is anticipated that a decision on how to

address transportation fuels will be informed by economic modeling and additional analysis over the course of Spring 2008.

- Residential and Commercial Fuel Combustion: Emissions from residential and commercial combustion, including natural gas, fuel oil and other liquid fuels, while collectively only about 8% of emissions in the region, could be usefully addressed through an effective combination of near-term and long-term policies. WCI members thus express interest in including these sectors within the cap-and-trade program. However, as with transportation fuels, prior to recommending how best to reduce emissions in this sector, analyses of the economic impacts of various options for including these fuels in the program will be examined, including the potential effectiveness of alternative policies for reducing these emissions. Options to be considered include the potential to phase in these fuels in a later stage of the program, and special consideration for low-income populations and for rural communities most adversely impacted by consequent price change in the sector. It is anticipated that a decision on how to address these fuels will be informed by economic modeling and additional analysis over the course of Spring 2008.
- Thresholds: The WCI recommends that thresholds be adopted to exempt small sources from the cap-and-trade program, while ensuring that the overall coverage of emissions remains high. The WCI has not yet set emissions thresholds, and is continuing its assessment of threshold values.
- Phasing: The WCI has discussed the potential need to phase in sources to the program over time. The WCI recommends that the base program (Option 1) be implemented in its entirety from the start of the program. However, the WCI acknowledges that phasing may be required for other sources given the additional complexities of their points of regulation, the organizational capabilities of the potentially regulated entities, and related issues.

In the event that only the base program is implemented throughout the WCI states and provinces (Option 1), the program will cover less than 50% of the emissions in the region. Aggressive and effective policies will be needed in the sectors outside the cap-and-trade program to ensure that the overall regional emissions goal will be achieved. In the event that a broader program is adopted, including transportation fuels and residential/commercial fuel combustion (Option 3), the coverage may exceed 80% of the regional emissions.

In all cases, complementary policies that work in conjunction with the cap-and-trade program will be needed to motivate investments in improved efficiency and other measures to reduce emissions. The WCI recommends that a full set of complementary policies be examined as part of the analyses supporting the design of the cap-and-trade program.

6. Issues Under Review

This draft recommendation is based on the information and analysis the WCI has done to date. However, a number of issues remain under consideration. These considerations may affect the final recommendation in August 2008.

6.1 Legal Issues

A number of legal issues may affect the scope recommendation. Among these issues is the potential need for additional statutory authority in some jurisdictions to authorize the implementation of the cap-and-trade program with the proposed scope. In addition, legal issues may arise regarding the mechanics of implementation and enforcement. These considerations may affect the final recommendation in August 2008.

6.2 Economic Impacts Analysis

WCI is conducting economic analyses of the major options under consideration for the cap-and-trade program. These analyses will be used to evaluate alternative design decisions, including cost containment mechanisms, offsets and allowance allocation. If the economic analysis indicates that including a certain industry in the scope would result in economic impacts or leakage that cannot be adequately mitigated through cost containment mechanisms of other design features, the WCI could revisit the decision to include that industry in the scope of the program. Similarly, if the economic analysis indicates that including a particular sector does not achieve significant emission reductions and leads to unacceptable price impacts that cannot be adequately mitigated through cost containment mechanisms, the WCI could decide to exclude that sector.

6.3 Analysis of Alternative and Complementary policies

WCI will examine the potential role of policies other than cap and trade in meeting its GHG targets. The results of this examination could affect decisions about the program scope. The analysis of some of these policies could indicate that they complement the scope of the cap-and-trade program. For example, demand-side energy efficiency programs can complement and reduce the cost of cap-and-trade programs by reducing market barriers to adoption of cost-effective technologies and practices. Similarly, vehicle performance standards may complement, and reduce the cost of complying with, the fuels portion of a cap-and-trade program.

Alternatively, analysis may indicate that there are policies for particular sectors that may be preferable to a cap-and-trade program. For example, analysis may indicate that a low-carbon fuel standard is preferred to including liquid transportation fuels in the cap-and-trade program. Similarly, natural gas equipment efficiency standards and energy efficiency programs may be preferred to including residential and commercial natural gas combustion in the cap-and-trade program.

Appendix A: Process and Fugitive Emissions

The WCI has adopted the position that to be included in the cap-and-trade program, a recognized protocol must be available for calculating or measuring emissions from the sources in the design elements, including in design element D, Process and Fugitive Emissions from Industrial and Waste Management Sources, and design element E, Fossil Fuel Production and Processing. Consequently, to assess the feasibility of including the sources in design elements D and E, the Scope Subcommittee reviewed the major sources of emissions in this design element, and identified available emission calculation and measurement protocols. The subcommittee's review is presented in the tables below.

The list of sources in design elements D and E was developed based on a review of national emission inventory guidelines. For each source, the subcommittee identified whether the source exists within the WCI partner states and provinces. For those sources within the WCI, the subcommittee identified whether The Climate Registry (TCR) includes the source in its General Reporting Protocol (GRP).[7] As shown in Table A-1, 11 industrial sources are included in the TCR GRP. For the sources not included in the TCR GRP, the subcommittee reviewed other reporting protocols, including mandatory reporting programs. The most comprehensive materials, the Intergovernmental Panel on Climate Change (IPCC) reporting guidelines, were examined to assess whether the guidelines could be applied at the entity level with sufficient precision to be adequate to support inclusion in a cap-and-trade program.[8] Four IPCC methods appear to be adequate, although additional review is recommended. Also shown in the table, the adequacy of several IPCC methods for use in a cap-and-trade program remains uncertain and will be further assessed.

Based on this assessment, the subcommittee recommends that the industrial sources included in the TCR GRP and for which the IPCC (or other) methods are adequate, or are in the near future deemed adequate based on expert review, be included within the design element D.

A similar assessment was conducted for the waste management process and fugitive emissions. As shown in Table A-2, these emissions sources do not have specific protocols in the TCR GRP. A review of the IPCC guidelines, and information from other programs, leads the subcommittee to conclude that adequate protocols are not available for these sources at this time. Based on this assessment, the subcommittee recommends that the waste management process and fugitive emissions not be included in design element D until adequate emissions reporting protocols are available.

Finally, the subcommittee reviewed protocols for sources in the fossil fuel production and processing sector. This sector includes a diverse set of emissions sources, including fuel combustion, equipment venting, and fugitive emissions. As shown in Table A-3, protocols are under development for several key sources in the oil and natural gas industries. The subcommittee recommends a high priority be assigned to completing these protocols so that these sources can be included in the cap-and-trade program.

TBD = To Be Determined.				

Appendix B: Points of Regulation for Liquid Transportation Fuels

1. What are the liquid fuels that might be covered?

If any emissions associated with liquid fossil fuels in larger emitters were picked up at the point of combustion, the other possible sectors to regulate would be transportation fuel, liquid fuels for residential/commercial use, and liquid fuel in small industrial applications. Biofuels and other non-petroleum fuels would either not be covered or given some credit for their lower life-cycle GHG emissions. Non-fuel uses of petroleum (e.g., for chemicals) would not be covered.

2. How significant a fraction of the emissions are they?

It depends on which emissions are covered: Transport only (gasoline, diesel, aviation fuel, marine and locomotive diesel, residual oil for ships)? Transport, residential and commercial combustion (propane, heating oil)? Off-road diesel?

Based on EIA data:

- Oil comprises 53% of total WCI CO_2 from fossil fuel combustion. Oil use for transportation is 49% of total CO_2 from fossil fuel. This means that 4% of the CO_2 emissions from oil is not related to oil used for transportation.
- Residential sector oil use is <0.2% of total fossil fuel CO_2 and about 0.3% of CO_2 from oil combustion.
- Commercial sector oil use is about 1% of total fossil fuel CO_2 and about 1.6% of CO_2 from oil combustion. This is probably mostly from larger institutional facilities and may include some diesel fuel for on-site generation.
- Propane for residential sector use is about 0.5% of total fossil fuel CO_2 and about 0.9% of CO_2 from oil combustion.

EIA Data on WCI Residential & Commercial Fuel/Emission Shares

	% WCI CO_2 From Oil	% of total WCI CO_2 from Fossil Fuels
Residential Oil	0.3%	<0.2%
Commercial Oil	1.6%	1%
Residential Propane	0.9%	0.5%

CO_2 emissions from liquid fuels in the residential/commercial sectors are very small, especially compared to the large numbers of facilities represented. Thus one is unlikely to achieve significant GHG reductions from regulating this sector. However, one would not want to create an incentive to switch to non-regulated fuels by regulating other fuels (e.g. natural gas) but not liquid fuels.

The remaining 2.8 percent of liquid fuels is used in industrial and farm equipment.

3. What are the options for point of regulation?

This depends, in part, on which sectors are regulated.

- *Regulation at the refinery/importer*

  Regulation at the refinery is challenging because a significant fraction of WCI's liquid fuel use comes from refineries that are outside of WCI. Appendix B1 shows the estimated supply/demand balance for fuel products (gasoline, jet and distillate) in each of the WCI states and provinces. [9] Utah is close to balanced in supply and demand. Washington is long, as is Montana. California appears balanced, but there are a lot of imports into and exports out of California (see notes on the Appendix B1 table). Arizona, Oregon, and the two Canadian provinces are very short product with none (or minimal) instate or in-province production. New Mexico is somewhat short.

  Utah's situation is probably the most balanced of the states, but Holly Corporation (which has a refinery in Utah) announced plans to construct a 300 mile pipeline to move product from Utah refineries to Las Vegas, beginning in 2009 or 2010. So Utah may wind up exporting more of its product (and possibly expanding refineries) through that pipeline. In other words, the situation may change in the future and whatever system is put in place must recognize, and be designed to cover, changing balances in the future.

  There are 34 refineries in the WCI region.

  One could cover the bulk of the importers with a similarly small number of entities, but there may be many very small importers. In combination with the refinery approach, this would require tracking all the pipelines that move products into and out of the WCI states. Volumes (by product grade and owner of shipment) moved in or out via pipeline are documented at the receiving terminals. One would also need to track waterborne imports and exports. The railcar volumes that move into the region are primarily ethanol, with much smaller gasoline volumes. Railcar movements should also be trackable, but further analysis is needed to determine the exact mechanism. The truck movements in and out are likely small, and may net out. These may need to be ignored in an "upstream model", but would be captured automatically in the state tax or EIA model described below.

  On net, the WCI states and provinces are importing product from non-WCI states or provinces to meet demand of roughly 340 TBD, or 12 percent of demand. If the intent is only to get the net balance right, one possibility is to ignore the flows and cover the refineries for all of the product they move, plus the importers.

- *Regulation at the transportation level: pipeline, truck, barge or rail car.*

  Regulation at the transportation level would be quite complicated due to the multiple potential paths, the difficulty of determining where the product is going for which application, and the high potential for double-counting.

- *Regulation at the terminal.*

  The point with the smallest number of regulated points and best connection to end users is probably the petroleum distribution terminal, a facility designed to receive, store and distribute fuel to others. A terminal rack is an industry's point of distribution to its local distributors, wholesalers (including marketers) and certain bulk end users. There are

[9] This estimate is rough. The state demand numbers come from the EIA for the US and the Canada Energy Statistics website for Canada (www.statcan.ca). The supply estimates come from Oil and Gas Journal refinery capacities, estimated utilization based on actual history, and yield estimates for each state based on an assessment of typical yield of the different products for the types of refineries in each state.

legitimate concerns about double-counting at this level but they are probably addressable. Some states collect their fuel taxes on distributors at the terminal rack, so the distinction between the terminal and wholesaler/distributor is fuzzy.

- *Regulation at the wholesale or distribution level*

  At the wholesale level, there starts to be a differentiation between transportation fuels and fuels for stationary applications. The number of regulated entities also increases from tens per state to hundreds per state. There is overlap between distribution terminals, wholesalers, distributors, and retailers that creates some difficulty identifying where some of the entities fall.

- *Regulation at the blender*

  Fuel blenders prepare fuels for final sale, blending in oxygenates and other additives for compliance with fuel standards.

- *Regulation at the prime supplier*

  The EIA tracks fuel data from each prime supplier, which EIA defines as "a firm that produces, imports, or transports any of the selected petroleum products across State boundaries and local marketing areas and sells the product to local distributors, local retailers, or end users." They were selected due to their small number and the relative size of their sales volumes. The Prime Supplier can be producing product in the state itself, or importing or transporting product into the state. There are 185 prime suppliers in the U.S.

Appendix B2 presents publicly available sources of data on fuel flows.

4. What data do we have available from which states and provinces and at what point of regulation?

There are already existing data on sales of most of the transportation fuels in all of the participating states at both the refineries and some combination of terminal racks, wholesalers and distributors. While there are still some definitional questions, it appears that gasoline, aviation fuel, jet fuel and on-road diesel are tracked in all the WCI states and BC. At least some jurisdictions also track off-road diesel fuel. While regulating at the distributor level entails regulating more entities, it appears that in many cases most of the data are already being collected for tax collection purposes. It should be relatively easy to expand these programs to track off-road diesel fuel and even fuel sales for stationary applications, if desired.

The table below summarizes how each jurisdiction collects fuel taxes.

BC collects volume information for tax purposes at the terminal and first fuel importer level. Currently only some of the states seem to have volumetric data at this level. Some of the available U.S. terminal volume data are from environmental permits and are not highly accurate.

WCI State/ Province	Fuels Covered Under Tax Data Collection					Where Tax is Collected	How Many Entities Report	Comments
	Motor Gasoline	On-Road Diesel	Off-Road Diesel	Jet Fuel	Aviation Fuel			
Arizona	X	X		X	X	Rack Suppliers[1]	117*	Exports not taxed; imports are taxed (truck, rail)
California	X	X		X	X	Rack Suppliers	117	Exports not taxed; believe imports are taxed (truck, rail)
Montana	X	X		X	X	Last sale between distributor[2] and final destination	75	Exports not taxed; believe imports are taxed (truck, rail)
New Mexico	X	X		X	X	First receiver[3] from product terminal.	170	For gasoline only, first receiver can pass on tax obligation to next wholesaler. The next wholesaler is then responsible for tax obligation
Oregon	X	X		X	X	Gasoline: First receiver from product terminals Diesel: Retailers	150	Exports not taxed; believe imports are taxed (truck, rail)
Utah	X	X	X	X	X	Gasoline: First receiver from terminal; Diesel - rack suppliers. Imports taxed for both.	127	Jet and aviation fuel taxed in the same manner as gasoline.
Washington	X	X	X	X	X	Rack Suppliers and any imports.	215	Exports not taxed; imports are taxed (truck, rail)
British Columbia	X	X	X	X	X	Importer[4] or manufacturer pays a "security" that is equal to the tax	100	The "security" is passed through the supply chain in the price until the consumer finally actually pays the tax at the retail station.

*Assumed similar to CA until confirmed from AZ source.

[1] A company that owns product and sells that product at the terminal rack.

[2] A middleman that purchases products for resale to other wholesalers, jobbers and/or retail stations. A distributor may sell to another distributor.

[3] The company that first lifts the product from the terminal rack. A distributor could be a first receiver if it buys at the terminal rack, however if they buy from another distributor they are not a first receiver. Another example is service stations that send their own trucks to lift product from the rack. A third example is a service station who receives product directly from a rack supplier.

[4] A company that crosses state lines to deliver product in another state.

5. What data could be made available from which states and at what point of regulation?

It may be that entities are reporting some or all of this information to the federal government, and states could require them to report the same information to the states. For example, EIA Form 782C is submitted by Prime Suppliers to report statewide sales of all petroleum products. This form is submitted monthly by the Prime Suppliers to EIA. The supplier is required to put in one aggregate number for total sales for each product in a given state for each month. It is not clear whether this form and its submissions are "audit-tested", as there is no apparent obligation to provide supporting data, nor any process to match sales to any production or inventory data. In addition, WCI needs to check with EIA to verify that all parties are required to fill out these forms.

There are other existing sources of data (for example, NM and AZ have data on volumes of product moved through terminals from their air quality agency); however none seem to provide complete and/or reliable data on volumetric throughput. It is possible to establish new reporting requirements but not clear how difficult that would be in each jurisdiction.

6. What is the potential for double-counting for different points of regulation? How could the potential for double-counting be addressed?

The potential for double-counting seems lowest at the beginning (refinery) and end (retail) of the supply chain and highest in the middle (transportation and distribution) where there is potential for multiple levels of delivery and receipt. Double counting can be addressed through careful tracking, but it does create an extra level of administration.

7. What are the leakage issues?

The potential for emission leakage is significant for components of the transportation sector:

- *Marine:* Ocean-going vessels can easily obtain fuel outside the WCI partner jurisdictions.
- *Aviation:* Airline operations are particularly sensitive to fuel costs. Opportunities to obtain fuel outside the WCI partner jurisdictions may be significant.

Gasoline use in passenger cars, light duty trucks, and medium duty vehicles is less vulnerable to leakage, as motorists typically obtain fuel in close proximity to their residences and places of employment.

Long-haul trucking may also be vulnerable to leakage if trucks can operate within WCI jurisdictions with fuel obtained from outside the WCI jurisdictions. However, the International Fuel Tax Agreement (IFTA) requires diesel trucks operating in multiple jurisdictions to calculate fuels consumed in each state and province based on the miles traveled in each state/province.

8. Ease of Administration by Partner

Based on discussions in each WCI jurisdiction of the liquid fuels scope and point of regulation issues and data availability, and some other information sources, our preliminary assessment is that it appears that the following points of regulation would be the most straightforward to administer by the following partners:

AZ: Terminal Rack Suppliers

BC: Terminal Rack

CA: Point of final blending

MT: Distributor/wholesaler

NM: Distributor: First Receiver

OR: Distributor: First Receiver

UT: Refinery

WA: Terminal Rack

It is possible that each jurisdiction could cover liquid fuels differently, but WCI would need to ensure no double counting between jurisdictions.

9. Number and characteristics of regulated entities

Regulating at the refinery/importer or at the terminal involves regulating tens of entities, whereas regulating at the distributors/wholesalers would involve hundreds. Some argue that it's not a matter of the number of entities but rather their capability to participate effectively in an allowance market. Unlike larger corporations which own the stationary sources typically subject to regulatory requirements, distributors and wholesalers may not have the institutional resources to fold such a compliance mechanism into their standard operations. However, they could contract with outside experts to fulfill this function.

10. Challenge of including liquid fuels at any point of regulation

A problem with covering oil upstream is that the only compliance options available to regulated entities are buying allowances, selling or blending non-fossil fuels, or reducing fuel sales. Since the liquid fuels cap would be just one part of an economy-wide cap and trade program, regulated entities could buy allowances from other covered sectors. A low carbon fuel standard would be a possible alternative to including liquid fuels in the cap and trade program.

Appendix B1

Estimated State Supply/Demand Balances (Approximations)

State/ Province	Refinery Capacity (TBD)	Refinery Throughput 2006 (TBD)	G+D+J Yield (%)	G+D+J Yield (TBD)	Demands (EIA, Canada) (TBD)	Net Long vs (Short) (TBD)	Supply and Demand Comments
Arizona	0	0		0	260.8	(260.8)	Receives all product from California plus pipeline deliveries from Texas
California	1,983	1,804.6	90	1,624.2	1,590.7	33.5	California appears on net slightly long, but the balance is not as obvious as shown. California imports about 60 TBD ethanol by rail, 120 TBD gasoline (most from the Gulf Coast; some from Washington), 70 TBD jet fuel, and about 30 TBD distillate. They export to Arizona and Nevada about 145 TBD gasoline, 70 TBD jet, and about 90 TBD distillate. They also export about 30 TBD gasoline to Oregon, and some distillate overseas (10 TBD). None of the imports or exports are included in the numbers shown, which are instate production and in state sales (ethanol is part of the in state gasoline sales)
Montana	187	170.3	86	146.4	81.1	65.3	Montana exports gasoline to Idaho, Wyoming, Washington & Oregon
New Mexico	104.6	95.2	80	76.1	102.5	(26.4)	New Mexico's shortfall is made up from imports from Texas (primarily)
Oregon	0	0.0		0.0	170.3	(170.3)	Receives all product from 1) Washington (most); 2) California; 3) pipeline from Montana and Utah and 4) imports
Utah	173.9	158.2	85	134.5	131.6	2.9	This shows Utah at over 95% coverage, but Utah does export via Chevron pipeline to Idaho and Washington/Oregon some volume of product; my guess is that they are also getting some imports into the region.
Washington	634.9	577.8	86	496.9	311.6	185.3	All product from in state refineries plus minor import from Montana and Utah

Estimated State Supply/Demand Balances (Approximations)

State/ Province	Refinery Capacity (TBD)	Refinery Throughput 2006 (TBD)	G+D+J Yield (%)	G+D+J Yield (TBD)	Demands (EIA, Canada) (TBD)	Net Long vs (Short) (TBD)	Supply and Demand Comments
British Columbia	65.2	59.3	78	46.3	167.3	(121.0)	British Columbia may be getting a limited supply from Washington to make up their shortfall, and also Alberta; Manitoba is also likely getting product from Alberta
Manitoba	0	0	0	0.0	47.1	(47.1)

Monthly Motor Vehicle Fuel Distributions Report. 10 yr diesel and jet fuel report.

PIIRA requires petroleum products refiners, marketers, storers, importers and exporters to file reports. For instance, refiners must submit monthly fuel use and sales reports, and weekly production and storage information. The information is aggregated for public release to protect proprietary data. Each type of company must file one or more reporting forms to the Energy Commission on a weekly, monthly, and annual basis. Some of these companies must also submit copies of certain forms they submit to the federal Energy Information Administration (EIA). Refineries are required to send copies of their weekly EIA-800 and monthly EIA-810 Refinery Reports to the Energy Commission. Major marketers who currently file the monthly EIA-782B report are required to submit a CEC-782B to the Energy Commission. The Retail Fuel Outlet Survey (CEC A15) form must be filed annually by each retail fuel outlet in California. More information is here: http://www.energy.ca.gov/oil/piira/index.html

WCI Economic Analysis
Scope of Work

Task 1 – Kickoff Meeting and Project Management

The purposes of this task are to: (1) review and finalize the technical approach for this project; and (2) manage this project throughout its period of performance. The contractor shall participate in a kickoff meeting with WCI representatives to: review the activities that will be conducted; develop a schedule of conference calls and meetings; and establish deadlines for interim and final products. The contractor shall prepare a memo summarizing the kickoff meeting decisions for WCI review.

To manage the project, the contractor shall participate in weekly conference calls with WCI representatives to review progress and gain feedback on various deliverables. The contractor shall prepare a monthly status report summarizing activities performed, progress on deliverables, budget expended, and budget remaining.

<u>Deliverables</u>: (1) Kickoff Meeting; (2) Weekly conference calls; (3) Monthly status reports.

Task 2 – Assemble Data and Prepare Modeling Tools to Support Phase 1 Analysis

The purpose of this task is to assemble the data and prepare the modeling tools needed to support the Phase 1 analysis through the May 2008 WCI public workshop. The Phase 1 analysis will use the standard model data and additional data that are readily available and easily inputted, and consequently is designed to require a minimum of customization of the model and its data. Under the guidance of WCI, the contractor shall incorporate selected complementary policies into the model that are likely to have a large impact on GHG emissions and/or program costs (e.g., tailpipe standards, low carbon fuel standard, demand-side management, renewable portfolio standard, travel demand management).

The contractor shall assemble the data necessary and prepare the ENERGY 2020 model to support the Phase 1 analysis. The contractor shall prepare an Assumptions Book as the key document for managing the process of choosing and recording inputs and data sources. The Assumptions Book will be a living document that evolves over the course of the project under the direction of WCI.

The contractor shall use ENERGY 2020 to generate reference case forecasts out to 2030, combining historic data, a macroeconomic forecast, a simulation of energy demand and supply, and other model inputs. The contractor shall provide outputs at the regional and partner levels that include GHG emissions, energy production and consumption, and other outputs as agreed to with WCI.

<u>Deliverables</u>: (1) Briefing on ENERGY 2020; (2) Draft Assumptions Book; (3) Memo describing the complementary policies incorporated into the model; (4) Reference case forecasts summarized in PowerPoint and data tables.

Task 3 – Perform Phase 1 Analysis to Support Program Design

The purpose of this task is to perform the Phase 1 analysis to support WCI program design deliberations through the May 2008 stakeholder meeting. The contractor shall simulate and analyze various cap-and-trade program designs, as directed by WCI. The contractor shall assist and advise WCI in thinking through which designs to model.

Each model run will generate:

- Costs, savings, and allowance prices.
- Industry-specific impacts including impacts on emission leakage, and output; along with fuel prices, fuel consumption, electricity prices, production, and generation mix.

Deliverables: (1) List of analyses being performed and standard outputs; (2) Results for each analysis conveyed by PowerPoint presentations, tables, and interpretation.

Task 4 – Assemble Data and Prepare Modeling Tools to Support Phase 2 Analysis

The purpose of this task is to assemble the data and prepare the modeling tools needed to support the Phase 2 analysis through the August 2008 release of the WCI program design. The Phase 2 analysis will include refined model inputs and specifications that enable partner-specific conditions to be reflected.

The contractor shall refine the data and assumptions assembled under Task 2 by incorporating selected partner-specific inputs and additional complementary policies, under the guidance of WCI. In consultation with WCI partners, the contractor shall incorporate high-impact GHG mitigation policies that partners have adopted or are considering, especially those likely to reduce energy demand and/or promote non-emitting energy sources. The contractor shall consult with WCI partners and adjust data inputs and parameters to ensure that all parties view the revised reference cases and policy specifications as reasonable.

The contractor shall perform this task in parallel with Tasks 2 and 3 so that the Phase 2 analysis can be presented at the July WCI stakeholder meeting.

Deliverables: (1) Revised Assumptions Book; (2) Memo describing the selected state-specific inputs and complementary policies incorporated into the model; (3) Refined reference case forecasts summarized in PowerPoint and data tables. (4) Paper describing the data, assumptions, and model tools.

Task 5 – Perform Phase 2 Analysis to Support Program Design

The purpose of this task is to perform the Phase 2 analysis through the August 2008 release of the WCI program design, with particular emphasis on the July 2008 stakeholder meeting. The contractor shall simulate and analyze various cap-and-trade program designs, as directed by WCI. The contractor shall assist and advise WCI in thinking through which designs to model.

Each model run will generate:

- Costs, savings, and allowance prices.
- Industry-specific impacts including impacts on emission leakage, and output; along with fuel prices, fuel consumption, electricity prices, production, and generation mix.

Deliverables: (1) List of analyses being performed and standard outputs; (2) Results for each analysis conveyed by PowerPoint presentations, tables, and interpretation; (3) Summary Paper presenting the results.

Task 6 – Stakeholder Process Support

The purpose of this task is to support the WCI stakeholder process for this economic modeling project. The contractor shall provide the following support:

- Prepare and present summaries of the methods, data, and results at two stakeholder meetings, in May and July 2008. Prepare draft presentations for WCI review. Incorporate WCI comments prior to delivering the presentations.
- Prepare for, present to, and participate in stakeholder conference calls dedicated to economic analysis and modeling.
- Prepare summary responses to summaries of comments received from stakeholders on economic analysis and modeling issues.

Deliverables: (1) Presentations to two stakeholder meetings; (2) Participation in stakeholder conference calls; (3) Review and response to summaries of stakeholder comments as prepared by WCI.

Schedule of Stakeholder Events

Event	Date
Stakeholder Conference Call: Present an overview of the economic modeling activities. Present a detailed description of Energy 2020	Friday, March 28, 2008
Stakeholder Conference Call: Present the *Assumptions Book* listing all the model inputs.	Monday, April 14, 2008
Stakeholder Conference Call: Preview of initial model results, including reference scenarios.	Monday, May 12, 2008
Stakeholder Workshop, Salt Lake City: Present model results, including reference scenarios.	Wednesday, May 21, 2008
Stakeholder Conference Call: Present revised *Assumptions Book* with updated model inputs for Phase 2 analysis, and reflecting stakeholder comments.	Monday, June 9, 2008
Stakeholder Conference Call: Present initial Phase 2 results using updated model inputs and reflecting stakeholder comments.	Monday, July 21, 2008
Stakeholder Workshop, (location to be determined): Present Phase 2 model results.	Tuesday, July 29, 2008

Stakeholder comments will be solicited throughout the process.

Western Climate Initiative

Economic Modeling and Analysis to Support the Western Climate Initiative

Economic Modeling Team

March 28, 2008

Objective

- Support WCI in the development of a regional, multi-sector cap-and-trade program to reduce greenhouse gas (GHG) emissions.
  - Program Scope
  - Allowance Allocations
  - Stringency
  - Flexible Compliance Mechanisms

Objective (continued)

- Outcomes of interest
  - Economy-wide costs and savings
  - Cap-and-trade program outcomes
    - Allowances prices, allowance trading
  - Emissions
    - Sources within the cap-and-trade program
    - All sources economy wide
  - Sector impacts

Approach

- Energy 2020 -- Integrated model of the economy and energy for Canada and the U.S.
- Focus on design decisions
  – Alternative program designs
  – Sensitivity of the outcomes to assumptions and inputs:
    - Fuel prices, availability and cost of relevant technologies, growth rates, others
- Build on the body of previous work

Approach (continued)

- Statement of Work – WCI website
  - Open process: all data and assumptions
- Seven Stakeholder Events (so far)
  - Five conference calls
  - Two workshops (May, July)
- Written Comments
  - Timely
  - Accepted throughout

Approach (continued)

- Phase 1:
  - Initial results using aggregate data
  - Exercise the model
  - Engage stakeholders
- Phase 2:
  - Customize the model
  - Detailed analyses
  - Engage stakeholders

Events

Event	Date
Stakeholder Conference Call: Present an overview of the economic modeling activities. Present a detailed description of Energy 2020	Friday, March 28, 2008
Stakeholder Conference Call: Present the *Assumptions Book* listing all the model inputs.	Monday, April 14, 2008
Stakeholder Conference Call: Preview of initial model results, including reference scenarios.	Monday, May 12, 2008
Stakeholder Workshop, Salt Lake City: Present model results, including reference scenarios.	Wednesday, May 21, 2008
Stakeholder Conference Call: Present revised *Assumptions Book* with updated model inputs for Phase 2 analysis, and reflecting stakeholder comments.	Monday, June 9, 2008
Stakeholder Conference Call: Present initial Phase 2 results using updated model inputs and reflecting stakeholder comments.	Monday, July 21, 2008
Stakeholder Workshop (location to be determined): Present Phase 2 model results.	Tuesday, July 29, 2008

Comments and Questions Regarding the Proposed Process

Climate Change Modeling Using ENERGY 2020

Presented to

Western Climate Initiative Stakeholders

March 28, 2008

ENERGY 2020 Applied in the U.S.

- Illinois – Governor's Climate Change Advisory Group
  - Target - reduce emissions to 1990 level by 2020
  - Policies in all sectors including cap-and-trade & links to regional trading systems.
  - Economic impacts analyzed in conjunction with a macro-economic model
  - http://www.epa.state.il.us/air/climatechange/documents/index.html
- Wisconsin – Global Warming Task Force
  - Up to 30 GHG mitigation policies being analyzed in 10-12 portfolios
  - Scenarios include cap-and-trade variations and sensitivity analyses on the Reference Case forecast
  - Integrated emission/economic modeling with REMI
  - http://dnr.wi.gov/environmentprotect/gtfgw/AG_t.html
- California – Adaptation of ENERGY 2020 for CARB Policy Analysis
  - Customized version of ENERGY 2020 that will be used by the California Air Resources Board for the analysis and development of multi-sector climate change response policies and programs

ENERGY 2020 is used extensively in Canada

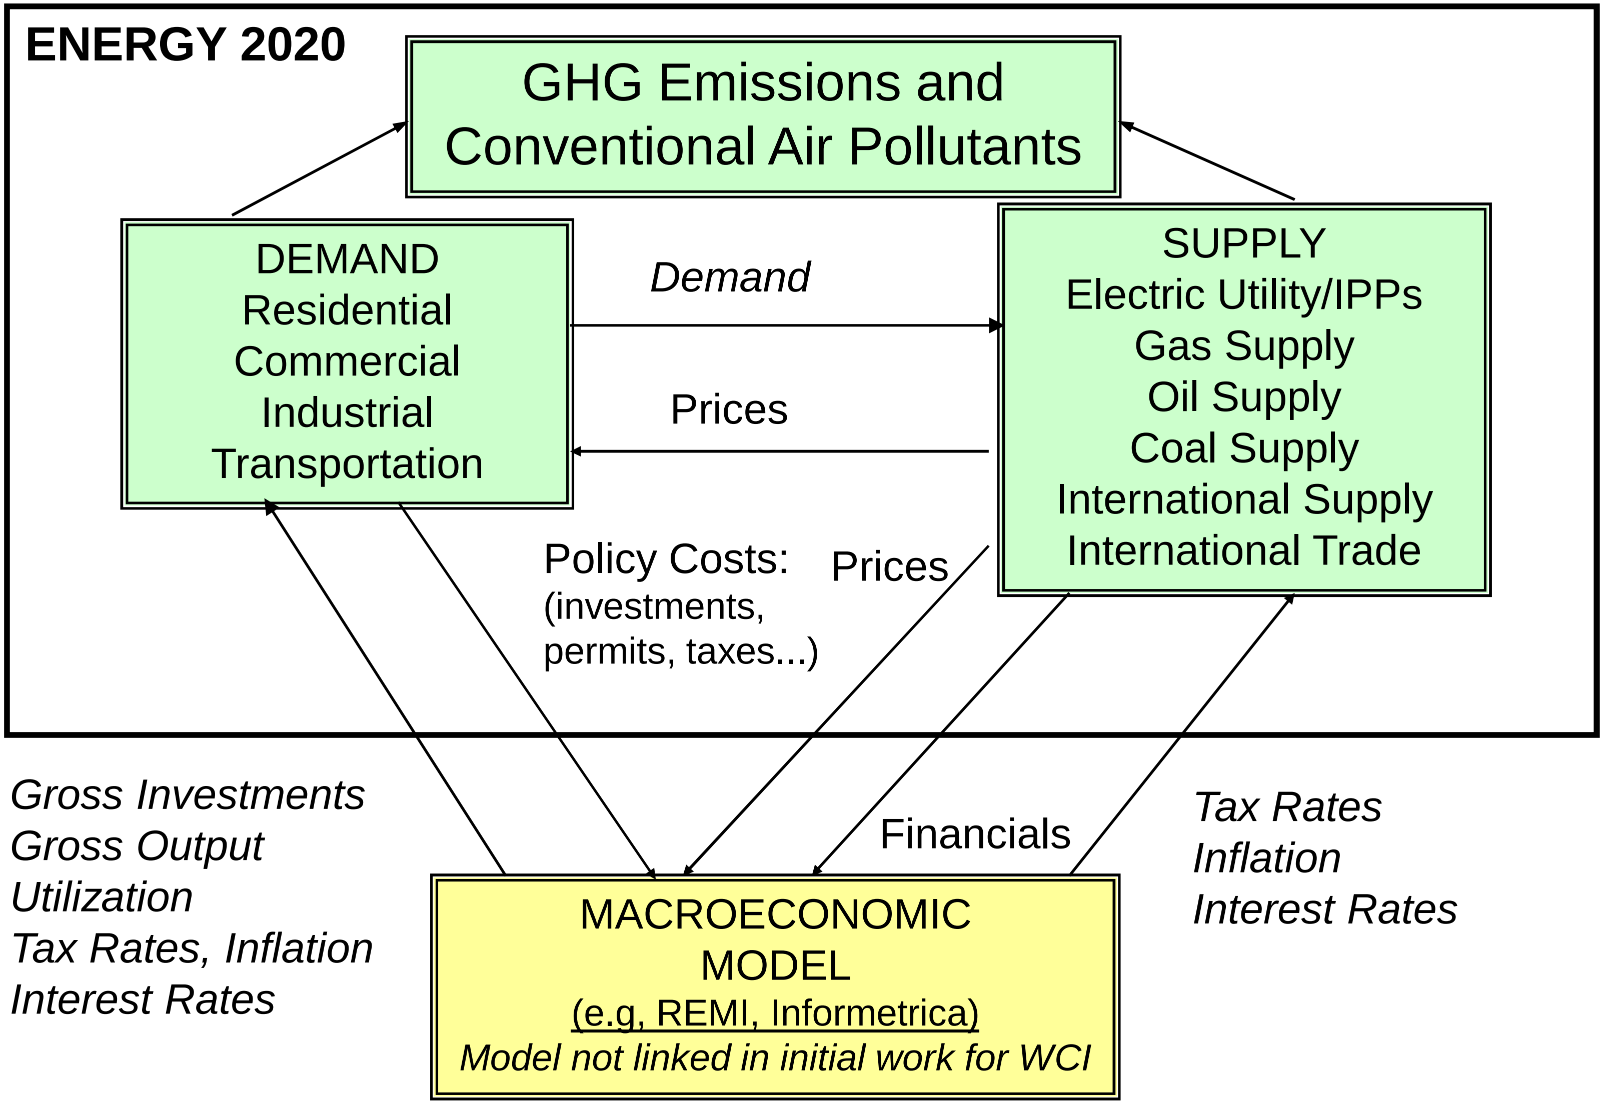
- Environment Canada – “Turning the Corner” - Multi-Sector Climate Change Policy Modeling:
  - Analyzing GHG emissions for reference case and policy scenarios
  - Modeling federal and provincial level emissions and emission policies
  - Macroeconomic impacts of policies (relative to the reference case)
  - Analysis extends to 2050
  - http://www.ec.gc.ca/default.asp?lang=En&n=75038EBC-1 (esp. Chap. 5)
- NRTEE (National Round Table on the Environment and the Economy - Canada)
  - Long-Term Energy and Climate Change Strategy to reduce GHG emissions by 60% below 1990 levels by 2050
  - Measures included energy efficiency across all sectors, renewable fuels for transportation and electric generation, restructuring industrial and urban mix, and carbon capture and sequestration.
  - http://www.nrtee-trnee.ca/eng/publications/wedge-advisory-note/ecc-wedge-advisory-note-eng.pdf
- Additional work for Environment Canada and Ontario

ENERGY 2020 Model Overview

Overview of ENERGY 2020

- Integrated North American economy, energy and emissions model
- Includes all U.S. States and Canadian Provinces
- Energy demand end-use sector disaggregation
- Energy supply for electricity, oil, gas, coal, renewables,
- Separate outputs can be provided for each type of air emission:
  - Greenhouse Gas (CO2, N2O, CH4, SF6, HFC, PFC)
  - Conventional Pollutants (SOx, NOx, VOC, CO, PMT, PM10, PM2.5)
- Model can be extended out to 2050

Model Structure & Relationships



Major Model Inputs

- Historical Data
  - Energy demand, supply, prices, and emissions by state/province
  - Unit-by-unit generator data
- Projected Economic Activity (from a macro-economic forecast)
  - GDP, Gross output by sector, personal Income
- Projected Fuel Prices
  - World oil prices, US natural gas and coal prices
  - Biomass, ethanol, biodiesel prices
- Projected Technology Cost and Performance
  - Power generation, vehicles, etc.
  - End-use and energy efficiency, including potential for improvements
- Availability and Cost of Offsets

Major Model Outputs

- Emissions – GHG and conventional air pollutants
  - With market-clearing allowance price for GHG cap-and-trade program
  - GHG offset prices and quantities used
- Power Sector
  - Demand, generation, capacity, wholesale prices, LSE revenues and rates
- Fuel use and market shares
  - Oil, natural gas, coal, gasoline, diesel, ethanol, biodiesel, etc.
- Levels of Energy Efficiency
- All outputs broken out by states/province and by economic sector

Modeling Principles

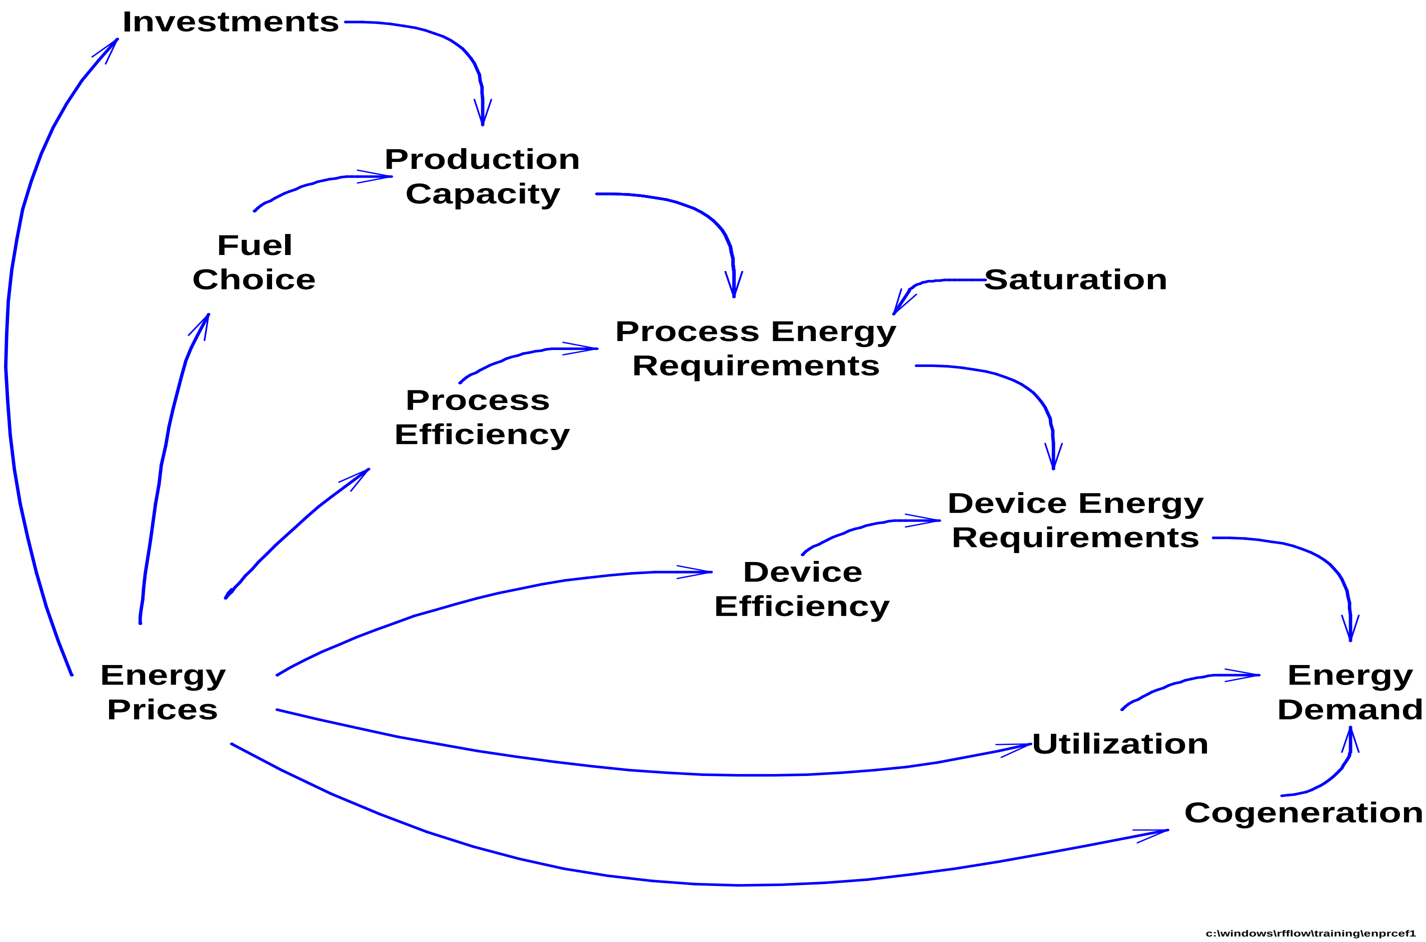
- Key Decisions are Endogenous
- Stocks and Flows
- Marginal Decisions
- Causality vs. Correlation
- Actual vs. Optimal Decisions
- Dynamically describes the behavior of both energy suppliers and consumers for all fuels and for all end-uses

What makes ENERGY 2020 Different?

- Not Optimization
  - Models behavior based on past experience, not optimal solution
- Not Classical Econometrics
  - Enables modeling of unprecedented actions and events
- Uses Qualitative Choice Theory
  - Recognizes price and non-price elements of decisions, market imperfections, time delays, etc.
  - "Maximizes utility" within constraints of imperfect market
  - Simulates actual, as opposed to assumed, responses
  - e.g. choice of vehicle considers non-price factors of style, comfort, space, safety, affordability, and reliability in addition to vehicle efficiency or lowest operating cost.
- Decisions are endogenous to the model
- Capable of flexible policy analysis and multiple scenarios

Demand Overview

Energy Demand Structure



Energy Demand Determination

- Energy is a “derived demand”
  - Users want “energy services” not “energy.” Energy demand is driven by several discrete choices:
  - Choice of fuel
  - Choice of energy conversion process
  - Choice of energy device
  - Choice of utilization level
  - Examples
- Fuel and Technology Market Shares
  - ENERGY 2020 simulates decisions on fuel, process, device, and utilization
- Stock and Flow Accounting
  - Simulates capital stocks by vintage over time
- Conversion of energy service requirements into actual energy demand
  - Simulates utilization of capital stocks

Demand – Sectors & End Uses

- Detailed model of sectors:
  - Residential – 3 structure types
  - Commercial/Institutional – 14 sub-sectors
  - Industrial – 39 sub-sectors (including construction, agriculture & forestry)
  - Transportation – separates passenger, freight & off-road
- End Uses:
  - Specific to each sector
  - Separates “substitutable” loads (multiple fuel choices) from “non-substitutable” (electric only).
  - Transportation divided into 7 “modes” as well as by vehicle classes within passenger and freight.

Demand – Sectors & End Uses (cont.)

Residential	Commercial	Transportation	Other
1. Single Family 2. Multi Family 3. Other Residential	1. Transportation Services 2. Pipelines 3. Communication 4. Electric Utilities 5. Gas Utilities 6. Water & Other Utilities 7. Wholesale 8. Retail 9. FIRE (Finance, Insurance, & Real Estate) 10. Offices - Business Services 11. Education 12. Health & Social 13. Food, Lodging, Recreation 14. Government	1. Passenger 2. Freight 3. Off Road	1. Misc. & Street Lighting 2. Electric Resale 3. Utility Electric 4. Generation 5. Industry Electric 6. Generation 7. Steam Generation 8. Solid Waste 9. Waste Water 10. Incineration 11. Land Use

Demand – Sectors & End Uses (cont.)

Industrial Sectors		
1. Food & Tobacco 2. Textiles 3. Apparel 4. Lumber 5. Furniture 6. Paper 7. Printing 8. Chemicals 9. Petroleum Products 10. Rubber 11. Leather 12. Cement 13. Glass	14. Lime & Gypsum 15. Other Non-Metallic 16. Iron & Steel 17. Aluminium 18. Other Nonferrous 19. Fabricated Metals 20. Machines 21. Computers 22. Electric 23. Equipment 24. Transport Equipment 25. Other Manufacturing 26. Metal Mining	27. Non-metal 28. Mining 29. Light Oil Mining 30. Heavy Oil Mining 31. Frontier Oil Mining 32. Oil Sands In-Situ 33. Oil Sands Mining 34. Oil Sands Upgraders 35. Gas Mining 36. Coal Mining 37. Construction 38. Forestry 39. Agriculture

Demand – Sectors & End Uses (cont.)

Residential	Commercial	Industrial	Transportation
1. Space heating	1. Space heating	1. Process heat	1. Highway (automobile & trucks)
2. Water heating	2. Water heating	2. Electric motors	2. Buses
3. Lighting	3. Lighting	3. Other substitutable [c]	3. Trains
4. Air conditioning	4. Air conditioning	4. Miscellaneous [d]	4. Planes
5. Refrigeration	5. Refrigeration		5. Marine
6. Other substitutable [a]	6. Other substitutable [a]		6. Others (electric vehicles, fuel cells and ethanol)
7. Other non-substitutable [b]	7. Other non-substitutable [b]		

a *an aggregate category to include cooking and drying end-use services*

b *represents miscellaneous electric appliances*

c *hot water or drying that is not part of the primary-process heat*

d *lighting and electrochemical process*

Supply Overview

Electricity Supply

- Functional Divisions
  - Distribution
  - Transmission
  - Marketing
  - Generation
- Capacity Expansion
  - developed endogenously to maintain a reserve margin target
  - committed capacity can be specified exogenously
- Generation and Fuel Use
- Electricity Prices
- Emissions

Other Supplies

- Extensive choice of fuel types
  - 33 fuels/sources can be modeled
  - Sub-sector detail will depend on available time and resources
- Oil production (6 sub-sectors including non-conventional)
- Gas production
- Coal Mining
- Combined Heat & Power & Steam Production
- Ethanol Production
- Renewables

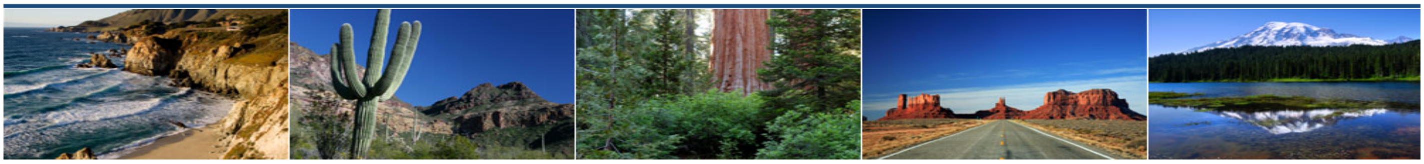
Modeling of Complementary Policies

- Flexibility in ENERGY 2020 allows modeling of a broad range of policies, e.g.,
  - DSM policies
  - Building codes
  - Efficiency standards for vehicles, appliances, etc.
  - Renewable portfolio standards
  - Low-carbon fuel standard
  - Carbon capture and sequestration
  - GHG offsets

Inputs and Assumptions

- An "Assumptions Book" catalogs key inputs and assumptions
  - This book is a "living document" that evolves over the course of the project
  - The current Assumptions Book will be available on the WCI website as it evolves
- WCI will seek stakeholder comment on the Assumptions Book inputs and assumptions
  - The Assumptions Book will be the topic of the stakeholder conference call on April 14, 2008
  - Comments on the Assumptions Book will be welcome throughout the process

Western Climate Initiative



Draft Allocations Design Recommendations

April 2, 2008

I. Introduction

As stated in the WCI Work Plan, the WCI Allocations Subcommittee was established to:

1. Recommend a methodology for determining the number of allowances to be apportioned, either individually to each WCI partner and thereby establishing each Partner's overall emissions allowance budget for the WCI program, or regionally for the WCI region overall; and

2. Determine whether to recommend that the Partners establish a common method for distributing the budgeted emissions allowances (a) among covered sectors; and (b) within each sector to covered entities. If a common allowance distribution method is recommended, the Subcommittee will recommend a distribution method or methods for consideration by the WCI Partners.

To accomplish this mission, the WCI Work Plan directed the Allocations Subcommittee to:

- Develop design principles to guide the Subcommittee's deliberations;
- Determine whether an allowance budget should be established (a) for each Partner or (b) for the region, with subsequent allocation to sectors within the region;
- Develop a methodology for determining the amount of overall allowances;
- Determine whether and what to recommend concerning how allowances are divided among economic sectors;
- Determine whether and what to recommend concerning how allowances are distributed (i.e., by free allocation, auction, or a hybrid of these two);
- Address specific issues identified in the Work Plan related to free allocations (if recommended) and auctions (if recommended);
- Determine whether the method for allocating allowances (i.e., free allocation, auction, or hybrid) should be the same for all sectors or may/should vary by sector;
- Determine whether the amount of allowances should decline, and if so, at what rate;
- Determine whether and what to recommend concerning how appropriate recognition and incentives for early emission reductions can/should be considered in distributing allowances;

- Determine whether banking of allowances should be permitted, and if so, the criteria and condition for banking (e.g., the length of time and amount of allowances that may be banked); and
- Determine whether borrowing of allowances should be permitted, and if so, the criteria and condition for borrowing (e.g., the length of time and amount of allowances that may be borrowed and the rate of repayment of borrowed allowances).

Pursuant to the WCI Work Plan, the Allocations Subcommittee established the following design principles to guide its deliberations. These design principles were identified in the Allocations Stakeholder Discussion Document (January 2, 2008):

- Maximize program simplicity,
- Minimize unfair competition among covered industries across the region,
- Provide for state and provincial flexibility,
- Promote consistent regional program standards and methods,
- Provide appropriate recognition and incentives for early emissions reductions,
- Maximize the program's GHG reduction potential, and
- Avoid undue economic impacts on consumers and industries.

In the Stakeholder Discussion Document, the Allocations Subcommittee recognized that some of these principles are potentially in conflict. The Subcommittee therefore sought stakeholder comments on how, among other things, to achieve the best balance between them and carefully considered the range of stakeholder perspectives in developing its recommendations.

The draft Allocations Design recommendations set forth herein take into account the above design principles, as well as the draft WCI recommendations on Scope and Electricity, public comments received on the WCI Work Plan (October 29, 2007) and the Allocations Stakeholder Discussion Document (January 2, 2008), and information gathered during conference calls and in-person meetings, including a conference call with stakeholders.

The Partners have agreed upon the draft Allocations Design recommendations set forth below. These draft recommendations are a first step for inclusion of allowance allocations in the overall cap and trade design. The Partners will continue to work on various allocations issues and will have additional recommendations after further deliberations and public input.

For example, the Partners will evaluate how to monitor the market and protect against manipulation.

In addition, while the Partners have agreed that a minimum amount of allowances should be auctioned, a number of issues related to the auction remain to be addressed. The Partners will take into account the RGGI and European experiences with auctions. RGGI has a complete auction design (based on a comprehensive study) and is planning its first auction for later this year. Some of the issues to be considered include who will administer the auction; the frequency of the auctions; the procedure for establishing the price of allowances sold at auction; use of auction proceeds; who may participate in the auction; and how to monitor the auction market and protect against market manipulation, among other questions. The Partners also will consider whether there should be a safety valve.

II. Draft Allocations Design Recommendations

The Partners agree to the following draft Allocations Design recommendations:

Regional Cap and Allowance Budgets:
The WCI will establish a regional cap that will decline over time, and each Partner will have an allowance budget within the cap. The emissions from any given Partner could be greater or less than its allowance budget depending on the extent of inter-jurisdictional allowance trading.

The regional cap will be equal to the sum of the Partner allowance budgets. Reductions achieved by the cap plus reductions from uncapped sources resulting from complementary measures should achieve the WCI regional goal of a 15% reduction below 2005 levels by 2020.

The initial regional cap and Partner allowance budgets will be set through 2020. The regional cap and each Partner's allowance budget will not be adjusted except as necessary to account for changes in WCI membership, sectors added to the cap, errors discovered in data used to determine the cap or the Partner budgets, which may become apparent after the start of mandatory reporting, or errors that resulted in either under-allocation or over-allocation of allowances. Such adjustments will take effect at a regionally-coordinated and designated time, such as the beginning of the relevant compliance period.

Distribution of Allowances by Partners:
Once the allowance budget has been established for each Partner, allowances will be issued by each Partner rather than issued by a regional organization. Through mutual reciprocal recognition by the Partners, allowances will be of equivalent use and value throughout the WCI region, regardless of which Partner issues the allowances.

Establishment of Cap and Trade Partner Budgets:
Each Partner's allowance budget will be established in a transparent manner that is consistent with the emission reductions that the WCI must realize from the sources covered by the cap and trade program in order to achieve the WCI economy-wide emissions reduction goal.

The Partners will develop a methodology for calculating the Partner allowance budgets. The methodology should set the Partner allowance budgets at the levels needed to achieve the WCI economy-wide emissions reduction goal.

The WCI seeks comments from stakeholders on the methodology for establishing Partners' allowance budgets and the factors to be included in the methodology.

Partners' Initial Allowance Budgets:
The Partners recognize the potential conflict between the need to begin the cap and trade program as soon as possible to bring about reductions in GHG emissions and the need for accurate data on which to base the calculation of allowances for the regional cap and individual

Partner budgets. Substantial emissions data is already available due to reporting under existing regulatory requirements for other pollutants and energy consumption, as well as the GHG emissions inventories and forecasts compiled by the Partners, but data from mandatory reporting of GHG emissions may be necessary for more precise allocations of allowances. With this in mind, the calculation of the regional cap and the Partner allowance budgets for the initial years of the cap and trade program will recognize potential concerns about data accuracy and be adjusted in ensuing years as necessary if mandatory reporting reveals significant data errors.

Partner Discretion to Issue Allowances:

Each Partner initially will have flexibility to issue, beyond the minimum percentage auction amount discussed below and subject to the sector-specific assessments discussed below, its remaining allowances as it sees fit, including (i) auctioning more than the minimum amount of allowances; (ii) issuing some or all of the remaining allowances for free; (iii) holding some or all of the remaining allowances within a compliance period; and/or (iv) retiring some or all of the remaining allowances.

Each Partner initially will have discretion to issue allowances differently to different sectors within its jurisdiction. Each Partner may decide how and to whom to issue the allowances in its allowance budget, subject to the minimum auction requirement and the sector-specific assessments of competition outlined below.

While each Partner initially will have flexibility in how it allocates the allowances beyond the minimum auction amount, each Partner will be required to advise the other WCI Partners at the beginning of the relevant compliance period how it intends to allocate the remaining allowances, so that the WCI can make public the Partners' plans in a coordinated fashion. This procedure will help reduce the potential for adverse impacts on auction prices by preventing allowances from being "dumped" into the market unexpectedly.

Any Partner that has chosen to hold allowances must allocate or retire those allowances by the end of the applicable compliance period. A Partner will not be able to hold allowances beyond the end of the compliance period. These requirements will help reduce market instability by providing more certainty about the volume of allowances available during a compliance period.

The Partners will continue to examine the impacts of Partners utilizing different approaches to allocate allowances to the same sectors and seek comments from stakeholders on this issue.

The Partners also will continue to consider the impacts of Partners making different use of auction proceeds and seek comments from stakeholders on this issue.

While the Partners initially will have flexibility to issue allowances, the WCI will seek to achieve standardized distribution of allowances over time to the extent possible.

- ***Sector-Specific Assessment of Competition Among WCI Jurisdictions*:**
  While the Partners initially will have significant flexibility in issuing allowances, a diverse array of allocation procedures could yield significant cost differentials among competing firms or industries among WCI jurisdictions. There may be cases where it is necessary to assess whether allocations to a particular sector should be treated uniformly

by all Partners in the WCI region to address competition among entities within the WCI region. This potential could be minimized through a continued dialogue among the Partners and harmonization of allocation procedures and the use of auction proceeds where appropriate. The Partners believe that only a few sectors face significant risks of unfair competition from differing allocation methods among the WCI Partners, and a harmonized approach would be limited to carbon-intensive industries facing significant competition among WCI jurisdictions. For such cases, a case-by-case sector-specific analysis will be conducted jointly by the WCI Partners to determine whether consistent allocation is needed to address such disparities within the WCI. This approach will provide for sufficient standardization for an efficient cap and trade program while providing the Partners flexibility to address their individual priorities.

- ***Sector-Specific Assessment of Competition with Non-WCI Jurisdictions*:**
  While the Partners initially will have significant flexibility in issuing allowances, a diverse array of allocation procedures could yield significant cost differentials among competing firms or industries within the WCI and those outside the WCI, resulting in leakage outside the WCI region. There may be cases where it is necessary to assess whether allocations to a particular sector should be treated uniformly by all Partners in the WCI region to address competition and leakage from entities outside the WCI region. This potential can be minimized through a continued dialogue among the Partners and harmonization of allocation procedures and the use of auction proceeds where appropriate. The Partners believe that leakage of this type is likely an issue only for bulk commodity sectors with high GHG emissions per unit of output that face significant non-WCI competition, and a harmonized approach would be limited to carbon-intensive industries facing significant competition outside the WCI region. For such cases, a sector-specific analysis will be conducted jointly by the WCI Partners to determine whether consistent allocation is needed to address non-WCI region leakage. This approach will provide for sufficient standardization for an efficient cap and trade program while providing the Partners flexibility to address their individual priorities.

Minimum Auction Percentage:

Each Partner will auction a minimum percentage between 25% and 75% of its allowance budget through a coordinated regional auction process by which each Partner will auction allowances throughout the WCI region and receive the proceeds of the auction.

The Partners will determine a specific minimum percentage auction amount. The WCI seeks comments from stakeholders on this question.

Because multiple Partners would be simultaneously auctioning allowances through a single pool, the auction could result in Partners auctioning or selling some of their allowances to entities in other jurisdictions. This outcome is fully consistent with the concept of regional trading and the importance of allowances having equivalent use/value for compliance purposes throughout the WCI region.

Phased Increase of Auctioning:
Greater emphasis could be given to free allocation in the early years of the program (and more to auctions in later years) as a means of mitigating business and consumer cost impacts and providing transition assistance, in addition to utilizing auction proceeds for these purposes. Some Partners may choose to provide more time for an allowance market to develop before capped entities must purchase larger portions of their allowances in an auction.

The minimum percentage of allowances to be auctioned should be increased over time, potentially to 100%. Even before such an increase, each Partner will have discretion to auction a greater portion of its allowances at the program outset or gradually over time as it sees fit.

Credits for Early Reductions:
Each Partner will have discretion to give credit for early actions, but any credit for early action must come from within the cap and will come out of the individual Partner's allowance budget. Early action credits will not be added to or be on top of the amount of allowances in each Partner's allowance budget.

Banking:
Purchasers and covered entities will be allowed to bank allowances without restrictions on the amount of allowances that may be banked or for how long.

Borrowing:
Borrowing of allowances from future compliance periods will not be allowed.

Compliance Periods:
The compliance periods will be three years long.

Multi-year compliance periods will provide covered entities with flexibility for compliance and in planning for (or responding to) large and unexpected changes in the allowance market or in other markets, such as energy markets, which may affect allowance prices, as well as programmatic flexibility for the WCI, to for example, ensure a steadily declining cap. The Partners note that three years is the length of the compliance periods chosen by RGGI.

Initial Compliance Period:
To accommodate start-up issues both from the covered entity standpoint and the regulatory standpoint, the initial compliance period will include special rules, such as a two-year period, or other measures to assist in the transition into a cap and trade system, while maintaining the integrity of the cap and value of the allowances.

Regional Organization:
Although allowances will be issued by each Partner, the Partners will create a regional entity (similar to RGGI, Inc.), to coordinate the regional auction of allowances, track emissions and allowances, monitor and report on market activity, and other activities. The regional organization also could be the forum through which each Partner updates the other Partners every two years on its progress toward achieving the regional goal and the Partners' individual goals.

There may also be a need to resolve other coordination issues, such as competitiveness and leakage issues resulting from potentially divergent allocation procedures among the WCI Partners. Such issues could be resolved through this regional organization or some other forum.

New Partners:
Allowances for new Partners will be in addition to the existing allowance budgets for current Partners. The regional cap will be expanded to accommodate emissions from the new Partner.

Once the cap and trade program has been instituted, new Partners will come into the cap and trade program at a regionally-coordinated and designated time, such as the beginning of the relevant compliance period.

Timelines for Partner Activities:
The Partners will develop a schedule for various WCI efforts, including launching the cap and trade program, establishing emissions baselines and Partner allowance budgets, undertaking any case-by-case discussions on competition or leakage issues which may affect Partner allocation plans and other various allocation-related efforts.

Draft Offsets Design Recommendations

April 3, 2008

I. Introduction

The Offsets Subcommittee is examining the potential design, scope, and operation of a greenhouse gas offset program for the Western Climate Initiative (WCI) cap and trade system. The Subcommittee is developing draft recommendations within each of the four task areas identified in the Offsets section of the WCI Workplan released in October, 2007:

1. the role and objectives of a WCI offset program,
2. the core design elements of a WCI offset program,
3. offset eligibility and fungibility, and
4. offset program structure and authority.

In preparing these draft recommendations, the Subcommittee took into account the draft recommendations of other WCI subcommittees, public comments received on the WCI Work Plan (October 29, 2007) and the Summary of Major Options for a GHG Offsets System (January 3, 2008), and information gathered and discussed by the Subcommittee during several conference calls and in-person meetings, including the workshop on Designing an Offsets Program for the WCI (March 26, 2008).

The Subcommittee's draft recommendations are a first step for inclusion of offsets in the overall cap and trade design and are intended to solicit stakeholder input before the Subcommittee takes its draft recommendations to the Partners. The Subcommittee will continue its work and intends to have additional draft recommendations after further deliberations, public input, and interaction with other WCI subcommittees. The Subcommittee is particularly interested in stakeholder comments on how to implement, or alternatives to, the draft recommendations described below.

II. Evaluation Criteria

Based on overall WCI design principles, the Subcommittee identified the following criteria to guide the evaluation of offset program design options:

Administratively simple and cost effective,

Operationally straightforward for participants,

Ensures integrity of emission reductions,

Adds to economic efficiency of the cap and trade system,

Stimulates innovation and provides co-benefits,

Enhances transparency and minimizes uncertainty, and

Facilitates linkage with other programs.

III. Draft recommendations

Based on the guidance provided by the overall WCI design principles and feedback from stakeholders, the Subcommittee recommends that a greenhouse gas offset program be an element of the WCI cap and trade design to facilitate the achievement of WCI Partners' emission reduction goals.

Role of the Offset Program

A primary role of the offset program could be to reduce the overall compliance costs for the cap-and-trade system, by enabling the offset market to deliver lower-cost emission reduction options than are available in the sectors/sources included in the cap-and-trade system. In addition, by lowering overall costs, an offset program could support a more aggressive reduction cap than might otherwise be feasible for the cap and trade system. Another role could be to encourage innovation, co-benefits, greenhouse gas emission reductions from sources not covered by the cap and trade system and removals by sinks.

Offset project types and protocols

The WCI should:

- aim to develop an initial set of eligible project types and approved protocols prior to cap and trade program launch;
- provide a process to review and approve other project types and related protocols proposed by project developers;
- use protocols that are standardized to the extent possible; and,
- make use of, and adapt if needed, existing protocols as appropriate.

Offset projects approved through the WCI offsets program

In addition to those offset projects approved within its jurisdictions, the WCI should consider approving offset projects located throughout Canada, the United States, and Mexico, where such projects would be subject to comparably rigorous oversight, validation, verification and enforcement as those located within the WCI jurisdictions and would not undermine the ability for the WCI to link to other trading systems.

The WCI should consider a method that gives priority to offset projects located within WCI jurisdictions. The method should also consider other roles of the offset system.

Tradable units from government regulated GHG emission trading systems

The WCI should consider allowing for compliance purposes by individual regulated entities the use of tradable units (offsets and allowances) from other government regulated GHG emission trading systems that are recognized by the WCI as meeting similarly rigorous criteria for environmental integrity.

The WCI should ensure accounting systems are in place to prevent using tradable units more than once for compliance.

Limits

To ensure that meaningful emission reductions take place within the sources covered by the cap-and-trade system, the WCI should limit the use of offsets and non-WCI tradable units for compliance by individual regulated entities. The Subcommittee will consider making a specific draft recommendation to the WCI based on further analysis and considering the level of the cap set for the cap and trade system.

Offset program administrative structure and function

The WCI should use an administrative structure for the offset program that combines optimal aspects of jurisdiction-by-jurisdiction, public-private partnership, and centralized regional approaches and may draw from existing programs.

A regional organization should:

- coordinate review and adoption of protocols;
- coordinate review and issuing of offsets;
- provide the criteria and means to accredit service providers to deliver validation and verification services.

The subcommittee recognizes that each jurisdiction may need to retain regulatory authority for offset protocol and project approval, issuing offsets and enforcement.

The WCI should select or develop a centralized offset registry and ensure integration with the emissions reporting and allowance tracking system of the cap and trade system. Public-private partners could be involved in the registration and tracking of WCI offsets.

Draft Program Reporting Recommendations

1. Introduction

This paper presents the WCI draft recommendation for the greenhouse gas (GHG) emissions reporting system to support the WCI cap-and-trade program. The recommendation is based on the WCI's analysis and assessment of the Reporting Major Options paper it released in January 2008, entitled "Summary of Major Options for a GHG Reporting System to Support the WCI Program". The WCI evaluated these major options in light of general WCI design principles and needs and capabilities of individual Partner jurisdictions. It also took into account stakeholder comments received in writing by February 1, 2008, as well as comments at the January 10, 2008 stakeholder meeting and the February 15, 2008 stakeholder conference call on reporting issues.

The WCI welcomes stakeholder input regarding these recommendations. A stakeholder call to discuss this draft will be scheduled for the week of April 7, 2008. Written comments may be submitted through the WCI web site and are due by Wednesday, April 16, 2008.

Background

A robust and credible reporting system will be the backbone of the WCI program. This system will need to ensure that emissions are quantified and reported in an accurate and transparent manner. It will allow regulators in the participating jurisdictions to assess compliance of regulated sources, measure progress against state, provincial and regional targets and generate public trust in this progress. Additionally, market participants of all stripes will rely on the reporting system and the data it generates to make decisions on which significant transactions will be based. Confidence in the reporting system will be critical to the success of the WCI program.

WCI Design Principles Relevant to Reporting

Several of the WCI Design Principles outlined in the October 29, 2007 WCI Work Plan are especially relevant to reporting and were given serious consideration in development of the recommendations in this paper (shown in bold below).

1. ***Is equitable, administratively simple for government and private participants, minimizes administrative costs, and has a clear compliance path;***

2. **Maximizes total benefits throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts;**
3. **Requires all reductions to be real, surplus/additional, verifiable, permanent, and enforceable;**
4. **Stimulates investment, especially in low carbon technologies, and rewards innovations that will lead to long-term permanent greenhouse gas reductions;**
5. ***Covers as many sources as is practical, while encouraging pollution reductions beyond the capped sources and sectors;***
6. ***Provides appropriate recognition and incentives for early emissions reductions;***
7. ***Assures a transparent and robust accounting system that will measure and report emissions rigorously and consistently across all sectors and throughout the region;***
8. **Minimizes the potential for leakage; and**
9. ***Facilitates linkage to similarly rigorous regional and international greenhouse gas reduction markets and encourages other states, provinces, and countries to join the market.***

Starting Assumptions

The WCI is fortunate in that several GHG reporting systems exist that can inform the design of and perhaps even underpin the reporting system it will require. The Reporting Subcommittee has assessed many of these systems and anticipates that the reporting system it ultimately recommends will attempt to establish as much consistency with as many of them as the details and rigor of the WCI program allow. Many of the details of the WCI reporting system however will necessarily depend on other decisions still being considered by the Partners.

This reality aside, the WCI partners are unanimous in their view that the reporting component of the program should rely as heavily as possible upon the infrastructure currently under design by The Climate Registry (TCR). The TCR is a nonprofit corporation that is a collaborative effort between U.S. states, Canadian provinces and Mexican states to establish a common infrastructure for measuring and reporting GHG emissions. All of the WCI partners are members of the governing board of the TCR. The objective of the TCR is to provide a common set of tools for the measurement and reporting of GHG emissions that can support a broad range of state or provincial policies.

TCR's mission includes not only the establishment and operation of a voluntary GHG emissions registry, but also providing support for mandatory GHG reporting programs that may differ from the voluntary registry. In the first phase of its development, the TCR is designing a voluntary entity wide GHG reporting program. This program can be conceptualized of as consisting of three major components: 1) entity reporting specifications, 2) quantification methodologies and 3) reporting services and systems. The reporting specifications dictate all parameters specific to the TCR voluntary reporting program--what must be reported, how an entity is defined for reporting purposes, the sources and gases it must report, the frequency of reporting and verification, etc. The quantification methodologies dictate how emissions from specific sources are measured or calculated. Finally, the TCR’s services and systems will provide assistance to reporters, support verification, and collect, store and make data available to the public. In its second phase of development, the TCR will develop systems for the support of reporting mandated by its Partner jurisdictions and regional organizations of which the Partners are members.

A WCI reporting system could rely heavily on the TCR's quantification methodologies and its services and systems (components 2 and 3 listed above). Doing so should reduce the costs of implementation for partners, ease the reporting burden on regulated entities, and ensure the basic consistency both between data collected within the WCI region and data collected in other regions that also rely on the TCR. However, the WCI will necessarily need to develop its own reporting specifications (component 1 listed above), consistent with the scope of the sources and gases it regulates and other program parameters. The WCI reporting specifications will necessarily differ from the reporting specifications of TCR's voluntary registry. In the Appendix, Figure 1 and Table 1 illustrate how the WCI could rely on the TCR to provide major components of its reporting system.

2. Recommendations

Beyond the WCI's intention to rely on TCR infrastructure to the maximum extent possible, the January 2008 Major Options paper identified several issues crucial in the design and implementation of a reporting system. For most of these, two alternative approaches were offered for stakeholder comment. This paper presents, for each of these issues, the alternatives presented in the Major Options paper, the WCI recommendation, a discussion of stakeholder comments, and other considerations taken into account by WCI in making its recommendations.

Data reporting is essentially a support or enabling function to serve the other components of the WCI program. Final decisions on the WCI reporting system will therefore necessarily depend on the final decisions regarding scope, electricity, allocations, and offsets.

Breadth/Scope of Reporting

The alternatives presented in the Reporting Major Options paper were:

a. Should reporting be required only for sectors/sources included within the cap?
b. Or, should reporting be required for sectors/sources not included in the cap-and-trade program (e.g., ones that are likely to be phased in over time)?

Stakeholder Comments: Commenters mostly favored Option (b), allowing for reporting of sources and sectors not included in the cap-and-trade program. Commenters noted that this option allows for more accurate accounting across all sectors, provides a better basis for allocations, and provides for more comprehensive public information. Some commenters favoring this option urged that a reasonable threshold for reporting be set to relieve burdens for small operations. One commenter favoring Option (a) suggested that non-capped sources could be eligible for offsets.

WCI Recommendation: ***Include capped sectors in reporting and certain non-capped sectors that may be phased in later (will have to determine which ones, and lower thresholds may apply).***

WCI Considerations: WCI recommends Option (b), with some rewording for greater clarity. In particular, rewording was intended to indicate that reporting may be required not only for sources in some sectors outside the cap, but also for some sources that are within a capped sector but below the threshold for the cap-and-trade program. WCI Partners believe that the advantages of this option greatly outweigh the disadvantages. The Draft Program Scope Recommendations paper (March 3, 2008) identifies several conditions that warrant the consideration of phasing of sectors/sources into the cap-and-trade program, including the need to obtain emissions data for sources under consideration for future inclusion. Uniform mandatory reporting will be needed to obtain such data. WCI is also considering whether emissions reporting from additional sources/sectors might be needed in the future for such purposes as improving regional GHG emissions inventories, evaluating the effectiveness of emissions reduction strategies that are complementary to the cap-and-trade system, and determining whether there is shifting of emissions to sub-threshold sources. WCI's first priority is establishment of reporting for sources/sectors under the cap and for those under consideration for coming under the cap.

Initiation of Reporting

The alternatives presented in the Reporting Major Options paper were:

a. Should mandatory reporting begin before cap and trade commences?
b. Or should mandatory reporting begin only with the start of the cap's first compliance period?

Stakeholder Comments: Commenters overwhelming favored Option (a), beginning mandatory reporting before cap-and-trade commences. Several commenters pointed to the need for accurate data as a basis for allocations, citing the EU experience in which an excess of allocations was distributed. Commenters also noted that preliminary reporting data could be useful in setting the threshold for capped sources. Others suggested that a period of reporting prior to setting the cap and trading would allow for a 'shake-out' period to ensure the proper functioning of the system, and one commenter suggested that a period of voluntary reporting prior to cap-and-trade could serve as a training period.

WCI Recommendation: ***Begin reporting before cap-and-trade commences. Strive to avoid reporting-related delays to the start of the cap-and-trade program.***

WCI Considerations: WCI recommends Option (a), with the addition of language to clarify that initiation of cap-and-trade should not be delayed until all sources and sectors can be included in the reporting program. WCI recognizes the lesson learned from the EU program, which is that accurate emissions data are necessary for setting allocation levels. The electricity generation sector and possibly other sources may have sufficiently high-quality emissions data to support their early inclusion in the cap-and-trade program, while inclusion of other sectors might be delayed pending collection of high quality emissions data. Pending final decisions on scope, point of regulation for the electricity sector, and emissions quantification issues, WCI reporting should begin as soon as possible not only for sources and sectors initially included in the cap-and-trade program, but also for others that might potentially be included later.

Coordination Among Partner Jurisdictions on Reporting

The alternatives presented in the Reporting Major Options paper were:

a. Should WCI develop a single WCI reporting rule that stipulates all reporting specifications?
b. Or should individual WCI jurisdictions have loosely coordinated rules possessing common core elements? If so, what aspects should the common core elements cover or include?

Stakeholder Comments: Commenters overwhelmingly recommended Option (a), the development of a single reporting rule for WCI (i.e., a model rule to be adopted by each jurisdiction). These commenters pointed to the advantages of consistency in providing administrative effectiveness and cost efficiency. They said that lack of consistency would increase gaming of the system, lead to errors in reporting, and make reporting and verification more costly for reporters. Commenters favoring Option (b) cited the advantages of continuity with existing state/provincial reporting programs, and noted that this option would likely face fewer legal and technical challenges. One commenter favored a hybrid system, with a single uniform rule but allowing Partners to supplement this core with additional reporting they thought useful.

WCI Recommendation: ***Develop essential requirements for a model WCI reporting rule by the end of 2008. Incorporate consideration for jurisdictions that already have reporting rules adopted or in process.***

WCI Considerations: WCI agrees with stakeholders regarding the value of uniformity and consistency in reporting, and recommends Option (a). Wording was slightly changed ("essential" rather than "minimum") to avoid any implication that the rule should not be comprehensive and specific. WCI also recognizes that several Partner jurisdictions have already adopted or are in the process of adopting their own reporting rules. Consequently, development of the model WCI reporting rule should not be *de novo*, but should take into account existing reporting rules, seek to retain common elements where possible, and minimize disruption of existing programs where possible. Inclusion of 'bridge' and 'glide path' provisions could provide for a smooth transition from disparate jurisdictional rules to eventual harmonization. The model rule should also allow for some flexibility in reporting, particularly for sources not in the cap or under consideration for inclusion in the cap, and could allow jurisdictions to go beyond the essential reporting requirements. Higher-tier quantification methods are likely to be required for sources under the cap or under consideration for inclusion in the cap. Stakeholders should be involved in development of the model rule.

Data Management and TCR Interaction

The alternatives presented in the Reporting Major Options paper were:

a. Should WCI require that all capped sources report directly to and verify through the TCR?
b. Or should sources report to and verify at the level of the individual jurisdiction (with data then uploaded to the TCR or otherwise shared centrally)

Stakeholder Comments: Commenters were divided on this question, and several recommended neither of the options presented. Commenters favoring Option (a) cited the advantage of simplified reporting for companies with facilities in multiple WCI jurisdictions. Commenters favoring Option (b) pointed to the advantages of coupling greenhouse gas reporting with other pollutant discharge reporting which is made directly to the state or provincial jurisdictions. Some commenters noted that Partners might face legal issues if they were to require reporting directly to an entity other than the state or province. Some commenters suggested a hybrid system where the reporter had the option of reporting to the state/province or to TCR. Some commenters recommended that TCR not be used at all, on the grounds that reporting to TCR would trigger a requirement to report all North American emissions (which is incorrect, as explained below).

WCI Recommendation: ***Sources will report either (a) directly to jurisdictions (which would then upload the data to TCR's central repository), or (b) through the TCR's program framework (which would then download the data to the necessary jurisdiction(s)).***

WCI Considerations: WCI recommends a hybrid approach, in which individual jurisdictions would have the option of requiring reporting directly to TCR or requiring reporting to the jurisdiction for later upload to TCR. Verification issues are addressed below, so the option language referring to verification was removed. Some Partners believe that direct reporting to TCR will be sufficient for their mandatory reporting, while other Partners believe they will face legal difficulties in requiring reporting to an outside entity, even one such as TCR of which the Partner is a member. Some Partners believe it is essential that they get the 'first touch' of the data. WCI notes that Partners will continue to evaluate TCR support of mandatory reporting to determine that it is the best value for the expense. WCI would particularly emphasize that use of TCR to support mandatory reporting would <u>not</u> thereby require sources to report all North American emissions. Although WCI's design of its mandatory reporting program might draw upon some elements of TCR's reporting requirements, WCI would not cede authority over reporting requirements to those in TCR's General Reporting Protocol for Voluntary Reporting (GRP), nor will the GRP supersede WCI reporting requirements. WCI does intend to rely on TCR's quantification methodologies and reporting tools and database(s). WCI will also seek to minimize the imposition of additional burdens on sources that voluntarily report their entity-wide North American emissions to TCR.

Verification

The alternatives presented in the Reporting Major Options paper were:

a. Should WCI require third party verification?
b. Or should WCI allow multiple approaches to ensuring data quality (other than third party verification)?

Stakeholder Comments: A majority of commenters favored Option (b), allowing multiple approaches to ensuring data quality. Many who expressed this view cited concerns over the potential costs of third party verification. Others, particularly in the electricity generation sector, thought that third party verification would not be needed for emissions measured by continuous emissions monitors and/or other federally approved methods subject to existing compliance monitoring. Commenters favoring third party verification (i.e., Option (a)) cited the need for consistency and credibility of emissions data, especially in a program where emissions relate directly to financial obligations and benefits.

WCI Recommendation: ***WCI will establish essential quality assurance elements for reported data that will be consistent across jurisdictions. Each jurisdiction will have an oversight mechanism to ensure compliance with the reporting requirements. As part of this mechanism, each jurisdiction will establish procedures to ensure that the quality assurance elements are met, which could include requiring 3rd party verification, rigorous compliance audits or other appropriate approaches.***

WCI Considerations: WCI's recommendation is similar to Option (b), but is substantially modified to ensure that consistent standards of data quality are maintained across jurisdictions. WCI recognizes stakeholder concerns regarding the costs and burdens of third party verification. WCI also recognizes the advantages of combining greenhouse gas reporting with existing air pollutant reporting, particularly for the many sources operating in only a single jurisdiction. Partners also believe that they, rather than a third party, should ultimately be responsible for accuracy of the data. Some WCI Partners may wish to delegate or contract out verification activities, while others may want to perform this function themselves. To allow this flexibility while at the same time ensuring consistency, WCI will establish uniform quality assurance elements required for all jurisdictions. Depending on the verification approach used by a jurisdiction, there may be fees/costs associated with verification.

Administrative Costs & Fees

The alternatives presented in the Reporting Major Options paper were:
a. Should states and provinces mandate that fees go directly to TCR and TCR administers the reporting database?
b. Or should states and provinces collect fees and contract with TCR to administer the reporting database?

Stakeholder Comments: Most commenters choosing either option preferred Option (a), where fees would go directly to TCR. Those favoring Option (a) thought this would avoid administrative complexity. One commenter favoring Option (a) noted that implementation might require enabling legislation, and suggested that Option (b) could be used in the interim. Several commenters did not choose either of the options presented, but recommended that fees should be paid to the entity where data are reported, whether TCR or the WCI partner jurisdiction. Several commenters said that fees should only be used to support the costs of the program and should not be diverted to state/provincial general funds. State/provincial jurisdictions were also asked to exercise oversight of TCR to ensure that fees were reasonable.

WCI Recommendation: ***Jurisdictions will collect fees from sources reporting directly to them and contract with TCR to administer the program. Jurisdictions may also accept data directly from TCR if they choose to do so; entities that report through TCR may have to pay an additional fee if one is required by the jurisdiction(s).***

WCI Considerations: WCI recommends a modified hybrid approach, with fees going to the TCR or the Partner jurisdiction depending on which entity is the direct recipient of data reported from the source. In addition, some Partner jurisdictions may want to charge a registration or other fee to sources reporting directly to TCR. Other Partner jurisdictions may not wish to charge a fee at all, but to cover fees themselves for reporters. Although WCI would like to have complete uniformity regarding fee payments, some jurisdictions may have legal issues in requiring the payment of fees to an entity other than the jurisdiction itself. With agreement of their jurisdiction, sources voluntarily reporting their entity-wide North American emissions to TCR should not have any additional fees imposed, unless an additional fee is required by a Partner jurisdiction.

Mandatory Federal Greenhouse Gas Reporting

The question presented in the Major Options paper concerned how WCI states/provinces and The Climate Registry should incorporate and interface with the new Congressional mandate for US EPA to develop an economy-wide GHG reporting rule and new Canadian Federal GHG reporting requirements in designing and implementing the WCI GHG reporting program?

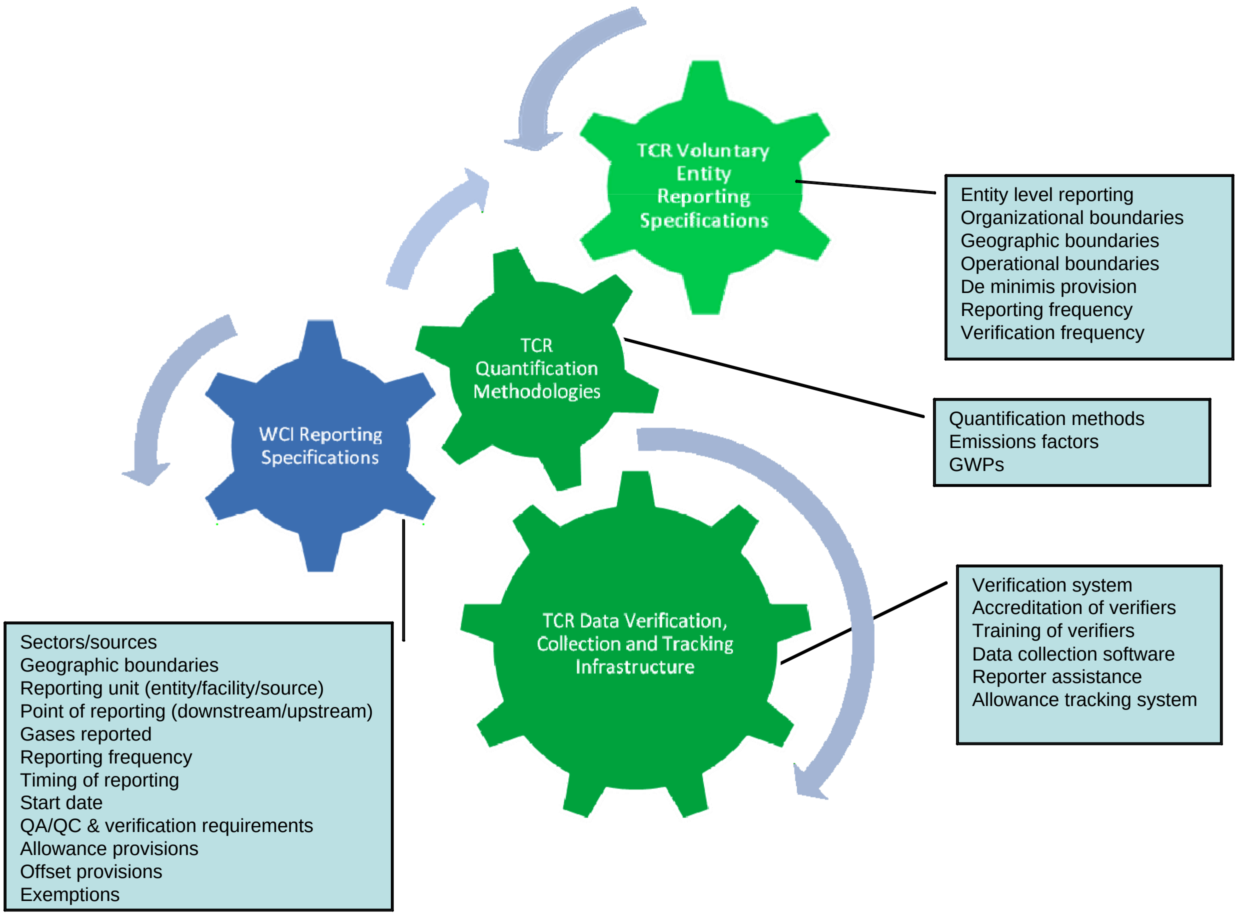
Stakeholder Comments: Commenters overwhelmingly called for consistency and single (i.e., one-time) reporting. Commenters varied in their assumptions or preferences for priority of federal versus WCI reporting. Some called for WCI to follow development of the US federal program and strive for consistency with it, while others said that WCI and TCR should seek to influence and guide development of the US federal program. Several commenters urged that WCI strive for consistency with the Canadian federal program, which has already established some GHG reporting requirements.

WCI Recommendation: ***Get involved in federal GHG reporting program development in the U.S. and Canada to ensure that federal reporting programs are harmonized with the jurisdictions' interests to the greatest extent possible.***

WCI Considerations: WCI strongly agrees with stakeholders on the advantages of a single, unified reporting system. Since the US federal reporting system is in the early stages of development, there is considerable opportunity for WCI to influence the development of that system. WCI will seek a dialogue with US EPA officials involved in developing their program. Other regional programs (RGGI, Midwest Greenhouse Gas Accord) should also be at the table. Given that a Canadian federal system exists and a new more detailed system is under development, WCI reporting should initially seek to minimize differences with the Canadian system to the extent possible, and later work cooperatively to harmonize the rules. Many issues need to be addressed, including preemption, so it is difficult to specify at this time precisely how harmonization among the different jurisdictions' reporting systems will occur.

Appendix: Figures and Tables

Figure 1. WCI Interaction with TCR Reporting System Components*



* The requirements for allowance and offset tracking and trading systems are being considered by other WCI Subcommittees, and decisions are still pending on whether these systems might be provided by TCR or other parties.

Acronyms & Definitions

AEO	Annual Energy Outlook (published by EIA)
ARB	California Air Resources Board
BPA	Bonneville Power Administration
Btu	British Thermal Units
CAC	Criteria Air Contaminants (SOx, NOx, PM, etc.)
CFL	Compact Fluorescent Light bulb
CHP	Combined Heat and Power
CO_2e	Carbon Dioxide equivalent
GDP	Gross Domestic Product
GO	Gross Output
GWP	Global Warming Potential
DG	Distributed Generation
EIA	Energy Information Administration
EPACT	Energy Policy Act of 2005
ESCO	Energy Service Company
GHG	Greenhouse Gas
IECC	International Energy Conservation Code
IGCC	Integrated Gasification Combined Cycle
kW	Kilowatt
kWh	Kilowatt-hour
Mt	Mega tonne
MW	Megawatt
MWe	Megawatt electric
MTCE	Megatonnes Carbon Equivalent (also as Mt CO_2e)
NOx	Nitrogen Oxides
OGCC	Oil/Gas Combined Cycle Turbine
OGCT	Oil/Gas Combustion Turbine
OGST	Oil/Gas Steam Turbine
PC	Pulverized Coal
REMI	Regional Economic Models, Inc.
RECS	Renewable Energy Certificates
Rest of US	Balance of systems in US
SOx	Sulphur Oxides (including sulphur dioxide)
USEPA	United States Environmental Protection Agency
W	Watt
WCI	Western Climate Initiative

1 Background and Project Scope

The Western Climate Initiative (WCI) has retained ICF International and its partner Systematic Solutions Inc., to assist in modeling a cap-and-trade system for the western US and Canada. The Scope of Work for the modeling is posted on the WCI website.[1] The WCI envisions a trading program that may ultimately link with other similarly rigorous programs.

The ICF Team has offered a suite of models that represent the state-of-the-art to support the WCI in this plan; starting with ENERGY 2020. This report outlines the assumptions and data inputs used in developing the Reference Case which will be used as a reference point and a base for evaluating proposed policy changes.

This report is organized as follows. Section 2 describes the analytic approach used by ENERGY 2020 and the characteristics of the model. Section 3 describes the model inputs. A more detailed explanation of the ENERGY 2020 model is included as Appendix A.

2 Analytic Approach

This project uses ENERGY 2020 to model the likely business-as-usual outlook and the impact of potential GHG reduction policies for the states and province partners in the WCI[2] as well as surrounding states and provinces.

ENERGY 2020 is an integrated multi-region energy model that provides complete and detailed, all-fuel demand and supply sector simulations. The model can be used in regulated as well as deregulated and transitioning environments. Greenhouse Gas (GHG) and Criteria Air Contaminant (CAC) pollution emissions and costs, including allowances and trading, are endogenously determined, thereby allowing assessment of environmental risk and co-benefit impacts.

The basic implementation of ENERGY 2020 for North America contains a user-defined level of aggregation down to the 10 provincial and 50 state (and sub-

[1] See http://www.westernclimateinitiative.org/ewebeditpro/items/O104F16124.pdf

[2] Arizona, California, Montana, New Mexico, Oregon, Utah, Washington, British Columbia and Manitoba.

state) level. ENERGY 2020 contains historical information on all electric generating units in the US and Canada (data for Mexico can be incorporated as needed). ENERGY 2020 is parameterized with local data for each region/state/province as well as all the associated energy suppliers it simulates. Thus, it captures the unique characteristics (physical, institutional and cultural) that affect how people make choices and use energy. Collections of state and provincial models are currently validated from 1986 to the latest quarterly numbers.[3]

ENERGY 2020 can be linked to a detailed macroeconomic model to determine the economic impacts of energy/environmental policy and the energy and environmental impacts of national economic policy. For US regional and state level analyses, the REMI macroeconomic model is regularly linked to ENERGY 2020.[4] The Informetrica macroeconomic model is linked to ENERGY 2020 for Canadian national and provincial efforts.[5] The REMI and Informetrica macroeconomic models include inter-state/provincial, US and world trade flows, price and investment dynamics, and simulate the real-time impact of energy and environmental concerns on the economy and vice versa.

The structure of the model is well tested and has been used to simulate not only US and Canadian energy and environmental dynamics, but also those of several countries in South America, Western, Central, and Eastern Europe. These efforts include strategic and tactical analyses for both planning and energy industry restructuring/deregulation. In the 1990's, the US EPA made ENERGY 2020 available to interested states to analyze emissions, energy, and economic impacts of state-level climate change initiatives Further, the model has been used successfully for deregulation analyses in all the US states and Canadian provinces. Many US and Canadian energy suppliers use the model for the analysis of combined electricity and gas deregulation dynamics.[6]

The default model simulates demand by three residential categories (single family, multi-family, and agriculture/rural), over 40 NAICS commercial and industrial categories, and three transportation services (passenger, freight, and off-road). There are approximately six end-uses per category and six

[3] Energy supplier data comes from FERC and US DOE for the US and Statistics Canada. US and Canadian fuel and demand data come from the US Department of Energy and Natural Resources Canada, respectively. US and Canadian pollution data come from US EPA and Environment Canada, respectively.

[4] Regional Economic Models, Inc. www.remi.com

[5] Informetrica Limited www.informetrica.ca

[6] ENERGY 2020 is the only model known to have simulated and predicted the dynamics that occurred in the UK electric deregulation. These include gaming, market consolidation and re-regulation dynamics.

technology/mode families per end-use.[7] Currently the technology families correspond to six fuels groups (oil, gas, coal, electric, solar and biomass) and 30 detailed fuel products. The transportation sector contain 45 modes including various types of automobile, truck, off-road, bus, train, plane, marine and alternative-fuel vehicles. More end-uses, technologies, and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical, locale-specific data. The load duration curves are dynamically built up from the individual end-uses to capture changing conditions under consumer choice and combined gas/electric programs.

Each energy demand sector includes cogeneration, self-generation, and distributed generation simulation, including mobile-generation, micro-turbines, and fuel-cells. Fuel-switching responses are rigorously determined. The technology families (which can be split, as an option, to portray specific technology dynamics) are aggregates that, within the model, change building shell, economic-process and device efficiency and capital costs as price or other information that the decision makers see, change. ENERGY 2020 utilizes the historical and forecast data developed for each technology family to parameterize and disaggregate the model.

The supply portion of the model includes endogenous detailed electric supply simulation of capacity expansion/construction, rates/prices, load shape variation due to weather, and changes in regulation.[8] The model dispatches plants according to the specified rules whether they are optimal or heuristic and simulates transmission constraints when determining dispatch.[9] A sophisticated dispatch routine selects critical hours along seasonal load duration curves as a way to provide a quick but accurate determination of system generation. Peak and base hydro usage is explicitly modeled to capture hydro-plant impacts on the electric system.

[7] End-uses include Process Heat, Space Heating, Water Heating, Other Substitutable, Refrigeration, Lighting, Air Conditioning, Motors, and Other Non-Substitutable (Miscellaneous). Detailed modes include: small auto, large auto, light truck, medium-weight truck, heavy-weight truck, bus, freight train, commuter train, airplane, and marine. Each mode type can be characterized by gasoline, diesel, electric, ethanol, NG, propane, fuel-cell, or hybrid vehicles.

[8] ENERGY 2020 includes a complete, but aggregate representation of the electric transmission system. Electric transmission data is provided by FERC, the Department of Energy, and the National Electric Reliability Council. The dispatch technologies in the basic model include: Oil/Gas Combustion turbine, Oil/Gas Combined Cycle, Oil/Gas Combined Cycle with CCS, Oil/Gas Steam Turbine, Coal Steam Turbine, Advanced Coal, Coal with CCS, Nuclear, Baseload Hydro, Peaking Hydro, Small Hydro, Wind, Solar, Wave, Geothermal, Fuel-cells, Flow-Battery Storage, Pumped Hydro, Biomass, Landfill Gas, Trash, and Biogas.

[9] A 110 node transmission system is used in the default model, but a full AC load-flow bus representation model has also been interfaced with ENERGY 2020.

ENERGY 2020 supply sectors include electricity, oil, natural gas, refined petroleum products, ethanol, land-fill gas, and coal supply. Energy used in primary production and emissions associated with primary production and its distribution is included in the model. The supply sectors included in a particular implementation of ENERGY 2020 will depend on the characteristics of the area being simulated and the problem being addressed. If the full supply sector is not needed, then a simplified simulation determines delivered-product prices.

The ENERGY 2020 model includes pollution accounting for both combustion (by fuel, end-use, and sector) and non-combustion, and non-energy (by economic activity) for SO_2, NO_2, N_2O, CO, CO_2, CH_4, PM_T, $PM_{2.5}$, PM_5, PM_{10}, VOC, CF_4, C_2F_6, SF_6, and HFC at the state and provincial level by economic sector. Other (gaseous, liquid, and solid) pollutants can be added as desired. Pollution does not need to be determined directly by coefficients but can recognize the accumulation of capital investments that result in pollution emission with usage. National and international allowance trading is also included. Plant dispatch can consider emission restrictions.

The model captures the feedback among energy consumers, energy suppliers, and the economy using Qualitative Choice Theory and co-integration.[10] For example, a change in price affects demand that then affects future supply and price. Increased economic activity increases demand; increased demand increases the investment in new supplies. The new investment affects the economy and energy prices. The energy prices also affect the economy.

Finally, the system includes confidence and validity testing software that places uncertainty bounds on simulation results, quantifies confidence intervals, and ranks the contributions to uncertainty in future conditions. This feature can be used to limit data efforts to information most important to the analysis.

In order to assess the potential impacts of proposed policy options, a b*usiness-as-usual* scenario is developed as a point of reference. This "Reference Case" represents a scenario that is viewed as a reasonable expectation of how the economy, energy use and emissions might develop over time.

Part of the nature of developing a Reference Case is the need to address inherently uncertain issues that can have significant impacts on future energy use and emissions. No forecast is going to be "right" or "accurate" in that no one

[10] The model has used the work of Daniel McFadden and Clive Granger since its inception in the late 1970's.

can tell today how some of the key underlying issues may develop. Given the level of uncertainty involved in any projection of a possible future, caution should be used in applying a high level of precision to the modeling results. Understanding the Reference Case, however, is useful for providing an underlying structure against which to model proposed policies, and in determining directionality and cause and effect.

Numerous assumptions are required to perform an analysis of this type across a range of topic areas, including economic developments, fuel and electric markets, and regulatory structures. Projected outcomes are only as good as the input assumptions upon which they are based, with more rigorous assumptions leading to a more rigorous analysis. The inputs and assumptions described in this document were developed to provide an initial representation of the activities and structures underlying energy use and greenhouse gas emissions in the WCI region. These inputs and assumptions will be updated as the project progresses.

3 Reference Case Inputs

ENERGY 2020 derives energy demands, such as the demand for electricity based on economic activity and device efficiency. The following sections provide a brief overview of the data inputs and assumptions as well as the sources of data used in the Reference Case.

As a multi-sector analytical tool, ENERGY 2020 requires data and assumptions covering a broad range of economic sectors and their interactions. In most cases, the necessary data – both historical and projected – is available from the federal government (EIA, EPA, etc.). In past analyses, ENERGY 2020 has relied heavily on these federal sources to populate and calibrate the model. In developing the model used for the WCI partners a considerable amount of state-specific information is being developed and will be used where possible.

The following sections provide an overview of the data and assumptions that will be required to perform the multi-sector analysis, and list the data sources that have been used to populate ENERGY 2020 to this point. It is expected that this data will change as the model is reviewed and evolves to incorporate more detailed data specific to the WCI region.

Data[11] inputs for ENERGY 2020 will be required in five areas:

1. Population and economic
2. Fuel prices
3. Energy use and consumption
4. Emissions and air regulations
5. Electricity generation capacity and operation

The sections below list the key data elements required in each of these areas, along with the sources that have been used to supply this data for other analyses. Appendix B lists a number of default data sources used by the model. The sections that follow provide a more specific description of the data used for this project including state-specific data used in place of national sources.

ENERGY2020 requires both historical data and projections to calibrate and generate forward-looking projections. Historical data will be required from a base year (1985) to the last historic year (2005). Projections for the period to be

[11] "Data" here refers to both historical data and assumptions and projections of future inputs.

modeled (e.g. through 2030) will be gathered where possible to provide points of comparison and check the reasonableness of the projection.

The implementation of ENERGY 2020 for the WCI project includes the geographic areas of Arizona, California, Montana, New Mexico, Oregon, Utah, Washington, British Columbia and Manitoba. Interactions between these states and provinces are modeled, particularly with respect to electricity generation. To ensure consistency the assumptions used within the WCI region are applied to other states to the extent possible.

3.1 *Population and Economic Data*

Demographic and economic data is required to generate demands for services. The historic data for the US states was obtained from the US Bureau of Economic Analysis (BEA). For the Canadian provinces, historic data is from Statistics Canada's CANSIM database while the forecast is provided by Informetrica. Default economic forecasts for US states are being developed.

The following data sources are currently being used in the model:

Description of Data/Input	Sources Used/Available
Total population, historical and growth over time	US Census Bureau Statistics Canada/Informetrica
Population by housing type (single-family, multi-family, etc.)	US Census Bureau Statistics Canada/Informetrica
Households by housing type (single-family, multi-family, etc.)	US Census Bureau Statistics Canada/Informetrica
Personal income	US Bureau of Economic Analysis EDRAM for California Statistics Canada/Informetrica
Employment by sector	US Bureau of Economic Analysis Statistics Canada/Informetrica

Summary information for each WCI partner will be provided for review as the project proceeds.

3.2 *Price data*

Energy prices can play a significant role in end user decisions on equipment, capital and operating decisions. Fuel costs can be critical in determining the costs of electric dispatch, as well as input costs of some industrial processes and home heating. ENERGY2020 calculates future electric prices based in part on these fuel costs.

Energy prices are largely determined by international markets, although domestic demand, such as electric sector demand for natural gas can influence prices. As a result, fuel prices are treated by the model as an exogenous input.

The default energy price forecast for the US is based on the Energy Information Administration's Annual Energy Outlook Reference Case forecast for 2007 to 2030. For Canada, the National Energy Board's price forecast is used.

Biomass prices in the model are based on research completed for a previous project, shown in the table below. Unlike other fuels, biomass prices are significantly influenced by local cost and supply issues.

Biomass Cost *(per MMBtu in 2006$)*	
Residential	$11.53
Commercial	$10.09
Industrial	$10.06

- Power prices are calculated endogenously by the model based on generation costs and dispatch. While, the model calculates retail electricity prices, actual consumer prices may differ as a result of political, regulatory or market influences. The model can be calibrated to actual prices, within reasonable parameters, for the historic period.
- Given the limited time available the project is not intended to model the different regulatory regimes among the partner jurisdictions to reflect actual retail prices delivered in each market. The intent of the modeling is rather to show relative changes in electricity prices as a result of the proposed policies.

3.3 *Historic Energy Consumption Data*

ENERGY 2020 models energy use at the end-use level within each economic sector based on the existing physical stock and the efficiency of that stock. The database of device efficiencies reflects both the average efficiency of energy use for current stocks and the efficiency/energy alternatives available to consumers at the margin. Technology and efficiency choices are modeled based on past experience with consumer choice rather than on a purely economic evaluation.

Historic energy use and consumption data used in the model is derived from the federal Energy Information Administration (EIA) State Energy Data (SEDS) database. Where state-specific data was available, this data was used to replace national data sources.

Default sectoral and end-use data as well as energy intensities are based on the Residential Energy Consumption Survey (RECS), Commercial Energy Consumption Survey (CECS) and Manufacturers Consumption Energy Survey (MECS).

Description of Data/Input	Sources Used/Available
Residential Data - Household income by housing type - No. of people per household - End-use consumption data, including fuels used for space and water heating, air conditioning, etc.	2001 EIA Residential Energy Consumption Survey (RECS), by Census Region and Division (2005 RECS in process) http://www.eia.doe.gov/emeu/recs/contents.html For Canada – NRCan OEE Database
Commercial Data - Floor area by sub-sector - End-use consumption data, including fuels used for space and water heating and energy intensities	2003 EIA Commercial Buildings Energy Consumption Survey (CBECS), by Census Region and Division (2007 CBECS underway) http://www.eia.doe.gov/emeu/cbecs/contents.html For Canada – NRCan OEE Database
Industrial/Manufacturing Data - Energy use by fuel for each sub-sector and end-use	2002 EIA Manufacturing Energy Consumption Survey (MECS), by Census Region (2006 MECS underway) http://www.eia.doe.gov/emeu/mecs/contents.html For Canada – NRCan OEE Database
State/Provincial Energy Data: - Energy consumption and expenditures by sector and energy source	2004 EIA State Energy Data System (SEDS) http://www.eia.doe.gov/emeu/states/_seds.html For Canada – NRCan OEE Database and CANSIM

Household data for the WCI region was gathered from the US Census Bureau supplemented by data from the EIA's State data on Prices and Expenditures.

3.4 *Historic Emission Data*

3.4.1 Emissions and Air Regulations

Historic GHG emissions are based on the Canadian national inventory published by Environment Canada and the US GHG emissions inventory as published by the EPA[12]. More specific state and provincial inventories will be sought from WCI partners. ENERGY 2020 is calibrated using historic information on all of the major greenhouse gas emissions including:

- Carbon dioxide (CO_2),
- Nitrous oxide (N_2O),
- Methane (CH_4),
- Sulphur hexafluoride (SF_6),
- Hydrofluorocarbons (HFCs) and
- Perfluorocarbons (PFCs).

GHG emissions are presented in CO_2 equivalent (CO_2e) terms. The global warming potentials used to convert the different greenhouse gas emissions into CO_2e terms are provided in Appendix I.

Input	Sources Used/Available
Emissions by sector, end-use, fuel and GHG	US EPA http://www.epa.gov/climatechange/emissions/usinventoryreport.html Environment Canada http://www.ec.gc.ca/pdb/ghg/inventory_e.cfm

3.4.2 Emission Factors

Emission factors for most fuels are based on values used by ICF in developing national and state inventories. For the transportation sector however, the emission factors for CH_4 and N_20 pollutants were adapted from the Canadian National Inventory Report.[13] ENERGY 2020 calculates GHG emissions at the point of combustion for most fuels. Upstream emissions from extraction and processing are captured as part of those respective economic sectors.

[12] EPA website: http://www.epa.gov/climatechange/emissions/usinventoryreport.html

[13] Environment Canada. National Inventory Report 1990-2005, Greenhouse Gas Sources and Sinks in Canada, April 2007. (Annex 12 Emission Factors)

Emissions associated with the use of biomass as a fuel are deemed to be biogenic and therefore not contribute to global warming. As a result, the model assumes no GHG emissions are created from the use of biomass.

Emissions from ethanol and other biofuels represent an exception from a modeling perspective. In order to capture the emissions associated with their production and distribution, the model applies full cycle emission factors for these fuels. While the combustion of ethanol and biodiesel are not deemed to result in any anthropogenic emissions, the model uses an emission factor to recognize upstream emissions.

The full-cycle emission factor used in the model for each biofuels type are shown in the table below[14]:

Corn Ethanol	76 gCO2-e / MJ
Cellulosic Ethanol	14 gCO2-e / MJ
Biodiesel	30 gCO2-e / MJ

When these fuels are used in combination with other fuels, for example in a mix of gasoline and ethanol, the emissions associated with gasoline combustion are reported as part of total gasoline-related emissions.

3.5 *Electricity Sector Data*

3.5.1 Generation Data

The electricity sector differs from other sectors in the extent to which emissions associated with power use within the state may result from emissions outside the WCI as power is imported from or exported to other areas.

ENERGY 2020 contains information on every generating unit in the state or province, as well as in neighboring jurisdictions which may supply power to the state. The model tracks and uses the following information for each generating unit:

[14] Alexander Farrell, UC Berkeley and Daniel Sperling, UC Davis, A Low-Carbon Fuel Standard for California Part 1: Technical Analysis May 29, 2007 Table 2-3 http://www.energy.ca.gov/low_carbon_fuel_standard/UC-1000-2007-002-PT1.PDF

- Historic Peak Capacity (MW);
- Historic generation levels (GWh);
- Type of fuel used;
- Heat rate;
- Historic annual fuel use (PJ);
- Emissions by pollutant type;
- O&M costs;
- Capacity factors;
- Emission rates;
- Outage rates;
- State or Province;
- Physical location (latitude and longitude);
- Ownership information;
- Plant type (Hydraulic, Coal, Combined Cycle Turbine, etc.)

The data on existing and committed generating units in the US was obtained from the National Electric Energy Data System (NEEDS) 2006 database and reconciled with a list of plants from BPA. The database of plants in Canada was developed based on the Canadian IPM module, modified and updated based on information from Statistics Canada, Environment Canada and the National Energy Board.

3.5.2 Electricity Generation Capacity and Operation Data

ENERGY 2020 will be populated with data describing the type, operation and performance of every generating unit in the western US and the two Canadian provinces. In order to improve model performance, some smaller units with common characteristics may be combined (i.e., wind units at the same site, or small hydraulic units). In addition to plant-level data, the table below includes other inputs necessary to describe the electric system, including transmission capability.

Input	Sources Used/Available
Plant type	FERC reports for US Statistics Canada for Canada
Plant capacity	FERC reports for US Statistics Canada for Canada
Plant historical generation	FERC reports for US Statistics Canada for Canada Total generation output by plant type for California from CEC

Input	Sources Used/Available
Plant fuel type	FERC reports for US Statistics Canada for Canada
Plant Heat Rate	FERC reports for US Statistics Canada for Canada
Plant fuel consumption	FERC reports for US Statistics Canada for Canada
Plant emissions by pollutant	EPA or Environment Canada
Plant costs (operation and maintenance, variable and fixed)	FERC reports for US Statistics Canada for Canada
Plant historical capacity factor	FERC reports for US Statistics Canada for Canada
Plant availability (outages)	FERC reports for US Statistics Canada for Canada
Plant owner and location	FERC reports for US Statistics Canada for Canada
Planned capacity additions and retirements	California Public Utility Commission GHG Modeling process (E3)
Transmission Capability	NERC

This data has been compared to generation data provided as part of modeling for the California Public Utilities Commission.[15]

The resulting list of generating units was matched to emission data from the EPA in order to calculate emission rates. The resulting emission rates for the targeted GHG emissions were then reviewed for reasonableness based on plant type and capacity factors, etc.

Historic generation by plant type will be calibrated with historic generation data available from the EIA.

3.5.3 Transmission Structure and Dispatch

Power flows between neighboring US states are modeled within ENERGY 2020 based on existing transmission capabilities and interconnections as obtained from NERC reports. Appendix C describes the inter-regional transmission capabilities between model regions (or nodes) as well as the maximum capacity limit of each transmission path used in the model. Interconnection capacities

[15] www.ethree.com/cpuc_ghg_model.html

used in the model were based on the IPM Model 2006[16] updated to reflect changes in the region based on past work for past clients.

Generation is dispatched at the node level for a set of sample hours in each season. Each node is economically dispatched, selecting lowest cost generation first with the resulting clearing price determining the generation price for that node as described in Appendix A. As part of the calculation the model can utilize resources from a neighboring node within the constraints of the transfer capacity between nodes. The transfer of energy between nodes is subject to a 1% loss to represent additional transmission losses.

3.5.4 Planned Capacity Changes

As part of the modeling process, ENERGY 2020 builds new capacity endogenously as needed to meet capacity and reserve requirements. At any given time, however, plans may already be in place to build, re-furbish, upgrade or retire generation facilities. These plans must be incorporated into the model in order to reflect decisions and commitments that have already been made. Of necessity, some decisions had to be made on which planned projects and which scheduled plant retirements to incorporate in the model based on best judgment. As part of the process of developing the Reference Case, WCI partners will be asked to provide information on known new capacity commitments and planned retirements in their respective jurisdictions.

ENERGY 2020 can determine the need for new generation based on a pre-determined reserve requirement. Normally, this determination is based on the highest level of demand for power and the available capacity at the time of that peak. Some types of generation, such as wind or some types of hydro-electric generation however, may not be available at the time of the peak. For modeling purposes the model assumes that only 15% of installed wind capacity is available at the time of the peak.

[16] Table 3.5 of section 3 of the documentation for the EPA Base Case 2006 (v3.0) posted on the EPA website: http://epa.gov/airmarkets/progsregs/epa-ipm/index.html#docs

3.5.5 New Generation Characteristics

The costs and characteristics of new generation are based on information developed as part of the GHG modeling process for the California Public Utility Commission[17] and are shown in Appendix F.

3.5.6 Industrial Generation and Co-generation

ENERGY 2020 models both utility generation, which supplies the power grid, and industrial generation which supplies a particular end user. Industrial generation is defined as power generation that is within the industrial end user's facility and is not used to supply power to the grid. Industrial generation, as defined in ENERGY 2020, could also be referred to as self-generation or load displacement generation. Industrial generation may be supplied by any of the fuels listed below:

- Biomass
- Coal
- LPG
- Oil
- Solar
- Steam

Co-generation, or combined heat and power facilities, simultaneously generate electricity and supply a heat load. ENERGY 2020 recognizes that co-generation may occur either as industrial generation or as utility generation and may use any of a number of fuels.

- Within the power sector, these plants are treated as 'must run' units, meaning that they will always operate when available. Power from these units contributes to overall electricity supply. Heat from these units may be captured as part of a separate steam supply system, however, limited data is available regarding overall US steam demand.
- Within the industrial sector, co-generation capacity will run based on heating requirements. Heat produced from co-generation is used to meet industrial heat requirements based on a co-generation heat rate. Co-generated electricity is used to meet industrial power requirements, reducing net demand from the grid.

[17] www.ethree.com/cpuc_ghg_model.html.

Where the heat contribution of co-generation is significant, the preferred modeling approach is to include these units in the industrial sector.

The databases used to represent electricity generation often include all significant generators, including both utility and industrial boilers and generators. By contrast, reported electricity consumption information tends to be based on metered electricity sales, and as such are net of self generation. Total electricity consumption and generation will generally be slightly higher than reported electricity sales. It is therefore important in calibrating the model with historic electricity consumption that existing generation used as industrial or self-generation be appropriately identified.

3.6 *Transportation*

ENERGY 2020 models passenger, freight and off road transportation separately, based on different underlying drivers. Passenger and freight transportation are modeled by mode and vehicle type. Changes in transportation demand, in terms of passenger miles traveled and ton-miles of freight, are calibrated for the historic period.

The bulk of existing and forecast passenger transportation is attributable to personal vehicles. The model does not currently assume any changes in the CAFÉ Standard, however, this will be modified as the requirements of *Energy Independence and Security Act of 2007* are incorporated into the model (see section 4.8).

Off road transportation energy use is modeled in ENERGY 2020 based on drivers including Agriculture, Forestry and Construction activity.

3.7 *Built Environment*

Several of the jurisdictions involved in the WCI have had a long history of promoting energy efficiency and demand side management for electricity and natural gas energy use. As a result, average appliance and equipment efficiencies are expected to be higher than for the US and Canada as a whole. As part of Tasks 4 and 5 we will attempt to gather information on current levels of equipment efficiency and the state of the market for efficiency technologies. This information will then be used to adjust end-use data within the model to reflect current levels of efficiency and market saturations.

The Reference Case does not assume any increase in equipment or appliance efficiency other than the improvements due to the *Energy Independence and Security Act of 2007*, as noted in section 4.8.

3.8 *Programs/Policies Incorporated in Reference Case*

As this assumptions document is further refined and developed, a table listing the specific laws and regulations included in the Reference Case will be inserted here.

Of particular importance, the *Energy Independence and Security Act of 2007* was passed into law in early January 2008. The following assumptions will be used to model the Act in the Reference Case:

- Transportation: The current marginal vehicle efficiency for passenger cars and light trucks will be incrementally increased by a fixed percentage each year starting in 2011 to reach the mandated fleet efficiency in 2020.
- Renewable Fuels: The model will assume that each of the US states will continue to use the same relative volume of the renewable fuels produced nationally (as per the schedules outlined in the Act) as are currently consumed in the state.
- Residential Boilers and Furnace Fans: Savings estimates developed by the ACEEE for each state will be used to model this portion of the Act, using only the benefits realized by upgrades to the residential energy boilers, leaving out any energy benefits associated with reduced electricity consumption by furnace fans.
- Walk-In Coolers and Walk-In Freezers: Savings estimates developed by the ACEEE for each state will be used to model this portion of the Act.
- Electric Motor Efficiency Standards: The model will utilize the ACEEE savings projections, pro-rated to California's relative industrial electricity sales.
- External Power Supply Efficiency Standard: savings estimates developed by the ACEEE for each state will be used to model this portion of the Act.
- Energy Efficient Light Bulbs: Information will be collected on existing market shares for efficient lighting in the WCI region in order to estimate the impact of this aspect of the Act. The base assumptions are that

general service lighting accounts for about 90% of residential lighting, 10% of commercial lighting and 5% of industrial lighting.

- Metal Halide Lamp Fixtures: The model assumes that 15% of commercial lighting and 60% of industrial lighting now use metal halide fixtures. For new installations the model assumes that 80% of this market would use pulse start ballasts.

The model will also include regulations affecting the power sector which have been approved but have not yet come into effect. Such regulations may be significant to the extent that they influence dispatch decisions which in turn will affect CO_2 emissions.

A listing of future legislation/regulation changes to be included in the modeling is currently being compiled and will be provided in subsequent versions of this report.

Appendix A: The Energy 2020 Model

The Model – ENERGY 2020

ENERGY 2020 is an integrated multi-region, multi-sector energy analysis system that simulates the supply, price and demand for all fuels. It is a causal and descriptive model, which dynamically describes the behavior of both energy suppliers and consumers for all fuels and for all end-uses. It simulates the physical and economic flows of energy users and suppliers. It simulates how they make decisions and how those decisions causally translate to energy-use and emissions.

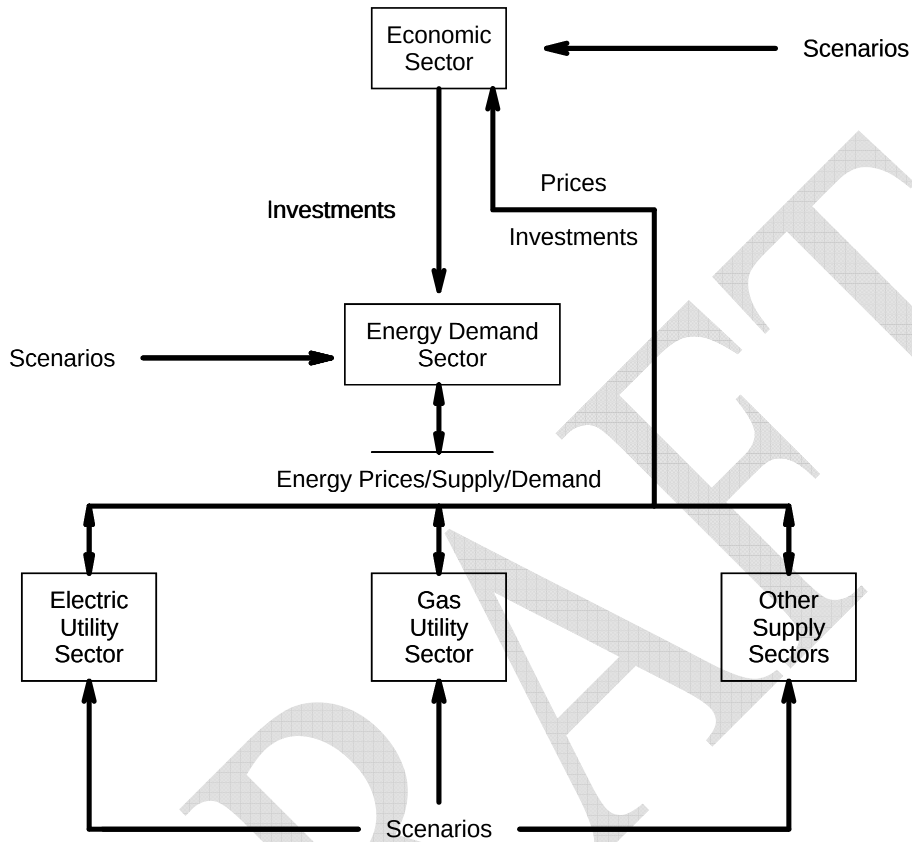
ENERGY 2020 is an outgrowth of the FOSSIL2/IDEAS model developed for the US Department of Energy (DOE) and used for all national energy policy since the Carter administration.[18] This early version of ENERGY 2020 was developed in 1978 at Dartmouth College for the DOE's Office of Policy Planning and Analysis.

Model Overview:

The basic structure of ENERGY 2020 is provided in Figure A-1. Energy Demand sector interacts with the Energy Supply sector to determine equilibrium levels of demand and energy prices. Energy Demand is driven by the Economy sector, which in turn provides inputs to the Economy sector in terms of investments in energy using equipment and processes and energy prices. The model has a simplified Economy sector to capture the linkages between the energy system and the macro-economy. However, the model is best run with full integration with a macroeconomic model such as REMI. Given the modular nature of ENERGY 2020, additional sectors or modules from other, non-ENERGY 2020 related, models (macroeconomic, supply such as oil, gas, renewables etc.) can be incorporated directly into the ENERGY 2020 framework.

[18] FOSSIL2 was the original version but was renamed to IDEAS a few years ago to reflect its evolutionary development since its original construction.

Figure A-1: ENERGY 2020 Overview



Energy Demand:

The demand sector of the model represents the geographic area by disaggregating the four economic sectors into subsectors based on energy services. As many or as few subsectors can be incorporated as required. Multiple technologies, multiple end-uses and multiple fuels are detailed. The level of detail that can be incorporated is of course subject to the data availability. The four economic sectors are:

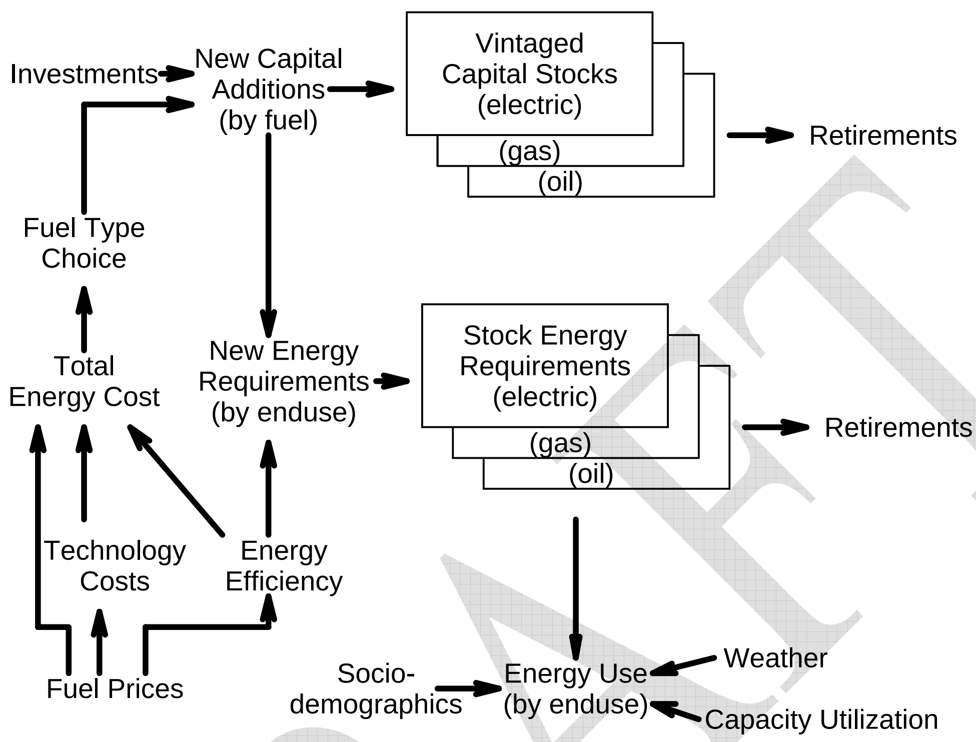
- Residential sector which includes three classes, single family, multifamily and rural/agricultural with 8 end-uses including space heating, water heating, lighting, cooling, refrigeration, other substitutable, and other non-substitutable.

- Commercial sector which is aggregated into one class and end-uses including space heating, water heating, cooling, lighting, other substitutable, other non-substitutable.
- Industrial sector which includes 10 (23 for US) 2-digit SIC categories and is further broken down into process heat, motors, lighting, miscellaneous as the end uses.
- Transportation sector which includes several modes of transportation including automobile, truck, bus, train, plane, marine and electric vehicles. Also, each of the residential, commercial and industrial sectors has separate transportation demands.

For each of the end-uses, up to six fuels are modeled, for example, the residential space heating has the choice of a gas, oil, coal, electric, solar and biomass space heating technologies. Added end-uses, technologies and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical locale-specific data. The load duration curves are dynamically built up from the individual end-uses to capture changing condition under consumer choice and combined gas/electric programs.

A few basic concepts are crucial to an understanding of how the model simulates the energy system. These concepts including, the capital stock driver, the modeling of energy efficiency through trade-off curves, the fuel market share calculation, utilization multipliers and the cogeneration module are discussed below in abbreviated form. Figure A-2 (Demand Overview) illustrates the demand sector interactions.

Figure A-2: Demand Overview



Energy Demand as a Function of Capital Stock:

The model assumes that energy demand is a consequence of using capital stock in the production of output. For example, the industrial sector produces goods in factories, which require energy for production; the commercial sector requires buildings to provide services; and the residential sector needs housing to provide sustained labor services. The occupants of these buildings require energy for heating, cooling, and electromechanical (appliance) uses.

The amount of energy used in any end-use is based on the concept of energy efficiencies. For example, the energy efficiency of a house along with the conversion efficiency of the furnace determines how much energy the house uses to provide the desired warmth. The energy efficiency of the house is called the capital stock energy or process efficiency. This efficiency is primarily technological (e.g. insulation levels) but can also be associated with control or life-style changes (e.g. less household energy use because both spouses work outside the home.) The furnace efficiency is called the device or thermal efficiency. Thermal efficiency is associated with air conditioning, electromotive devices, furnaces and appliances.

The model simulates investment in energy using capital (buildings and equipment) from installation to retirement through three age classes or vintages. This capital represents embodied energy requirements that will result in a specified energy demand as the capital is utilized, until it is retired or modified.

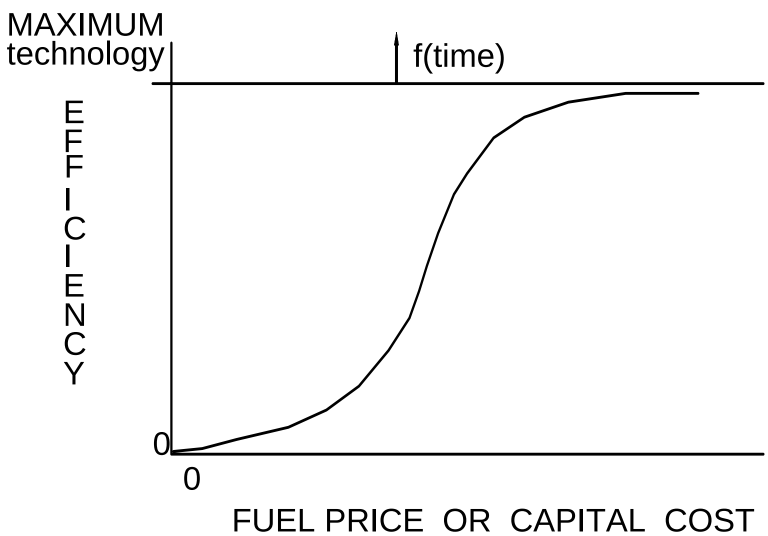
The size and efficiency of the capital stock, and hence energy demands, change over time as consumers make new investments and retire old equipment. Consumers determine which fuel and technology to use for new investments based on perceptions of cost and utility. Marginal trade-offs between changing fuel costs and efficiency determine the capital cost of the chosen technology. These trade-offs are dependent on perceived energy prices, capital costs, operating costs, risk, access to capital, regulations and other imperfect information.

The model formulates the energy demand equation causally. Rather than using price elasticities to determine how demand reacts to changes in price, the model explicitly identifies the multiple ways price changes influence the relative economics of alternative technologies and behaviors, which in turn determine consumers' demand. In this sense, price elasticities are outputs, not inputs, of the model. The model accurately recognizes that price responses vary over time, and depend upon factors such as the rate of investment, age and efficiency of the capital stock, and the relative prices of alternative technologies.

Device and Process Energy Efficiency:

The energy requirement embodied in the capital stock can be changed only by new investments, retirements, or by retrofitting. The efficiency with which the capital uses energy has a limit determined by technological or physical constraints. The trade-off between efficiency and other factors (such as capital costs) is depicted in Figure A-3 (Efficiency/Capital Cost Trade-Off). The efficiency of the new capital purchased depends on the consumer's perception of this trade-off. For example, as fuel prices increase, the efficiency consumers choose for a new furnace is increased despite higher capital costs. The amount of the increase in efficiency depends on the perceived price increase and its relevance to the consumer's cash flow.

Figure A-3: Efficiency/Capital Cost Trade-Off



The standard the model efficiency trade-off curves are called consumer-preference curves because they are estimated using cross-sectional (historical) data showing the decisions consumers made based on their perception of a choice's value. Many planners are now interested in measure-by-measure or least-cost curves which use engineering calculations and discount rates to show how consumers should respond to changing energy prices. Another analysis focuses on the technical/price differences in alternative technologies and the incentives needed to increase the market-share or market penetration of a specific technology. This perspective on the choice process uses market share curves. The model allows the user to select any of these three types of curves to represent the way consumers make their choices. Shared savings, rebate, subsidy programs, etc. can be tested using any of the curves.

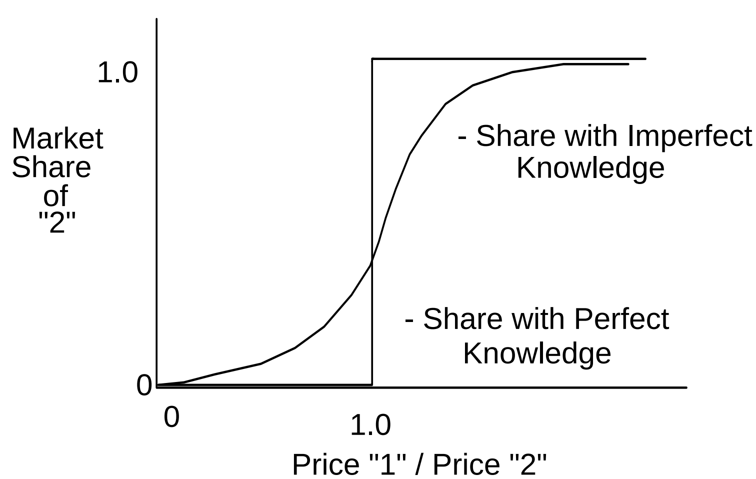
Cumulative investments determine the average "embodied" efficiency. The efficiency of new investments versus the average efficiency of existing equipment is one measure of the gap between realized and potential conservation savings.

The model uses saturation rates for devices to represent the amount of energy services necessary to produce a given level of output. Saturation rates may change over time to reflect changes in standard of living or technological improvements. For example, air conditioning has historically increased with rising disposable incomes. These rates can be specified exogenously or can be defined in relation to other variables within the model (such as disposable income).

The Market Share Calculation:

Not all investment funds are allocated to the least expensive energy option. Uncertainty, regional variations, and limited knowledge make the perceived price a distribution. The investments allocated to any technology are then proportional to the fraction of times one technology is perceived as less expensive (has a higher perceived value) than all others. This process is shown graphically in Figure A-4 (Market Share Dynamics).

Figure A-4: Market Share Dynamics



Short Term Budget Responses:

A short-term, temporary response to budget constraints is included in the model. Customers reduce usage of energy if they notice a significant increase in their energy bills. The customers' budgets are limited and energy use must be reduced to keep expenditures within those limits. These cutbacks are temporary behavioral reactions to changes in price, and will phase out as budgets adjust and efficiency improvements (true conservation) are implemented. This causes the initial response to changing prices to be more exaggerated than the long-term response, a phenomenon called "take-back" in studies of consumer behavior.

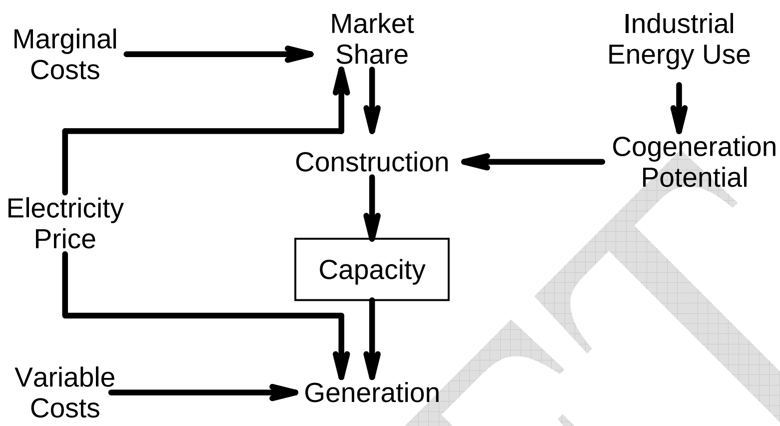
Accounting for Fungible Demand:

Some furnaces and processes can use multiple fuels. That is, they can switch almost instantaneously between, for example, gas and oil or coal and biomass as prices or the market dictates. Energy demand that is affected by this short-term fuel switching phenomena is called fungible demand. The model explicitly simulates this market share behavior.

Modeling Cogeneration:

Most energy users meet their electricity requirements through purchases from a utility. Some users (industrial and commercial) can, however, convert some of their own waste heat into usable electricity when economics warrant such action. Other users (residential and commercial) can purchase self-generation energy sources such as gas turbines, diesel-generators or fuel cells. Figure A-5 shows a simplified overview of the cogeneration structure.

Figure A-5: Cogeneration Concepts



In the model all energy used for heating is a candidate for cogeneration. The cost of cogeneration is the fixed capital cost of the investment plus the variable fuel costs (net of efficiency gains). This cogeneration cost is estimated for all technologies and compared to the price of electricity. The marginal market share for each cogeneration technology is based on this comparison.

Cogeneration is restricted to consumers who directly produce part of their own electricity requirement. Companies which generate power primarily for resale to the electric utility, are considered independent power producers and are model in the electric supply model.

Energy Supply:

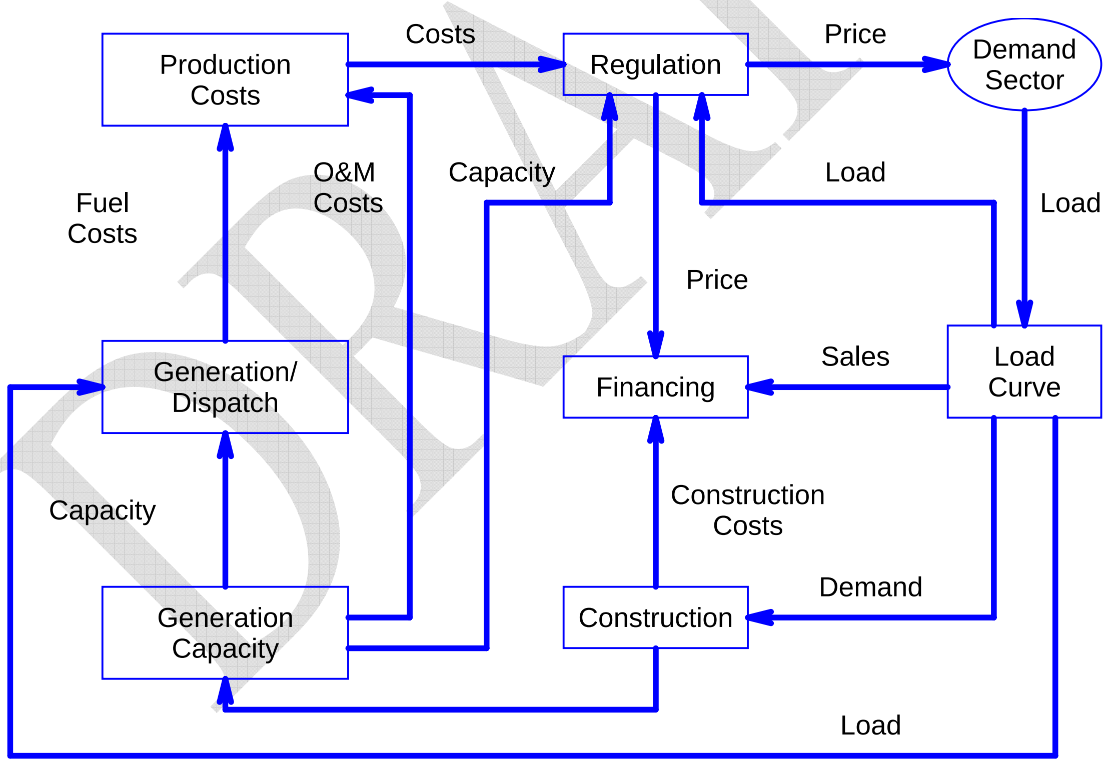
For electric and gas utilities (separate or combined), ENERGY 2020 internally and self-consistently simulates sales, load (by end-use, time-of-use, and class), production (across thirty-six dispatch types), demand-side management (by technology), forecasting, capacity expansion (new generation, independent power producers, purchases, and DSM), all important financial variables, and rates (by class, end-use, and time-of-use.)

The version currently used in this analysis only has the electricity utility sector (a full fledged natural gas utility sector for Canada is currently unavailable in the model, only a simplified natural gas supply function is used to calculate the supply price response).

With the inclusion of the electric utility sector, the generic supply model turns over the calculation of electricity prices to that sector. The model endogenously simulates the forecasting of capacity needs, as well as the planning, construction, operation and retirement of generating plants and transmission facilities. Each step is financed in the model by revenues, debt, and the sale of stock. The simulated utility, like its real world counterpart, pays taxes and generates a complete set of accounting books. In ENERGY 2020, the regulatory function is modeled as a part of the utility sector. The regulator sets the allowed rate of return, divides revenue responsibility among customer classes, approves rate base, revenues and expenses, and sets fuel adjustment charges.

The interactions in the electric utility sector are summarized in Figure A-6

Figure A-6: Electric Utility Structure Overview



Expansion Planning:

The utility sector endogenously forecasts future demand for electricity. From the forecast it projects the future capacity required meeting future demand by taking into account retirements and plants already under construction. If future electricity requirements, including reserves, are forecasted to exceed available capacity (using seasonal ratings), then construction of additional capacity is initiated. The model can also make a decision to build new capacity on an economic basis where that is appropriate. .

If additional capacity is needed to meet forecasted needs, the basic capacity expansion module in ENERGY 2020 determines whether base or peaking capacity is required. The model determines the maximum number of hours that new peaking capacity can be economically operated, before it would be less expensive to construct and operate base load capacity instead. If the forecasted peaking capacity would operate more than that economic maximum, base loads units are initiated, otherwise peaking units are initiated. Any plant type including geothermal, wind, biomass and storage can be considered.

New plants, of a pre-specified minimum size, are initiated when the reserve margin would be violated if the plants were not built or if base load capacity is inadequate to serve base load energy needs at the end of the forecast period. The model does allow the minimum reserve margin to be temporarily violated at the peak if new base load capacity is scheduled to be available within the year. Peaking units are allowed to serve more than the "maximum economical" number of hours until base load capacity comes on-line.

Minimum plant size is exogenous. The mix of new base load plants (i.e. alternative coal technologies, hydro, or nuclear) is user-specified in the standard ENERGY 2020 configuration. The model also evaluates the financial implications of new construction, including total construction costs, cost schedules, and AFUDC/CWIP. The gross rate on AFUDC equals the weighted average cost of capital. The actual construction progress and financial impacts are simulated on a year by year basis.

ENERGY 2020 can also be configured to consider intermediate load units, firm purchases contracts, external sales, independent power producers, and demand-side options. These options can be "optionally" selected based on endogenous least-cost analysis or can be chosen by user-specified criteria to meet. A detailed automatic Integrated Resource Planning module that would endogenously choose (with user control) from DSM measures utility and non-utility generation and purchase alternatives using linear programming techniques is now being offered as an enhancement.

Financing:

The ENERGY 2020 utility finance subsector simulates the activities of a utility's finance department. It forecasts funding requirements and follows corporate policies for obtaining new funds. The model simulates borrowing and issuing of stock, and can repurchase stock or make investments if it has excess cash. Cash flows are explicitly modeled, as are any decision that affects them. Coverage ratios, intermediate- and long-term debt limits, capitalization, rates of return, new stock issues, bond financing, and short-term investments are endogenously calculated. The model keeps track of gross, net, and tax assets. It also calculates the depreciation values used for the income statement and tax obligations.

Regulation:

The utility sector sets electricity prices according to regulatory requirements. The regulatory procedures use allowed rate-of-return and test year cost and demands to determine allowed revenues. Electricity prices are calculated from peak-demand fractions by allocation of costs. Any other allocation scheme can also be considered. The regulatory subsector of ENERGY 2020 automatically factors in a wide variety of regulatory policies and options. More importantly, the model can be readily modified to consider a wide spectrum of scenarios.

The regulatory process revolves around a test year, usually one year forward, when proposed rates will go into effect. The utility sector forecasts test year sales and peak demands by season and customer class, just as it does to determine capacity needs. These test year demand estimates are used to allocate responsibility for system peak, and therefore, generation capacity costs.

Fuel costs for the test year are estimated by dispatching the plants that will be available in the test year, using the dispatching routine explained below. Fuel costs and operating and maintenance costs are adjusted for expected inflation, and these costs are factored into the electricity rates using forecasted sales.

ENERGY 2020 calculates the utility rate-base according to a detailed conventional rate making formula. The model allows the user to adjust allowable costs, and has been used extensively to evaluate alternative rate-base scenarios for individual plants, including allowing return of, but no return on investment, and partial disallowment of construction and interest costs.

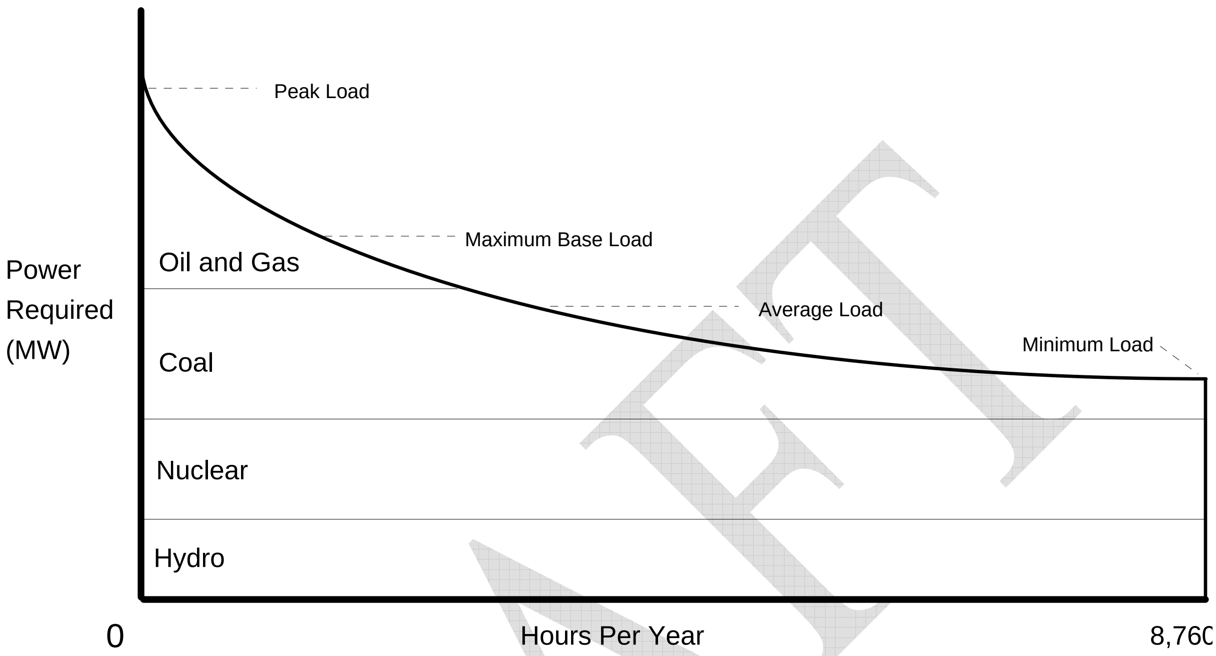
The ENERGY 2020 system also includes estimation of avoided costs, which determines when the utility may be required to purchase third party power. Environmental constraints, such as air pollution restrictions, can also be included in the model. If ENERGY 2020 is configured as a regional or state-wide system, municipal utilities, with their unique tax and rate structures, are incorporated. Similarly, regional or power pool interchange is also recognized by ENERGY 2020. As with the other sectors of ENERGY 2020, the regulatory subsector is flexible enough to accommodate any existing or hypothetical circumstance.

Operations:

Each end-use in ENERGY 2020 has a related set of load shape factors. Typically, these factors define the relationship between peak, minimum and average load for each season. These factors when combined with the weather-adjusted energy demand by end-use and corrected for cogeneration, resale, and load management programs, form the basis of the approximated system load duration curve. Alternatively, unit hourly loads for each end-use for three days per month (average weekday, weekend and peak weekday) are used.

The standard ENERGY 2020 production subsector uses an advanced de-rating or chronological method to estimate the seasonal or hourly dispatch of plants. It purchases power externally when economic or necessary. Plant availability and generation for coal, nuclear, hydroelectric, oil and gas are currently considered, as well as pumped storage, firm purchases, interruptible load, and fuel switching and qualified facilities. Figure A-7 also shows a typical plant dispatch schedule.

Figure A-7: Generation from the Load Curve



The ENERGY 2020 system estimates conventional fuel costs based on the unit dispatch, heat rates, and fuel prices (from the supply sector.) Nuclear fuel costs are capitalized and depreciated throughout the re-fuelling cycle. Nuclear fuel expenses also include fuel disposal costs.

ENERGY 2020 explicitly models the costs of maintaining the transmission and distribution (T&D) system. New facility investments are scheduled and incurred endogenously. In addition, the user can specify the decision rules that dictate T&D expenditures. ENERGY 2020 also explicitly models both fixed and variable operation and maintenance costs, power pool interchanges, nuclear decommissioning costs, plant capital additions, plant cancellations, and general administration costs.

Model Applications:

The structure of the model is well tested and has been used to simulate not only US and the Canada energy and environmental dynamics but also those of several countries in Western, Central and Eastern Europe. Current efforts include strategic and tactical analyses for South America deregulation. In the

1990s, the US EPA made ENERGY 2020 available to interested states to analyze emissions, energy, and economic impacts of state-level climate change initiatives. Further, the model has been used successfully for deregulation analyses in over 50 energy suppliers and in all the US states and Canadian provinces. Several US and Canadian energy suppliers currently use the model for the analysis of combined electricity and gas deregulation dynamics.[19] The model contains confidence and validity packages that allow it to determine how to take maximal advantage of RTO rules. The ISO NE used the model to find "gaps" in its rules and to develop more efficient market conditions. The model was used for the CAPX/ISO to model to show, before the fact, many of the "games" played in the California market.

[19] Energy 2020 is the only model known to have simulated and predicted the dynamics that occurred in the UK electric deregulation. These include gaming, market consolidation and re-regulation dynamics.

Appendix B: Data Sources

Historical Energy Prices and Demands
Historic energy prices and demands are from *State Energy Data 2000*, Integrated Energy Statistics Divisions of the Office of Energy Markets and End Use, Energy Information Administration, USDOE. This document provides annual time series estimates of State-level energy consumption, prices, and expenditures by major economic sectors. In 2000, *State Energy Data 2000* is EIA's replacement of two former reports: State Energy Data Report (SEDR) and State Energy Price and Expenditure Report (SEPER). Tables by major economic sector can be found at: http://www.eia.doe.gov/emeu/states/_states.html. New tables by energy source can be found at: http://www.eia.doe.gov/emeu/states/multi_states.html.

Future Energy Prices
To estimate future energy prices, we apply the forecasted price growth rates in the High Price Case from the *Annual Energy Outlook (AEO) 2007* to the prices from the last historical year (obtained from *State Energy Data*). The Annual Energy Outlook 2007 presents a forecast and analysis of US energy supply, demand, and prices through 2030. http://www.eia.doe.gov/oiaf/aeo/supplement/index.html

Note that there is a gap between the most recently reported historical year of data and the first forecast year. We resolve this by including one year's worth of price data from the AEO of the previous year.

Future Energy Demands
Future energy demands are computed by the model, but the model can calibrate to future energy demands if desired. In this case we use the forecasted energy demands from the Annual Energy Outlook.

Device Energy Efficiency Standards
Device efficiency standards come mainly from the *Energy Policy Act of 1992*, with some efficiencies coming from other selected sources.
http://energy.navy.mil/publications/law_us/92epact/hr776toc.htm

Device Capital Cost, Efficiency, and Device Lifetimes; Cogeneration Capital Costs, Heat Rates and Parameters
The values all come from ARC 80 with the exception of some end uses which come from other selected sources. *Annual Report to Congress, 1980: Volume 3*. Energy Information Administration, USDOE, Report #: DOE/EIA-0173(80)/3.

End-Use Load Shapes
The end use load shapes were extracted from 1995 NEPOOL published reports.

Industrial Energy Splits, Industrial End Use Splits and Commercial End-Use Splits
The energy that we obtain from *State Energy Data 2000* is a total value that needs to be split among different industries and/or uses (end use demands, cogeneration demands, feedstock demands). We obtain the splits among industries and uses from the *1998 Manufacturing Energy Consumption Survey*, Energy Information Administration, USDOE. The Manufacturing Energy Consumption Survey is conducted every five years and provides detailed data on energy consumption in the manufacturing sector.
http://www.eia.doe.gov/emeu/mecs/contents.html

Residential Devices Saturations and Market Shares
Residential devices saturations and market shares are obtained from the *2001 Residential Energy Consumption Survey*, Energy Information Administration, USDOE.
http://www.eia.doe.gov/emeu/recs/contents.html

Inflation Rate
Historical inflation rates are calculated from the consumer price index reported by the Bureau of Labor. Projections for inflation from 2004 through 2030 are calculated from the consumer price index projections of the *Annual Energy Outlook 2007*, Energy Information Administration, USDOE. http://www.eia.doe.gov/oiaf/aeo/index.html.

Fuel Choice Variance Factors, Return on Investment, and Maximum Process Efficiency Multiplier
The fuel choice variance factors, return on investment and maximum process efficiency multiplier variables come from projections obtained from the DEMAND81 energy model. Backus, George A. 1981. DEMAND81: National Energy Policy Model. Four Volumes. AFC 7-10. School of Industrial Engineering. Purdue University. West Lafayette, Indiana.

Process Capital Costs
The data was developed from the US I/O Tables by REMI in $1987

Residential Energy Usage Per Appliance
The average usage per appliance comes from *NEPOOL April 1994 Forecast for Massachusetts*. The miscellaneous end use category is computed by adding the residential energy for all miscellaneous end uses and dividing by the number of households.

Number of Households
The number of households comes from the United States Census 2000, US Census Bureau. http://www.census.gov/main/www/cen2000.html.

Appendix D: Data Sets Used in ENERGY 2020

This Appendix describes the initial "set" definitions for ENERGY 2020 used for this project. The "sets" are the dimensions of the variables (sometimes called indexes) which delineate the scope and detail of the model. For example, the time frame set could be defined as a base year 1990 and every 5 years.

Time Frame

The initial historical year for calibration is 1990.
The end year of the analysis is 2030.
The last historic year of data will be 2005.
All data sets include annual data for each year of history and the forecast.

For some data sets, the period covered by actual data will depend on available data (e.g., emissions).

Geographical Areas

Each area in the model will represent a state or a province (no sub-state break-outs).
The model will provide separate results for the WCI partners, the surrounding Region, the rest of the US and Canada.

The States and Provinces included in the "WCI Region" for modeling purposes include:

- Arizona
- California
- Montana
- New Mexico
- Oregon
- Utah
- Washington
- British Columbia
- Manitoba

Generating Units

The list of units is based on the NEEDS database for the US plus a similar database for the units in Canada. Within the Region and the rest of the US, some of the smaller plants may be aggregated by plant type in order to allow the expedite model operation. With that aggregation, the model will likely end up with approximately 3000 units/plants.

Electric Companies

The model currently represent seven utilities within California including: PG&E, SCE, SDG&E, LADWP, SMUD, Other North and Other South. In the broader western region, the model currently assumes that each state has a single aggregate electric company. The exception to this is BPA.

Sectors and Classes

The energy demand portion of the model will simulate residential, commercial, industrial, and transportation demands. There will be an electric sales class for each sector.

Emission Only Sectors

Several sectors generate emissions, but do not have full energy demand simulations in the model. These include solid waste, waste water, incineration, and land use. It may be possible to develop a full energy demand simulation for one or more of these.

Offsets

Possible offset categories, if broken out as a set, could include:

- Sequestration
- Landfill Gas Capture
- Agricultural Methane
- Energy Efficiency (for each sector)

Pollutants

The model currently has the capability to cover 15 pollutants, although the final set will depend on the WCI partner's requirements and available data. The GHG pollutants include Carbon Dioxide, Methane, Nitrous Oxide, Sulfur-Hexafluoride, Perfluorocarbon, and Hydrofluorocarbon. The criteria air pollutants include Sulfur Dioxide, Nitrogen Oxides, Total Particulate Matter, Volatile Organic Compounds, Carbon Monoxide, Particulate Matter 2.5, Particulate Matter 10, Mercury, and Ozone.

Fuels

There are currently two sets of fuels in the model. The largest category contains 33 fuels (shown below). The second category is the list of technologies which the energy demand sectors choose from. This smaller set contains only the basic types of fuels (Electricity, Natural Gas, Oil, LPG, Biomass, Solar). The aggregate category oil is later broken out into the different types of oil (LFO, HFO, petroleum coke, etc.).

Entire List of Fuels

- Asphalt
- Aviation Fuel
- Biomass
- Coal
- Coke
- Coke Oven Gas
- Diesel
- Electric
- Ethanol
- Geothermal
- Heavy Fuel Oil
- Hydro
- Hydrogen
- Kerosene
- Landfill Gases
- Light Fuel Oil
- LPG
- Lubricants
- Motor Gasoline
- Naphtha Specialties
- Natural Gas
- Nuclear
- Oil, Unspecified
- Other Non-Energy Products
- Petrochemical Feedstocks
- Petroleum Coke
- Solar
- Steam
- Still Gas
- Wave
- Wind
- Unknown 1
- Unknown 2

Electric Generation Plants Types

The electric generation plant types are used to hold the data for future generic plants which the model will construct endogenously. The list currently includes:

- Gas/Oil Peaking
- Gas/Oil Combined Cycle
- Gas/Oil Steam
- Coal
- Coal Advanced
- Coal with CCS
- Gas CC with CCS
- Nuclear
- Base Hydro
- Peak Hydro
- Other Generation
- Biomass
- Landfill Gas
- Wind
- Solar
- Fuel Cells
- Pumped Hydro
- Small Hydro
- Wave
- Geothermal
- Other Storage
- Biogas
- Trash

Residential Sectors

The residential sector is split into housing types:

- Single Family
- Multi-Family
- Other Residential

Commercial Sectors

- Transportation Services
- Pipelines
- Communication
- Electric Utilities
- Gas Utilities
- Water & Other Utilities
- Wholesale
- Retail
- FIRE
- Offices - Business Services
- Education
- Health & Social
- Food, Lodging, Recreation
- Government

Industrial Sectors

- Food & Tobacco
- Textiles
- Apparel
- Lumber
- Furniture
- Pulp & Paper Mills
- Converted Paper
- Printing
- Petrochemicals
- Industrial Gas
- Other Chemicals
- Fertilizers
- Petroleum Products
- Rubber
- Leather
- Cement
- Glass
- Lime & Gypsum
- Other Non-Metallic
- Iron & Steel
- Aluminum
- Other Nonferrous
- Fabricated Metals
- Machines
- Computers
- Electric Equipment
- Transport Equipment
- Other Manufacturing
- Iron Ore Mining
- Other Metal Mining
- Non-metal Mining
- Light Oil Mining
- Heavy Oil Mining
- Frontier Oil Mining
- Oil Sands In-Situ
- Oil Sands Mining
- Oil Sands Upgraders
- Gas Mining
- Coal Mining
- Construction
- Forestry
- Agriculture

Transportation Sectors

- Passenger
- Freight
- Off Road

Miscellaneous Sectors

- Misc. & Street Lighting
- Electric Resale
- Utility Electric Generation
- Industry Electric Generation
- Steam Generation
- Solid Waste
- Waste Water
- Incineration
- Land Use

Residential End-Uses

- Space Heating
- Water Heating
- Other Substitutable
- Refrigeration
- Lighting
- Air Conditioning
- Other Non-Substitutable

Commercial End-Uses

- Space Heating
- Water Heating
- Other Substitutable
- Refrigeration
- Lighting
- Air Conditioning
- Other Non-Substitutable

Industrial End-uses

- Process Heat
- Electric Motors
- Other Substitutable
- Miscellaneous

Transportation End-Uses

- Ground
- Air/Water

Residential, Commercial, and Industrial Technology Types

Each technology type has its own trade-off curve which determines the efficiency and the capital cost of the technology type. These curves allow the model to contain many different technologies within these broad types.

- Electric
- Gas
- Coal
- Oil
- Biomass
- Solar
- LPG
- Steam

Transportation Technology Types

Several technology types are provided for transportation, and each of these contains a trade-off curve which allows the model to simulate even more individual technologies.

- Plug-in Hybrids
- Light Gasoline
- Light Diesel
- Light Propane
- Light CNG
- Light Electric (Plug-in)
- Light Ethanol
- Light Hybrid Gasoline
- Light Hybrid Diesel
- Light Fuel Cell Gasoline
- Light Fuel Cell CNG
- Light Fuel Cell Hydrogen
- Medium Gasoline
- Medium Diesel
- Medium Propane
- Medium CNG
- Medium Ethanol
- Medium Hybrid Gasoline
- Medium Hybrid Diesel
- Medium Fuel Cell Gasoline
- Medium Fuel Cell CNG
- Medium Fuel Cell Hydrogen
- Heavy Gasoline
- Heavy Diesel
- Heavy Propane
- Heavy CNG
- Heavy Ethanol
- Heavy Hybrid Gasoline
- Heavy Hybrid Diesel
- Heavy Fuel Cell Gasoline
- Heavy Fuel Cell CNG
- Heavy Fuel Cell Hydrogen
- Motorcycle
- Bus Gasoline
- Bus Diesel
- Bus Propane
- Bus CNG
- Bus Fuel Cell Gasoline
- Bus Fuel Cell Hydrogen
- Bus Fuel Cell Ethanol
- Train
- Plane
- Marine
- Off Road

Prices

Delivered energy prices are presented for the following fuels:

- Residential Electricity
- Residential Natural Gas
- Residential Coal
- Residential Oil
- Residential Biomass
- Residential LPG
- Residential Steam
- Commercial Electricity
- Commercial Natural Gas
- Commercial Coal
- Commercial Oil
- Commercial Biomass
- Commercial LPG
- Commercial Steam
- Industrial Electricity
- Industrial Natural Gas
  Industrial Coal
- Industrial Oil
- Industrial Biomass
- Industrial LPG
- Industrial Steam
- Gasoline
- Diesel
- Aviation Fuel
- Transportation HFO
- Transportation Natural Gas
- Transportation LPG
- Electric Utility Residual Oil
- Electric Utility Distillate Oil
- Electric Utility Natural Gas
- Electric Utility Coal
- Electric Utility Nuclear
- Electric Utility Biomass
- Ethanol
- Hydrogen

Electric Load Segments

The model dispatches for 6 different hour types (high peak, low peak, high intermediate, low intermediate, high base load, low base load) for each of the four seasons.

Appendix F: New Generation Performance and Cost Assumptions

Table 1A. Input Values to Busbar Energy Costs - California Resources (2008 $)

Resource Technology	2020 Overnight Capital Cost ($/kW) ($/kW)		Fixed O&M Cost ($/kW-year)		Variable O&M Cost ($/MWh)		Capacity Factor	Nominal Heat Rate (Btu/kWh)
	Low (if range)	High (if range)	Low (if range)	High (if range)	Low (if range)	High (if range)		
Biogas	$3,065		$139		1.20		80%	13,648
Biomass	$4,484		$65		1.20		80%	8,911
Geothermal	$3,339	$8,131	$157	$226	1.20		90%	n/a
Hydro - Small	$2,539	$5,170	$14	$31	0.94	1.81	25% - 65%	n/a
Solar - Thermal	$3,235		$64		1.20		37% - 40%	n/a
Wind	$1,962		$37		1.20		27% - 40%	n/a
Coal ST	$2,479		$33		1.20		85%	8,844
Coal IGCC	$2,866		$47		1.20		85%	8,309
Coal IGCC with CCS	$4,101		$55		1.20		85%	9,713
Gas CCCT	$1,054		$14		1.20		90%	6,917
Gas CT	$807		$15		1.20		5%	10,807
Hydro - Large	$1,486	$2,193	$9	$13	0.63	0.89	12% - 57%	n/a
Nuclear	$3,999		$83		1.20		85%	10,400

Table 1B. Input Values to Busbar Energy Costs - Rest of WECC Resources (2008 $)

Resource Technology	2020 Overnight Capital Cost ($/kW) ($/kW)		Fixed O&M Cost ($/kW-year)		Variable O&M Cost ($/MWh)		Capacity Factor	Nominal Heat Rate (Btu/kWh)
	Low (if range)	High (if range)	Low (if range)	High (if range)	Low (if range)	High (if range)		
Biogas	$2,350	$2,835	$107	$128	0.92	1.11	80%	13,648
Biomass	$3,438	$4,148	$50	$60	0.92	1.11	80%	8,911
Geothermal	$1,582	$19,451	$157	$226	0.96	1.11	90%	n/a
Hydro - Small	$1,758	$4,782	$11	$28	0.71	1.69	22% - 65%	n/a
Solar - Thermal	$2,588	$2,939	$51	$58	0.96	1.09	36% - 39%	n/a
Wind	$1,504	$1,815	$28	$34	0.92	1.11	27% - 40%	n/a
Coal ST	$1,901	$2,293	$26	$31	0.92	1.11	85%	8,844
Coal IGCC	$2,197	$2,651	$36	$43	0.92	1.11	85%	8,309
Coal IGCC with CCS	$3,144	$3,794	$42	$51	0.92	1.11	85%	9,713
Gas CCCT	$808	$975	$11	$13	0.92	1.11	90%	6,917

Hydro - Large	$1,122	$2,031	$5	$11	0.41	0.78	15% - 65%	n/a
Nuclear	$3,066	$3,699	$63	$76	0.92	1.11	85%	10,400

Source: Energy and Environmental Economics, Inc., CPUC GHG Modeling - Generation Costs, www.ethree.com/cpuc_ghg_model.html

Appendix G: Global Warming Potential

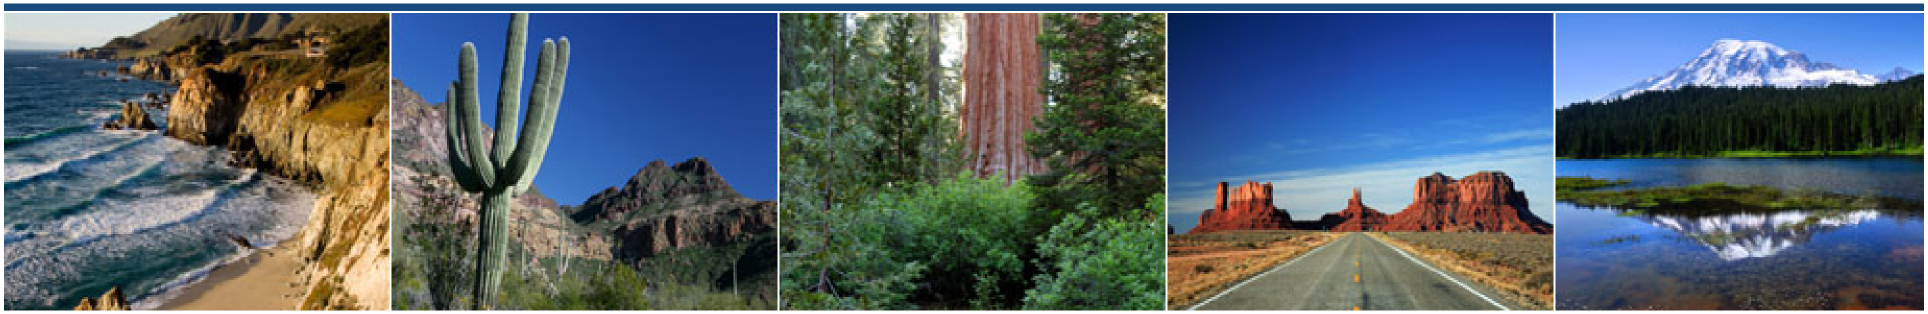
ENERGY 2020 models emissions of each of the six greenhouse gases reported under the Kyoto protocol. These emissions are then translated into equivalent quantities of CO_2 emissions (CO_2e) based on the global warming potential of each of the gases.

The Global Warming Potential (GWP) values used in ENERGY 2020 are shown in the table below.

Greenhouse Gas	Global Warming Potential
Carbon Dioxide (CO2)	1
Methane (CH4)	21
Nitrous Oxide (N2O)	310
Sulphur Hexafluoride (SF6)	23,900
Perfluorocarbons (PFC)	7,000
Hydrofluorocarbons (HFC)	1,300

These values are consistent with the Global Warming Potential values used in the 1996 Second Assessment Report based on 100-year warming potential for the individual gases. In the case of HFCs and PFCs the GWP values used in the model are based on an estimated average GWP for these gases.

Western Climate Initiative



Preliminary Phase 1 Modeling Results

Presented to

Western Climate Initiative Stakeholders

May 12, 2008

Topics

- Phase 1 Challenges
- Preliminary Results
- Example Model Outputs
- Status of Assumptions Book

Phase 1 Challenges

- Reference case
  - Aim for “reasonable closeness” to 9 partners’ 2005 inventories
  - Incorporate 2007 national energy bill (EISA) and existing renewable portfolio standards
- Complementary policies
  - CA car standards, VMT reduction
  - Energy efficiency programs (electric & gas utilities, LPG, heating oil)
- Cap-and-trade scenarios
  - First-jurisdictional deliverer (proxy with WECC-wide cap)
  - Proper treatment of tribal power plants

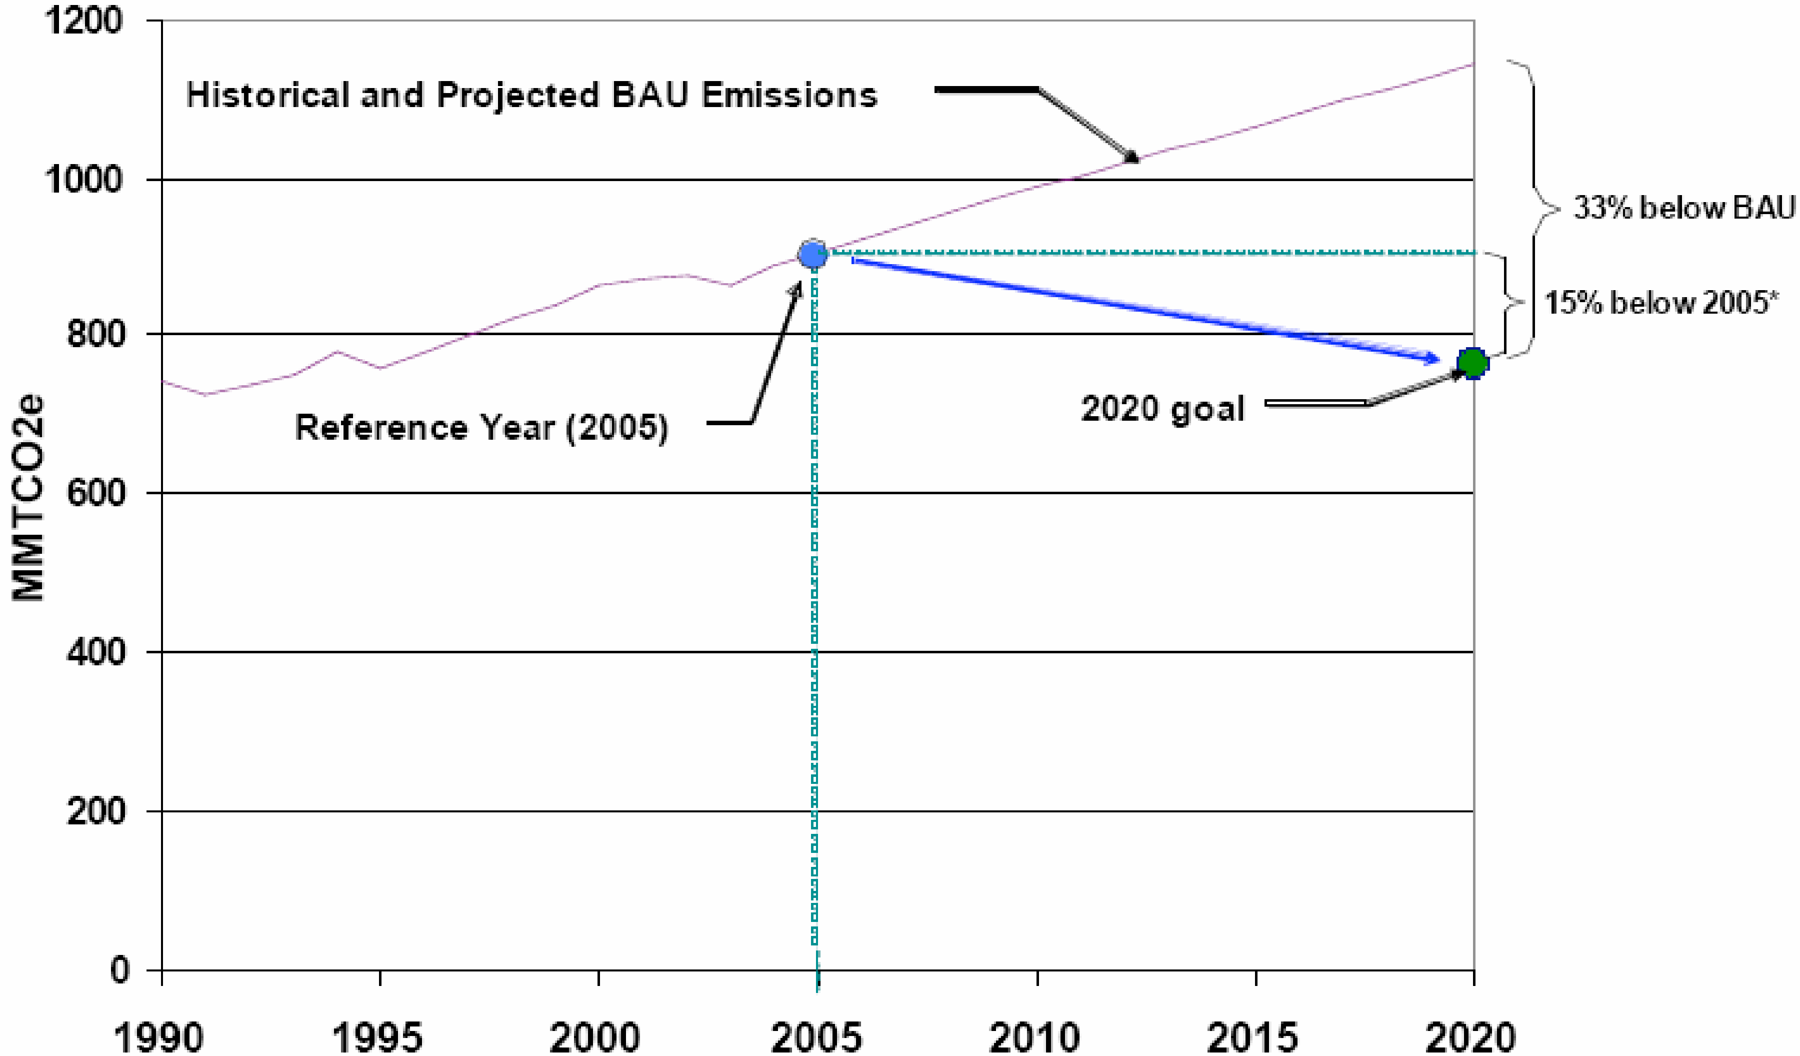
Status

- Model simulation of 2005 inventories align reasonably well (not perfectly) with WCI partners' 2005 inventories.
- Preliminary results for Reference Case projections are plausible and lower than partners' projections.
- Complementary Policies model run produces plausible results.
- Cap-and-trade model runs are in progress
- Manitoba and Quebec not yet modeled

WCI Partner Data

- WCI compiled GHG inventories and forecasts in August 2007
- The forecasts suggested aggregate growth of >25% in emissions from 2005-2020
- Reducing emissions to 15% below 2005 levels would thus require a 33% reduction from BAU ("Business As Usual" or "Reference Case")
- See graph on next slide

WCI Partner GHG Emissions and Regional Goal[3]



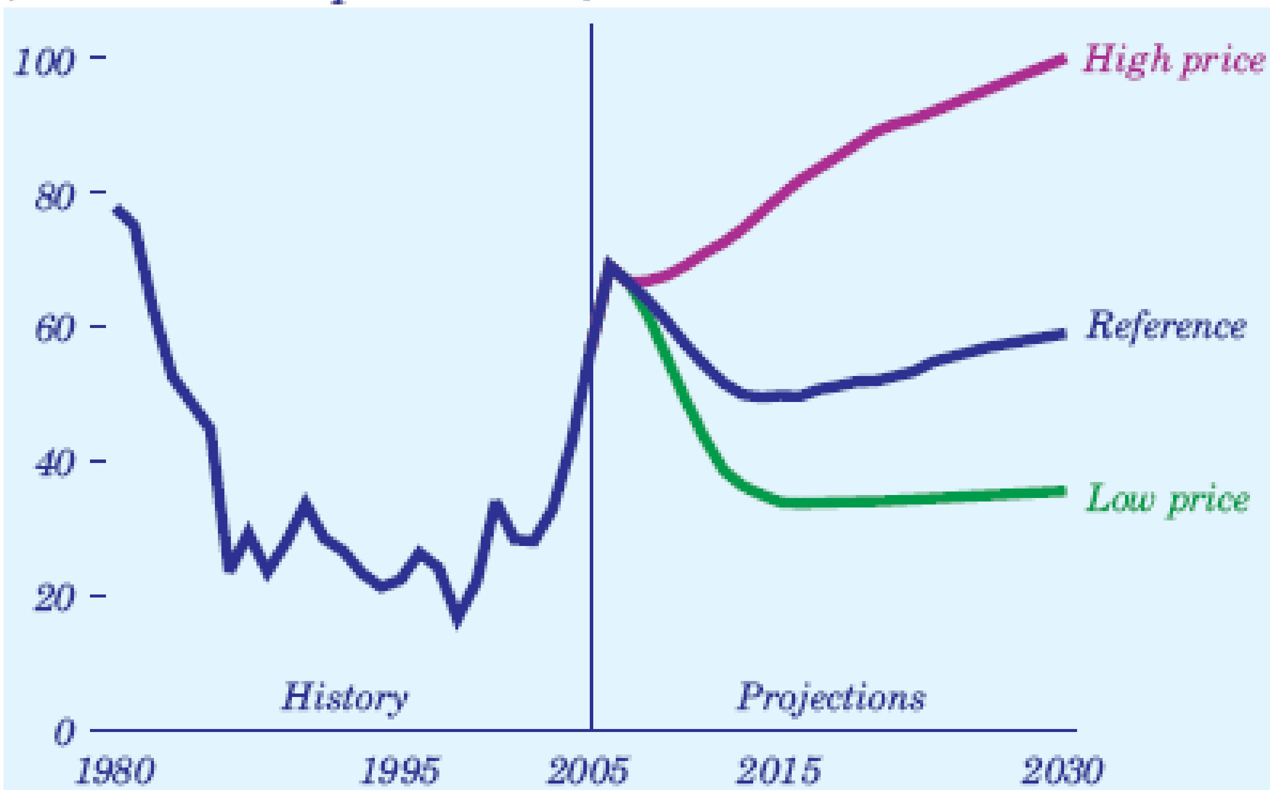
ENERGY 2020 Reference Case

- The model can simulate the partner inventories for 2005 reasonably well
- GHG emissions in 2020 in the Reference Case are significantly lower. Why?
  - Partner forecasts are ~1 to 5 years old
  - Energy prices are projected to be higher
  - Reference Case includes EISA and state RPS's
  - Reference Case assumes no new conventional coal plants (beyond "committed coal plants")
  - Not using partner-specific population growth rates in Phase 1 modeling

AEO 2007: World Price Projection

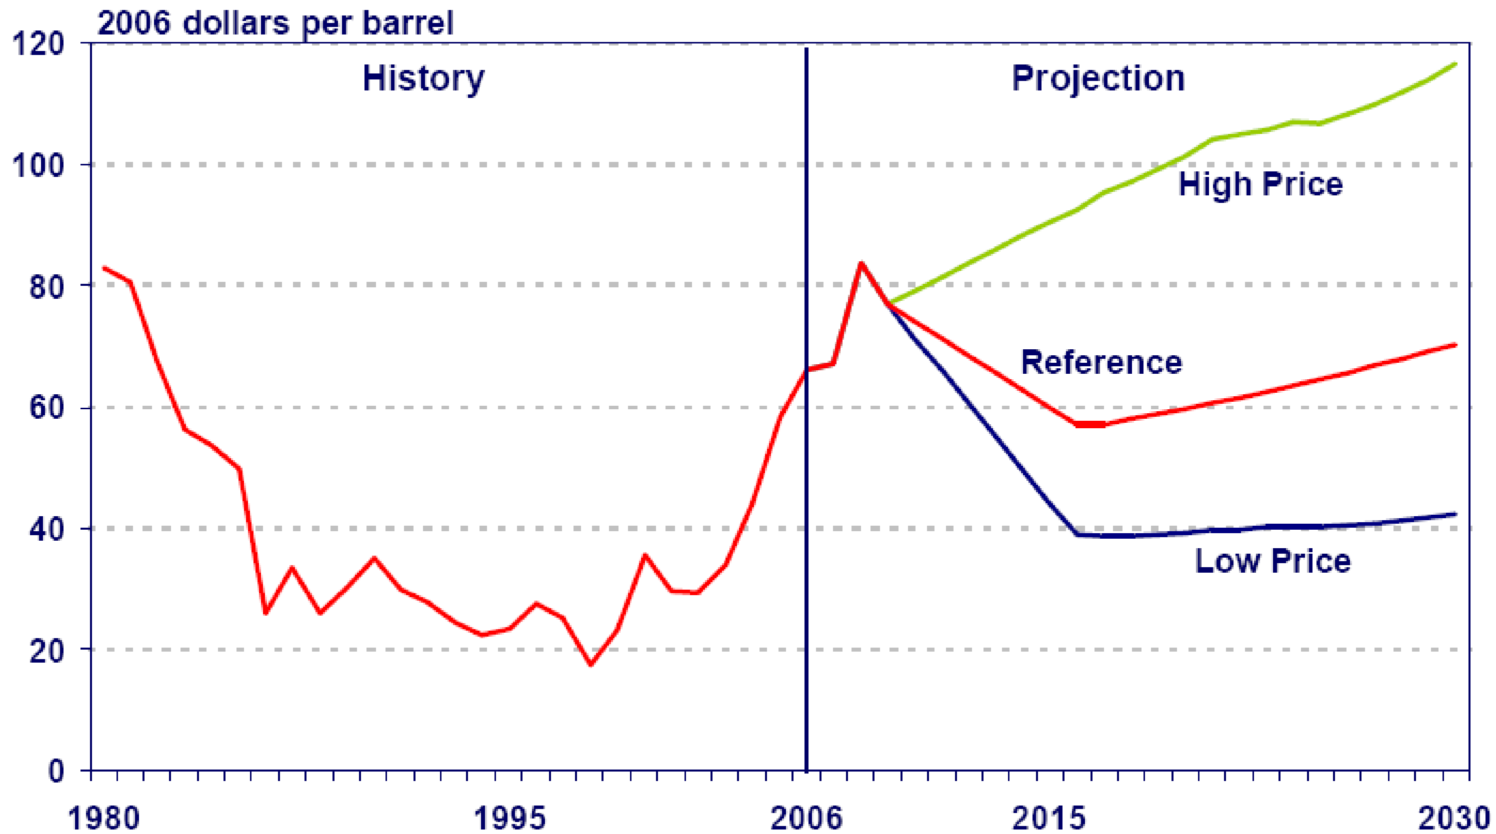
Oil Price Cases Show Uncertainty in Prospects for World Oil Markets

Figure 29. World oil prices, 1980-2030 (2005 dollars per barrel)



AEO 2008: World Price Projection

Figure 2. World oil prices are higher in all *AEO2008* cases.

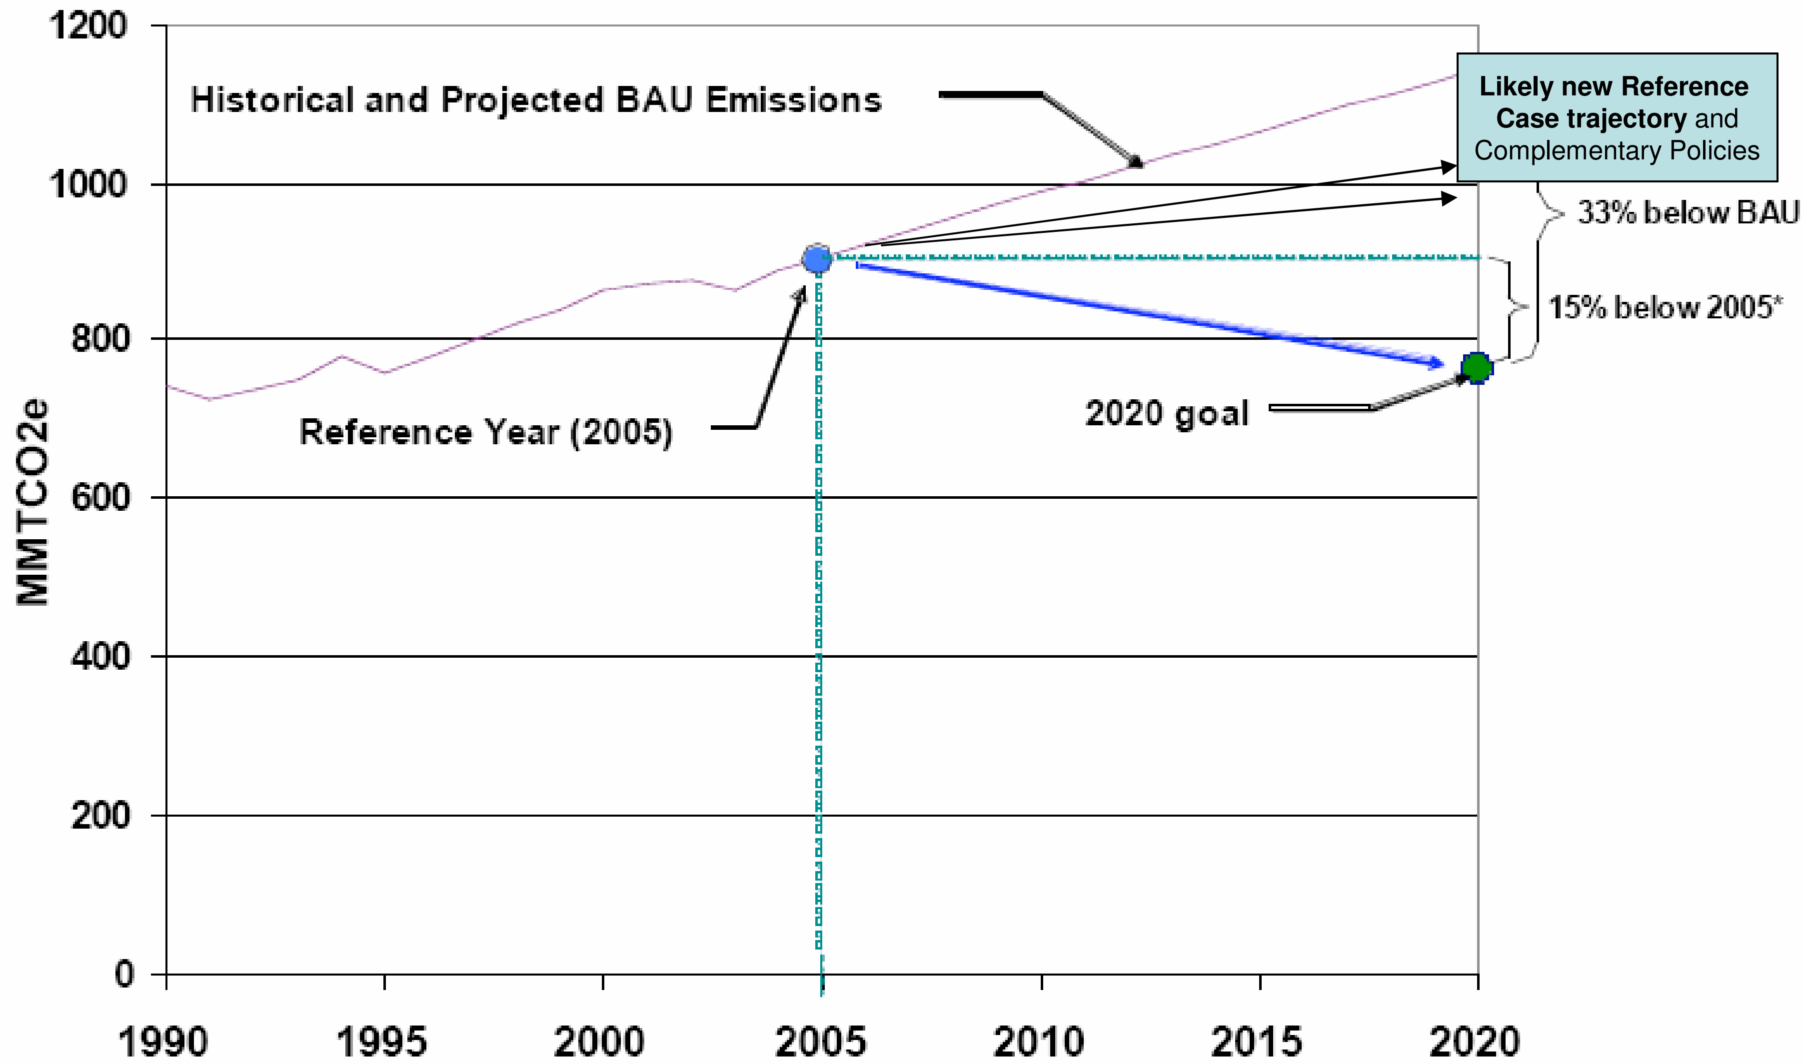


Comparison of AEO 2007 vs. 2008

		AEO 2007		AEO 2008	
	2005	2020	% Incr	2020	% Incr
Total CO2 Emissions (MMT)	5982	6944	16%	6384	7%
Ave Annual Growth 2005-2030					
Energy Consumption			1.2%		0.7%
Economic Growth			2.9%		2.4%

- Significant decreases in projected CO2: 16% vs. 7%
- Energy consumption grows more slowly
- Economy grows more slowly
- All projections are from AEO “mid-price” cases, Table 18.

WCI Partner GHG Emissions and Regional Goal[3]



ENERGY 2020 Reference Case and Complementary Policies

- Graph illustrates likely trajectories of Reference Case and Complementary Policies model run
- Reference Case reflects
  - Higher energy prices
  - EISA 2007: Stronger CAFÉ standards, biofuel mandate, efficiency standards, current state RPS's
  - Assumption of no new conventional coal plants (beyond "committed coal plants")

Model Run: Complementary Policies Only

- Rationale for model run
- Includes three WCI-wide policies:
  - CA car standards (and assumes that there will be a "Part 2" to these standards per California ARB)
  - Total VMT reduced below levels in 2020 Reference Case
  - Aggressive energy efficiency programs that annually reduce demand below the annual percentage growth rate in the Reference Case for electricity, natural gas, LPG, and heating oil

Example Model Outputs

- Emissions – GHG and conventional air pollutants
  - With market-clearing allowance price for GHG cap-and-trade program
  - GHG offset prices and quantities used
- Power Sector
  - Demand, generation, capacity, wholesale prices, retail electric rates
- Fuel use and market shares
  - Oil, natural gas, coal, gasoline, diesel, ethanol, biodiesel, etc.
- Levels of Energy Efficiency
- Examples of model output
  - http://www.epa.state.il.us/air/climatechange/documents/07-09-06/modeling-of-policy-proposals.ppt (Illinois)
  - http://dnr.wi.gov/environmentprotect/gtfgw/documents/reference_case_outputs_20080416.pdf (Wisconsin)

Status of Assumptions Book

- We are processing input from April 14 stakeholder call and from emails
- We will post a new version prior to June 9 stakeholder call

Regional Organization – Draft Recommendations 21

Introduction

The Western Climate Initiative (WCI) began in February 2007 when the Governors of Arizona, California, New Mexico, Oregon, and Washington agreed to:

- join The Climate Registry;
- develop a regional greenhouse gas reduction goal consistent with their state goals; and
- design a multi-sector market-based mechanism by August 2008 to help meet the greenhouse gas reduction goal.

The five Governors invited other states, provinces and tribes to join the WCI or to participate as observers. Since the initial signing, the Premiers of British Columbia, Manitoba, and Quebec and the Governors of Montana and Utah have joined the Initiative. The states of Alaska, Colorado, Idaho, Kansas, Nevada and Wyoming participate as observers, as do the provinces of Ontario and Saskatchewan and the Mexican border states of Baja California, Chihuahua, Coahuila, Nuevo Leon, Sonora, and Tamaulipas.

The WCI Partners issued their regional greenhouse gas reduction goal on August 22, 2007 (see: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F13006.pdf). The regional goal is a 15 percent reduction from 2005 levels by 2020. This regional, economy-wide goal is consistent with the state and provincial goals of the WCI Partners and does not replace the Partners' existing goals. The WCI Partners also re-committed to do their share to reduce regional GHG emissions sufficiently over the long term to significantly lower the risk of dangerous threats to the climate. Current science suggests that this will require worldwide reductions in carbon dioxide emissions of 50 percent to 85 percent below current levels by 2050.

On October 29, 2007, the WCI Partners released their Work Plan of WCI activities through August 2008 for public review and comment. Comments on the Work Plan were requested and more than 100 organizations and individuals submitted comments. As directed by the Governors and Premiers, the Work Plan describes the process for developing design recommendations for a proposed cap-and-trade program as one element of the WCI's effort to identify, evaluate, and implement ways to reduce greenhouse gas (GHG) emissions and achieve related co-benefits.

Developing Design Recommendations for a Cap-and-Trade Program – The Process

Five WCI subcommittees (each chaired by one of the Partners) are working toward a cap-and-trade program design that all Partners can embrace and implement. The five subcommittees and their purposes are:

- **Reporting:** Recommend the reporting system needed to support the WCI program.
- **Electricity:** Define the point of regulation for the electricity industry.
- **Scope:** Identify the other sectors and sources to include in the cap-and-trade program in addition to the electricity sector.
- **Allocations:** Specify how to distribute emission allowances.
- **Offsets:** Examine whether and how emission offset projects should be included.

Each subcommittee is comprised of staff from partner and observer jurisdictions, and each has support from various consultants working under contract to WCI. The subcommittees meet regularly by conference call and at times hold face-to-face meetings.

All subcommittees have incorporated stakeholder involvement and feedback to help design the program. The stakeholder process includes three workshops. The first was held in Portland on January 10, 2008 and was attended by more than 300 people with another 200 people participating via Webinar. Before the workshop, each of the five subcommittees released for public review and comment papers describing the major options under consideration. After the workshop, each subcommittee held a conference call to get extra stakeholder input and answer questions.

Information about the WCI is regularly updated on the WCI website. The website is also the portal through which stakeholders and the public can submit comments to the Partners and sign up for the WCI listserv (www.westernclimateinitiative.org).

Outreach during March – August 2008

The WCI outreach activities described below supplement the individual outreach conducted by each of the partner states and provinces.

Activity	Date
Scope of Work for Economic Analysis ▪ See http://www.westernclimateinitiative.org/Economic_Analysis.cfm for stakeholder involvement opportunities .	March 3, 2008
Initial Draft Design Recommendations Released	
▪ Scope and Electricity	March 5
▪ Offsets, Allocations, and Reporting	April 3
▪ Offsets Workshop in Vancouver, BC	March 26
Stakeholder Workshop in Salt Lake City to discuss draft subcommittee recommendations	May 21
Draft Program Design Recommendations for public review and comment	Mid-July
Stakeholder Workshop in San Diego	July 29
WCI Program Design Recommendations released	Early September 2008

As called for in the WCI agreement, the WCI Partners are working diligently toward a set of recommendations for the design of a regional cap-and-trade program. The Partners will complete their work on this first phase of the regional program by the end of August and will release their report in early September. The report will also describe next steps, including the expected timelines and critical paths for states and provinces to implement the program.

Draft Recommendations on Elements of the Cap-and-Trade Program

The draft recommendations that follow were developed collaboratively by the WCI Partners. As WCI continues to refine and assess these draft recommendations, it welcomes stakeholder feedback on all the concepts presented in this document. **Comments on this document should be submitted to the WCI website by June 6.**

The goal is to present the draft recommendations for a preferred, fully-integrated program at the July 29 stakeholder workshop in San Diego. Between now and then work will continue to create a program design that helps achieve GHG reduction goals fairly and effectively.

The WCI Partners stress that as they continue to evaluate the scope and design of the cap-and-trade program, they will carefully examine economic impacts, including the impact on consumers and businesses in each jurisdiction. The WCI will model the economic impacts for all sectors that may be included to ensure that the program is cost-effective and fair to consumers and businesses while also meeting the environmental objective.

Also, WCI recognizes that policies that complement the cap-and-trade program will be needed to motivate investments in improved efficiency and other measures to reduce emissions. The WCI will examine a full set of complementary policies as part of the analyses supporting implementation of the cap-and-trade program.

Finally, it is important to point out that the programs developed through this regional initiative will ultimately be implemented through laws, regulations, and policies at the state and provincial level. A high degree of regional consistency is important for the success of the program, but the WCI Partners are diverse geographically, economically, and demographically, and each state and province has unique factors that it will have to address when implementing this program.

Therefore, the WCI Partners are focused on developing a program that builds on the strength of consistent regional approaches, while at the same time understanding that each Partner must have the flexibility to implement the program in a way that addresses the unique characteristics of their jurisdiction.

Draft Recommendations

The WCI Partner states and provinces are pleased to present these draft recommendations on the regional cap-and-trade program for ongoing review and comment by stakeholders and the public. The recommendations focus on the following:

- Reporting
- Scope
- Electricity
- Allocations
- Offsets
- Regional Organization

Reporting

A robust and credible reporting system will be the backbone of the WCI cap-and-trade program. This system must ensure that emissions are quantified and reported accurately and transparently. This will allow regulators in participating jurisdictions to assess compliance of regulated sources, measure progress against state, provincial and regional targets, and generate public trust in this progress. Also, all market participants will rely on the reporting system to make decisions that will be the basis for transactions. Confidence in the reporting system will be critical to the success of the WCI program.

The WCI is fortunate that several GHG reporting systems exist that can inform the design of and perhaps even underpin the WCI reporting system. The Reporting Subcommittee has assessed many of these systems and anticipates that the WCI reporting system will be as consistent as possible with existing systems.

The WCI Partners unanimously agree that the WCI reporting system should rely heavily on the infrastructure that The Climate Registry (TCR) is designing. TCR is a collaboration between U.S. states, Canadian provinces and Mexican states to establish a common infrastructure for measuring and reporting GHG emissions. TCR's objective is to provide a common set of tools that will support a broad range of state and provincial policies. All of the WCI Partners are members of the Board of Directors of TCR.

Draft Recommendations for Reporting

- Breadth/Scope of Reporting
  The WCI recommends that reporting requirements apply to the capped sectors and to certain non-capped sectors that may be phased in later (will have to determine which sectors - lower thresholds may apply).

- Initiation of Reporting
  The WCI recommends that reporting start before cap-and-trade commences in order to avoid reporting-related delays to the start of the cap-and-trade program.

- Coordination Among Partner Jurisdictions
  The WCI recommends developing essential requirements for a model WCI reporting rule by the end of 2008 and will incorporate consideration for jurisdictions that already have reporting rules adopted or in process.

- Data Management and TCR Interaction
  The WCI recommends sources report either (a) directly to jurisdictions (which would then upload the data to TCR's central repository), or (b) through TCR's program framework (which would then download the data to the necessary jurisdiction(s)).

- Verification
  The WCI recommends establishing essential quality assurance elements for reported data. These elements will be consistent across jurisdictions. Each jurisdiction will have an oversight mechanism to ensure compliance with the reporting requirements. As part of this mechanism, each jurisdiction will establish procedures to ensure that the quality assurance elements are met. This could include requiring third-party verification, rigorous compliance audits or other appropriate approaches.

- Administrative Costs & Fees
  The WCI recognizes that jurisdictions may collect fees from sources that report directly to them and contract with TCR to administer the program. Jurisdictions may also accept data directly from TCR if they choose to do so; entities that report through TCR may have to pay an additional fee if one is required by the jurisdiction(s).

- Mandatory Federal Greenhouse Gas Reporting
  The WCI recommends getting involved in federal GHG reporting program development in the U.S. and Canada to ensure that federal reporting programs are harmonized with the jurisdictions' interests to the greatest extent possible.

Summary of Major Comments Received to Date on Reporting Recommendations

Stakeholders have expressed general agreement with the WCI Design Principles relevant to reporting. Stakeholders want a reporting system that is fair, easy to manage, and not costly for reporters or Partner jurisdictions. Stakeholders generally support a transparent and robust accounting system for consistent and accurate reporting of emissions across sectors and jurisdictions. WCI's efforts to harmonize WCI reporting and future federal greenhouse gas reporting are also supported.

Most stakeholders agree that reporting should not be limited to sectors and sources within the cap, but should also include sectors that are likely to be phased in to the market system later. Opinion is divided on whether reporting should extend beyond this scope to sources that are not likely to be in the cap-and-trade system.

Stakeholders overwhelmingly support the idea of beginning reporting before cap-and-trade commences. Many commenters cited the need for WCI to have accurately measured emissions as a basis for allocating allowances.

Commenters generally support development of a single WCI reporting rule, citing the advantages of administrative simplicity and cost effectiveness. Stakeholders are concerned that a lack of consistency would undermine confidence in the use of reported data in a market system. For some commenters, however, continuity with existing jurisdictional reporting systems was a higher priority, and these commenters favored more loosely coordinated rules with common core elements.

Stakeholder opinion remains divided on whether reporting should made directly to The Climate Registry (TCR) or to the Partner jurisdictions for upload to TCR. In part, this disagreement may reflect the different interests of reporters with sources in multiple jurisdictions versus those with sources in only a single jurisdiction. Multi-jurisdictional reporters tend to favor direct reporting to TCR for the simplicity of one-stop reporting, while single-jurisdiction reporters tend to favor combining greenhouse gas emissions reporting with their existing air pollutant reporting directly to the jurisdictions.

Stakeholders also differ on whether third-party verification should be required, either WCI-wide or as an option for individual jurisdictions. Supporters generally see third-party verification as essential to ensuring the accuracy and consistency of data that will be converted to financial credits or liabilities, and point to corporate financial audits as an appropriate analogy. Others see third-party verification as redundant to the jurisdictional compliance and enforcement provisions that will be applicable to reported data. This latter view is held most strongly by electricity generation commenters, who cite their existing requirements for continuous emissions monitoring of carbon dioxide from power plants. Reducing uncertainty over verification costs may help to resolve this issue.

Commenters are divided on whether reporting fees should go directly to TCR or to Partner jurisdictions which would then contract with TCR for its data management services. This issue is related to the question of where the data should be reported, and similar considerations are raised on either side. Some commenters are also concerned that governmental accountability for funds will be lacking or diminished if fees go directly to a non-profit entity.

Design of the reporting system will continue beyond the September 2008 announcement of WCI Program Design. Completion of the essential requirements for GHG reporting rules is scheduled for December 2008. During this period, the Reporting Subcommittee will develop more specific proposals and will seek stakeholder comment. Greater specificity may help to resolve some stakeholder concerns. Comment will be sought on key issues including:

- Emissions quantification methodologies for specific sectors and source types;
- Design of the reporting system, including the user interface and the relationship to TCR's mandatory reporting support function;
- Thresholds for reporting;
- Operational boundaries for reporting;
- Verification and/or other quality assurance requirements; and
- Other details in the essential requirements for Partner GHG emissions reporting rules.

Scope

Scope defines the GHG emissions that are included in the cap-and-trade program, including:

- The sectors that fall under the cap.
- The emissions sources that fall under the cap.
- The greenhouses gases that fall under the cap.
- The point(s) of regulation where the cap would be enforced.

From the scope definition, any entity or facility must be able to tell whether it has a compliance obligation under the cap, and which of its emissions are subject to the obligation. The "point of regulation" is the portion of the scope definition that identifies the entities that have the obligation to surrender GHG emission allowances to cover GHG emissions.

The draft recommendations are based on the WCI's analysis and assessment of the Major Options released in January 2008. The WCI developed and applied evaluation criteria to the major options, taking into account stakeholder comments received in writing and during conference calls.

Draft Recommendations for Scope

- Industrial and Commercial Sources
  The WCI recommends a base program from the start of the cap-and-trade program that includes the electricity sector, large stationary combustion sources, industrial process and waste management emissions, and fossil fuel production and processing. (Please see Electricity section for information on recommended approaches for that sector.) All six GHGs are recommended for inclusion.

  The WCI recommends that high priority be placed on developing GHG reporting protocols for the fossil fuel production and processing sector so that as much of this sector as possible can be included in the cap-and-trade program from the start.

- Transportation Fuels
  Emissions from transportation fuels are the single largest source in the region (about 36 percent of total emissions), and must be addressed through an effective combination of near-term and long-term policies. Most Partners have a strong interest in including transportation fuels in the cap-and-trade program. However, before recommending how best to reduce emissions in this sector, analyses of the economic impacts of various options for including transportation fuels in the program will be examined, including the potential effectiveness of alternative policies for reducing these emissions. Options to be considered include the potential to phase in transportation fuels in a later stage of the program, other fiscal measures to regulate this sector, and special consideration for low-income populations and other communities most adversely impacted by consequent price change in the sector. It is anticipated that a decision on how to address transportation fuels will be informed by economic modeling and additional analysis in the coming months.

- Residential and Commercial Fuel Combustion
  The WCI recommends including residential and commercial fuel combustion in the cap-and-trade program and acknowledges that individual jurisdictions may instead utilize comparable

fiscal measures, such as British Columbia's carbon tax, to regulate these sectors. The WCI is also considering whether to include these emissions within the program beginning with the first or second compliance period. The point of regulation for including the emissions from this fuel use would be at the point where these fuels are distributed, including: local distribution companies for natural gas; an appropriate upstream point for propane (LPG), such as refineries and wholesalers; and fuel oil distribution points (which may vary among partner jurisdictions).

- Thresholds
  The WCI recommends using an emission threshold to define the facilities that would have a regulatory compliance obligation under the cap-and-trade program. The WCI recommends setting the threshold so that at least 90 percent of non-power plant stationary source fuel combustion emissions WCI-wide are covered by the program. Based on an initial review of available data, the WCI believes that a threshold within the range of 10,000 to 25,000 metric tons of CO_2e per year per facility may achieve this objective and to assure consistent coverage of facilities within industries and across jurisdictions. The WCI is continuing to evaluate this threshold range, and is examining whether categories of facilities should be included or excluded from coverage regardless of their annual emissions rate. WCI is still considering whether, and at what level, to apply thresholds to electricity sector entities that have compliance obligations.

- Future Program Expansion
  The WCI recommends that the scope of the cap-and-trade program be capable of expanding over time. Possible factors for bringing in additional sources into the program include:

  - Advancements in monitoring technologies, procedures, and/or protocols which would enable the cost-effective inclusion of additional sources and types of greenhouse gas emissions, or smaller-sized sources within currently covered categories, particularly if mandatory reporting data show these sources to be larger contributors than expected;
  - Sources or sectors whose exclusion from the program leads to emissions leakage or competitiveness issues;
  - Resolution of legal or administrative issues that had precluded the inclusion of a source or sector; and
  - Addition of new jurisdictions to the cap-and-trade program.

  Sources that are considered as viable offset projects at the start of the cap-and-trade program may become part of the program at a future date.

Summary of Major Comments Received to Date on Scope Recommendations

The WCI Scope Subcommittee has received public comment at in-person meetings, on conference calls for stakeholders, and in written form. These public comments responded to the options papers released by the WCI in January 2008 and the draft recommendations released in March 2008.

The WCI received written comments from 38 organizations in response to the major options paper, and from 43 organizations in response to the draft recommendations. Many of these organizations represented multiple entities, including businesses and non-profits. Stakeholders also provided comments at teleconferences on February 12 and March 11, 2008 and at the public workshop in Portland on January 10, 2008. The subcommittee requested and received comments on a large number of topics, including sector coverage, point of regulation, thresholds for inclusion of specific sources, greenhouse gas coverage, phasing of source inclusion, coverage of transportation fuels and residential and commercial natural gas, as well as specific concerns for various industries, sectors and sources.

In general, most comments supported a broad coverage of sources under a cap-and-trade program with a point of regulation as close to the point of emissions as possible. Stakeholders asked the subcommittee to include as many sources as administratively and technically possible in order to increase the availability of low-cost emission reductions and to lower the total cost of the cap-and-trade program. Comments also addressed the following:

- Many comments emphasized the importance of available and correct quantification methods in order to include a source in the program, and of reliable data for the design and operation of the program. These comments focused on a desire to avoid double counting emission reductions and to ensure the integrity of a trading system.
- Comments also reflected a desire for certainty about which sources would be included, especially if the program phased in new sources over time.
- Some comments asked for further analysis of outstanding issues such as the inclusion of transportation fuels and commercial and residential natural gas, and suggested varying approaches for these sources. These issues, particularly the inclusion of transportation fuels, received substantial attention. One-third of the comments received after the release of the major options paper related to the issues of transportation fuels.
- Many comments expressed concern that sources not covered under a cap-and-trade program remain responsible for the emission reductions necessary to achieve the regional greenhouse gas emissions target.

The subcommittee remains interested in receiving stakeholder comments. The subcommittee's recommendations include a number of topics that will require further consideration, including transportation fuels and emission source thresholds. The subcommittee has carefully reviewed and considered stakeholder comments in order to formulate the draft recommendations contained in this document.

Electricity

Draft Recommendations for Electricity

- Point of Regulation and Coverage
  The WCI recommends a point of regulation for the electricity sector that maximizes coverage and minimizes emissions leakage.

    - A generator-based approach to covering the electricity sector is preferable.
    - The generator-based option will be most effective with universal participation throughout the Western interconnect.
    - A proposal to bring in additional generators serving the Western interconnect will be developed, including a date by which those other jurisdictions will join the WCI. If the additional Western Electric Coordinating Council (WECC) jurisdictions do not join by that date, the WCI will continue to develop the first jurisdictional deliverer approach described below.
    - Because not all generators serving the western interconnect are currently within the WCI, additional measures are needed to maximize coverage and minimize leakage.
    - The first jurisdictional deliverer approach should address the coverage and leakage issues during the transition to full WECC participation in the WCI:
        - The first jurisdictional deliverer approach covers all emissions generated in WCI and all emissions attributable to electricity delivered in WCI but generated outside WCI.

- Leakage
  The WCI recommends exploring additional complementary measures to reduce leakage.

- Allocation in the Electricity Sector
  The point of regulation does not dictate the method of allocation, and the Partners are continuing to work on the allocation issue.

The Electricity Subcommittee is now in the process of working through questions raised by the Partners, including how additional generation in the WECC can be brought into the WCI, and how the first jurisdictional deliverer approach would actually be implemented in Partner jurisdictions.

Summary of Major Comments Received to Date on Electricity Recommendations

To date, the WCI Electricity Subcommittee has received more than 100 comments from more than 60 parties, or coalitions of parties. The comments have come from utilities, trade groups, environmental NGOs (non-governmental organizations), religious institutions, and public interest groups interested in social justice.

Some commenters have noted that a federal approach would be preferable to WCI because leakage would be reduced. Others have called for no action by the WCI because a federal approach may eventually appear. Initially, the subcommittee suggested five options for the point of regulation for electricity. Each option had some support from at least a portion of those who commented, while many parties have requested that WCI not make a final decision until economic modeling is completed. However, consensus seems to have emerged around two approaches: generator-based and first jurisdictional deliverer (FJD).

Many commenters have called for a generator-based approach if all WECC jurisdictions participate in the WCI. Some commenters have argued that additional measures beyond a generator-based approach would be necessary to prevent contract shuffling and windfalls to electricity importers. Parties have suggested that the additional measures could include complementary measures, a load-generator hybrid, and FJD.
Some commenters have advocated starting with a generator-based approach and eventually shifting to FJD. Others have called for optional phasing in of FJD. Still others have advocated using FJD as the starting point. Some parties are concerned about the tracking necessary for load-based approaches and FJD, and they are worried that either method may have high administrative costs. Commenters have also expressed concern about the potential for gaming the system under the hybrid approaches. Some commenters are concerned about grid stability with any approach. The WCI Partners are still assessing the public comments and other analyses to determine the appropriate point of regulation for this sector within the regional program.

Many parties have commented on allowance allocation in the electricity sector. Requests have run the gamut from advocating for 100 percent auctioning to promoting 100 percent free allocation. Many parties have called for auctioning with auction revenues used for the benefit of consumers by giving the auction proceeds to rate-regulated entities or directly to consumers. Many commenters have worried about competitive impacts to businesses in the WCI under designs that include auctions. Some parties have requested that one or more economic sectors be exempted from auctioning. Parties have advocated allocation protocols based upon historical emissions, load, or output singularly or in combination. Similarly, commenters have advocated for apportionment among Partners based upon Partner targets, averaging of Partner targets, historical emissions, load, output, population, and GDP (gross domestic product), singularly or in combination.

Many parties have commented that combined heat and power (CHP) facilities should be covered under a separate sector and given credit for lower emissions. Other parties have noted that if a CHP facility produces fewer emissions, it should do well if it is regulated under the electricity sector like other generators. Some parties have called for unique treatment for their particular situations, while other commenters have requested even treatment for all entities across the sector. Parties have also called for a set-aside of allowances for the voluntary renewables market to ensure that market's viability.

Allocations

Draft Recommendations for Allocations

- Regional Cap and Allowance Budgets
  The WCI recommends establishing a regional cap that will decline over time, and each Partner will have an allowance budget within the cap. Actual emissions from any given Partner could be greater or less than its allowance budget, depending on the extent of inter-jurisdictional allowance trading.

  The regional cap will be equal to the sum of the Partner allowance budgets. Reductions achieved by the cap plus reductions from uncapped sources resulting from complementary measures should achieve the WCI regional goal of a 15 percent reduction below 2005 levels by 2020.

  The initial regional cap and Partner allowance budgets will be set through 2020. The regional cap and each Partner's allowance budget will not be adjusted except as necessary to account for changes in WCI membership, sectors added to the cap, errors discovered in data used to determine the cap or the Partner budgets, which may become apparent after the start of mandatory reporting, or errors that resulted in either under-allocation or over-allocation of allowances. Such adjustments will take effect at a regionally coordinated and designated time, such as the beginning of the relevant compliance period.

- Distribution of Allowances by Partners
  The WCI recommends that once the allowance budget has been established for each Partner, allowances will be issued by each Partner rather than issued by a regional organization. Allowances will be of equivalent use and value throughout the WCI region, regardless of which Partner issues the allowances.

- Establishment of Cap-and-Trade Partner Budgets
  The WCI recommends that each Partner's allowance budget will be established in a transparent manner. This will be consistent with the emission reductions that the WCI must realize from the sources covered by the cap-and-trade program in order to achieve the WCI economy-wide emissions reduction goal.

  The Partners will develop a methodology for calculating the Partner allowance budgets. The methodology should set the Partner allowance budgets at the levels needed to achieve the WCI economy-wide emissions reduction goal.

  The WCI seeks comments from stakeholders on the methodology for establishing Partners' allowance budgets and the factors to be included in the methodology.

- Partners' Initial Allowance Budgets
  The WCI recognizes the potential conflict between the need to begin the cap-and-trade program as soon as possible to reduce GHG emissions, and the need for accurate data to calculate allowances for the regional cap and individual Partner budgets. Substantial emissions data is already available due to reporting under existing regulatory requirements for other pollutants and energy consumption, as well as the GHG emissions inventories and forecasts compiled by the Partners, but data from mandatory reporting of GHG emissions may be necessary for more precise allocations of allowances. With this in mind, the calculation of the regional cap and the Partner allowance budgets for the initial years of the cap-and-trade program will recognize potential concerns about data accuracy and will be adjusted in ensuing years as necessary if mandatory reporting reveals significant data errors.

- Partner Discretion to Issue Allowances
  The WCI recommends each Partner initially have flexibility to issue, beyond the minimum percentage auction amount discussed below and subject to the sector-specific assessments discussed below, its remaining allowances as it sees fit, including:
    - auctioning more than the minimum amount of allowances;
    - issuing some or all of the remaining allowances for free;
    - holding some or all of the remaining allowances within a compliance period; and/or
    - retiring some or all of the remaining allowances.

  The WCI recommends each Partner initially have discretion to issue allowances differently to different sectors within its jurisdiction. Each Partner may decide how and to whom to issue the allowances in its allowance budget, subject to the minimum auction requirement and the sector-specific assessments of competition outlined below.

  While each Partner initially will have flexibility in how it allocates the allowances beyond the minimum auction amount, at the beginning of the relevant compliance period, each Partner will be required to advise the other WCI Partners how it intends to allocate the remaining allowances, so that the WCI can make the Partners' plans public in a coordinated fashion. This procedure will help reduce the potential for adverse impacts on auction prices by preventing allowances from being "dumped" into the market unexpectedly.

  Any Partner that chooses to hold allowances must allocate or retire those allowances by the end of the applicable compliance period. A Partner will not be able to hold allowances beyond the end of the compliance period. These requirements will help reduce market instability by providing more certainty about the volume of allowances available during a compliance period.

  The Partners will continue to examine the impacts of Partners using different approaches to allocate allowances to the same sectors and will seek comments from stakeholders on this issue.

  The Partners also will continue to consider the impacts of Partners making different use of auction proceeds and will seek comments from stakeholders on this issue.

  While the Partners initially will have flexibility to issue allowances, over time, the WCI will seek to standardize distribution of allowances as much as possible.

    - *Sector-Specific Assessment of Competition Among WCI Jurisdictions*:
      While the Partners initially will have significant flexibility in issuing allowances, a diverse array of allocation procedures could yield significant cost differentials among competing firms or industries among WCI jurisdictions. There may be cases where it is necessary to assess whether allocations to a particular sector should be treated uniformly by all Partners in the WCI region to address competition among entities within the WCI region. This potential could be minimized through a continued dialogue among the Partners and harmonization of allocation procedures and the use of auction proceeds where appropriate.

      The Partners believe that only a few sectors face significant risks of unfair competition from differing allocation methods among the WCI Partners, and a harmonized approach would be limited to carbon-intensive industries facing significant competition among WCI jurisdictions. For such cases, a case-by-case sector-specific analysis will be conducted jointly by the WCI Partners to determine whether consistent allocation is needed to address such disparities within the WCI. This approach will provide for an efficient cap-and-trade program while providing the Partners flexibility to address their individual priorities.

  - *Sector-Specific Assessment of Competition with Non-WCI Jurisdictions*:
    While the Partners initially will have significant flexibility in issuing allowances, a diverse array of allocation procedures could yield significant cost differentials among competing firms or industries within the WCI and those outside the WCI, resulting in leakage outside the WCI region. There may be cases where it is necessary to assess whether allocations to a particular sector should be treated uniformly by all Partners in the WCI region to address competition and leakage from entities outside the WCI region. This potential can be minimized through a continued dialogue among the Partners and harmonization of allocation procedures and the use of auction proceeds where appropriate.

    The Partners believe that leakage of this type is likely an issue only for bulk commodity sectors with high GHG emissions per unit of output that face significant non-WCI competition, and a harmonized approach would be limited to carbon-intensive industries facing significant competition outside the WCI region. For such cases, a sector-specific analysis will be conducted jointly by the WCI Partners to determine whether consistent allocation is needed to address non-WCI region leakage. This approach will provide for sufficient standardization for an efficient cap-and-trade program while providing the Partners flexibility to address their individual priorities.

- Minimum Auction Percentage
  The WCI recommends each Partner auction a minimum percentage, between 25 percent and 75 percent, of its allowance budget through a coordinated regional auction process. Each Partner will auction allowances throughout the WCI region and will receive the proceeds of the auction.

  The Partners will determine a specific minimum percentage auction amount. The WCI seeks comments from stakeholders on this question.

  Because multiple Partners would be simultaneously auctioning allowances through a single pool, the auction could result in Partners auctioning or selling some of their allowances to entities in other jurisdictions. This outcome is fully consistent with the concept of regional trading and the importance of allowances having equivalent use/value for compliance purposes throughout the WCI region.

- Phased Increase of Auctioning
  Greater emphasis could be given to free allocation in the early years of the program (and more to auctions in later years) as a means to mitigate business and consumer cost impacts and to provide transition assistance, in addition to using auction proceeds for these purposes. Some Partners may choose to provide more time for an allowance market to develop before capped entities must purchase larger portions of their allowances in an auction.

The minimum percentage of allowances to be auctioned should be increased over time, potentially to 100 percent. Even before such an increase, each Partner will have discretion to auction more than the minimum percentage of its allowances as it sees fit.

- Credits for Early Reductions
  The WCI recommends each Partner have discretion to give credit for early actions, but any credit for early action must come from within the cap and will come out of the individual Partner's allowance budget. Early action credits will not be added to or be on top of the amount of allowances in each Partner's allowance budget.

- Banking
  The WCI recommends purchasers and covered entities be allowed to bank allowances, without restrictions on the amount of allowances that may be banked or on how long they may be banked.

- Borrowing
  The WCI recommends that borrowing of allowances from future compliance periods not be allowed.

- Compliance Periods
  The WCI recommends the compliance periods be three years long.

  Multi-year compliance periods will provide covered entities with flexibility for compliance and in planning for (or responding to) large and unexpected changes in the allowance market or in other markets, such as energy markets, which may affect allowance prices. They also will provide programmatic flexibility for the WCI—for example, to ensure a steadily declining cap. The Partners note that three years is the length of the compliance periods chosen by the Regional Greenhouse Gas Initiative (RGGI).

- Initial Compliance Period
  To accommodate start-up issues, both from the covered entity standpoint and the regulatory standpoint, the WCI recommends that the initial compliance period include special rules, such as a two-year period, or other measures to assist in the transition into a cap-and-trade system, while maintaining the integrity of the cap and value of the allowances.

- New Partners
  The WCI recommends allowances for new Partners be in addition to the existing allowance budgets for current Partners. The regional cap will be expanded to accommodate emissions from the new Partner.

  Once the cap-and-trade program has been instituted, new Partners will come into the cap-and-trade program at a regionally coordinated and designated time, such as the beginning of the relevant compliance period.

- Timelines for Partner Activities
  The Partners will develop a schedule for various WCI efforts, including launching the cap-and-trade program, establishing emissions baselines and Partner allowance budgets, undertaking any case-by-case discussions on competition or leakage issues which may affect Partner allocation plans and other various allocation-related efforts.

Summary of Major Comments Received to Date on Allocations Recommendations

The WCI Allocations Subcommittee issued its Draft Design Recommendations for public comment on April 2, 2008. Fifty-six (56) comments were received from stakeholders by the April 16, 2008 deadline, with an additional five (5) comments received after the deadline. The subcommittee is still reviewing the comments and has not yet determined whether any of the draft allocations recommendations should be modified in light of the comments.

A diverse group of stakeholders provided comments on the draft allocations recommendations, including industry/trade associations (15), utilities (13), NGOs (11), government agencies (3), private citizens (2), and miscellaneous business entities (12). Nineteen (19) of the comments came from stakeholders with multi-state operations or interests; the remainder came as follows: Washington (10), California (9), Oregon (5), British Columbia (4), Arizona (4), Canada (3) and New Mexico (2).

Not surprisingly, the commenters provided a wide diversity of comments on the draft recommendations, with little consensus on several key issues. For example, comments on the WCI's draft recommendations regarding the regional cap and the Partner allowance budgets included the following divergent perspectives:

- The allowance budgets should be based on load or output.
- The allowance budgets should be based on historical emissions.
- The allowance budgets should be based on the state and provincial goals.
- Partner budgets should be identical to Partner commitment to the regional goal.
- Budgets should not be determined until accurate data are available.
- Budgets should include some set aside (3-5 percent) of allowances for new entrants.

Similarly, while some commenters called for free allocation of allowances to utilities, others argued for auctioning a significant percentage of the allowances. A number of commenters (e.g., NGOs) called for 100 percent auctioning, while others (e.g., utilities) argued that only a very small percentage (5 percent or less) of allowances should be auctioned, if at all.

There also were differences of opinion about the degree of flexibility that Partners should have to allocate allowances. Some who opposed flexibility expressed concern that the lack of uniformity could result in leakage. To minimize potential for leakage, one commenter suggested adopting consistent rules for reporting, tracking and compliance obligations. Another suggested distributing allowances to a third party.

There was a general level of support expressed for the WCI's draft recommendation regarding credits for early reductions, but a few commenters preferred that credits come from outside each Partner's allowance budget.

By the same token, more commenters than not supported the WCI's draft recommendations to allow unlimited banking but prohibit borrowing of allowances. Commenters supported the recommended three-year compliance periods by a wide margin. And to the extent that comment was received on the desirability of a regional organization, it was well received.

Finally, some commenters offered advice on topics not directly addressed in the draft allocations recommendations, including the following:

- Develop an independent Market Oversight Committee to develop best practices to guard against market manipulation, hold down consumer costs and avoid burdens on state economies.
- Consider more practical alternatives to address hoarding of allowances.
- Have a cost containment mechanism
- Have a safety valve.
- Do not have a safety valve.
- Have a price ceiling for allowances for a defined period.
- Allow only emitters to participate in auctions.
- Allow anyone to purchase allowances at auctions.

The WCI appreciates the range of ideas and perspectives expressed in the comments and will give them serious consideration as we move develop the draft design document.

Offsets

Draft Recommendations for Offsets

The primary role of the offset program is to reduce the overall compliance costs for the cap-and-trade system, by enabling the offset market to deliver lower-cost emission reduction options than are available in the sectors/sources included in the cap-and-trade system. In addition, by lowering overall costs, an offset program can potentially offer greater environmental benefits. The offset program can also serve to encourage innovation, co-benefits, greenhouse gas emission reductions from sources not covered by the cap-and-trade system and removals by sinks.

- <u>Offset project types and protocols</u>
  The WCI recommends:
  - development of an initial set of eligible project types and approved protocols prior to cap-and-trade program launch;
  - developing a process to review and approve other project types and related protocols proposed by project developers;
  - using protocols that are standardized to the extent possible; and,
  - making use of, and adapting if needed, existing protocols as appropriate.

- <u>Offset projects approved through the WCI offsets program</u>
  The WCI should consider a method that gives priority to offset projects located within WCI jurisdictions. The method should also consider other roles of the offset system, such as ensuring that co-benefits occur within the region.

  In addition to those offset projects approved within its jurisdictions, the WCI should consider approving offset projects located throughout Canada, the United States, and Mexico, where such projects would be subject to comparably rigorous oversight, validation, verification and enforcement as those located within the WCI jurisdictions and would not undermine the ability for the WCI to link to other trading systems.

- <u>Tradable units from government-regulated GHG emission trading systems</u>
  For compliance purposes, the WCI should consider allowing individual regulated entities to use tradable units (offsets and allowances) from other government-regulated GHG emission trading systems that the WCI recognizes as meeting similarly rigorous criteria for environmental integrity.

  The WCI should ensure accounting systems are in place to prevent using tradable units more than once for compliance.

- <u>Quantity Limits</u>
  The WCI recommends limiting the use of offsets and non-WCI tradable units for compliance by individual regulated entities:
  - to ensure that meaningful emission reductions take place within the sources covered by the cap-and-trade system.
  - in recognition that foregoing emission reductions at facilities covered by the cap-and-trade program in the WCI states has the potential to forego health benefits and other benefits near those facilities.

The WCI Offsets Subcommittee will consider making a specific draft recommendation to the WCI, based on further analysis and considering the level of the cap set for the cap-and-trade system.

Summary of Major Comments Received to Date on Offsets Recommendations

In each of the opportunities for stakeholder engagement on the design of a cap-and-trade system for the Western Climate Initiative, there has been strong support for including an offset program. Stakeholders have expressed a desire to see the offset program focus on ways to reduce the overall cost of meeting GHG emission reduction targets, whether through reduced compliance costs for emitters, reduced economic impact for consumers, or increased economic opportunities to encourage emission reductions. Stakeholders have also shown a strong and consistent concern for the environmental integrity of the offset program, realizing the direct connection between the integrity of the offsets and the integrity of the regional target.

Many stakeholders feel that offsets should be allowed to enter the WCI system from sources outside the WCI, by project approval through the WCI process or as approved trading units from other cap-and-trade systems. A number of stakeholders also believe there are compelling economic, environmental and social reasons to give priority to offset projects from within the WCI or to phase in other regions over time as experience grows. Several stakeholders suggested ways to develop or design limits on the type of offsets, including basing limits on project location. The WCI Offsets Subcommittee recognizes that offset projects must reduce or remove GHG emissions and may have co-benefits regardless of where the project is located, and will continue to examine the balance of economic, environmental and social benefits in the design of the program.

Given the encouragement to focus the offset program on reducing cost for the cap-and-trade system, some stakeholders find the concept of limiting the use of offsets to be counterproductive, reasoning that limiting the use of lower cost compliance alternatives simply means higher cost compliance. Other stakeholders argue that an oversupply of inexpensive offsets could reduce the impetus for capped emitters to make progress on direct emission reductions. The subcommittee invites further suggestions on the design of limits or alternative methods to balance the use of offsets with reductions under the cap.

Stakeholders generally supported the recommendation to establish a centralized administrative body to perform routine processing and management functions.

Regional Organization

Draft Recommendations for Regional Organization

WCI recognizes that a regional organization will be helpful for coordinating Partner activities and improving efficiency by centralizing the execution of administrative tasks. While WCI is continuing to identify suitable roles for a regional organization, the following options have been identified to date:

- Although emission allowances will be issued and distributed by each Partner, a regional organization may be directed to coordinate the regional auction of allowances, track emissions and allowances, monitor and report on market activity, and conduct other activities. A centralized offset registry is also required that integrates with the emissions and allowance tracking system.

- A regional organization may provide a venue for coordinating analyses of competitiveness and leakage issues resulting from potentially divergent allocation procedures among the WCI Partners. Such issues could be resolved through this regional organization or some other forum.

- A regional organization may provide a forum through which each Partner updates the other Partners every two years on its progress toward achieving the regional goal and its individual goal

- The administrative structure of the offsets program should combine optimal aspects of jurisdiction-by-jurisdiction, public-private partnership, and centralized regional approaches, and may draw from existing programs. The role of a regional organization may include:
  - coordinating review and adoption of protocols for offsets;
  - coordinating review and issuing of offsets;
  - providing the criteria and means to accredit service providers to deliver validation and verification services for offsets.

Each jurisdiction will retain its regulatory authority and enforcement responsibilities. By centralizing administrative tasks and coordinating Partner activities, the regional organization will help reduce administrative costs and improve program transparency and consistency.

Western Climate Initiative

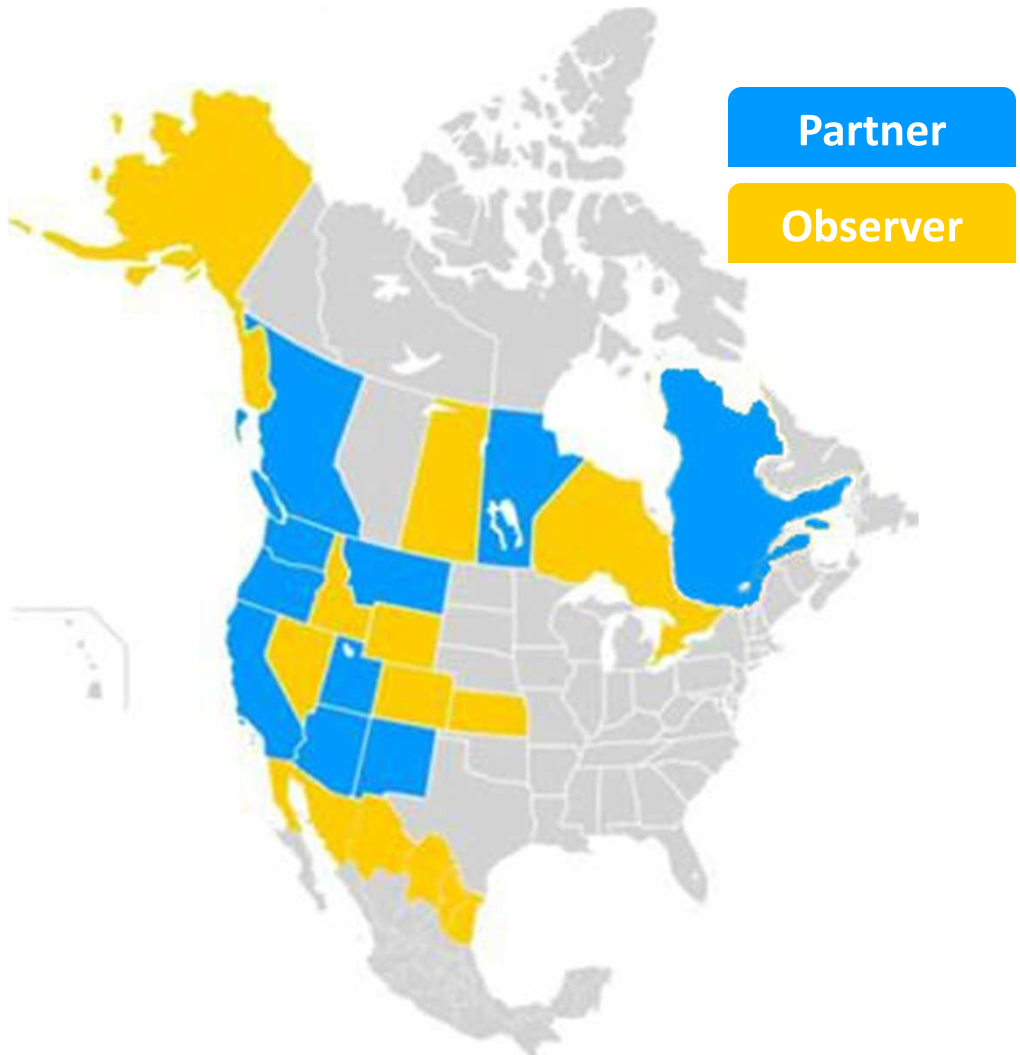
WCI Overview and Status

May 21, 2008

Salt Lake City, Utah

Western Climate Initiative

- **Develop regional strategies to address climate change**
- **Washington, Oregon, California, Arizona, and New Mexico signed in February, 2007**
- **Montana, Utah, British Columbia, Manitoba and Quebec have signed on**
- **6 US states, 6 Mexican states and 2 Provinces are official observers**



Collaboration includes

Three specific directives:

- Set a regional emissions reduction goal
- Join a multi-state registry to track, manage and credit reductions
- Design a regional multi-sector market-based mechanism

Joint work to:

- Promote clean and renewable energy in the region
- Increase energy efficiency
- Advocate for regional and national climate policies that are in the interest of western states
- Identify measures to adapt to climate change impact

Western Climate Initiative Status

Achieved two of the three directives:

- A regional goal established
  - 15% below 2005 by 2020
  - Committed to long term reductions to significantly lower the risk of dangerous threat

- All partners and observers have joined The Climate Registry as founding members

Timeline

- 5 subcommittees underway
  - Preliminary recommendations released in Feb and March, 2008
- Consolidated recommendations released on May 16, 2008
- Initial draft design mid-Summer, 2008
  - Next workshop July 29 in San Diego
- 'Final' design recommendations late-Summer, 2008
  - Will include next steps on design details and program implementation

Subcommittees

- Scope
  - Sectors; sources; gases; and point(s) of regulation
- Allocations
  - Apportioning allowances under the cap
- Electricity
  - Point(s) of regulation
- Reporting
  - Coordination: Regional, TCR, EPA; Verification
- Offsets
  - Project location and types; limits; links to other systems

Subcommittees are also starting to identify areas for coordination through a regional organization

Stakeholder Involvement

- Stakeholder input is critical to the success of the initiative
- All WCI Partners appreciate the interest and input to date
- A number of important design issues are still under discussion
- Today's workshop will help inform the dialogue among the partners on these issues
- Additional input opportunities over the summer
- Stakeholder process will continue in the next phase of program development

Western Climate Initiative

Scope Draft Recommendations

Michael Gibbs, Cal/EPA

Scope Subcommittee, Chair

May 21, 2008

Salt Lake City, Utah

Overview

- Mission
- Process
- Draft Recommendations
- Comments

Mission

- Recommend the scope of a proposed cap and trade program:
  - The sectors that fall under the cap.
  - The emissions sources that fall under the cap.
  - The greenhouses gases that fall under the cap.
  - The point(s) of regulation where the cap would be enforced.
- Electric Sector evaluated by the Electricity Subcommittee.

Mission (Continued)

- The Subcommittee is balancing multiple objectives, consistent with the WCI design principles
  - …administratively simple …
  - …minimizes administrative costs…
  - …covers as many sources as is practical…
  - …minimizes the potential for leakage…
  - …facilitates linkage…

Mission (Continued)

- Evaluate:
  - Emissions
  - Ability to measure/calculate emissions at the entity level
  - Administrative feasibility
  - Risk of emission leakage

Process

- Work Plan: October 2007
- Major Options: January 2008
- Workshop: January 2008
- Conference Call: February 2008
- Draft Recommendations: March 2008
- Conference Call: March 2008
- Written comments throughout

Draft Recommendations

- Industrial and Commercial Sources
  - Stationary combustion
  - Industrial processes
  - Waste management
  - Fossil fuel production and processing
  - All six GHGs
- Subject to:
  - Thresholds
  - Quantification methods

Draft Recommendations

- Thresholds
  - Balance emission coverage with administrative burden
  - Cover at least 90% of non-power plant stationary source fuel combustion
  - Assure consistency of coverage within industries and across jurisdictions
  - Examining:
    - 10,000 to 25,000 metric tons of CO_2e per year
    - Categories of facilities

Draft Recommendations

- Residential and Commercial Fuel Combustion
  - Include CO_2 emissions with upstream points of regulation
    - Local distribution companies
    - Refineries, wholesalers, distributors
    - Continuing work on points of regulation
  - Other fiscal measures
  - Examining: 1^{st} or 2^{nd} compliance period

Draft Recommendations

- Transportation Fuels
  - Continuing to evaluate

Draft Recommendations

- Future Program Expansion
  - Scope may expand over time
    - Monitoring technologies, procedures, protocols
    - Address leakage
    - Resolution of legal or administrative issues
    - New jurisdictions

Comments

- Diverse set of commenters
- Broad coverage
  - Technically and administratively feasible
  - Lower total cost of compliance
- Point of regulation close to emissions
- Emphasized:
  - Transportation fuels
  - Quantification methods; reliable data
  - Certainty of coverage
  - Non-covered sector emission reduction responsibilities

Questions

Western Climate Initiative

The Electricity Subcommittee Recommendations

David Van't Hof, Chair

Regional Stakeholders' Meeting
Salt Lake City
May 21, 2008

Overview

- Review Recommendation Process
- Review Draft Recommendation
- First Jurisdictional Deliverer Explained
- Questions

Recommendation Process

- Identified options for covering electricity
- Identified opportunities and challenges of each
- Sought stakeholder input
- Identified and ranked design principles
- Applied design principles to the options
- Discussed and ranked options
- Released Draft Recommendation March 3rd
- Sought stakeholder input
- Included recommendation in Initial Program Design May 16th

Draft Recommendation

- Key Starting Point:

  "The point of regulation for the electricity sector should maximize coverage and minimize emissions leakage."
- Partners recognize that this coverage could be realized through a generator-based program with broad participation in western interconnect
- The initial recommendation calls for greater participation in WCI.

Draft Recommendation

- In the absence of broad participation in WECC region, first jurisdictional deliverer approach would achieve the coverage goal.
- First jurisdictional deliverer, or “FJD”, covers nearly all emissions related to the electricity consumed in the WCI partner jurisdictions, because it focuses on all deliverers of electricity.

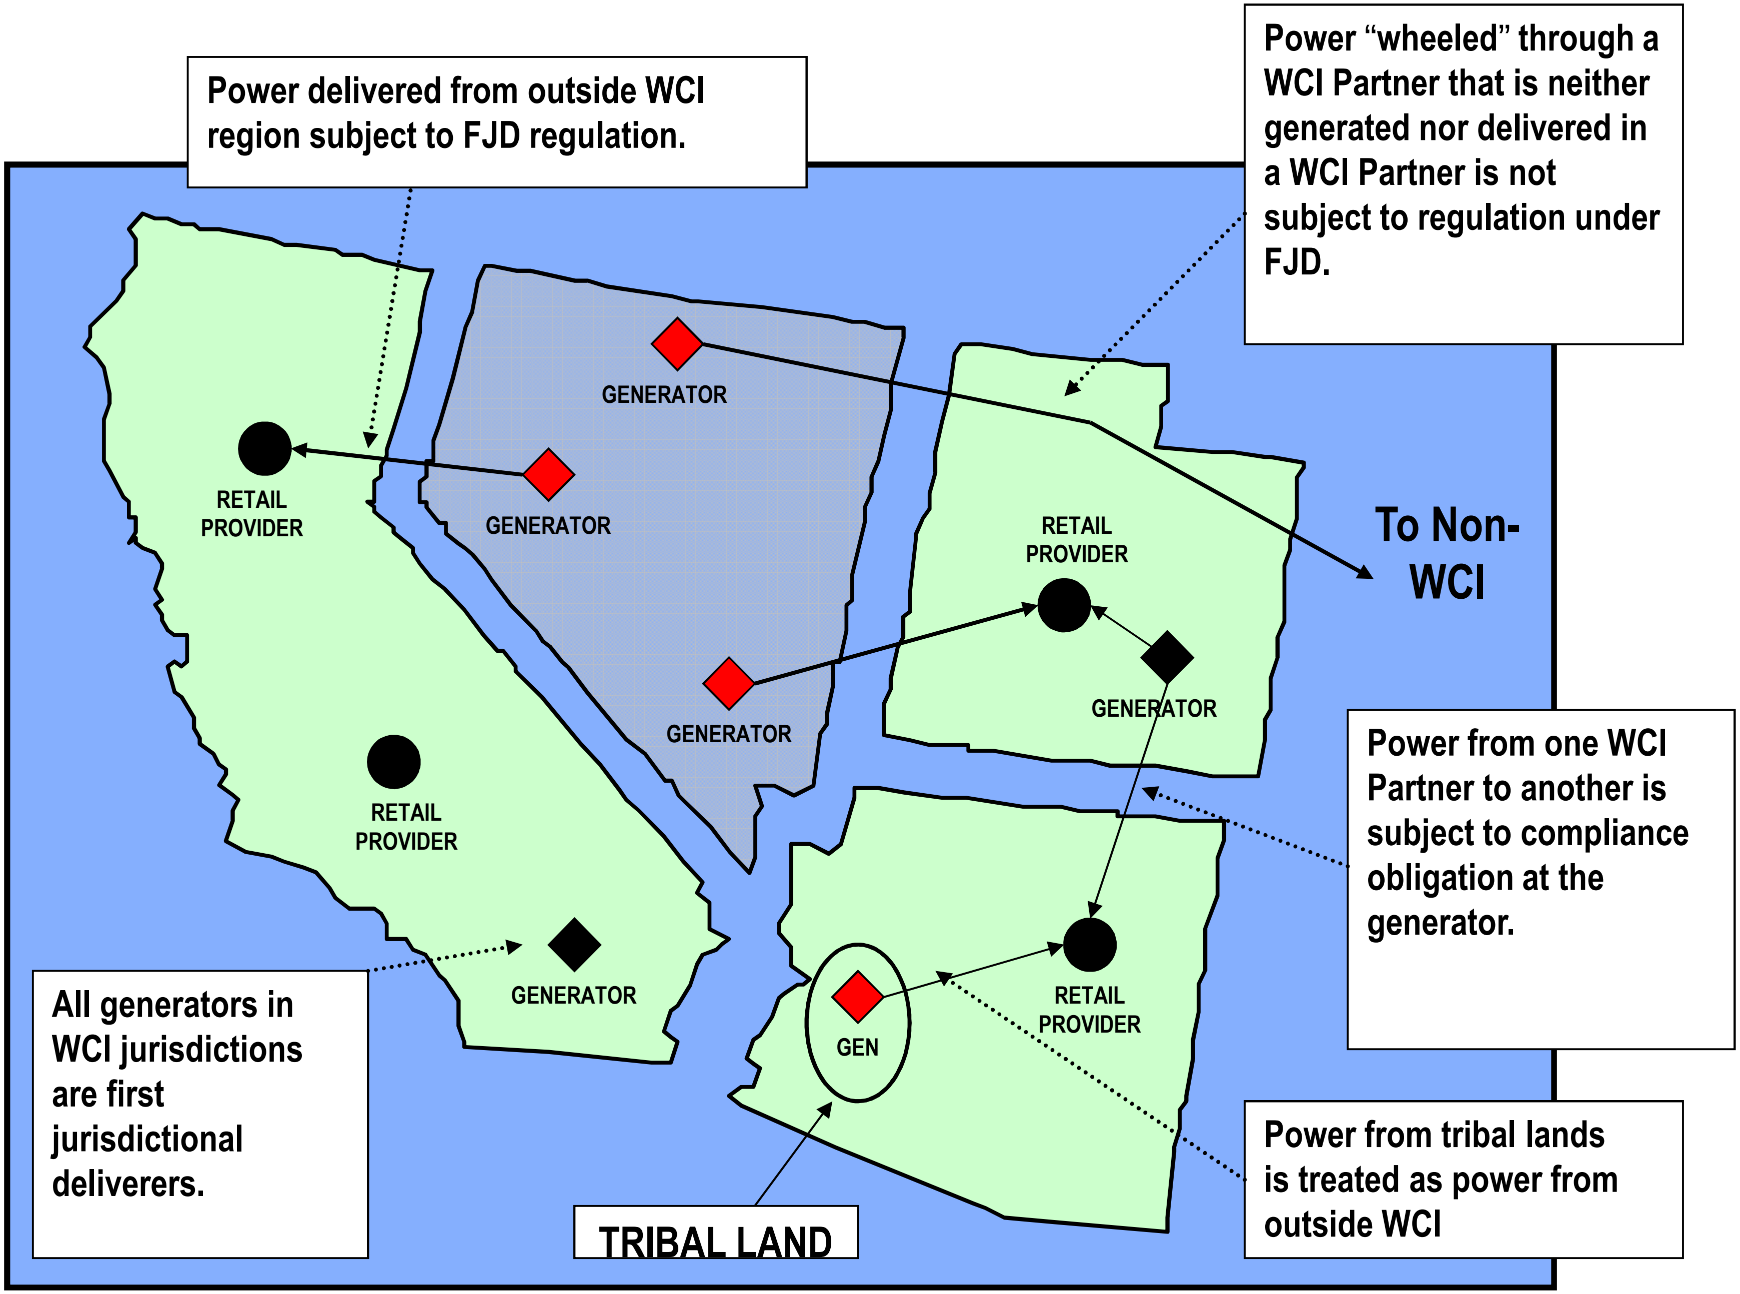
Since February

Subcommittee has focused on two priorities:

1. Better understanding how the FJD approach would be implemented in the region, including:
   – Answering questions from partners; and
   – Reviewing stakeholder input on the draft
2. Consider the allowance issues--both apportionment and allowance distribution--as they relate specifically to FJD or Generator and FJD

What is FJD?

- It is a point of regulation approach for electricity:
  - First deliverers are:
    - Generator deliverers in WCI jurisdictions
    - Deliverers of imported electricity in WCI jurisdictions
- Seeks to cover nearly all emissions related to electricity consumed in region, wherever that electricity is generated



Power delivered from outside WCI region subject to FJD regulation.
Power "wheeled" through a WCI Partner that is neither generated nor delivered in a WCI Partner is not subject to regulation under FJD.
GENERATOR
RETAIL PROVIDER
GENERATOR
RETAIL PROVIDER
To Non-WCI
GENERATOR
GENERATOR
RETAIL PROVIDER
Power from one WCI Partner to another is subject to compliance obligation at the generator.
GENERATOR
RETAIL PROVIDER
GEN
All generators in WCI jurisdictions are first jurisdictional deliverers.
Power from tribal lands is treated as power from outside WCI
TRIBAL LAND

FJD Reporting

All FJDs would have a reporting obligation:

- *Deliverer of power generated in a WCI jurisdiction is the generator. The generator would report emissions measured at the stack or through fuel factors.*
- *Deliverer of power generated outside jurisdiction would report emissions attributable to the power delivered based on:*
  - NERC e-tag and/or bilateral contract. Emissions would be calculated based on MWhrs times emissions factor for generator type.
- In all cases where FJD is unable to supply good emissions data will require substitution of default emissions rate

FJD Compliance

- *All FJDs would have a compliance obligation:*
  - *Must surrender enough allowances to "cover" all emissions reported during the compliance period.*
- The emissions baseline for the FJDs would be established using available emissions data from generator FJDs in the region, plus emissions attributable to imported power based on all available information for imports during the baseline period.
- Emissions and allowances would be tracked in the same way as existing cap-and-trade programs:
  - FJDs have emissions account where emissions reporting data are "deposited"
  - FJDs have compliance accounts where allowances are deposited.

Questions?

Break

Western Climate Initiative

Draft Allocations Design Recommendations

Patrick Cunningham
Arizona Dep't of Environmental Quality

May 21, 2008
Salt Lake City, Utah

Regional Cap & Partner Allowance Budgets

- The WCI recommends establishing a regional cap that will decline over time, and each Partner will have an allowance budget within the cap.
- The regional cap will be equal to the sum of the Partner allowance budgets.
  - Reductions achieved by the cap plus reductions from uncapped sources resulting from complementary measures should achieve the WCI regional goal of a 15 percent reduction below 2005 levels by 2020.
- The initial regional cap and Partner allowance budgets will be set through 2020.

Establishment of Partner Allowance Budgets

- The WCI recommends that each Partner's allowance budget be established in a transparent manner.

- The Partners will develop a methodology for calculating the Partner allowance budgets. The methodology should set the Partner allowance budgets at the levels needed to achieve the WCI economy-wide emissions reduction goal.

  – *The WCI seeks comments from stakeholders on the methodology for establishing Partners' allowance budgets and the factors to be included in the methodology.*

Partner Discretion to Issue Allowances

- The WCI recommends that once the allowance budget has been established for each Partner, allowances will be issued by each Partner rather than issued by a regional organization.

- The WCI recommends each Partner initially have flexibility to issue its remaining allowances as it sees fit, subject to the minimum percentage auction amount and sector-specific assessments, including:

  - auctioning more than the minimum amount of allowances;
  - issuing some or all of the remaining allowances for free;
  - holding some or all of the remaining allowances within a compliance period; and/or
  - retiring some or all of the remaining allowances.

- The WCI recommends each Partner initially have discretion to issue allowances differently to different sectors within its jurisdiction.

Allocation of Allowances by Partners

- Each Partner will be required to advise the other WCI Partners how it intends to allocate the remaining allowances, so that the WCI can make the Partners' plans public in a coordinated fashion.
- Any Partner that chooses to hold allowances must allocate or retire those allowances by the end of the applicable compliance period.
- While the Partners initially will have flexibility to issue allowances, over time, the WCI will seek to standardize distribution of allowances as much as possible.
- The Partners will continue to examine the impacts of Partners using different approaches to allocate allowances to the same sectors
  - *WCI seeks comments from stakeholders on this issue.*
- The Partners also will continue to consider the impacts of Partners making different use of auction proceeds
  - *WCI seeks comments from stakeholders on this issue.*

Sector-Specific Assessments

WCI will conduct sector-specific assessments to assess whether allocations to a particular sector should be treated uniformly by all Partners in the WCI region:

- to address competition among entities within the WCI region
  - Only a few sectors face significant risks of unfair competition from differing allocation methods among the WCI Partners, and a harmonized approach would be limited to carbon-intensive industries facing significant competition among WCI jurisdictions WCI jurisdictions.
- to address competition and leakage from entities outside the WCI region
  - Leakage of this type is likely an issue only for bulk commodity sectors with high GHG emissions per unit of output that face significant non-WCI competition.

Allowance Auctions

- <u>Minimum Auction Percentage</u>
  - The WCI recommends each Partner auction a minimum percentage, between 25 percent and 75 percent, of its allowance budget through a coordinated regional auction process.
  - The Partners will determine a specific minimum percentage auction amount.
  - *The WCI seeks comments from stakeholders on this question.*
- <u>Phased Increase of Auctioning</u>
  - Greater emphasis could be given to free allocation in the early years of the program
  - The minimum percentage of allowances to be auctioned should be increased over time

Compliance Periods

- The WCI recommends the compliance periods be three years long.
- To accommodate start-up issues, both from the covered entity standpoint and the regulatory standpoint, the WCI recommends that the initial compliance period include special rules, such as a two-year period, or other measures to assist in the transition into a cap-and-trade system, while maintaining the integrity of the cap and value of the allowances.

Early Actions, Banking & Borrowing

- Credits for Early Reductions: The WCI recommends each Partner have discretion to give credit for early actions, but any credit for early action must come from within the cap and will come out of the individual Partner's allowance budget.

- Banking: The WCI recommends purchasers and covered entities be allowed to bank allowances, without restrictions on the amount of allowances that may be banked or on how long they may be banked.

- Borrowing: The WCI recommends that borrowing of allowances from future compliance periods not be allowed.

New Partners

- The WCI recommends that allowances for new Partners be in addition to the existing allowance budgets for current Partners. The regional cap will be expanded to accommodate emissions from the new Partner.

- Once the cap-and-trade program has been instituted, new Partners will come into the cap-and-trade program at a regionally coordinated and designated time, such as the beginning of the relevant compliance period.

Stakeholder Comments

- The WCI particularly sought comments on:
  - the methodology for establishing Partners' allowance budgets and the factors to be included in the methodology
  - different approaches to allocate allowances to the same sectors
  - making different use of auction proceeds
  - minimum percentage auction amount
- Fifty-six (56) comments received by the April 16, 2008 deadline:
  - Industry/trade associations (15); Utilities (13); NGOs (11); Government agencies (3); Private citizens (2); Miscellaneous business entities (12)
  - Five (5) additional comments received after the deadline
- Geographic distribution of commenters:
  - Nineteen (19) multi-state stakeholders; Washington (10); California (9); Oregon (5); British Columbia (4); Arizona (4); Canada (3); New Mexico (2)

Examples of the Wide Diversity of Stakeholder Comments

- Regional cap and the Partner allowance budgets
  - The allowance budgets should be based on load or output.
  - The allowance budgets should be based on historical emissions.
  - The allowance budgets should be based on the state and provincial goals.
  - Partner budgets should be identical to Partner commitment to the regional goal.
  - Budgets should not be determined until accurate data are available.
  - Budgets should include some set aside (3-5 percent) of allowances for new entrants.

- Allocation of Allowances
  - Allowances should be allocated free to utilities
  - A significant percentage of all allowances should be auctioned
  - Some commenters (e.g., NGOs) called for 100 percent auctioning
  - Others (e.g., utilities) opposed auctions or argued that only a very small percentage (5 percent or less) of allowances should be auctioned, if at all.

- Partner Discretion to Allocate Allowances
  - A lack of uniformity could result in leakage
  - To minimize potential for leakage, adopt consistent rules for reporting, tracking and compliance obligations
  - Distribute allowances to a third party

Stakeholder Comments (cont.)

- Banking & Borrowing: Most commenters supported the recommendations to allow unlimited banking but prohibit borrowing of allowances.

- Compliance Periods: Commenters supported the recommended three-year compliance periods by a wide margin.

- Other Comments (mostly relating to auctions):
  - Develop an independent Market Oversight Committee to develop best practices to guard against market manipulation, hold down consumer costs and avoid burdens on state economies.
  - Consider more practical alternatives to address hoarding of allowances.
  - Have a cost containment mechanism
  - Have a safety valve.
  - Do not have a safety valve.
  - Have a price ceiling for allowances for a defined period.
  - Allow only emitters to participate in auctions.
  - Allow anyone to purchase allowances at auctions.

Questions

Lunch Break

(Reconvene at 1:00 p.m.)

Western Climate Initiative

Phase 1 Modeling

Presented to

Western Climate Initiative Stakeholders

May 21, 2008
Salt Lake City, Utah

Topics

- Phase 1 Status
- Preliminary Results
- Example Model Outputs
- Status of Assumptions Book

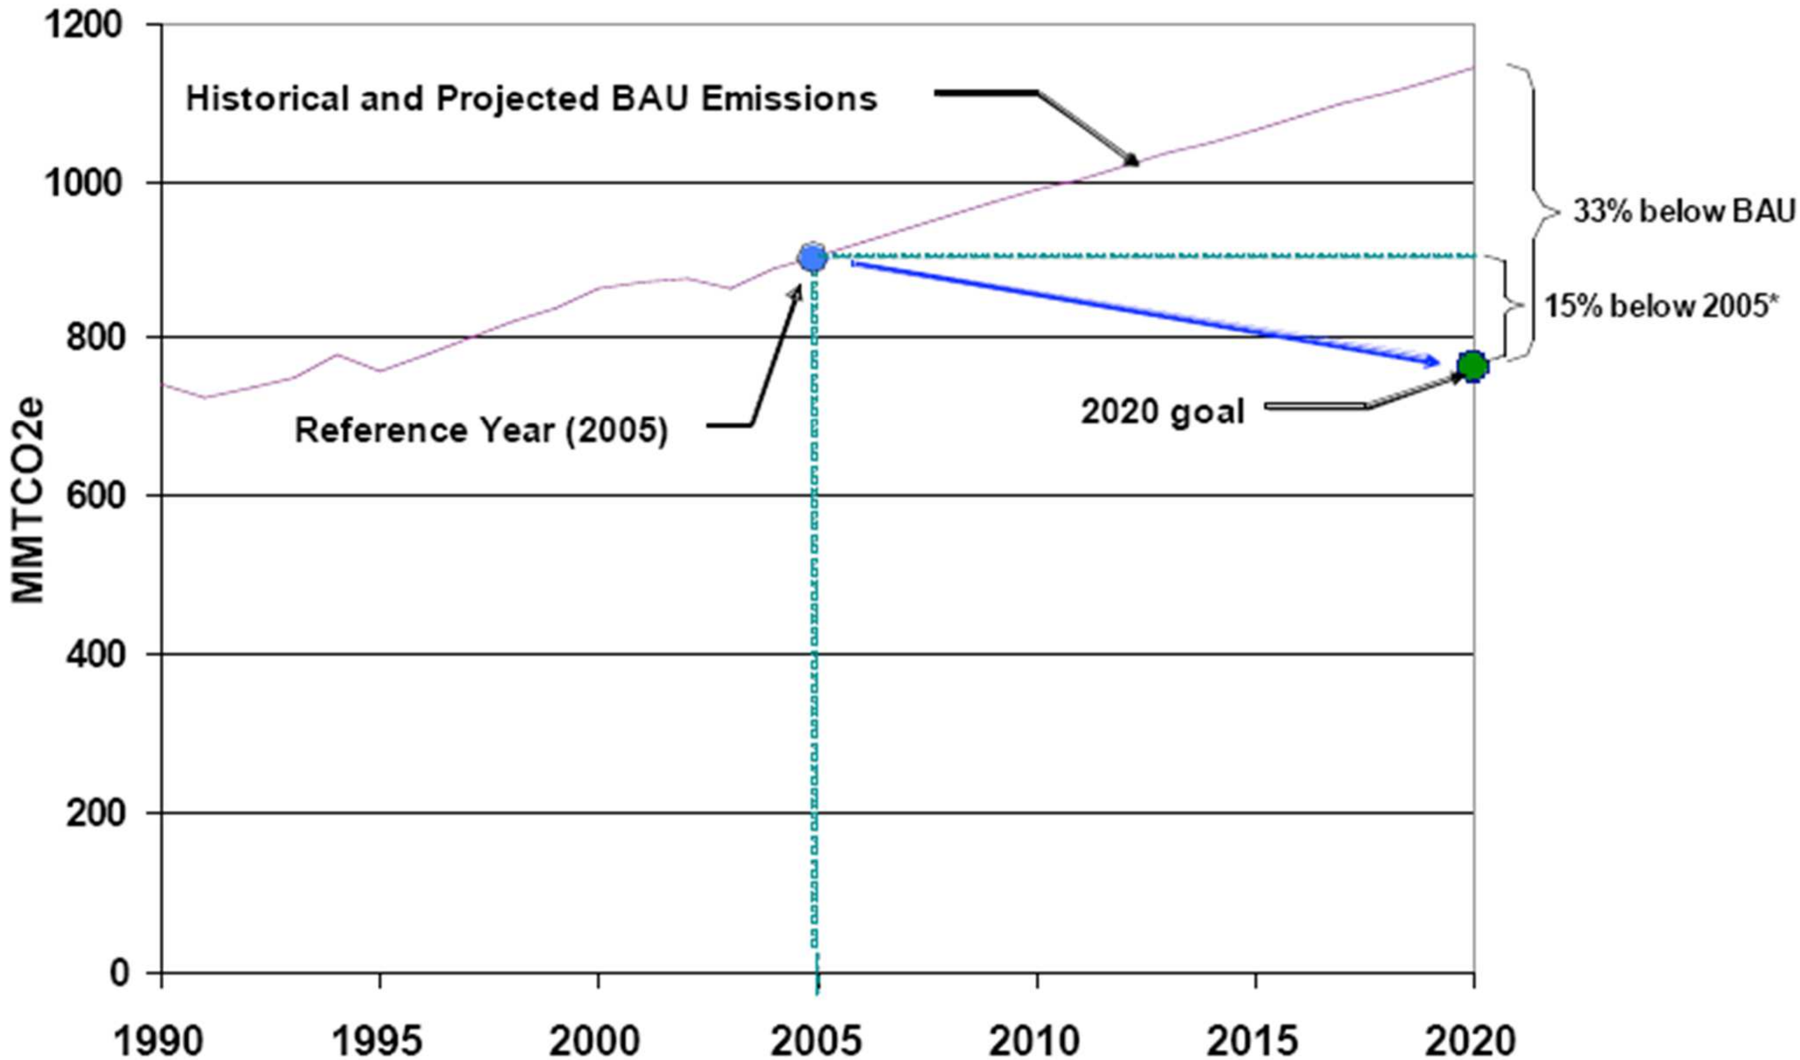
Phase 1 Status

- Reference case
  - "Reasonably close" to 8 partners' 2005 inventories
  - Incorporate 2007 national energy bill (EISA) and existing renewable portfolio standards
- Complementary policies
  - CA car standards, VMT reduction
  - Energy efficiency programs (electric & gas utilities, LPG, heating oil)
- Cap-and-trade scenarios (in progress)
  - First-jurisdictional deliverer (proxy with WECC-wide cap)
  - Proper treatment of tribal power plants
  - Manitoba and Quebec not yet incorporated

WCI Partner Data

- GHG inventories and forecasts (August 2007)
- The forecasts show aggregate growth of >25% in emissions from 2005-2020
- Reducing emissions to 15% below 2005 levels would require a 33% reduction from forecasted 2020 levels

WCI Partner GHG Emissions and Regional Goal[3]



ENERGY 2020 Phase 1 Reference Case

- The model simulates the partner inventories for 2005 reasonably well
- GHG emissions in 2020 in the Reference Case are significantly lower. Why?
  - Partner forecasts are ~1 to 5 years old
  - Energy prices are projected to be higher
  - Reference Case includes EISA and state RPS's
  - Reference Case assumes no new conventional coal plants (beyond "committed coal plants")
  - Not using partner-specific population growth rates in Phase 1 modeling

Impact of Higher Energy Prices AEO Estimates

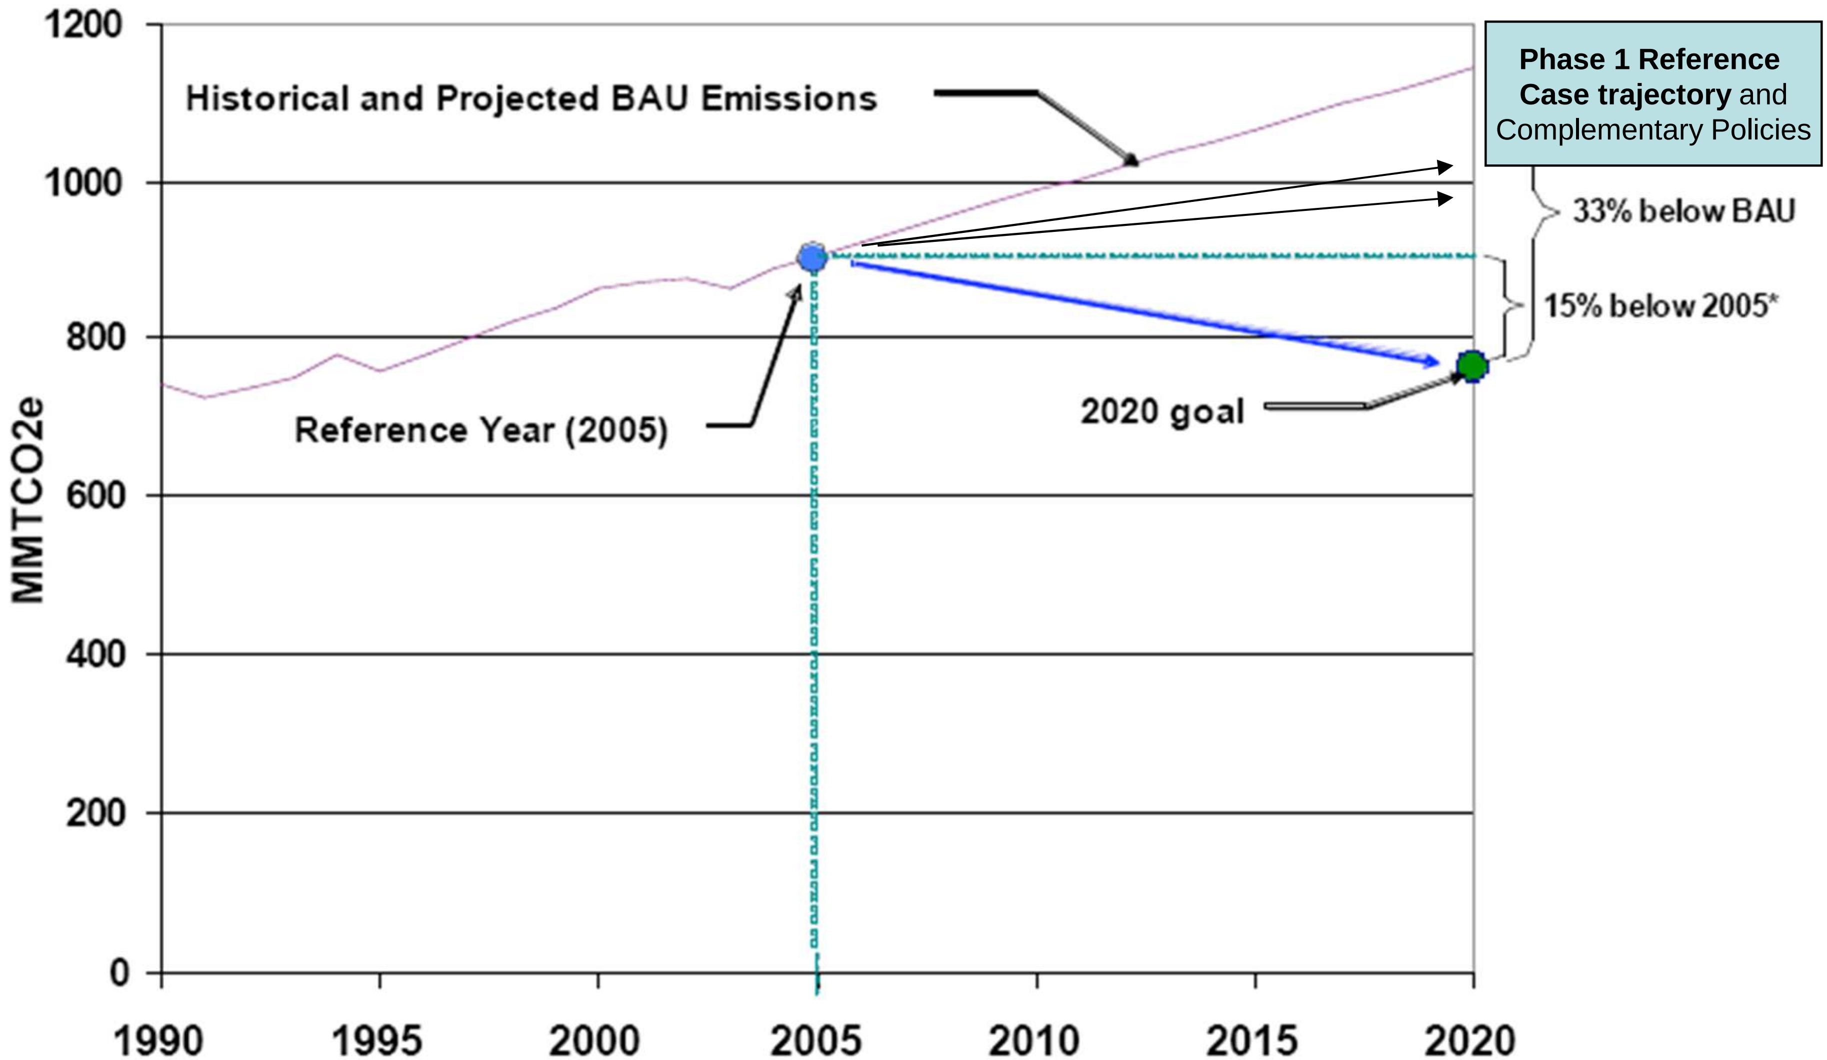
		AEO 2007		AEO 2008	
	2005	2020	% Incr	2020	% Incr
Total CO2 Emissions (MMT)	5982	6944	16%	6384	7%
Ave Annual Growth 2005-2030					
Energy Consumption			1.2%		0.7%
Economic Growth			2.9%		2.4%

- Significant decreases in projected CO2: 16% vs. 7%
- Oil prices substantially higher
- Energy consumption grows more slowly
- Economy grows more slowly
- All projections are from AEO “mid-price” cases, Table 18.

ENERGY 2020 Phase 1 Reference Case and Complementary Policies

- Graph illustrates likely trajectories of
  1) Reference Case and
  2) Complementary Policies model run
  which includes three WCI-wide policies:
  - CA car standards (including “Part 2” to these standards)
  - Total VMT reduced below levels in 2020 Reference Case
  - Aggressive energy efficiency programs that reduce demand below the Reference Case for electricity, natural gas, LPG, and heating oil

WCI Partner GHG Emissions and Regional Goal[3]



Example Model Outputs

- GHG Emissions
  - With market-clearing allowance price for GHG cap-and-trade program
  - GHG offset prices and quantities used
- Power Sector
  - Demand, generation, capacity, wholesale prices, retail electric rates
- Fuel use and market shares
  - Oil, natural gas, coal, gasoline, diesel, ethanol, biodiesel, etc.
- Levels of Energy Efficiency
- Examples of model output
  - http://www.epa.state.il.us/air/climatechange/documents/07-09-06/modeling-of-policy-proposals.ppt (Illinois)
  - http://dnr.wi.gov/environmentprotect/gtfgw/documents/reference_case_outputs_20080416.pdf (Wisconsin)

Status of Assumptions Book

- We are processing input from April 14 stakeholder call and from emails
- We will post a new version prior to June 9 stakeholder call

Questions

Western Climate Initiative

Offsets
Draft Design Recommendations

Tim Lesiuk (BC), Offsets Subcommittee Chair

May 21, 2008

Salt Lake City, Utah

Overview

- Revised Draft Recommendations
  - Offsets project types and protocols
  - Offsets project locations
  - Tradable units from government-regulated GHG emission trading systems
  - Quantity Limits
- Summary of Stakeholder Comments to date

Mission

- Recommend whether to include a greenhouse gas offset mechanism as an element of the Western Climate Initiative cap and trade system, and if so,
- Recommend design, scope and operation of such a mechanism.

Offsets project types & protocols

The WCI recommends:

- development of an initial set of eligible project types and approved protocols prior to cap-and-trade program launch;
- developing a process to review and approve other project types and related protocols proposed by project developers;
- using protocols that are standardized to the extent possible; and,
- making use of, and adapting if needed, existing protocols as appropriate.

Offsets Project Location

The WCI should consider:

- A method that gives priority to offset projects located within WCI jurisdictions (also considering other roles of the offset system, such as ensuring that co-benefits occur within the region).
- Approving offset projects located throughout Canada, the United States, and Mexico, where such projects would be subject to comparably rigorous oversight, validation, verification and enforcement as those located within the WCI jurisdictions and would not undermine the ability for the WCI to link to other trading systems.

Tradable units from other systems

The WCI should:

- For compliance purposes, consider allowing individual regulated entities to use tradable units (offsets and allowances) from other government-regulated GHG emission trading systems that the WCI recognizes as meeting similarly rigorous criteria for environmental integrity.
- Ensure accounting systems are in place to prevent using tradable units more than once for compliance.

Quantitative Limits

The WCI recommends limiting the use of offsets and non-WCI tradable units for compliance by individual regulated entities:

- to ensure that meaningful emission reductions take place within the sources covered by the cap-and-trade system.
- in recognition that foregoing emission reductions at facilities covered by the cap-and-trade program in the WCI states has the potential to forego health benefits and other benefits near those facilities.

Stakeholder Comments

- **Strong support for including an offset program**
- **Desire for strong environmental integrity of the offset program**
- **Support for establishing a centralized administrative body**
- **A mix of views on location:**
  - allow offsets from outside the WCI, by project approval through WCI or as certified trading units from other approved systems
  - give priority to offset projects from within the WCI or to phase in other regions over time as experience grows
- **A mix of views on quantitative limits:**
  - limits increase cost of compliance
  - oversupply of inexpensive offsets could reduce the impetus for capped emitters to reduce their own emissions

Questions

Western Climate Initiative

Reporting Recommendations

Reporting Subcommittee

Jim Norton, Chair

May 21, 2008

Salt Lake City, UT

Practical Impacts for Reporting

- Key Elements
  - Consistent, transparent, robust quantification and reporting across sources and states/provinces
  - Broadest possible coverage / inclusion
- Maximum reliance on and linkage with The Climate Registry (TCR) and international reporting programs
  - Anticipate employing TCR quantification protocols and reporting systems and services

Subcommittee Deliberations

- Subcommittee Conference Calls
- Subcommittee Work Plan
- Major Options Paper
  - Major Options (1 through 7)
- Draft Recommendations Paper
- Stakeholder Input:
  - Written Comments
  - Conference Calls
  - Stakeholder Workshops

Draft Program Reporting Recommendations for Comment

1. Breadth/Scope of Coverage
2. Initiation of Reporting
3. Coordination Among Partner Jurisdictions on Reporting
4. Data Management and TCR Interaction
5. Verification
6. Administrative Costs & Fees
7. Mandatory Federal GHG Reporting

1. Breadth/Scope of Coverage

Draft Recommendation:

The WCI recommends that reporting requirements apply to the capped sectors and to certain non-capped sectors that may be phased in later (will have to determine which ones -- lower thresholds may apply).

Representative Comments:

- Include only capped sectors initially; non-capped can be offsets
- Including sectors outside initial cap:
  - Allows for more accurate accounting across all sectors
  - Provides better basis for allocations
  - Provides more comprehensive public information
- Reasonable thresholds needed
- Divided opinion on inclusion of sectors/sources not likely to be phased in later

2. Initiation of Reporting

Draft Recommendation:

The WCI recommends that reporting start before cap-and-trade commences in order to avoid reporting-related delays to the start of the cap-and-trade program.

Representative Comments:

- Most commenters support early start to reporting
- Start reporting ASAP; phase in problematic sectors
- Reporting before cap-and-trade will help provide:
  - Accurate data for allocations and offsets
  - “shake out” period for program
- Some recommend voluntary reporting with no verification or enforcement (as training) before cap-and-trade
- Don’t let reporting delay the introduction of the cap; emissions from large sources are already being reported federally

3. Coordination Among Partner Jurisdictions

Draft Recommendation:

The WCI recommends developing essential requirements for a model WCI reporting rule by the end of 2008 and will incorporate consideration for jurisdictions that already have reporting rules adopted or in process.

Representative Comments:

- Wide range of opinion on uniformity needed vs. jurisdictional variation
- A universally consistent rule would be more administratively effective and cost-efficient
- Lack of consistency would increase gaming, lead to errors in reporting and higher costs for reporters, including verification costs
- Less burden for companies with facilities in multiple jurisdictions
- Desire continuity for existing state-mandated reporting; allow for nuances in certain sectors or jurisdictions
- Hybrid: Single rule, but allow partners to supplement core with additional reporting

4. Data Management & TCR Interaction

Draft Recommendation:

The WCI recommends that sources report either (a) directly to jurisdictions (which would then upload the data to TCR's central repository), or (b) through the TCR's program framework (which would then download the data to the necessary jurisdiction(s)).

Representative Comments:

- Relying on TCR would avoid patchwork, allow "one-stop shopping"
- TCR reporting simplifies reporting for companies with facilities in multiple jurisdictions
- Legal restrictions may not allow reporting except to states/provinces
- Partners should not cede authority to TCR; use TCR only for storage
- Jurisdictional reporting would allow coupling with other pollutant discharge reporting
- Divided opinion: some opposed to one option, some to the other
- Multi-jurisdictional companies tend to favor direct TCR reporting

5. Verification

The WCI recommends establishing essential quality assurance elements for reported data. These elements will be consistent across jurisdictions. Each jurisdiction will have an oversight mechanism to ensure compliance with the reporting requirements. As part of this mechanism, each jurisdiction will establish procedures to ensure that the quality assurance elements are met. This could include third-party verification, rigorous compliance audits or other appropriate approaches.

Representative Comments:

- Divergent opinions
- Consistency and credibility is vital, especially for capped sectors
- Some view third party verification as essential for market
- Potential costs of third party verification are a concern, especially for smaller companies
- Some say third party verification should not be needed if emissions are calculated using CEMS data and/or other federally approved methods

6. Administrative Costs & Fees

Draft Recommendation:

The WCI recognizes that jurisdictions may collect fees from sources reporting directly to them and contract with TCR to administer the program. Jurisdictions may also accept data directly from TCR if they choose to do so; entities that report through TCR may have to pay an additional fee if one is required by the jurisdiction(s).

Representative Comments:

- Opinions similar to views on reporting to TCR vs. jurisdictions
- Reporter payment to TCR could reduce administrative complexity
- Requiring TCR payment may need enabling legislation
- Need accountability for how fees are used
- Many recommend payment should go to wherever sources are required to report
- Must ensure that fees are used only to support the reasonable costs of the program
- Some jurisdictions may pay costs

7. Mandatory Federal GHG Reporting

Draft Recommendation:

The WCI recommends getting involved in federal GHG reporting program development in the U.S. and Canada to ensure that federal reporting programs are harmonized with the jurisdictions' interests to the greatest extent possible.

Representative Comments:

- Goal should be consistency and single (one-time) reporting
- WCI should seek to influence federal reporting
- WCI should seek to follow federal reporting (US & Canada)

Implementation Schedule

- Sign contract for development of essential requirements of WCI reporting rules in June 2008
- Contractor will work with Reporting Subcommittee
- Finish essential requirements for reporting rules by December 31, 2008
- Will provide opportunities for stakeholder review and comment

Additional Information on ENERGY 2020 Model Inputs

Presented to

Western Climate Initiative Stakeholders

June 9, 2008

Topics

1. Update on modeling & assumptions book.
2. Additional information on selected model input data, and guidance on exploring them
   a) 3.1 Population and Economic Data
   b) 3.2, 3.3 Energy Prices, Consumption, Expenditures
   c) 3.5 Electricity Sector Data
   d) Appendix C: Transmission Capacity

Objective

Stakeholder feedback indicated interest in data sources used in modeling.

Data sources are being enhanced in the revised “Assumptions Book” to include specific sources

Objective of presentation is to illustrate how stakeholders can follow these links to review actual source data.

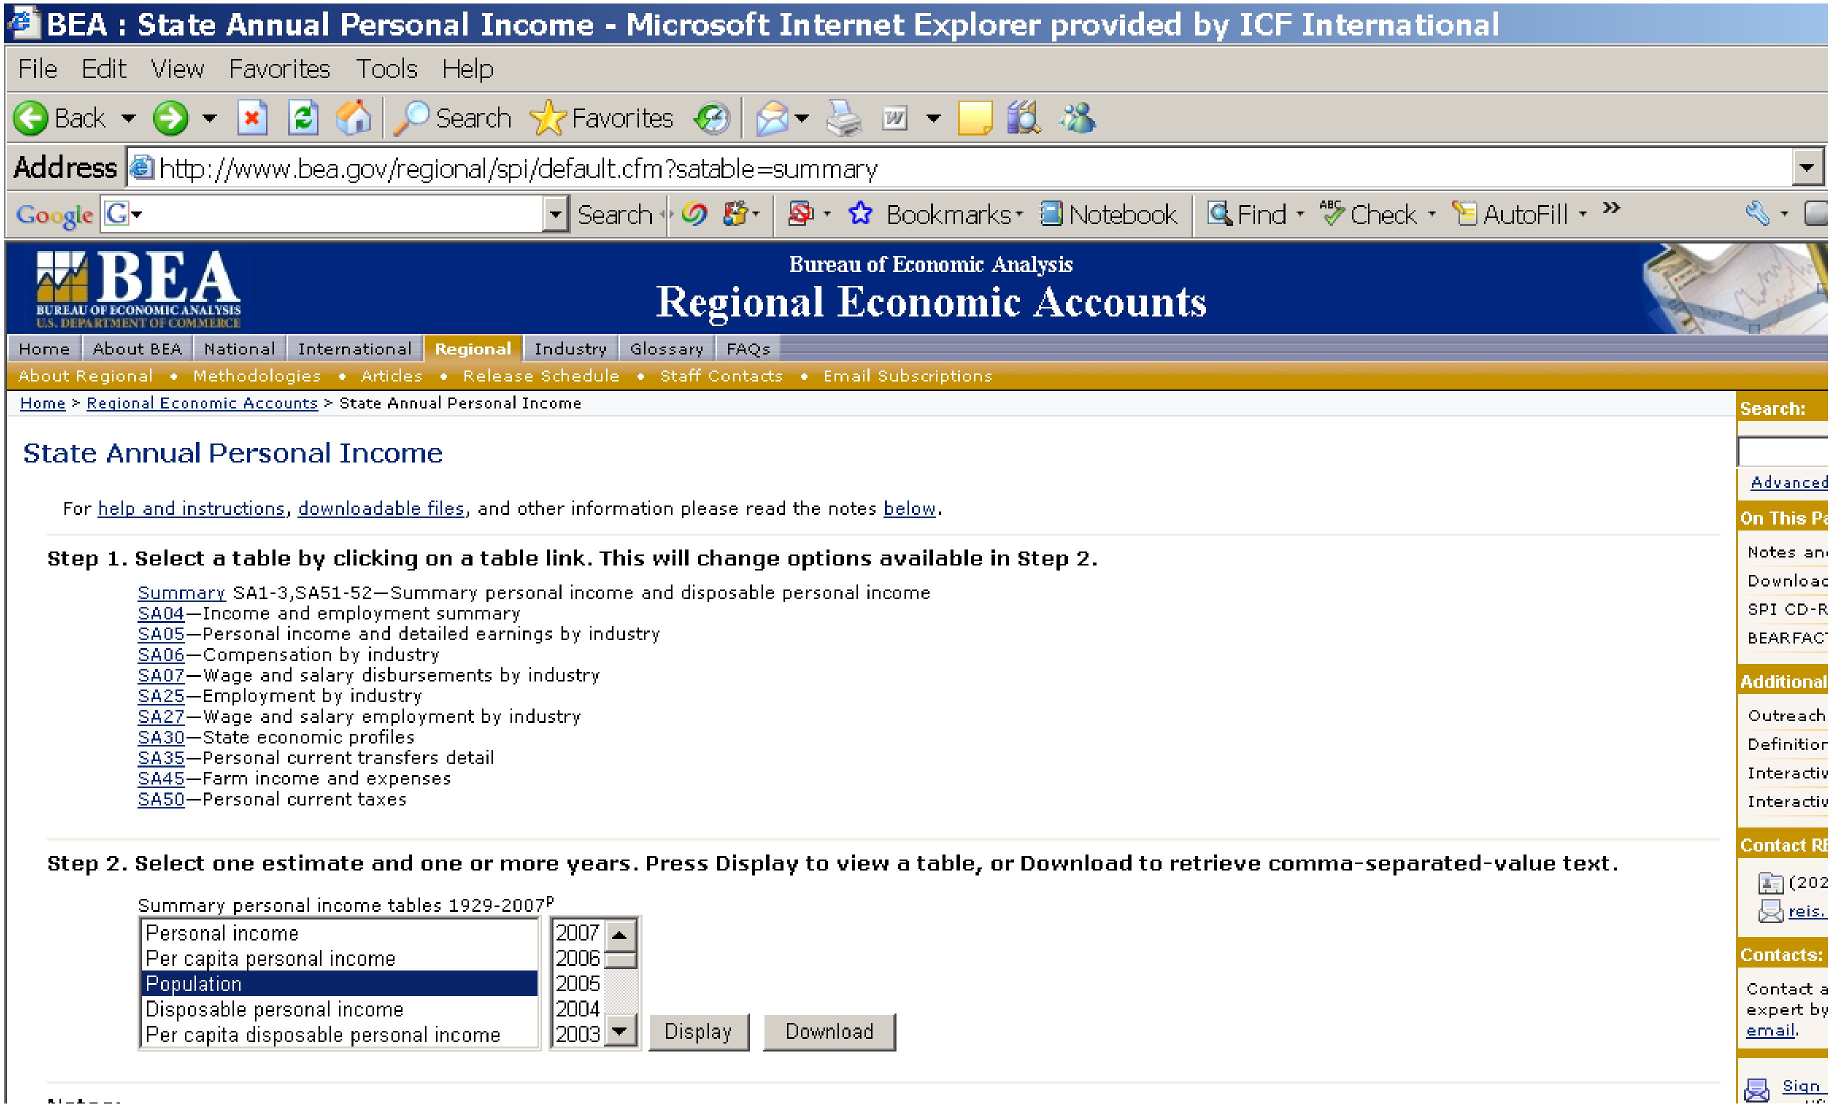
Partner-supplied data will not be discussed today, though some is already in the model, and more is being gathered and provided.

3

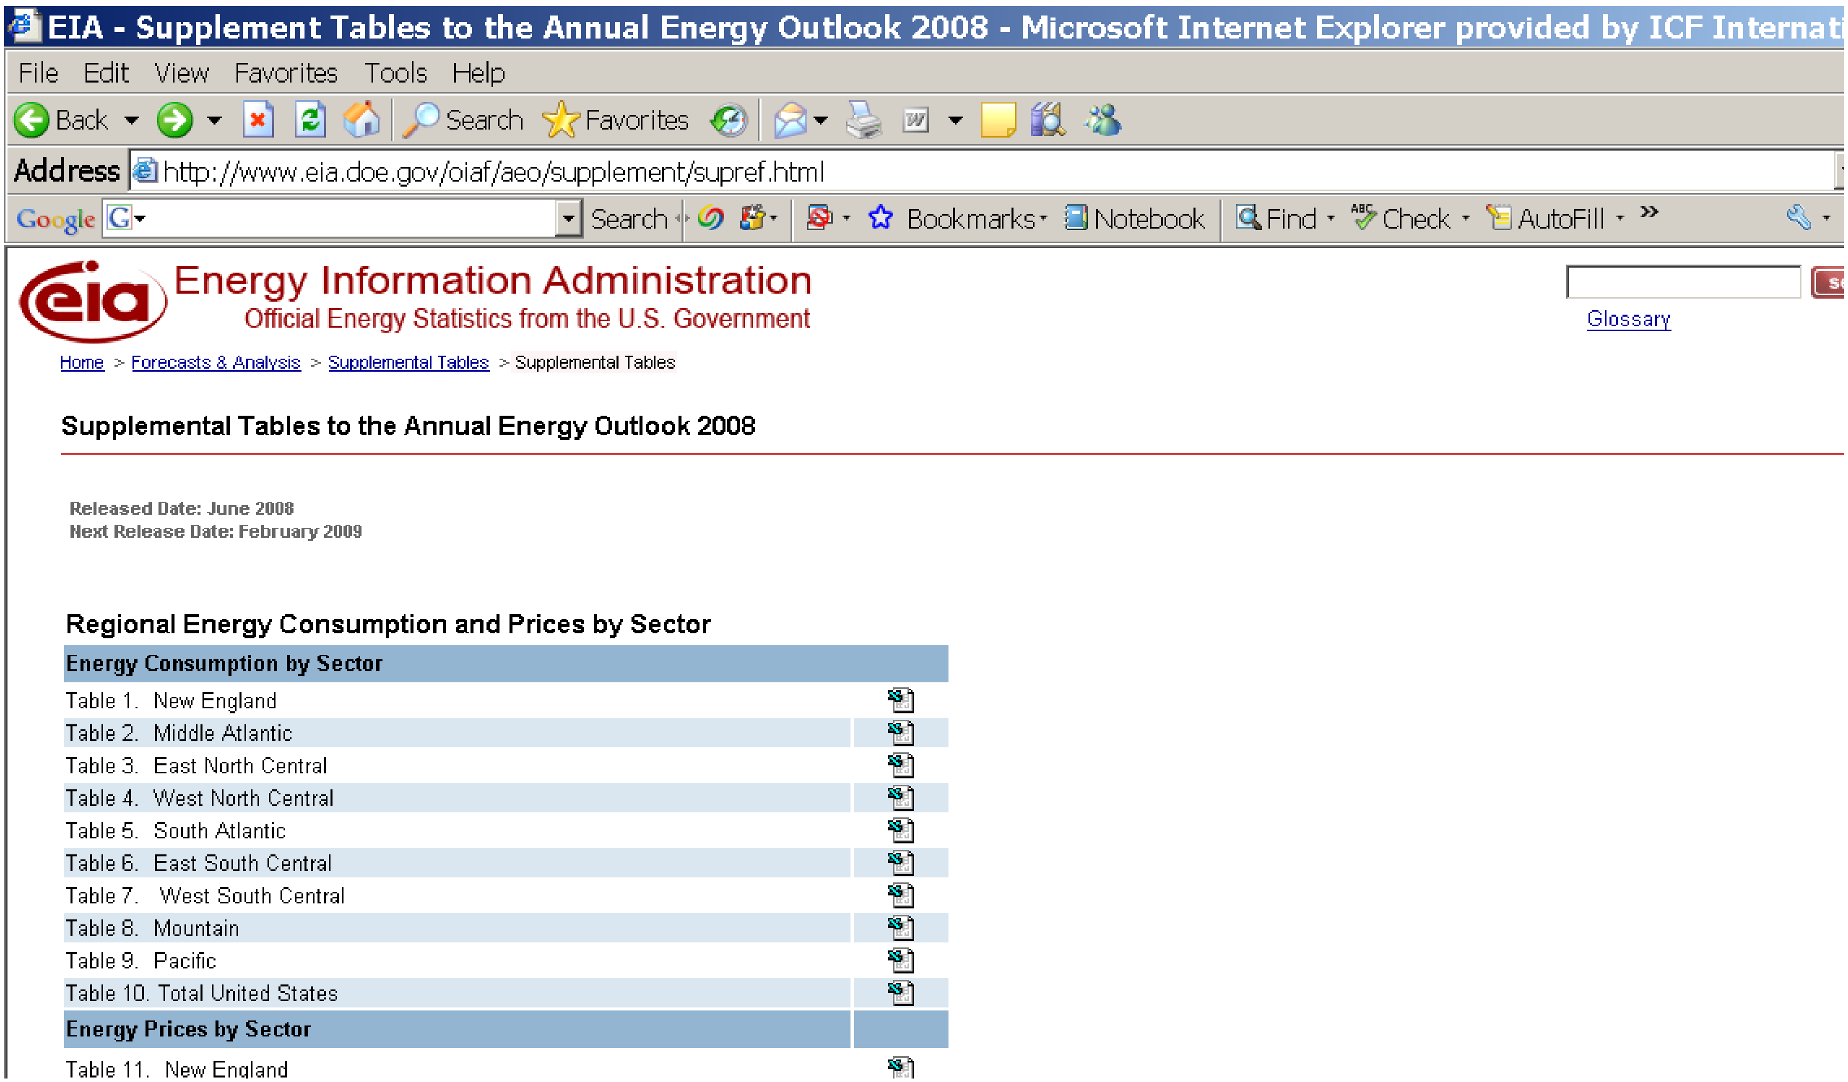
3.1 Population and Economic Data

- *Population - Historic (1985-2006)*:
  - Regional Economic Information System, Bureau of Economic Analysis, U.S. Department of Commerce. http://www.bea.gov/regional/spi/default.cfm?satable=summary
  - Statistics Canada Table 051-0001 (based on census data) http://www.statcan.ca/english/freepub/11-008-XIE/2006007/tables/soc_ind_pop_spr06.htm
- *Population – Forecast:* annual population growth rates are taken from Regional Forecasts from AEO then applied to the state historical population. Annual Energy Outlook 2007 (February 2007 release). http://www.eia.doe.gov/oiaf/aeo/supplement/suptab_1.xls through suptab_9.xls
- Households by housing type: *U.S. Census Bureau, Housing and Household Economic Statistics Division* http://www.census.gov/hhes/www/housing/census/historic/units.html

Historical U.S. Population data: Ignore Step 1; in step 2, click Population; highlight one or more years; click Display



U.S. Population forecast: Click on XLS for appropriate region; go to line 156 for regional population forecast; apply regional growth rate to state historical data.

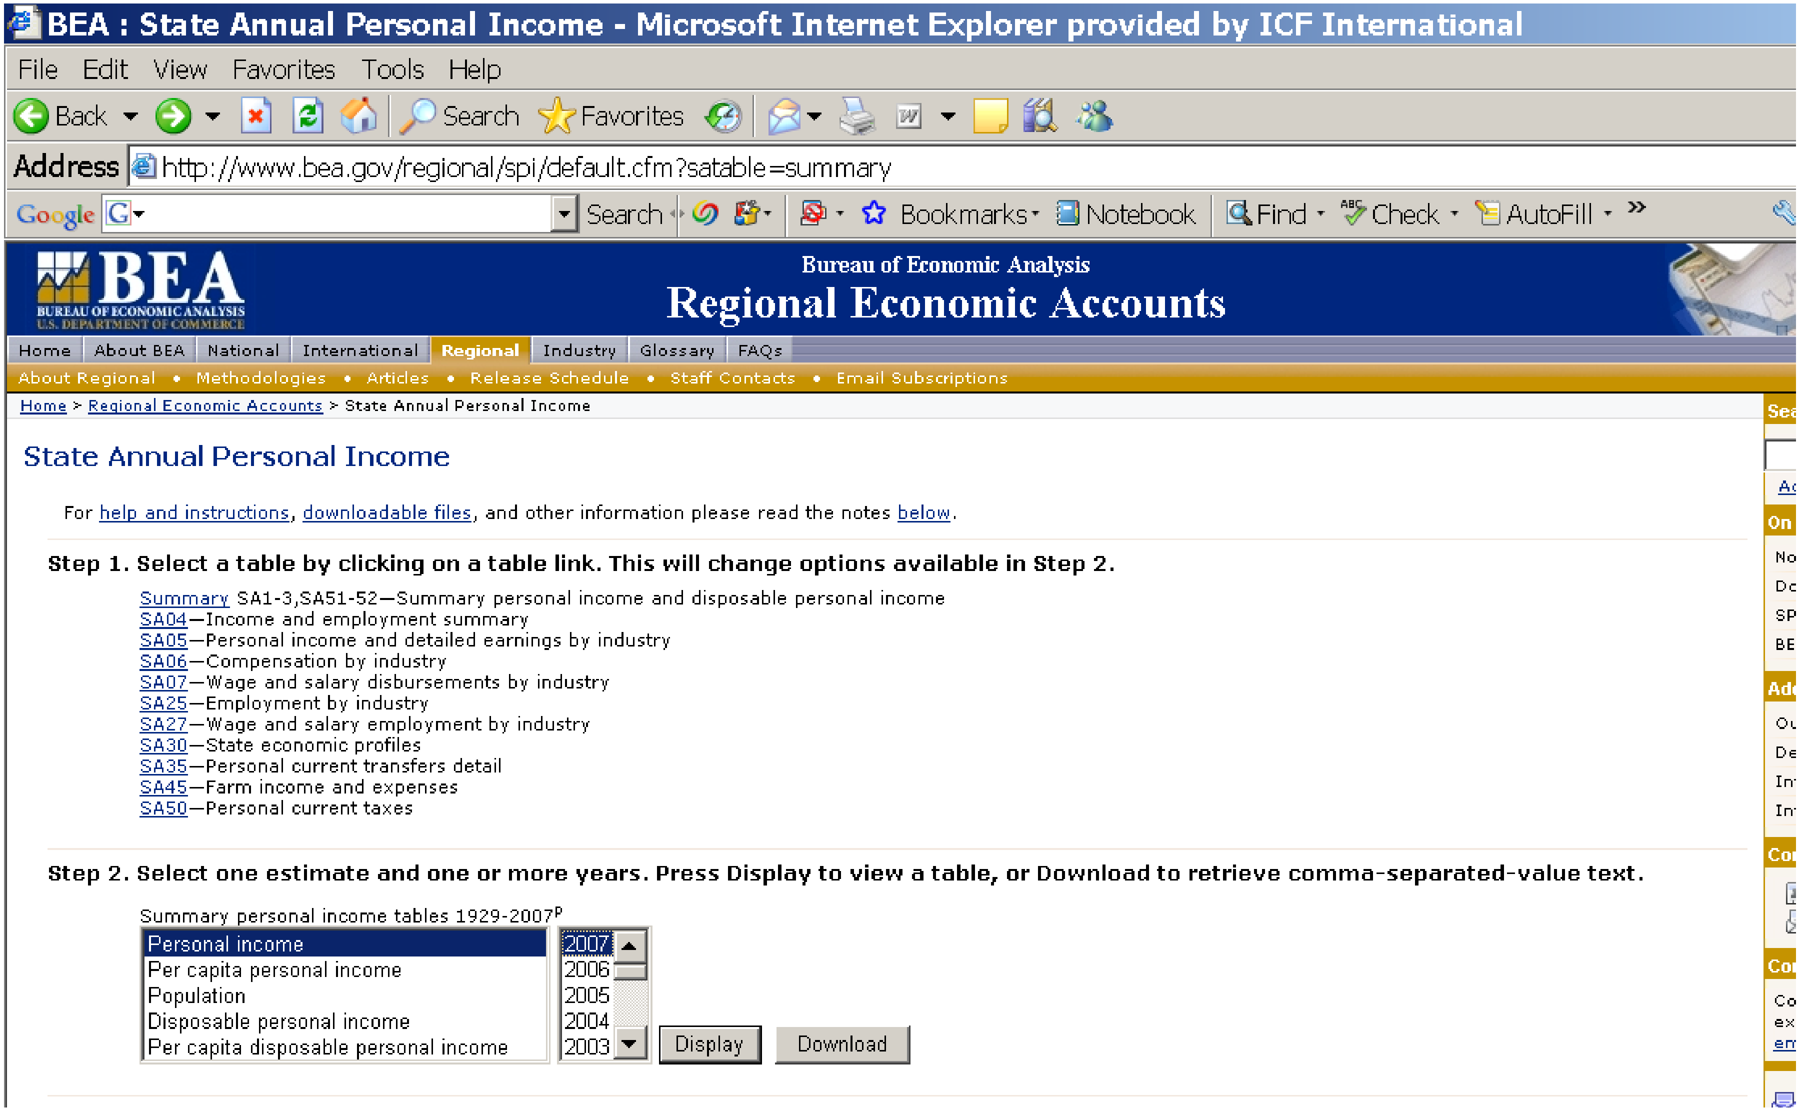


3.1 Population and Economic Data (cont.)

- *Personal Income - Historic (1985-2006)*: Bureau of Economic Analysis, 6/24/07http://www.bea.gov/regional/spi/default.cfm?satable=summary

- *Personal Income - Forecast:* Assume ratio of ratio of state-level historic Personal Income to state-level Gross Domestic Product remains constant. Apply the 2006 ratio to forecasted state-level GDP to forecast state-level Personal Income.
  - State-level GDP data: http://www.bea.gov/regional/gsp/default.cfm?series=NAICS

Historical U.S. Personal Income data: Ignore Step 1; in step 2, click Personal Income; highlight one or more years; click Display



3.1 Population and Economic Data (cont.)

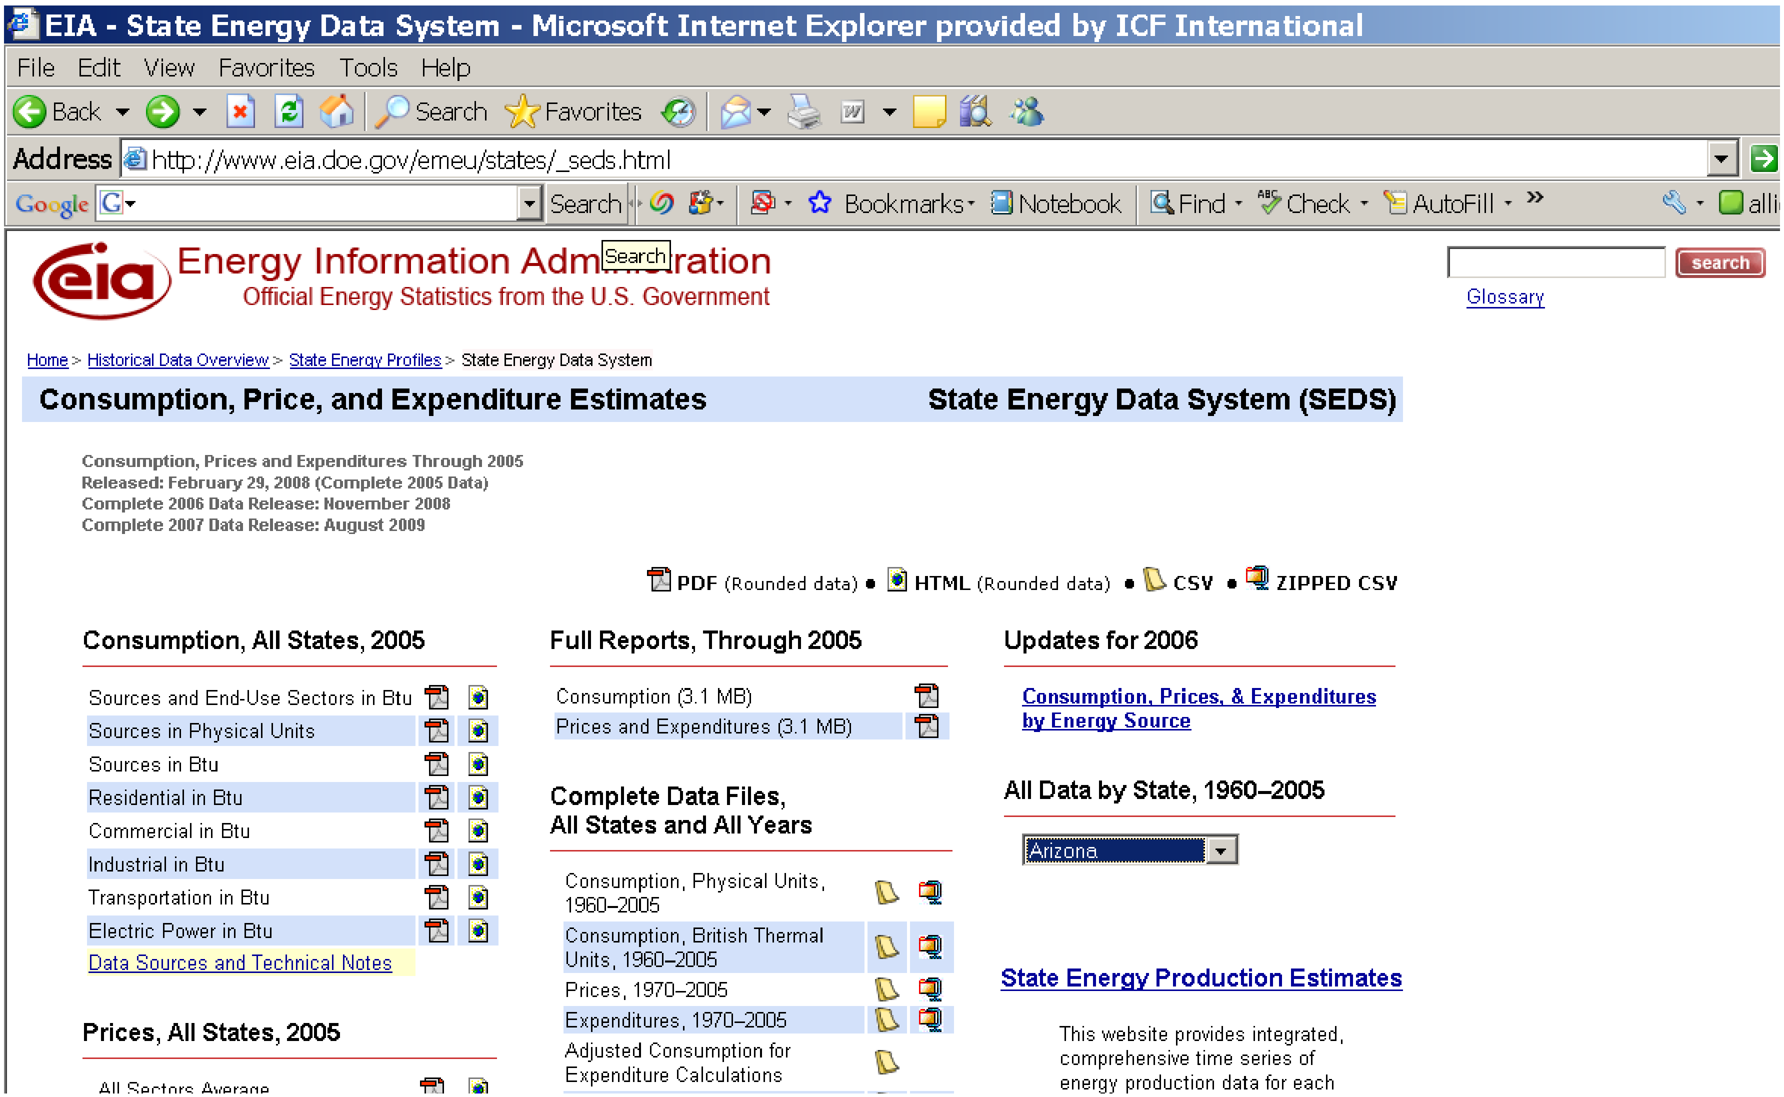
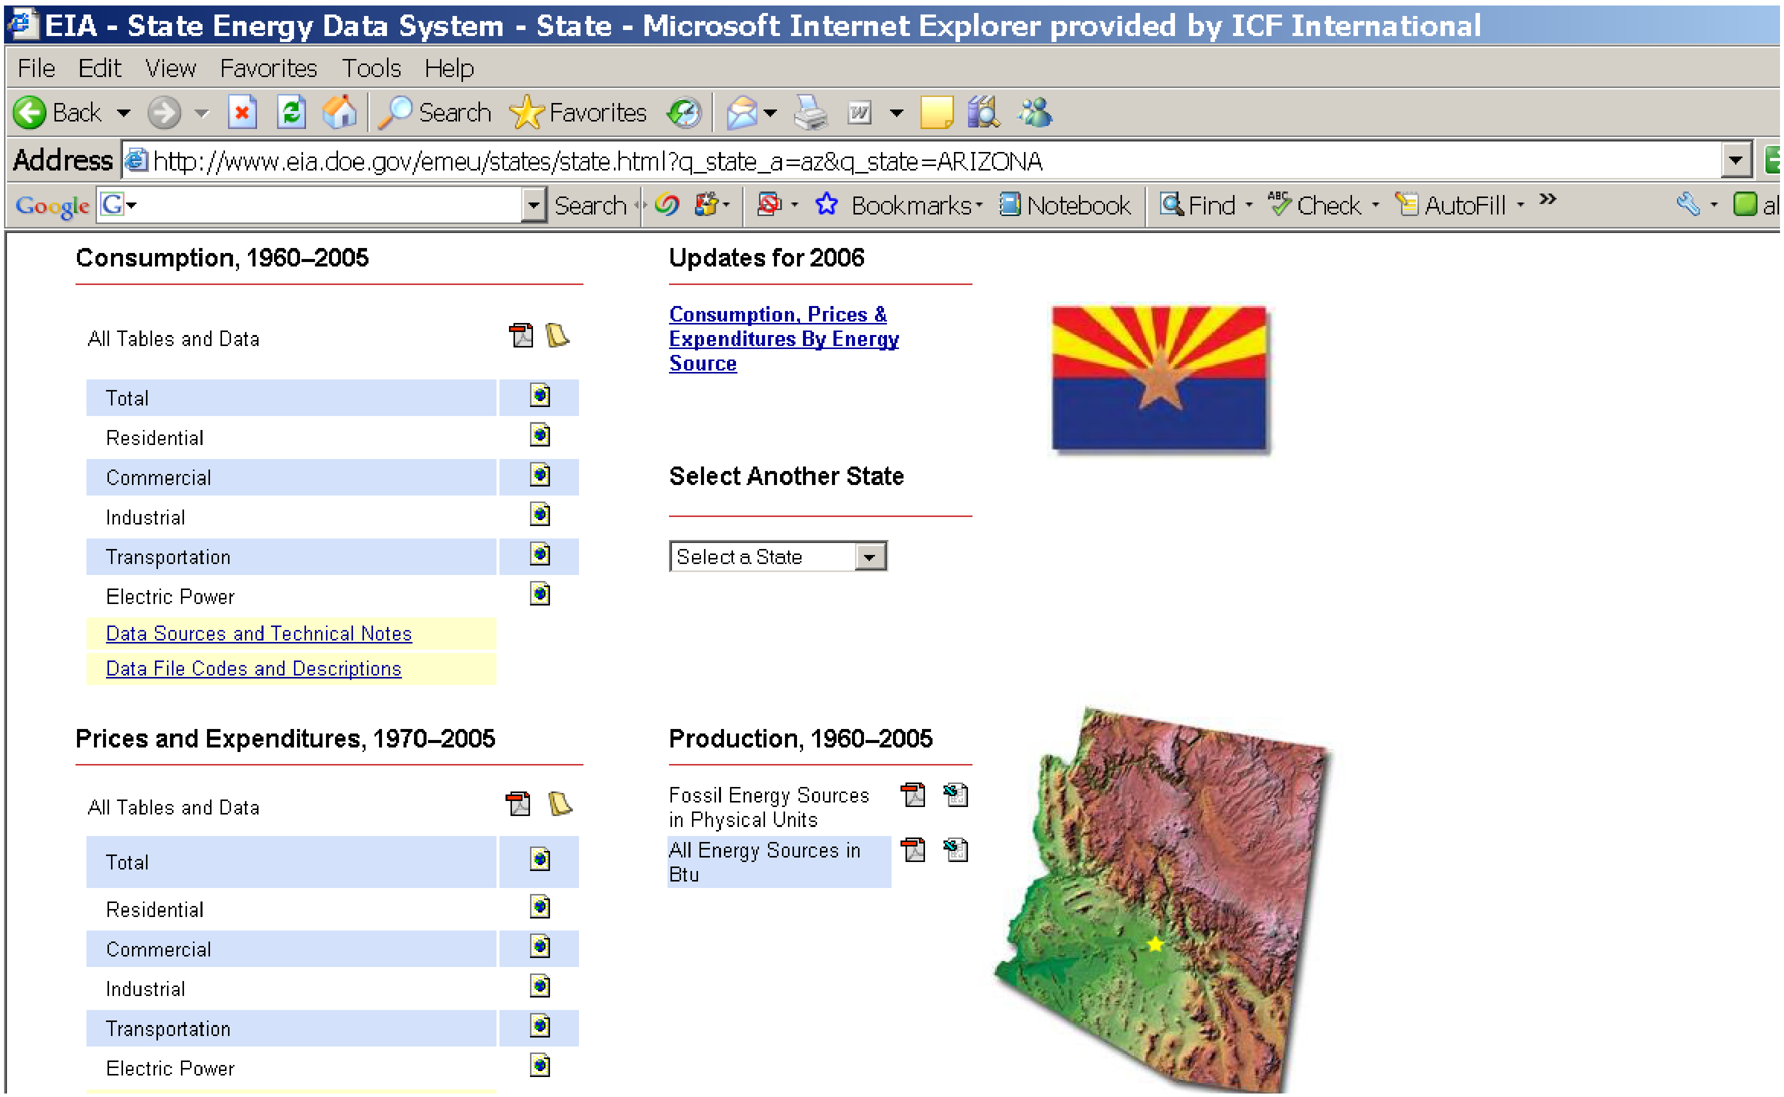
3.2 Energy Price Data by State
3.3 Energy Consumption and Expenditure Data by State

- *Historical prices/consumption/expenditures:* EIA State Energy Data System (SEDS) http://www.eia.doe.gov/emeu/states/_seds.html
- *Forecast prices (national):* EIA Annual Energy Outlook, 2007, High Price Case http://www.eia.doe.gov/oiaf/archive/aeo07/aeohighprice.html (to be replaced by 2008 High Price Case when available)
  - Estimate state-level prices using historical relationships between national and state-level delivered prices
- Energy consumption forecasts are endogenous

Historical energy price, consumption, and expenditure data by state: click on a state under “All Data by State, 1960-2005”



Arizona example



3.3 Energy Consumption Data (cont.)

- ***Residential:*** 2001 EIA Residential Energy Consumption Survey (RECS), by Census Region and Division (2005 RECS in process) http://www.eia.doe.gov/emeu/recs/contents.html
  - Household income by housing type
  - No. of people per household
  - End-use consumption data, including fuels used for space and water heating, air conditioning, etc.

3.3 Energy Consumption Data (cont.)

- ***Commercial:*** 2003 EIA Commercial Buildings Energy Consumption Survey (CBECS), by Census Region and Division (2007 CBECS is underway) http://www.eia.doe.gov/emeu/cbecs/contents.html
  - Floor area by sub-sector
  - End-use consumption data, including fuels used for space and water heating and energy intensities

3.3 Energy Consumption Data (cont.)

- ***Industrial:*** 2002 EIA Manufacturing Energy Consumption Survey (MECS), by Census Region (2006 MECS underway) http://www.eia.doe.gov/emeu/mecs/contents.html
  - Energy use by fuel for each sub-sector and end-use

- Combining national and state-level data for industry
  - Estimate state-level energy consumption by industrial sector by applying the proportions from the MECS data to state-level total industrial energy consumption.

Data in Form EIA-860

- Generator-specific information including:
  - Generating capacity
  - Energy sources
  - Status of existing and proposed generators, and proposed changes to existing generators
  - County and State location, ownership
  - FERC qualifying facility status
  - Ability to use multi-fuels, co-firing, and fuel switching.
- The 2006 data are compressed into a self-extracting (.exe) zip file that expands into 10 .XLS files, including 2 files on the ability to use multi-fuels.
  - XLS files are described on the EIA-860 home page.

Form EIA-860 Database

Form EIA-860 Database
Annual Electric Generator Report

The EIA-860 is a generator level data file that includes specific information about generators at electric power plants owned and operated by electric utilities and nonutilities (including independent power producers, combined heat and power producers, and other industrials). The file contains generator-specific information such as initial date of commercial operation, prime movers, generating capacity, energy sources, status of existing and proposed generators, proposed changes to existing generators, county and State location, ownership, and FERC qualifying facility status. Starting in 2004, data are included on the ability to use multi-fuels; specifically data on co-firing and fuel switching. Data on the ability to use multi-fuels are not available for previous years.

The 2006 data are compressed into a self-extracting (.exe) zip file that expands into 10 .XLS files, including 2 files on the ability to use multi-fuels. The files are UTILY06.XLS (Utility file), PLANTY06.XLS (Plant file), GENY06.XLS (Existing generators), MFEXISTY06.XLS (Multi-fuel data for existing generators), PRGENY06.XLS (proposed generators), MFPROPY06.XLS (Multi-fuel data for proposed generators), PCGENY06.XLS (Proposed changes to existing generators), OWNERY06.XLS (Owner file), INTCON06.XLS (interconnection data), and LAYOUT.XLS (File description).

The 2001-2003 data are compressed into a self-extracting (.exe) zip file that expands into 6 DBF files: 1 company file (UTILYyy.DBF*), 1 plant file (PLANTYyy.DBF*), and 4 generator files (GENYyy.DBF*, PCGENYyy.DBF*, PRGENYyy.DBF* and OWNERYyy.DBF*) and an EXCEL layout file (Layout.xls).

*Note: Substitute the applicable year for "yy" in the file nam

SO_x	Sulfur Oxides (including sulfur dioxide)
USEPA	United States Environmental Protection Agency
W	Watt
WCI	Western Climate Initiative
WECC	Western Electricity Coordinating Council

1. Background and Project Scope

The Western Climate Initiative (WCI) has retained ICF International and its partner Systematic Solutions Inc., to assist in modeling a cap-and-trade system for the western US and Canada. The WCI envisions a trading scheme that may ultimately link with the Midwestern Regional Greenhouse Gas Reduction Accord (MGA) and the Regional Greenhouse Gas Initiative (RGGI). The environmental, energy, and economic stakes are high in this endeavor.

The ICF Team has offered a suite of models that represent the state-of-the-art to support the WCI in this plan; starting with ENERGY 2020. This report outlines the assumptions and data inputs used in developing the Reference Case which will be used as the basis for evaluating proposed policy changes. The report describes the initial data and assumptions used, the sources of this data, and the processes used in developing the Reference Case.

2. Organization of the Report

The report is organized into four main sections. Section 1 provides background information regarding the purpose and scope of the project, this section (2) describes how the report is organized. Section 3 describes the analytic approach used by ENERGY 2020 and the characteristics of the model. The final section (4) describes the model inputs. A more detailed explanation of the ENERGY 2020 model is included as Appendix A.

3. Analytic Approach

This project uses ENERGY 2020 to model the business-as-usual outlook for the regions participating in the WCI (WCI partners)[1] as well as surrounding states and provinces and the impact of potential GHG reduction policies.

ENERGY 2020 is an integrated multi-region energy model that provides complete and detailed, all-fuel demand and supply sector simulations. These simulations can additionally include macroeconomic interactions to determine the benefits or costs to the local economy of new facilities or changing energy prices.

[1] *Arizona, California, Montana, New Mexico, Oregon, Utah, Washington, British Columbia, Manitoba, and Quebec.*

The model can be used in regulated as well as deregulated and transitioning environments. Greenhouse Gas and Criteria Air Contaminant pollution emissions and costs, including allowances and trading, are endogenously determined, thereby allowing assessment of environmental risk and co-benefit impacts.

The basic implementation of ENERGY 2020 for North America now contains a user-defined level of aggregation down to the 10 provincial and 50 state (and sub-state) level. ENERGY 2020 contains historical information on all generating units in the US and Canada. Data for Mexico can be incorporated as needed. ENERGY 2020 is parameterized with local data for each region/state/province as well as all the associated energy suppliers it simulates. Thus, it captures the unique characteristics (physical, institutional and cultural) that affect how people make choices and use energy. Collections of state and provincial models are currently validated from 1986 to the latest quarterly numbers.[2]

ENERGY 2020 can be linked to a detailed macroeconomic model to determine the economic impacts of energy/environmental policy and the energy and environmental impacts of national economic policy. For US regional and state level analyses, the REMI macroeconomic model is regularly linked to ENERGY 2020.[3] The Informetrica macroeconomic model is linked to ENERGY 2020 for Canadian national and provincial efforts.[4] The REMI and Informetrica macroeconomic models include inter-state/provincial, US and world trade flows, price and investment dynamics, and simulate the real-time impact of energy and environmental concerns on the economy and vice versa.

The structure of the model is well tested and has been used to simulate not only US and Canadian energy and environmental dynamics, but also those of several countries in South America, Western, Central, and Eastern Europe. These efforts include strategic and tactical analyses for both planning and energy industry restructuring/deregulation. In the 1990s, the US EPA made ENERGY 2020 available to interested states to analyze emissions, energy, and economic impacts of state-level climate change initiatives. Further, the model has been used successfully for deregulation analyses in all the US states and Canadian

[2] *Energy supplier data comes from FERC and US DOE for the US and Statistics Canada. US and Canadian fuel and demand data come from the US Department of Energy and Natural Resources Canada, respectively. US and Canadian pollution data come from US EPA and Environment Canada, respectively.*
[3] *Regional Economic Models, Inc. www.remi.com*
[4] *Informetrica Limited www.informetrica.ca*

provinces. Many US and Canadian energy suppliers use the model for the analysis of combined electricity and gas deregulation dynamics.[5]

The default model simulates demand by three residential categories (single family, multi-family, and agriculture/rural), over 40 NAICS commercial and industrial categories[6], and three transportation services (passenger, freight, and off-road). There are approximately six end-uses per category and six technology/mode families per end-use.[7] Currently the technology families correspond to six fuels groups (oil, gas, coal, electric, solar and biomass) and 30 detailed fuel products. The transportation sector contain 45 modes including various type of automobile, truck, off-road, bus, train, plane, marine and alternative-fuel vehicles. More end-uses, technologies, and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical, locale-specific data. The load duration curves are dynamically built up from the individual end-uses to capture changing conditions under consumer choice and combined gas/electric programs.

Each energy demand sector includes cogeneration, self-generation, and distributed generation simulation, including mobile-generation, micro-turbines, and fuel-cells. Fuel-switching responses are rigorously determined. The technology families (which can be split, as an option, to portray specific technology dynamics) are aggregates that, within the model, change building shell, economic-process and device efficiency and capital costs as price or other information that the decision makers see, change. ENERGY 2020 utilizes the historical and forecast data developed for each technology family to parameterize and disaggregate the model.

The supply portion of the model includes endogenous detailed electric supply simulation of capacity expansion/construction, rates/prices, load shape variation due to weather, and changes in regulation.[8] The model dispatches plants

---

[5] *ENERGY 2020 is the only model known to have simulated and predicted the dynamics that occurred in the UK electric deregulation. These include gaming, market consolidation and re-regulation dynamics.*
[6] *NAICS is the North America Industrial Classification System which was developed jointly by the U.S., Canada, and Mexico to provide new comparability in statistics about business activity across North America.*
[7] *End-uses include Process Heat, Space Heating, Water Heating, Other Substitutable, Refrigeration, Lighting, Air Conditioning, Motors, and Other Non-Substitutable (Miscellaneous). Detailed modes include: small auto, large auto, light truck, medium-weight truck, heavy-weight truck, bus, freight train, commuter train, airplane, and marine. Each mode type can be characterized by gasoline, diesel, electric, ethanol, NG, propane, fuel-cell, or hybrid vehicles.*
[8] *ENERGY 2020 does include a complete, but aggregate representation of the electric transmission system. Electric transmission data is provided by FERC, the Department of Energy, and the National Electric*

according to the specified rules whether they are optimal or heuristic and simulates transmission constraints when determining dispatch.[9] A sophisticated dispatch routine selects critical hours along seasonal load duration curves as a way to provide a quick but accurate determination of system generation. Peak and base hydro usage is explicitly modeled to capture hydro-plant impacts on the electric system.

ENERGY 2020 supply sectors include electricity, oil, natural gas, refined petroleum products, ethanol, land-fill gas, and coal supply. Energy used in primary production and emissions associated with primary production and its distribution is included in the model. The supply sectors included in a particular implementation of ENERGY 2020 will depend on the characteristics of the area being simulated and the problem being addressed. If the full supply sector is not needed, then a simplified simulation determines delivered-product prices.

The ENERGY 2020 model includes pollution accounting for both combustion (by fuel, end-use, and sector) and non-combustion, and non-energy (by economic activity) for SO_2, NO_2, N_2O, CO, CO_2, CH_4, PMT, $PM_{2.5}$, PM_5, PM_{10}, VOC, CF_4, C_2F_6, SF_6, and HFC at the state and provincial level by economic sector. Other (gaseous, liquid, and solid) pollutants can be added as desired. Pollution does not need to be determined directly by coefficients but can recognize the accumulation of capital investments that result in pollution emission with usage. National and international allowance trading is also included. Plant dispatch can consider emission restrictions.

The model captures the feedback among energy consumers, energy suppliers, and the economy using Qualitative Choice Theory and co-integration.[10] For example, a change in price affects demand that then affects future supply and price. Increased economic activity increases demand; increased demand increases the investment in new supplies. The new investment affects the economy and energy prices. The energy prices also affect the economy.

Reliability Council. The dispatch technologies in the basic model include: Oil/Gas Combustion turbine, Oil/Gas Combined Cycle, Oil/Gas Combined Cycle with CCS, Oil/Gas Steam Turbine, Coal Steam Turbine, Advanced Coal, Coal with CCS, Nuclear, Baseload Hydro, Peaking Hydro, Small Hydro, Wind, Solar, Wave, Geothermal, Fuel-cells, Flow-Battery Storage, Pumped Hydro, Biomass, Landfill Gas, Trash, and Biogas.

[9] *A 110 node transmission system is used in the default model, but a full AC load-flow bus representation model has also been interfaced with ENERGY 2020.*

[10] *The model has used the work of Daniel McFadden and Clive Granger since its inception in the late 1970s.*

Finally, the system includes confidence and validity testing software that places uncertainty bounds on simulation results, quantifies confidence intervals, and ranks the contributions to uncertainty in future conditions. This feature can be used to limit data efforts to information most important to the analysis.

In order to assess the potential impacts of proposed policy options, a b*usiness-as-usual* scenario is developed as a point of reference. This *Reference Case* represents a scenario that is viewed as a reasonable expectation of how the economy, energy use and emissions might develop over time.

Part of the nature of developing a Reference Case is the need to address inherently uncertain issues that can have significant impacts on future energy use and emissions. No forecast is going to be *right* or *accurate* in that no one can tell today how some of the key underlying issues may develop. Given the level of uncertainty involved in any projection of a possible future, caution should be used in applying a high level of precision to the modeling results. Understanding the Reference Case, however, can be extremely useful in providing an underlying structure against which to model proposed policies, and in determining directionality and cause and effect.

Numerous assumptions are required to perform an analysis of this type across a range of topic areas, including economic developments, fuel and electric markets, and regulatory structures. Projected outcomes are only as good as the input assumptions upon which they are based, with more rigorous assumptions leading to a more rigorous analysis. The inputs and assumptions described in this document were developed to provide as accurate a representation as possible of the activities and structures underlying energy use and greenhouse gas emissions in the WCI region.

4. Reference Case Inputs

ENERGY 2020 derives energy demands, such as the demand for electricity based on economic activity and device efficiency. The following sections provide a brief overview of the data inputs and assumptions as well as the sources of data used in the Reference Case. Actual data inputs for specific elements such as generating units, emission factors, etc., can be provided separately in Excel spreadsheets as required.

As a multi-sector analytical tool, ENERGY 2020 requires data and assumptions covering a broad range of economic sectors and their interactions. In most cases, the necessary data – both historical and projected – is available from the federal government (EIA, EPA, etc.). In past analyses, ENERGY 2020 has relied heavily on these federal sources to populate and calibrate the model. In developing the model used for the WCI partners a considerable amount of state-specific information was available and has been used wherever possible.

The following sections provide an overview of the data and assumptions that will be required to perform the multi-sector analysis, and list the data sources that have been used to populate ENERGY 2020 to this point. It is expected that this data will change as the model is reviewed and evolves to incorporate more detailed data specific to the WCI region.

Data[11] inputs for ENERGY 2020 will be required in five areas:

1. Population and economic
2. Fuel prices
3. Energy use and consumption
4. Emissions and air regulations
5. Electricity generation capacity and operation

The sections below list the key data elements required in each of these areas, along with the sources that have been used to supply this data for other analyses. Appendix B lists a number of default data sources used by the model. The sections that follow provide a more specific description of the data used for this project including state-specific data used in place of national sources.

[11] *"Data" here refers to both historical data and assumptions and projections of future inputs.*

ENERGY2020 requires both historical data and projections to calibrate and generate forward-looking projections. Various historical data will be used for the period 1985-2005 (the last year for which certain detailed sectoral and end-use are available). Projections for the period to be modeled (e.g. through 2030) will be gathered where possible to provide points of comparison and check the reasonableness of the projection.

The implementation of ENERGY 2020 used for the WCI project will begin with inclusion of the geographic areas of Arizona, California, Montana, New Mexico, Oregon, Utah, Washington, and British Columbia. Manitoba and Quebec may be added later in the project. These provinces pose more complex modeling issues as they lay outside of the Western Electricity Coordinating Council (WECC). Interactions between these states and provinces are modeled, particularly with respect to electricity generation. To ensure consistency the assumptions used within the WCI region are applied to other states to the extent possible.

4.1 *Population and Economic Data*

Demographic and economic data is required to generate demands for services. The historic data for the US states was obtained from the US Bureau of Economic Analysis (BEA). For the Canadian provinces, historic data is from Statistics Canada's CANSIM.

4.1.1 Phase I data

The following data sources were used during Phase I modeling in which readily available data was used:

Description of Data/Input	Sources	Detailed Reference
Total population, historical and growth over time	US Census Bureau	*Historic (1985-2006):* Regional Economic Information System, Bureau of Economic Analysis, U.S. Department of Commerce. http://www.bea.gov/regional/spi/default.cfm?satable=summary *California:* California population taken from: CEC *California Energy Demand 2008-2018 Staff Revised Forecast*
	Statistics Canada	Statistics Canada Table 051-0001 (based on census data)
	Future	Future annual population growth rates are taken from Regional Forecasts from AEO then applied to the state historical population. Annual Energy Outlook 2007 (February 2007 release). http://www.eia.doe.gov/oiaf/aeo/supplement/suptab_1.xls through suptab_9.xls

Description of Data/Input	Sources	Detailed Reference
Population by housing type (single-family, multi-family, etc.)	US Census Bureau	Population Estimates Program, Population Division
	Statistics Canada	Household type, Structural Type of Dwelling and housing tenure for Private Households of Canada
Households by housing type (single-family, multi-family, etc.)	US Census Bureau	Household splits (data through 2001 then held constant): *Source: U.S. Census Bureau, Housing and Household Economic Statistics Division* Last Revised: *December 16, 2005* http://www.census.gov/hhes/www/housing/census/historic/units.html **Household size** US Census Bureau, Census 2000 - assumes household size is same for all housing types in state. **Number of households** Calculated based on population, household fraction, and household size.

4.1.2 Phase II data

In Phase II of the WCI partners had the opportunity to provide jurisdiction-specific data for use in the model.

The following states and provinces indicated that the readily available data used in Phase I could continue to be used in the Phase II modeling:

- Montana
- Oregon

- Utah
- British Columbia
- California

The other states provided the following data:

- Arizona: personal income; population (state total); and gross output (from REMI).
- New Mexico: population
- Washington: population

Data added in Phase II are included in Appendix C.

4.2 *Energy Price Data*

Energy prices can play a significant role in end user decisions on equipment, capital and operating decisions. Fuel costs can be critical in determining the costs of electric dispatch, as well as input costs of some industrial processes and home heating. ENERGY2020 calculates future electric prices based in part on these fuel costs.

Energy prices are largely determined by international markets, although domestic demand, such as electric sector demand for natural gas can influence prices. As a result, fuel prices are treated by the model as an exogenous input.

Historic energy price data are taken from US DOE State Energy Data and Statistics Canada. The model currently uses energy price forecast data for the US from the Energy Information Administration's 2008 Annual Energy Outlook High Price Case scenario for 2008 to 2030.[12] For Canada, the National Energy Board's price forecast is used.[13]

Biomass prices in the model are based on research completed for a previous project, shown in the table below. Unlike other fuels, biomass prices are significantly

Biomass Cost *(per MBtu in 2006$)*	
Residential	$11.53
Commercial	$10.09
Industrial	$10.06

[12] Energy Information Administration, Annual Energy Outlook 2008, Report #DOE/EIA-0383(2008), June 2008, http://www.eia.doe.gov/oiaf/aeo/
[13] Canada's Energy Future: An Energy Market Assessment, November 2007. http://www.neb-one.gc.ca/clf-nsi/rnrgynfmtn/nrgyrprt/nrgyftr/2007/nrgyftr2007-eng.html

influenced by local cost and supply issues.

Power prices are calculated endogenously by the model based on generation costs and dispatch. While, the model estimates retail electricity prices, actual consumer prices may differ as a result of political, regulatory or market influences. The model can be calibrated to actual prices, within reasonable parameters, for the historic period.

Given the time and resources available for the project, the model does not account for the different regulatory regimes among the partner jurisdictions with respect to electric price regulation (i.e., cost-of-service ratemaking vs. various forms of market-driven pricing). The intent of the modeling is rather to produce reasonable estimates of retail prices at the state or provincial level based on generation costs and historical mark-ups above generation costs.

4.3 *Historic Energy Consumption Data*

ENERGY 2020 models energy use at the end-use level within each economic sector based on the existing physical stock and the efficiency of that stock. The database of device efficiencies reflects both the average efficiency of energy use for current stocks and the efficiency/energy alternatives available to consumers at the margin. Technology and efficiency choices are modeled based on past experience with consumer choice rather than on a purely economic evaluation.

Historic energy use and consumption data used in the model is derived from the federal Energy Information Administration (EIA) State Energy Data (SEDS) database. Where state-specific data was available, this data was used to replace national data sources.

Default sectoral and end-use data as well as energy intensities are based on the Residential Energy Consumption Survey (RECS), Commercial Energy Consumption Survey (CECS) and Manufacturers Consumption Energy Survey (MECS).

Description of Data/Input	Sources Used/Available

4.4 *Historic Emission Data*

4.4.1 Emissions and Air Regulations

Historic GHG emissions are based on the Canadian national inventory published by Environment Canada and the US GHG emissions inventory as published by the EPA.[14] More specific state and provincial inventories will be sought from WCI partners. ENERGY 2020 is calibrated using historic information on all of the major greenhouse gas emissions including:

- Carbon dioxide (CO_2),
- Nitrous oxide (N_2O),
- Methane (CH_4),
- Sulfur hexafluoride (SF_6),
- Hydrofluorocarbons (HFCs) and
- Perfluorocarbons (PFCs).

[14] *EPA website: http://www.epa.gov/climatechange/emissions/usinventoryreport.html*

GHG emissions are presented in CO_2 equivalent (CO_2e) terms. The global warming potentials used to convert the different greenhouse gas emissions into CO_2e terms are provided in Appendix H.

Input	Sources Used/Available
Emissions by sector, end-use, fuel & GHG	US EPA http://www.epa.gov/climatechange/emissions/usinventoryreport.html Environment Canada http://www.ec.gc.ca/pdb/ghg/inventory_e.cfm

4.4.2 Emission Factors

Emission factors for most fuels are based on values used by ICF in developing national and state inventories. For the transportation sector however, the emission factors for CH_4 and N_20 pollutants were adapted from the Canadian National Inventory Report.[15] ENERGY 2020 calculates GHG emissions at the point of combustion for most fuels. Upstream emissions from extraction and processing are captured as part of those respective economic sectors.

Emissions associated with the use of biomass as a fuel are deemed to be biogenic and therefore not contribute to global warming. As a result, the model assumes no GHG emissions are created from the use of biomass.

Emissions from ethanol and other biofuels represent an exception from a modeling perspective. In order to capture the emissions associated with their production and distribution, the model applies full cycle emission factors for these fuels. While the combustion of ethanol and biodiesel are not deemed to result in any anthropogenic emissions, the model uses an emission factor to recognize upstream emissions.

The full-cycle emission factors used in the model for each biofuels type are shown in the table below:[16]

Corn Ethanol	76 gCO2e / MJ
Cellulosic Ethanol	14 gCO2e / MJ
Biodiesel	30 gCO2e / MJ

[15] *Environment Canada. National Inventory Report 1990-2005, Greenhouse Gas Sources and Sinks in Canada, April 2007. (Annex 12 Emission Factors)*
[16] *Alexander Farrell, UC Berkeley and Daniel Sperling, UC Davis, A Low-Carbon Fuel Standard for California Part 1: Technical Analysis May 29, 2007 Table 2-3 http://www.energy.ca.gov/low_carbon_fuel_standard/UC-1000-2007-002-PT1.PDF*

When these fuels are used in combination with other fuels, for example in a mix of gasoline and ethanol, the emissions associated with gasoline combustion are reported as part of total gasoline-related emissions.

4.5 *Electricity Sector Data*

4.5.1 Generation Data

The electricity sector differs from other sectors in the extent to which emissions associated with power use within the state may result from emissions outside the WCI as power is imported from or exported to other areas.

ENERGY 2020 contains information on every generating unit in the state or province, as well as in neighboring jurisdictions which may supply power to the state. The model tracks and uses the following information for each generating unit:

- Historic Peak Capacity (MW);
- Historic generation levels (GWh);
- Type of fuel used;
- Heat rate;
- Historic annual fuel use (PJ);
- Emissions by pollutant type;
- O&M costs;
- Capacity factors;
- Emission rates;
- Outage rates;
- State or Province;
- Physical location (latitude and longitude);
- Ownership information;
- Plant type (Hydraulic, Coal, Combined Cycle Turbine, etc.)

The data on existing and committed generating units in the US was obtained from the National Electric Energy Data System (NEEDS) 2006 database and reconciled with a list of plants from BPA. The database of plants in Canada was developed based on the Canadian IPM®[17] module, modified and updated based

[17] ICF's Integrated Planning Model®.

on information from Statistics Canada, Environment Canada and the National Energy Board.

4.5.2 Electricity Generation Capacity and Operation Data

ENERGY 2020 is populated with data describing the type, operation and performance of every generating unit in the western US and the two Canadian provinces. In order to improve model performance, some smaller units with common characteristics may be combined (i.e. wind units at the same site, or small hydraulic units). In addition to plant-level data, the table below includes other inputs necessary to describe the electric system, including transmission capability.

Input	Sources Used/Available
Plant type	Annual Electric Generator Report: EIA Form 860 (2006) Canadian IPM® Base Case 2004[18] Natural Resources Canada, Canada's Energy Outlook: Reference Case 2006[19] Supplemented by National Energy Board info.
Plant capacity	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Plant historical generation	EIA Form 906/920 (2001-2006) Total generation output by plant type for California from CEC Canada: as above
Plant fuel type	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Plant Heat Rate	EIA Form 906/920 (2001-2006) Canada: as above
Plant fuel consumption	EIA Form 906/920 (2001-2006)
Plant emissions by pollutant	EPA CAMD (2001-2006) Environment Canada

[18] http://www.ec.gc.ca/cleanair-airpur/caol/canus/IPM_TECHNICAL/ipm_technical_report/toc_e.cfm
[19] http://www.nrcan-rncan.gc.ca/com/resoress/publications/peo/peo-eng.php

Input	Sources Used/Available
Plant costs (operation and maintenance, variable and fixed)	CA: E3 model data Canada: as above
Plant historical capacity factor	EIA Form 906/920 (2001-2006) Statistics Canada
Plant availability (outages)	Calculated using generation data Statistics Canada
Plant owner and location	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Planned capacity additions and retirements	Annual Electric Generator Report: EIA Form 860 California Public Utility Commission GHG Modeling process (E3) NRCan Energy Outlook
Transmission Capability	Canada: National Energy Board, *Canadian Electricity Trends and Issues (2001)* & *Canadian Electricity Exports and Imports (2001)*; National Resources Canada, *Electric Power in Canada 1998 – 1999*; NERC, *2004 Summer Assessment* & *2004 Winter Assessment: Reliability in the Bulk Electricity Supply in North America* Western US – Additional data provided by BPA and reports from the WECC (Approved 2006 Spring OTC Limits, March 16, 2006).

This data has been compared to generation data provided as part of modeling for the California Public Utilities Commission.[20]

The resulting list of generating units was matched to emission data from the EPA in order to calculate emission rates. The resulting emission rates for the targeted GHG emissions were then reviewed for reasonableness based on plant type and capacity factors, etc.

Historic generation by plant type will be calibrated with historic generation data available from the EIA.

[20] *www.ethree.com/cpuc_ghg_model.html*

4.5.3 Transmission Structure and Dispatch

Power flows between neighboring US states are modeled within ENERGY 2020 based on existing transmission capabilities and interconnections as obtained from NERC reports.

Appendix D describes the inter-regional transmission capabilities between model regions (or nodes) as well as the maximum capacity limit of each transmission path used in the model. Interconnection capacities and transmission nodes used in the model were based on the IPM® Model 2006[21] updated to reflect changes in the region based on past work for past clients including the Bonneville Power Administration and review by the Economic Modeling Team.

Generation is dispatched at the node level for a set of sample hours in each season. Each node is economically dispatched, selecting lowest cost generation first with the resulting clearing price determining the generation price for that node as described in Appendix A. As part of the calculation the model can utilize resources from a neighboring node within the constraints of the transfer capacity between nodes. The transfer of energy between nodes is subject to a 1% loss to represent additional transmission losses.

4.5.4 Planned Capacity Changes

As part of the modeling process, ENERGY 2020 builds new capacity endogenously as needed to meet capacity and reserve requirements or to minimize the total cost of generation (e.g., in response to allowance prices). At any given time, however, plans may already be in place to build, re-furbish, upgrade or retire generation facilities. These plans must be incorporated into the model in order to reflect decisions and commitments that have already been made.

For this project, we reviewed information on a number of generation projects planned in the Region, with particular emphasis on planned coal facilities. This list was then reviewed with the WCI Economic Modeling Team to determine which projects were felt to be most likely to proceed based on the current status. While it is not possible to determine which specific projects will proceed, for

[21] *Table 3.5 of section 3 of the documentation for the EPA Base Case 2006 (v3.0) posted on the EPA website: http://epa.gov/airmarkets/progsregs/epa-ipm/index.html#docs*

modeling purposes we have assumed that the units listed in Appendix F will be built during the modeled period.

ENERGY 2020 can determine the need for new generation based on a pre-determined reserve requirement. Normally, this determination is based on the highest level of demand for power and the available capacity at the time of that peak. Some types of generation, such as wind or some types of hydro-electric generation however, may not be available at the time of the peak. For modeling purposes the model assumes that only 15% of installed wind capacity is available at the time of the peak.

4.5.5 New Generation Characteristics

The costs and characteristics of new generation are based on information developed as part of the GHG modeling process for the California Public Utility Commission[22] and are shown in Appendix G.

Carbon capture and storage (CCS) is assumed to be available after 2020. The performance and cost assumptions for new generating units equipped with CCS are shown in Appendix G. It should be noted that these costs represent capture costs only and do not include transportation or sequestration costs.

The model assumes that no new nuclear generation capacity will come online through 2020.

4.5.6 Industrial Generation and Co-generation

ENERGY 2020 models both utility generation, which supplies the power grid, and industrial generation which supplies a particular end user. Industrial generation is defined as power generation that is within the industrial end user's facility and is not used to supply power to the grid. Industrial generation, as defined in ENERGY 2020, could also be referred to as self-generation or load displacement generation. Industrial generation may be supplied by any of the fuels listed below:

- Biomass
- Coal
- LPG
- Oil

[22] *www.ethree.com/cpuc_ghg_model.html*

- Solar
- Steam

Co-generation, or combined heat and power facilities, simultaneously generate electricity and supply a heat load. ENERGY 2020 recognizes that co-generation may occur either as industrial generation or as utility generation and may use any of a number of fuels.

- Within the power sector, these plants are treated as 'must run' units, meaning that they will always operate when available. Power from these units contributes to overall electricity supply. Heat from these units may be captured as part of a separate steam supply system, however, limited data is available regarding overall US steam demand.
- Within the industrial sector, co-generation capacity will run based on heating requirements. Heat produced from co-generation is used to meet industrial heat requirements based on a co-generation heat rate. Co-generated electricity is used to meet industrial power requirements, reducing net demand from the grid.

Where the heat contribution of co-generation is significant, the preferred modeling approach is to include these units in the industrial sector.

The databases used to represent electricity generation often include all significant generators, including both utility and industrial boilers and generators. By contrast, reported electricity consumption information tends to be based on metered electricity sales, and as such are net of self generation. Total electricity consumption and generation will generally be slightly higher than reported electricity sales. It is therefore important in calibrating the model with historic electricity consumption that existing generation used as industrial or self-generation be appropriately identified.

4.6 *Transportation*

ENERGY 2020 models passenger, freight and off road transportation separately, based on different underlying drivers. Transportation is assumed to be a derived demand based on levels of economic output (for freight) or personal income (for passenger). As the economic drivers (industrial gross output and personal income) grow, transportation demand increases. The amount of transportation required per unit of economic output changes over time based on historic trends.

Transportation requirements are developed for each geographic area in the model based on historic demands for transportation, consumer preferences, business requirements, and the cost for each mode of transportation. Consumers of transportation select among available modes within the model based on preferences and relative costs. Mode choices include bus, train, and various types of personal and freight vehicles. Consumers choose among modes based on consumer preferences and cost. The model uses average vehicle lifetimes to vintage the vehicle stock.

Personal vehicle choices are made in a similar manner. Consumers consider capital cost, fuel cost and efficiency as well as non-price factors in their purchase decision and seek to maximize perceived utility. Historically, non-price factors such as vehicle size, performance and appearance have dominated the choice decision with efficiency playing a relatively minor role. Costs are presented in the model in terms of the capital cost per mile traveled for different vehicle classes. Larger vehicles therefore have a higher associated capital cost as well as lower energy efficiency for the level of delivered service (miles traveled).

The transportation categories represented in the model are shown below.

E2020 Classifications				
Economic Categories	**Modes**	**Vehicle Classes** *(for Personal Vehicles)*	**Fuel Types** *(for Personal Vehicles)*	**Technology Types**
Passenger	Personal Vehicles	Light	Gasoline	Internal Combustion Engine
Freight	Motorcycle	Medium	Diesel	Hybrids
Off Road	Train	Heavy	Propane	Fuel Cell
	Plane		CNG	Plug-In Hybrid
	Marine		Electric	
			Ethanol	
			Hydrogen	

At present, plug-in hybrid and fuel cell options are not populated in the model. As more information on the costs and characteristics of these options becomes available these choices can be made available to transportation consumers.

Vehicle and modal efficiencies used in the model are based on the *Transportation Energy Data Book* (Edition 26, 2007)[23] published by the US

[23] http://cta.ornl.gov/data/download26.shtml

Department of Energy's Oak Ridge National Laboratory. Specific data references are provided in the table below.

Input	Sources Used/Available
All tables below are from ***Transportation Energy Data Book*** *(Edition 26, 2007)*[24] *published by the US Department of Energy's Oak Ridge National Laboratory.*	
Average fuel economy	Tables 4.17 and 4.18
New Vehicle Efficiency	Tables 4.7 and 4.8
Scrap/Survival Rates	Tables 3.8, 3.9 and 3.10
Freight Truck Fuel Economy	Tables 5.1 and 5.2
Bus Efficiency	Table 2.13
Rail Efficiency – Passenger	Table 9.10 and 9.11
Rail Efficiency - Freight	Table 9.8
Marine - Freight	Table 9.5
Air Travel	Table 9.2

The model reflects the most recent changes in new passenger vehicle in CAFÉ standards, as embodied in the *Energy Independence and Security Act of 2007* (see section 4.8).

Off road transportation energy use in ENERGY 2020 is driven by activity in the Agriculture, Forestry and Construction sectors.

4.7 *Built Environment*

ENERGY2020 has been used to model energy for almost three decades. Much of the data on energy efficiency and costs was originally based on information provided by the Energy Information Administration's *Annual Report to Congress*[25] which was last published in 1980. Over the years, this data has been updated based on information gathered from clients as part of numerous projects. The resulting cost and efficiency data is used as default values in the model.

When a new model is built for a particular project, actual historic energy use is input to the model (generally from the EIA SEDS database) and allocated by

[24] http://cta.ornl.gov/data/download26.shtml
[25] EIA, *Annual Report to Congress, 1980: Volume 3*. Energy Information Administration, USDOE, Report #: DOE/EIA-0173(80)/3.

sector based on census region data from the most recent energy surveys available from the EIA (e.g. Residential Energy Consumption Survey, Commercial Building Energy Consumption Survey, etc). Average and maximum device efficiencies are adjusted within the model over time in calibrating to this actual energy use data. For the WCI project, ICF and SSI have subjected this data to an internal review and updated the values based on expert opinion and data from a variety of sources.

Appendix J presents the assumptions used in modeling the residential and commercial sectors, showing assumed levels of efficiency by period, maximum efficiency levels, initial and operating costs per mmBtu of energy use and device lifetimes for each end use for each fuel type. This data is used in the choice curves within the model.

Several of the jurisdictions involved in the WCI have had a long history of promoting energy efficiency and demand side management for electricity and natural gas energy use. As a result, average appliance and equipment efficiencies are expected to be higher than for the US and Canada as a whole. As part of Tasks 4 and 5 we will attempt to gather information on current levels of equipment efficiency and the state of the market for efficiency technologies. This information will then be used to adjust end-use data within the model to reflect current levels of efficiency and market saturations.

The Reference Case does not assume any increase in equipment or appliance efficiency other than the improvements due to the *Energy Independence and Security Act of 2007*, as noted in section 4.8.

4.8 *Programs/Policies Incorporated in Reference Case*

As this assumptions document is further refined and developed, a table listing the specific laws and regulations included in the Reference Case will be inserted here.

Of particular importance, the *Energy Independence and Security Act of 2007* was passed into law in early January 2008. The following assumptions will be used to model the Act in the Reference Case:

- Transportation: The current marginal vehicle efficiency for passenger cars and light trucks will be incrementally increased by a fixed percentage each year starting in 2011 to reach the mandated fleet efficiency in 2020.

- Renewable Fuels: The Act specifies a minimum volume of biofuels to be produced each year. For modeling purposes we have assumed that this volume of biofuels is produced and consumed in each year. The model assumes that each of the US states will use their pro-rata share of the available fuels.
- Residential Boilers and Furnace Fans: Savings estimates developed by the ACEEE for each state will be used to model this portion of the Act, using only the benefits realized by upgrades to the residential energy boilers, leaving out any energy benefits associated with reduced electricity consumption by furnace fans.
- Walk-In Coolers and Walk-In Freezers: Savings estimates developed by the ACEEE for each state will be used to model this portion of the Act.
- Electric Motor Efficiency Standards: The model will utilize the ACEEE savings projections, pro-rated to California's relative industrial electricity sales.
- External Power Supply Efficiency Standard: savings estimates developed by the ACEEE for each state will be used to model this portion of the Act.
- Energy Efficient Light Bulbs: Information will be collected on existing market shares for efficient lighting in the WCI region in order to estimate the impact of this aspect of the Act. The base assumptions are that general service lighting accounts for about 90% of residential lighting, 10% of commercial lighting and 5% of industrial lighting.
- Metal Halide Lamp Fixtures: The model assumes that 15% of commercial lighting and 60% of industrial lighting now use metal halide fixtures. For new installations the model assumes that 80% of this market would use pulse start ballasts.

The model will also include regulations affecting the power sector which have been approved but have not yet come into effect. Such regulations may be significant to the extent that they influence dispatch decisions which in turn will affect CO_2 emissions.

For the Canadian provinces, the model assumes that existing requirements for biofuels are met. Existing legislation requires that

The reference case includes Renewable Portfolio Standards for each WCI partner jurisdiction according to the rules in each jurisdiction. Please refer to Appendix I for summaries of each jurisdiction's RPS.

4.9 *Complementary Policies*

A *Complementary Policies* scenario is being modeled for the WCI that includes the following WCI-wide policies that are not part of the Reference Case:

- **Vehicle Miles Traveled** – Assumes that policies will be introduced to reduce VMT in all WCI partner jurisdictions by 2% from BAU levels in 2020.
- **Energy Efficiency Programs** – Assumes that energy efficiency programs will be undertaken in all WCI partner jurisdictions to reduce energy use (electricity, natural gas, fuel oil and propane) by 1% per year below the reference forecast between 2011 and 2020.
- **California Clean Cars** – Assumes that all WCI partners will implement the California clean car standards as currently formulated, along with Phase 2 standards currently contemplated by the California ARB.

Appendix A: The ENERGY 2020 Model

The Model – ENERGY 2020

ENERGY 2020 is an integrated multi-region, multi-sector energy analysis system that simulates the supply, price and demand for all fuels. It is a causal and descriptive model, which dynamically describes the behavior of both energy suppliers and consumers for all fuels and for all end-uses. It simulates the physical and economic flows of energy users and suppliers. It simulates how they make decisions and how those decisions causally translate to energy-use and emissions.

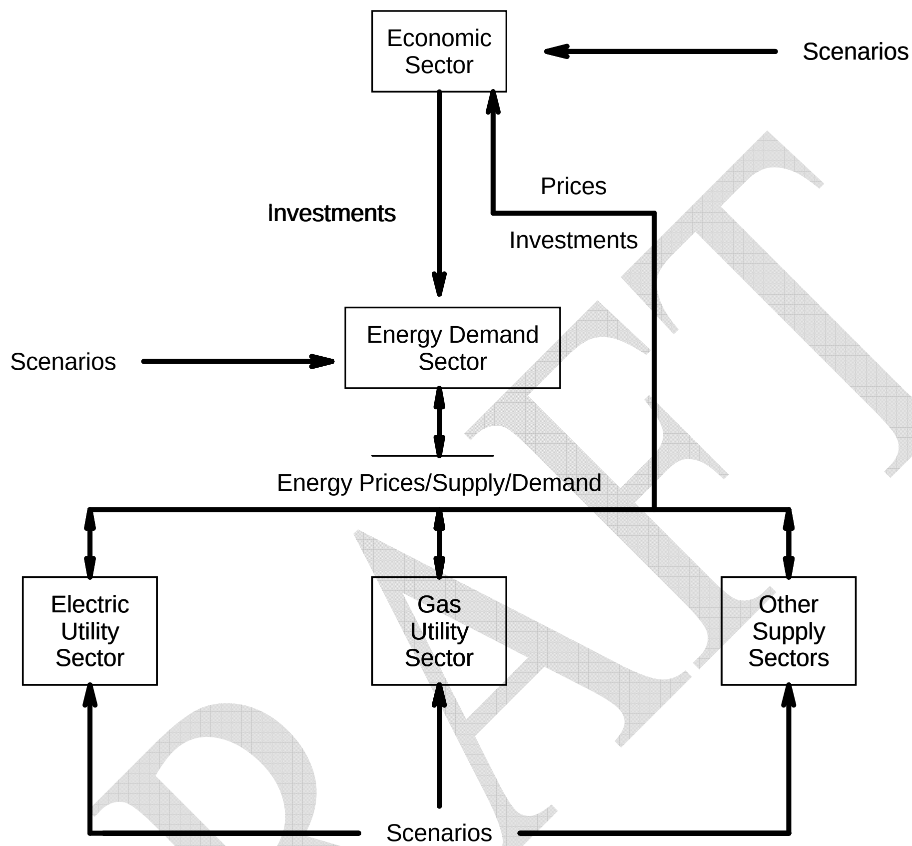
ENERGY 2020 is an outgrowth of the FOSSIL2/IDEAS model developed for the US Department of Energy (DOE) and used for all national energy policy since the Carter administration.[26] This early version of ENERGY 2020 was developed in 1978 at Dartmouth College for the DOE's Office of Policy Planning and Analysis.

Model Overview:

The basic structure of ENERGY 2020 is provided in Figure 1-1. Energy Demand sector interacts with the Energy Supply sector to determine equilibrium levels of demand and energy prices. Energy Demand is driven by the Economy sector, which in turn provides inputs to the Economy sector in terms of investments in energy using equipment and processes and energy prices. The model has a simplified Economy sector to capture the linkages between the energy system and the macro-economy. However, the model is best run with full integration with a macroeconomic model such as REMI. Given the modular nature of ENERGY 2020, additional sectors or modules from other, non-ENERGY 2020 related, models (macroeconomic, supply such as oil, gas, renewables etc.) can be incorporated directly into the ENERGY 2020 framework.

[26] *FOSSIL2 was the original version but was renamed to IDEAS a few years ago to reflect its evolutionary development since its original construction.*

Figure 1.1: ENERGY 2020 Overview



Energy Demand:

The demand sector of the model represents the geographic area by disaggregating the four economic sectors into subsectors based on energy services. As many or as few subsectors can be incorporated as required. Multiple technologies, multiple end-uses and multiple fuels are detailed. The level of detail that can be incorporated is of course subject to the data availability. The four economic sectors are:

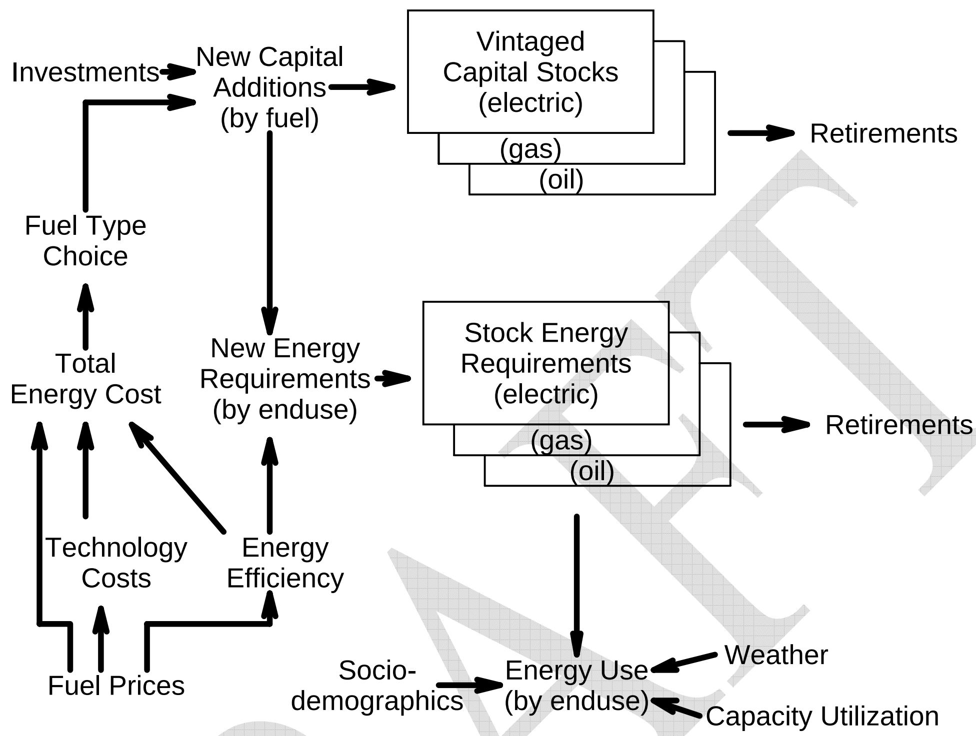
- Residential sector which includes three classes, single family, multifamily and rural/agricultural with 8 end-uses including space heating, water heating, lighting, cooling, refrigeration, other substitutable, and other non-substitutable.
- Commercial sector which is aggregated into one class and end-uses including space heating, water heating, cooling, lighting, other substitutable, other non-substitutable.

- Industrial sector which includes 10 (23 for US) 2-digit SIC categories and is further broken down into process heat, motors, lighting, miscellaneous as the end uses.
- Transportation sector which includes several modes of transportation including automobile, truck, bus, train, plane, marine and electric vehicles. Also, each of the residential, commercial and industrial sectors has separate transportation demands.

For each of the end-uses, up to six fuels are modeled, for example, the residential space heating has the choice of a gas, oil, coal, electric, solar and biomass space heating technologies. Added end-uses, technologies and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical locale-specific data. The load duration curves are dynamically built up from the individual end-uses to capture changing condition under consumer choice and combined gas/electric programs.

A few basic concepts are crucial to an understanding of how the model simulates the energy system. These concepts including, the capital stock driver, the modeling of energy efficiency through trade-off curves, the fuel market share calculation, utilization multipliers and the cogeneration module are discussed below in abbreviated form. Figure 3-1 (Demand Overview) illustrates the demand sector interactions.

Figure 3.2: Demand Overview



Energy Demand as a Function of Capital Stock:

The model assumes that energy demand is a consequence of using capital stock in the production of output. For example, the industrial sector produces goods in factories, which require energy for production; the commercial sector requires buildings to provide services; and the residential sector needs housing to provide sustained labor services. The occupants of these buildings require energy for heating, cooling, and electromechanical (appliance) uses.

The amount of energy used in any end-use is based on the concept of energy efficiencies. For example, the energy efficiency of a house along with the conversion efficiency of the furnace determines how much energy the house uses to provide the desired warmth. The energy efficiency of the house is called the capital stock energy or process efficiency. This efficiency is primarily technological (e.g. insulation levels) but can also be associated with control or life-style changes (e.g. less household energy use because both spouses work outside the home.) The furnace efficiency is called the device or thermal efficiency. Thermal efficiency is associated with air conditioning, electromotive devices, furnaces and appliances.

The model simulates investment in energy using capital (buildings and equipment) from installation to retirement through three age classes or vintages. This capital represents embodied energy requirements that will result in a specified energy demand as the capital is utilized, until it is retired or modified.

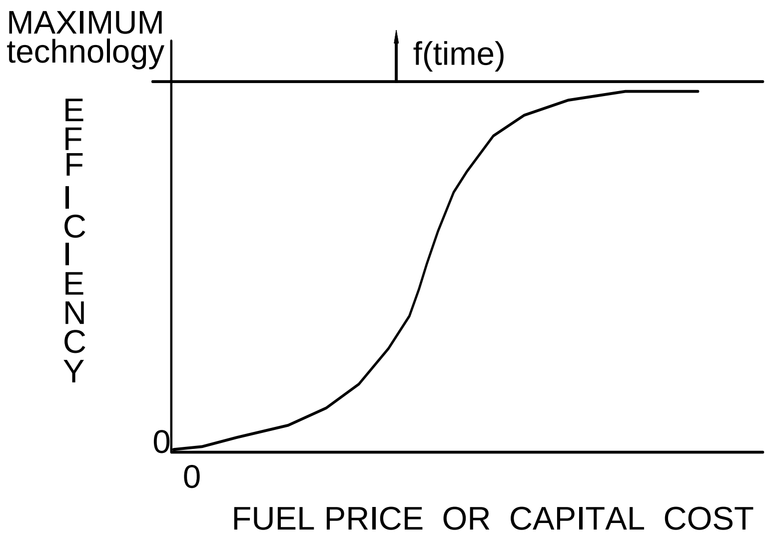
The size and efficiency of the capital stock, and hence energy demands, change over time as consumers make new investments and retire old equipment. Consumers determine which fuel and technology to use for new investments based on perceptions of cost and utility. Marginal trade-offs between changing fuel costs and efficiency determine the capital cost of the chosen technology. These trade-offs are dependent on perceived energy prices, capital costs, operating costs, risk, access to capital, regulations and other imperfect information.

The model formulates the energy demand equation causally. Rather than using price elasticities to determine how demand reacts to changes in price, the model explicitly identifies the multiple ways price changes influence the relative economics of alternative technologies and behaviors, which in turn determine consumers' demand. In this sense, price elasticities are outputs, not inputs, of the model. The model accurately recognizes that price responses vary over time, and depend upon factors such as the rate of investment, age and efficiency of the capital stock, and the relative prices of alternative technologies.

Device and Process Energy Efficiency:

The energy requirement embodied in the capital stock can be changed only by new investments, retirements, or by retrofitting. The efficiency with which the capital uses energy has a limit determined by technological or physical constraints. The trade-off between efficiency and other factors (such as capital costs) is depicted in Figure 3.3 (Efficiency/Capital Cost Trade-Off). The efficiency of the new capital purchased depends on the consumer's perception of this trade-off. For example, as fuel prices increase, the efficiency consumers choose for a new furnace is increased despite higher capital costs. The amount of the increase in efficiency depends on the perceived price increase and its relevance to the consumer's cash flow.

Figure 3.3: Efficiency/Capital Cost Trade-Off



The standard the model efficiency trade-off curves are called consumer-preference curves because they are estimated using cross-sectional (historical) data showing the decisions consumers made based on their perception of a choice's value. Many planners are now interested in measure-by-measure or least-cost curves which use engineering calculations and discount rates to show how consumers should respond to changing energy prices. Another analysis focuses on the technical/price differences in alternative technologies and the incentives needed to increase the market-share or market penetration of a specific technology. This perspective on the choice process uses market share curves. The model allows the user to select any of these three types of curves to represent the way consumers make their choices. Shared savings, rebate, subsidy programs, etc. can be tested using any of the curves.

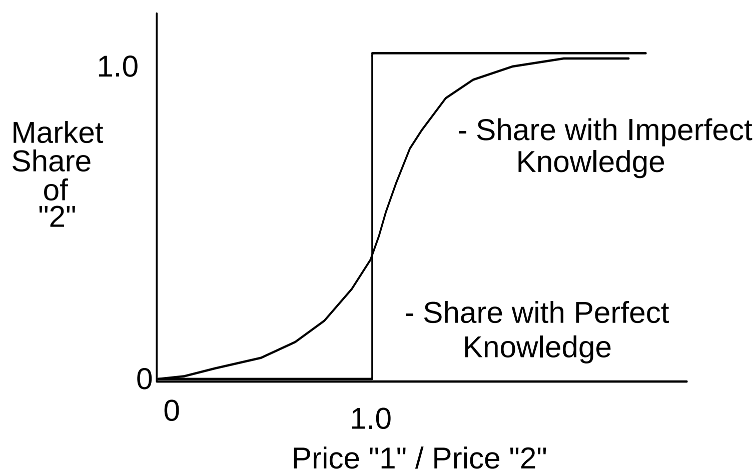
Cumulative investments determine the average embodied efficiency. The efficiency of new investments versus the average efficiency of existing equipment is one measure of the gap between realized and potential conservation savings.

The model uses saturation rates for devices to represent the amount of energy services necessary to produce a given level of output. Saturation rates may change over time to reflect changes in standard of living or technological improvements. For example, air conditioning has historically increased with rising disposable incomes. These rates can be specified exogenously or can be defined in relation to other variables within the model (such as disposable income).

The Market Share Calculation:

Not all investment funds are allocated to the least expensive energy option. Uncertainty, regional variations, and limited knowledge make the perceived price a distribution. The investments allocated to any technology are then proportional to the fraction of times one technology is perceived as less expensive (has a higher perceived value) than all others. This process is shown graphically in Figure 3.4 (Market Share Dynamics).

Figure 3.4: Market Share Dynamics



Short Term Budget Responses:

A short-term, temporary response to budget constraints is included in the model. Customers reduce usage of energy if they notice a significant increase in their energy bills. The customers' budgets are limited and energy use must be reduced to keep expenditures within those limits. These cutbacks are temporary behavioral reactions to changes in price, and will phase out as budgets adjust and efficiency improvements (true conservation) are implemented. This causes the initial response to changing prices to be more exaggerated than the long-term response, a phenomenon called "take-back" in studies of consumer behavior.

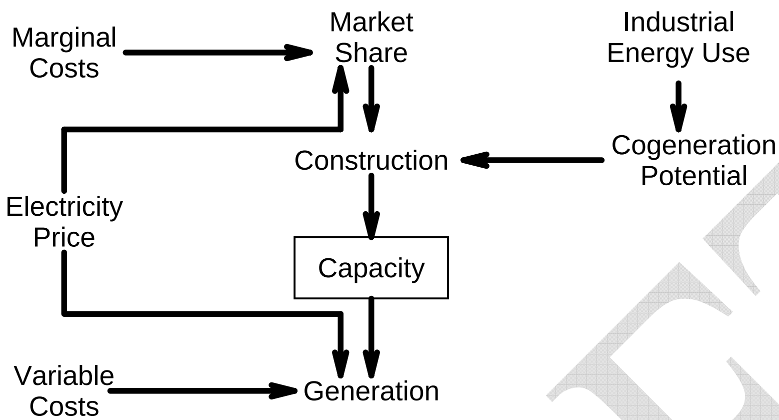
Accounting for Fungible Demand:

Some furnaces and processes can use multiple fuels. That is, they can switch almost instantaneously between, for example, gas and oil or coal and biomass as prices or the market dictates. Energy demand that is affected by this short-term fuel switching phenomena is called fungible demand. The model explicitly simulates this market share behavior.

Modeling Cogeneration:

Most energy users meet their electricity requirements through purchases from a utility. Some users (industrial and commercial) can, however, convert some of their own waste heat into usable electricity when economics warrant such action. Other users (residential and commercial) can purchase self-generation energy sources such as gas turbines, diesel-generators or fuel cells. Figure 3.4 shows a simplified overview of the cogeneration structure.

Figure 3.5: Cogeneration Concepts



In the model all energy used for heating is a candidate for cogeneration. The cost of cogeneration is the fixed capital cost of the investment plus the variable fuel costs (net of efficiency gains). This cogeneration cost is estimated for all technologies and compared to the price of electricity. The marginal market share for each cogeneration technology is based on this comparison.

Cogeneration is restricted to consumers who directly produce part of their own electricity requirement. Companies which generate power primarily for resale to the electric utility are considered independent power producers and are included in the electric supply model.

Energy Supply:

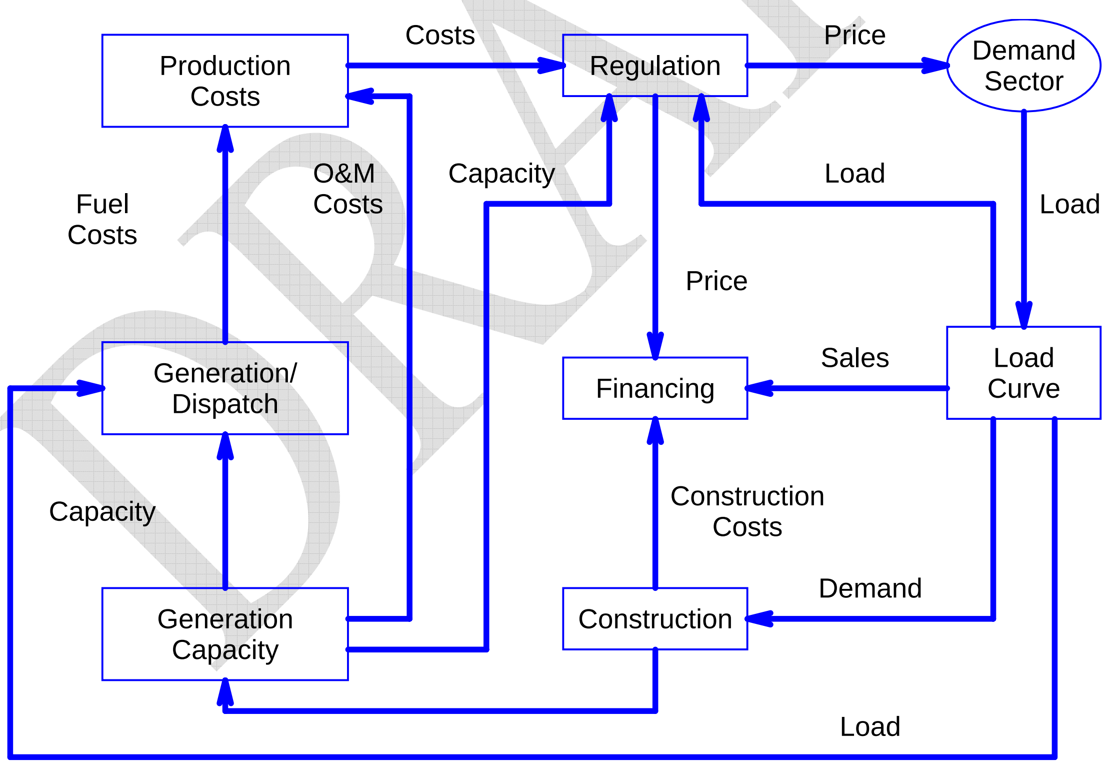
For electric and gas utilities (separate or combined), ENERGY 2020 internally and self-consistently simulates sales, load (by end-use, time-of-use, and class), production (across thirty-six dispatch types), demand-side management (by technology), forecasting, capacity expansion (new generation, independent power producers, purchases, and DSM), all important financial variables, and rates (by class, end-use, and time-of-use.)

The version currently used in this analysis only has the electricity utility sector (a full fledged natural gas utility sector for Canada is currently unavailable in the model, only a simplified natural gas supply function is used to calculate the supply price response).

With the inclusion of the electric utility sector, the generic supply model turns over the calculation of electricity prices to that sector. The model is capable of endogenously simulating the forecasting of capacity needs, as well as the planning, construction, operation and retirement of generating plants and transmission facilities. Each step is financed in the model by revenues, debt, and the sale of stock. The simulated utility, like its real world counterpart, pays taxes and generates a complete set of accounting books. In ENERGY 2020, the regulatory function is modeled as a part of the utility sector. The regulator sets the allowed rate of return, divides revenue responsibility among customer classes, approves rate base, revenues and expenses, and sets fuel adjustment charges.

The interactions in the electric utility sector are summarized in Figure 3.6

Figure 3.6: Electric Utility Structure Overview



Expansion Planning:

The utility sector endogenously forecasts future demand for electricity. From the forecast it projects the future capacity required meeting future demand by taking into account retirements and plants already under construction. Construction of additional capacity is initiated if future electricity requirements, including reserves, are forecast to exceed available capacity (using seasonal ratings).

If additional capacity is needed to meet forecasted needs, the basic capacity expansion module in ENERGY 2020 determines whether base or peaking capacity is required. The model determines the maximum number of hours that new peaking capacity can be economically operated, before it would be less expensive to construct and operate base load capacity instead. If the forecasted peaking capacity would operate more than that economic maximum, base loads units are initiated, otherwise peaking units are initiated. Any plant type including geothermal, wind, biomass and storage can be considered.

New plants, of a pre-specified minimum size, are initiated when the reserve margin would be violated if the plants were not built or if base load capacity is inadequate to serve base load energy needs at the end of the forecast period. The model does allow the minimum reserve margin to be temporarily violated at the peak if new base load capacity is scheduled to be available within the year. Peaking units are allowed to serve more than the maximum economical number of hours until base load capacity comes on-line.

Minimum plant size is exogenous. The mix of new base load plants (i.e. alternative coal technologies, hydro, or nuclear) is user-specified in the standard ENERGY 2020 configuration. The model also evaluates the financial implications of new construction, including total construction costs, cost schedules, and AFUDC/CWIP. The gross rate on AFUDC equals the weighted average cost of capital. The actual construction progress and financial impacts are simulated on a year by year basis.

ENERGY 2020 can also be configured to consider intermediate load units, firm purchases contracts, external sales, independent power producers, and demand-side options. These options can be optionally selected based on endogenous least-cost analysis or can be chosen by user-specified criteria to meet. A detailed automatic Integrated Resource Planning module that would endogenously choose (with user control) from DSM measures utility and non-utility generation and purchase alternatives using linear programming techniques is now being offered as an enhancement.

Financing:

The ENERGY 2020 utility finance sub-sector simulates the activities of a utility's finance department. It forecasts funding requirements and follows corporate policies for obtaining new funds. The model simulates borrowing and issuing of stock, and can repurchase stock or make investments if it has excess cash. Cash flows are explicitly modeled, as are any decision that affects them. Coverage ratios, intermediate- and long-term debt limits, capitalization, rates of return, new stock issues, bond financing, and short-term investments are endogenously calculated. The model keeps track of gross, net, and tax assets. It also calculates the depreciation values used for the income statement and tax obligations.

For WCI modeling, this element of the model is not used, and a simpler approach to estimating retail electricity prices is used.

Regulation:

The utility sector sets electricity prices according to regulatory requirements. The regulatory procedures use allowed rate-of-return and test year cost and demands to determine allowed revenues. Electricity prices are calculated from peak-demand fractions by allocation of costs. Any other allocation scheme can also be considered. The regulatory sub-sector of ENERGY 2020 automatically factors in a wide variety of regulatory policies and options. More importantly, the model can be readily modified to consider a wide spectrum of scenarios.

The regulatory process revolves around a test year, usually one year forward, when proposed rates will go into effect. The utility sector forecasts test year sales and peak demands by season and customer class, just as it does to determine capacity needs. These test year demand estimates are used to allocate responsibility for system peak, and therefore, generation capacity costs.

Fuel costs for the test year are estimated by dispatching the plants that will be available in the test year, using the dispatching routine explained below. Fuel costs and operating and maintenance costs are adjusted for expected inflation, and these costs are factored into the electricity rates using forecasted sales.

ENERGY 2020 calculates the utility rate-base according to a detailed conventional rate making formula. The model allows the user to adjust allowable costs, and has been used extensively to evaluate alternative rate-base scenarios for individual plants, including allowing return of, but no return on investment, and partial disallowment of construction and interest costs.

The ENERGY 2020 system also includes estimation of avoided costs, which determines when the utility may be required to purchase third party power. Environmental constraints, such as air pollution restrictions, can also be included in the model. If ENERGY 2020 is configured as a regional or state-wide system, municipal utilities, with their unique tax and rate structures, are incorporated. Similarly, regional or power pool interchange is also recognized by ENERGY 2020. As with the other sectors of ENERGY 2020, the regulatory subsector is flexible enough to accommodate any existing or hypothetical circumstance.

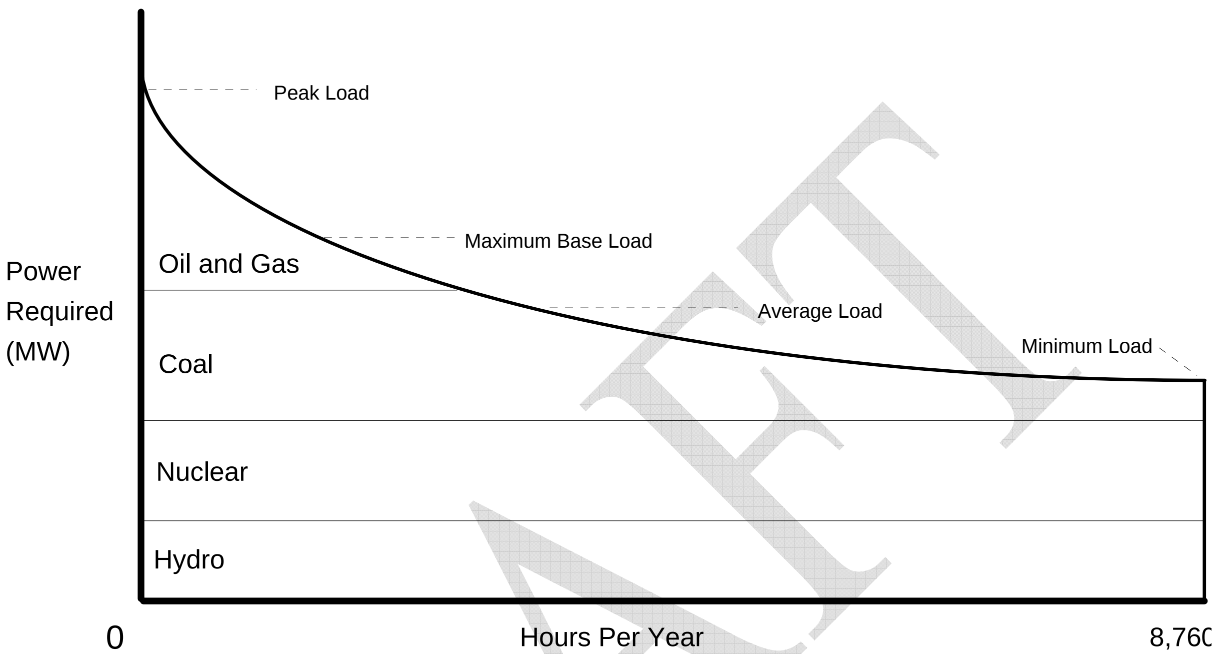
For WCI modeling, this element of the model is not used, and a simpler approach to estimating retail electricity prices is used.

Operations:

Each end-use in ENERGY 2020 has a related set of load shape factors. Typically, these factors define the relationship between peak, minimum and average load for each season. These factors when combined with the weather-adjusted energy demand by end-use and corrected for cogeneration, resale, and load management programs, form the basis of the approximated system load duration curve. Alternatively, unit hourly loads for each end-use for three days per month (average weekday, weekend and peak weekday) are used.

The standard ENERGY 2020 production subsector uses an advanced de-rating or chronological method to estimate the seasonal or hourly dispatch of plants. It purchases power externally when economic or necessary. Plant availability and generation for coal, nuclear, hydroelectric, oil and gas are currently considered, as well as pumped storage, firm purchases, interruptible load, and fuel switching and qualified facilities. Figure 3.7 also shows a typical plant dispatch schedule.

Figure 3.7: Generation from the Load Curve



The ENERGY 2020 system estimates conventional fuel costs based on the unit dispatch, heat rates, and fuel prices (from the supply sector.) Nuclear fuel costs are capitalized and depreciated throughout the re-fuelling cycle. Nuclear fuel expenses also include fuel disposal costs.

ENERGY 2020 explicitly models the costs of maintaining the transmission and distribution (T&D) system. New facility investments are scheduled and incurred endogenously. In addition, the user can specify the decision rules that dictate T&D expenditures. ENERGY 2020 also explicitly models both fixed and variable operation and maintenance costs, power pool interchanges, nuclear decommissioning costs, plant capital additions, plant cancellations, and general administration costs.

Model Applications:

The structure of the model is well tested and has been used to simulate not only US and the Canada energy and environmental dynamics but also those of several countries in Western, Central and Eastern Europe. Current efforts include strategic and tactical analyses for South America deregulation. Further, the model has been used successfully for deregulation analyses in over 50 energy suppliers and in all the US states and Canadian provinces. Several US and Canadian energy suppliers currently use the model for the analysis of combined electricity and gas deregulation dynamics.[27] The model contains confidence and validity packages that allow it to determine how to take maximal advantage of RTO rules. The ISO NE used the model to find gaps in its rules and to develop more efficient market conditions. The model was used for the CAPX/ISO to model to show, before the fact, many of the “games” played in the California market.

[27] *ENERGY 2020 is the only model known to have simulated and predicted the dynamics that occurred in the UK electric deregulation. These include gaming, market consolidation and re-regulation dynamics.*

Appendix B: Data Sources

The following describes the default data sources used in ENERGY 2020. Where this data has been replaced by jurisdiction-specific information, the jurisdiction-specific data is described in the main body of the document.

Historical Energy Prices and Demands

Historic energy prices and demands are from *State Energy Data*, Integrated Energy Statistics Divisions of the Office of Energy Markets and End Use, Energy Information Administration, USDOE. This document provides annual time series estimates of State-level energy consumption, prices, and expenditures by major economic sectors. In 2000, the *State Energy Data* replaced two former EIA reports: State Energy Data Report (SEDR) and State Energy Price and Expenditure Report (SEPER). Tables by major economic sector can be found at: http://www.eia.doe.gov/emeu/states/_states.html. New tables by energy source can be found at: http://www.eia.doe.gov/emeu/states/multi_states.html.

Future Energy Prices

To estimate future energy prices, we apply the forecasted price growth rates from the *Annual Energy Outlook (AEO) 2008* to the prices from the last historical year (obtained from *State Energy Data*). The Annual Energy Outlook 2008 presents a forecast and analysis of US energy supply, demand, and prices through 2030.
http://www.eia.doe.gov/oiaf/aeo/supplement/index.html

Note that there is a gap between the most recently reported historical year of data and the first forecast year. We resolve this by including one year's worth of price data from the AEO of the previous year.

Future Energy Demands

Future energy demands are computed by the model, but the model can calibrate to future energy demands if desired. In the modeling completed for WCI the model projections have been compared to other forecasts but have not been calibrated to any other forecast.

Device Energy Efficiency Standards

Device efficiency standards come mainly from the *Energy Policy Act of 1992*, with some efficiencies coming from other selected sources.
http://energy.navy.mil/publications/law_us/92epact/hr776toc.htm

This initial base of efficiency standards have been updated as new regulations have come into effect. Requirements in the ***Energy Independence and Security Act*** have also been included in the Reference Case.

Device Capital Cost, Efficiency, and Device Lifetimes; Cogeneration Capital Costs, Heat Rates and Parameters

These values were originally developed from the *Annual Report to Congress, 1980: Volume 3*. Energy Information Administration, USDOE, Report #: DOE/EIA-0173(80)/3. ICF and SSI have reviewed and updated this data which is used to provide the shape of choice curves within the model based on expert opinion and data from a variety of sources. The values used are presented in Appendix J.

End-Use Load Shapes

The end use load shapes were originally based on 1995 NEPOOL published reports. Load shapes for temperature sensitive loads are modified based on actual weather data for the state/region being modeled.

Industrial Energy Splits, Industrial End Use Splits and Commercial End-Use Splits

The energy that we obtain from *State Energy Data* is a total value that needs to be split among different industries and/or uses (end use demands, cogeneration demands, feedstock demands). We obtain the splits among industries and uses from the *Manufacturing Energy Consumption Survey*, Energy Information Administration, USDOE. The Manufacturing Energy Consumption Survey is conducted every five years and provides detailed data on energy consumption in the manufacturing sector. http://www.eia.doe.gov/emeu/mecs/contents.html

Residential Devices Saturations and Market Shares

Residential devices saturations and market shares are obtained from the *Residential Energy Consumption Survey*, Energy Information Administration, USDOE. http://www.eia.doe.gov/emeu/recs/contents.html

Inflation Rate

Historical inflation rates are calculated from the consumer price index reported by the Bureau of Labor. Projections for inflation from 2004 through 2030 are calculated from the consumer price index projections of the *Annual Energy Outlook 2008*, Energy Information Administration, USDOE. http://www.eia.doe.gov/oiaf/aeo/index.html.

Fuel Choice Variance Factors, Return on Investment, and Maximum Process Efficiency Multiplier

The fuel choice variance factors, return on investment and maximum process efficiency multiplier variables come from projections obtained from the DEMAND81 energy model. Backus, George A. 1981. DEMAND81: National Energy Policy Model. Four Volumes. AFC 7-10. School of Industrial Engineering. Purdue University. West Lafayette, Indiana. These factors are updated as part of the calibration process.

Process Capital Costs

The data was developed from the US I/O Tables by REMI in $1987 and have been updated based on work with past clients.

Residential Energy Usage Per Appliance

The average usage per appliance was originally based on *NEPOOL April 1994 Forecast for Massachusetts*. The miscellaneous end use category is computed by adding the residential energy for all miscellaneous end uses and dividing by the number of households. Average use per appliance has been updated since that time based on input from various clients and is calibrated to actual energy use as part of the process of calibrating to actual energy use.

Number of Households

The number of households comes from the United States Census, US Census Bureau. http://www.census.gov/main/www/cen2000.html.

Appendix E: Data Sets Used in ENERGY 2020

This Appendix describes the initial set definitions for ENERGY 2020 used for this project. The sets are the dimensions of the variables (sometimes called indexes) which delineate the scope and detail of the model. For example, the time frame set could be defined as a base year 1990 and every 5 years.

Time Frame

The initial historical year for calibration is 1990.
Current end year of the analysis is 2020, but analysis can be extended to 2030 or beyond.
The last historic year of data will be 2005.
All data sets include annual data for each year of history and the forecast.

For some data sets, the period covered by actual data will depend on available data (e.g., emissions).

Geographical Areas

Each area in the model will represent a state or a province (no sub-state break-outs).
The model will provide separate results for the eight WCI partners currently modeled with plans to extend the modeling to include Manitoba and Quebec.
The surrounding Region (the rest of the WECC) and the rest of the US and Canada are also modeled.

The States and Provinces included in the WCI Region for modeling purposes include:

- Arizona
- New Mexico
- Washington
- California
- Oregon
- British Columbia
- Montana
- Utah
- Manitoba

Generating Units

The list of units is based on the NEEDS database for the US plus a similar database for the units in Canada. Within the Region and the rest of the US, some of the smaller plants may be aggregated by plant type in order to allow the expedite model operation. Under these assumptions regarding aggregation, this version of the model will likely end up with approximately 3,000 units/plants.

Electric Companies

Although ENERGY 2020 can model individual utilities or groups of utilities, for the WCI project the model assumes that each state has a single aggregate utility.

Sectors and Classes

The energy demand portion of the model will simulate residential, commercial, industrial, and transportation demands. There will be an electric sales class for each sector.

Emission Only Sectors

Several sectors generate emissions, but do not have full energy demand simulations in the model. These include solid waste, waste water, incineration, and land use. It may be possible to develop a full energy demand simulation for one or more of these.

Offsets

Possible offset categories, if broken out as a set, could include:

- Sequestration
- Landfill Gas Capture
- Agricultural Methane
- Energy Efficiency (for each sector)

Pollutants

The model currently has the capability to cover 15 pollutants, although the final set will depend on the WCI partner's requirements and available data. The GHG pollutants include Carbon Dioxide, Methane, Nitrous Oxide, Sulfur-Hexafluoride, Perfluorocarbon, and Hydrofluorocarbon. The criteria air pollutants include Sulfur Dioxide, Nitrogen Oxides, Total Particulate Matter, Volatile Organic Compounds, Carbon Monoxide, Particulate Matter 2.5, Particulate Matter 10, Mercury, and Ozone.

Fuels

There are currently two sets of fuels in the model. The largest category contains 33 fuels (shown below). The second category is the list of technologies which the energy demand sectors choose from. This smaller set contains only the basic types of fuels (Electricity, Natural Gas, Oil, LPG, Biomass, Solar). The aggregate category oil is later broken out into the different types of oil (LFO, HFO, petroleum coke, etc.).

Entire List of Fuels

- Asphalt
- Aviation Fuel
- Biomass
- Coal
- Coke
- Coke Oven Gas
- Diesel
- Electric
- Ethanol
- Geothermal
- Heavy Fuel Oil
- Hydro
- Hydrogen
- Kerosene
- Landfill Gases
- Light Fuel Oil
- LPG
- Lubricants
- Motor Gasoline
- Naphtha Specialties
- Natural Gas
- Nuclear
- Oil, Unspecified
- Other Non-Energy Products
- Petrochemical Feedstocks
- Petroleum Coke
- Solar
- Steam
- Still Gas
- Wave
- Wind
- Unknown 1
- Unknown 2

Electric Generation Plants Types

The electric generation plant types are used to hold the data for future generic plants which the model will construct endogenously. The list currently includes:

- Gas/Oil Peaking
- Gas/Oil Combined Cycle
- Gas/Oil Steam
- Coal
- Coal Advanced
- Coal with CCS
- Gas CC with CCS
- Nuclear
- Base Hydro
- Peak Hydro

- Other Generation
- Biomass
- Landfill Gas
- Wind
- Solar
- Fuel Cells
- Pumped Hydro
- Small Hydro
- Wave
- Geothermal
- Other Storage
- Biogas
- Trash

Residential Sectors

The residential sector is split into housing types:

- Single Family
- Multi-Family
- Other Residential

Commercial Sectors

- Transportation Services
- Pipelines
- Communication
- Electric Utilities
- Gas Utilities
- Water & Other Utilities
- Wholesale
- Retail
- FIRE
- Offices - Business Services
- Education
- Health & Social
- Food, Lodging, Recreation
- Government

Industrial Sectors

- Food & Tobacco
- Textiles
- Apparel
- Lumber
- Furniture
- Pulp & Paper Mills
- Converted Paper
- Printing
- Petrochemicals
- Industrial Gas
- Other Chemicals
- Fertilizers
- Petroleum Products
- Rubber
- Leather
- Cement
- Glass
- Lime & Gypsum
- Other Non-Metallic
- Iron & Steel
- Aluminum
- Other Nonferrous
- Fabricated Metals
- Machines
- Computers
- Electric Equipment
- Transport Equipment
- Other Manufacturing
- Iron Ore Mining
- Other Metal Mining
- Non-metal Mining
- Light Oil Mining
- Heavy Oil Mining
- Frontier Oil Mining
- Oil Sands In-Situ
- Oil Sands Mining
- Oil Sands Upgraders
- Gas Mining
- Coal Mining
- Construction
- Forestry
- Agriculture

Transportation Sectors

- Passenger
- Freight
- Off Road

Miscellaneous Sectors

- Misc. & Street Lighting
- Electric Resale
- Utility Electric Generation
- Industry Electric Generation
- Steam Generation
- Solid Waste
- Waste Water
- Incineration
- Land Use

Residential End-Uses

- Space Heating
- Water Heating
- Other Substitutable
- Refrigeration
- Lighting
- Air Conditioning
- Other Non-Substitutable

Commercial End-Uses

- Space Heating
- Water Heating
- Other Substitutable
- Refrigeration
- Lighting
- Air Conditioning
- Other Non-Substitutable

Industrial End-uses

- Process Heat
- Electric Motors
- Other Substitutable
- Miscellaneous

Transportation End-Uses

- Ground
- Air/Water

Residential, Commercial, and Industrial Technology Types

Each technology type has its own trade-off curve which determines the efficiency and the capital cost of the technology type. These curves allow the model to contain many different technologies within these broad types.

- Electric
- Gas
- Coal
- Oil
- Biomass
- Solar
- LPG
- Steam

Transportation Technology Types

Several technology types are provided for transportation, and each of these contains a trade-off curve which allows the model to simulate even more individual technologies.

- Plug-in Hybrids
- Light Gasoline
- Light Diesel
- Light Propane
- Light CNG
- Light Electric (Plug-in)
- Light Ethanol
- Light Hybrid Gasoline
- Light Hybrid Diesel
- Light Fuel Cell Gasoline
- Light Fuel Cell CNG
- Light Fuel Cell Hydrogen
- Medium Gasoline
- Medium Diesel
- Medium Propane
- Medium CNG
- Medium Ethanol
- Medium Hybrid Gasoline
- Medium Hybrid Diesel
- Medium Fuel Cell Gasoline
- Medium Fuel Cell CNG
- Medium Fuel Cell Hydrogen
- Heavy Gasoline
- Heavy Diesel
- Heavy Propane
- Heavy CNG
- Heavy Ethanol
- Heavy Hybrid Gasoline
- Heavy Hybrid Diesel
- Heavy Fuel Cell Gasoline
- Heavy Fuel Cell CNG
- Heavy Fuel Cell Hydrogen
- Motorcycle
- Bus Gasoline
- Bus Diesel
- Bus Propane
- Bus CNG
- Bus Fuel Cell Gasoline
- Bus Fuel Cell Hydrogen
- Bus Fuel Cell Ethanol
- Train
- Plane
- Marine
- Off Road

Prices

Delivered energy prices are presented for the following fuels:

- Residential Electricity
- Residential Natural Gas
- Residential Coal
- Residential Oil
- Residential Biomass
- Residential LPG
- Residential Steam
- Commercial Electricity
- Commercial Natural Gas
- Commercial Coal
- Commercial Oil
- Commercial Biomass
- Commercial LPG
- Commercial Steam
- Industrial Electricity
- Industrial Natural Gas
- Industrial Coal
- Industrial Oil
- Industrial Biomass
- Industrial LPG
- Industrial Steam
- Gasoline

- Diesel
- Aviation Fuel
- Transportation HFO
- Transportation Natural Gas
- Transportation LPG
- Electric Utility Residual Oil
- Electric Utility Distillate Oil
- Electric Utility Natural Gas
- Electric Utility Coal
- Electric Utility Nuclear
- Electric Utility Biomass
- Ethanol
- Hydrogen

Electric Load Segments

The model dispatches for 6 different hour types (high peak, low peak, high intermediate, low intermediate, high base load, low base load) for each of the four seasons.

Appendix H: Global Warming Potential

ENERGY 2020 models emissions of each of the six greenhouse gases reported under the Kyoto protocol. These emissions are then translated into equivalent quantities of CO_2 emissions (CO_2e) based on the global warming potential of each of the gases.

The Global Warming Potential (GWP) values used in ENERGY 2020 are shown in the table below.

Greenhouse Gas	Global Warming Potential
Carbon Dioxide (CO2)	1
Methane (CH4)	21
Nitrous Oxide (N2O)	310
Sulfur Hexafluoride (SF6)	23,900
Perfluorocarbons (PFC)	7,000
Hydrofluorocarbons (HFC)	1,300

These values are consistent with the Global Warming Potential values used in the 1996 Second Assessment Report based on 100-year warming potential for the individual gases. In the case of HFCs and PFCs the GWP values used in the model are based on an estimated average GWP for these gases.

Appendix I: Renewable Portfolio Standards

State or Prov	Target	Policy
AZ	15% of generation from renewables by 2025	Renewable Energy Standards (formerly known as the Environmental Portfolio Standard) on February 27, 2006. The new rules require regulated electric utilities to generate 15% of their energy from renewable resources by 2025. By 2012, at least 30% of the sta
CA	Major utilities 20% from renewable sources by 2010 on a retail sales basis	California's Investor-Owned Utility, Electric Service Providers, Small and Multi-Jurisdictional Utilities and Community Choice Aggregators to produce at least 20% of their electricity using renewable sources by 2010 based on renewable retail sales. Eligib
MT	10% of generation load to be renewable by 2010; 15% by 2015	Each investor-owned and public utility should: Meet 20% of its load using renewable energy resources by 2020, increasing to 25% by 2025. The legislation contains a cost cap that encourages utilities to invest in renewable generation that is cost competiti
NM	10% of generation by 2011; 15% renewable by 2015; 20% by 2020	Applies to Investor-Owned Utility, Rural Electric Cooperative. IOUs: 15% power generation from renewable sources and 20% by 2020. RECs: 10% by 2020. This legislation expands on NM's current renewable portfolio standard requiring that 10% of the state's en
OR	25% of electric load must be renewable sources by 2025 (ramps up from 2015)	OR's largest utilities 25% of their electric load with new renewable energy sources by 2025. Interim targets of 5% by 2011; 15% by 2015; 20% by 2020; and 25% by 2025. Based on total retail sales volumes. Eligible technology: wind, solar, wave, geothermal,
UT	No Policy in place	Considering RPS through consultation process in 2007

State or Prov	Target	Policy
WA	All new long term baseload facilities must meet 1,100 lbs CO2/MWh starting July 2008	GHG performance standard for all new, long-term baseload electric power generation. Under the standard, all baseload generation for which utilities enter into long-term contracts must meet a greenhouse gas emissions standard of 1,100 pounds per megawatt-h
WA	15% of production to be renewable by 2020	All utilities serving >25,000 people to produce 15% of their energy using renewable sources by 2020. Eligible technology: wind, solar, and tidal power as well as landfill-methane capture.
BC	Offset all O&G grid power emissions by 2016.	All existing natural gas and oil-fired generating facilities part of the integrated grid will need to completely offset their GHG emissions by 2016. All coal will need to use CCS, sequester or otherwise offset emissions, and all new O&G will need to offs
BC	Maintain 90% "clean" sources - all new sources zero emissions.	Maintaining 90% 'clean' power supply, including hydro. Note that no nuclear will be built in the province. Government will issue guidelines to define what sources qualify as clean or renewable and provide additional policy direction as required. In 2004
MB	1,000 MW of wind power by 2016	Most of Manitoba's power production is already from renewable sources. Target: 1,000 MW of wind power by 2016. The 1,000 MW will reduce GHGs by 3.5 Mt annually, and stimulate $2 billion in new investments.

Appendix J: Efficiency and Cost Data – Built Environment

Residential:

Residential Device Standards	
Equipment	**Effective Efficiency Standard**
Gas hot water from 1990 to the final year	59%
Oil hot water from 1990 to the final year	51%
Electric hot water from 1990 to the final year (inc.tank losses)	92%
LPG hot water from 1990 to the final year	59%
Electric air conditioning for 1990	260% COP = 2.6
Electric air conditioning for 1991	261% COP = 2.61
Electric air conditioning for 1992 to 2006	265% COP = 2.65
Electric air conditioning for 2007 to the final year	344% COP = 3.44
Electric Refrigeration for 1990 to 1992	34.5%
Electric Refrigeration for 1993	40.0%
Electric Refrigeration for 1994 to 2000.	42.0%
Electric Refrigeration from 2001 to the final year	54.7%
Biomass space Heating from 1993 to the final year (wood burning equipment)	63.0%
Gas space Heating from 1993 to the final year	80.0%
Oil space Heating from 1993 to the final year	80.0%
LPG space Heating from 1993 to the final year	80.0%

Residential (cont'd.)

Western Climate Initiative

Draft Design of the Regional Cap-and-Trade Program

July 23, 2008

The Western Climate Initiative (WCI) Partners recommend a design for a broad cap-and-trade program as part of a comprehensive regional effort to reduce emissions of global warming pollution to achieve the WCI 2020 regional goal. The recommended design contains costs through emission trading, allowance banking, and inclusion of an offsets component that will provide opportunities to obtain low-cost emission reductions. Further, the WCI design is intended to mitigate the economic impact on consumers, and the costs passed onto consumers, through design features such as allowance distribution and the use of offsets.

1. SCOPE[1]

1.1. Gases covered: Carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

1.2. Emissions covered:

1.2.1. Electricity generation, including emissions from electricity imported into WCI from non-WCI jurisdictions;

1.2.2. Combustion at industrial and commercial facilities;

1.2.3. Industrial process emission sources, including oil and gas process emissions;

1.2.4. Residential, commercial, and industrial fuel combustion at facilities below the WCI thresholds (as described below in the Point of Regulation section, these emissions will be covered upstream). Coverage of these emissions will begin at the start of the second compliance period;

1.2.5. Transportation fuel combustion from gasoline and diesel (as described below in the Point of Regulation section, these emissions will be covered upstream). Coverage of these emissions will begin at the start of the second compliance period;

1.2.6. The WCI Partners recommend covering combustion from transportation, residential and commercial, and industrial fuel sources with the expectation that the individual Partner jurisdictions will:

- Mitigate the economic impact on consumers;
- Implement other policies that will reduce GHG emissions from the transportation sector and reduce demand for transportation fuels (such as vehicle standards, smart growth, low carbon fuel standards, transit options, etc.); and

[1] The *scope* defines the GHG emissions that are included in the cap-and-trade program, including the emissions sources and greenhouse gases that fall under the cap.

- Address any issues associated with the point of regulation and its implementation.

1.3. Carbon dioxide emissions from the combustion of biomass or biofuel are not included in the cap-and-trade program.

1.4. As described below under Role of Other Policies, WCI Partners acknowledge that individual jurisdictions may instead utilize comparable fiscal measures, such as British Columbia's carbon tax, to address transportation fuels and fuel use by residential and commercial sources.

1.5. Adequate quantification methods will be established for emissions sources prior to including them in the program.

2. POINT OF REGULATION[2]

2.1. Industrial sources (both process and combustion) with emissions above the threshold: At the point of emission.

2.2. Electricity: First Jurisdictional Deliverer: the generator for sources within WCI jurisdictions and the first entity over which a Partner has regulatory authority that delivers electricity generated outside the WCI into a WCI Partner jurisdiction for consumption in that Partner jurisdiction.

2.3. Residential, commercial, and industrial fuel combustion at facilities with emissions below the threshold: Where the fuels enter commerce in the WCI Partner jurisdictions; generally at a distributor; precise point to be determined and may vary by jurisdiction.

2.4. Transportation fuel combustion: Where the fuels enter commerce in the WCI Partner jurisdictions; generally at the terminal rack, final blender, or distributor; precise point to be determined and may vary by jurisdiction.

2.5. Cogeneration facilities: How to handle emissions associated with cogeneration facilities is still under consideration by the Partners.

[2] The *point of regulation* is the entity or facility with the compliance obligation, i.e., the requirement to surrender sufficient GHG allowances to cover actual emissions during the compliance period. An allowance is the tradable permit to emit one metric ton of GHG emissions. The term *entity* is generally used when the point of regulation is upstream of the point of emissions, to describe a company that has an obligation to surrender allowances to cover the carbon content of the fuel the company is moving through commerce. When the point of regulation is at the source or point of emissions, the term *facility* is generally used. The term *source* is used to refer to emissions from either a facility or an entity.

3. THRESHOLDS[3] FOR COVERAGE UNDER THE CAP-AND-TRADE PR0GRAM

3.1. Emission threshold: 25,000 metric tons of carbon dioxide equivalents (CO_2e) annually defines the facilities or entities (e.g., first jurisdictional deliverer, fuel distributor, fuel blender) that would have a regulatory compliance obligation under the cap-and-trade program. Mandatory reporting data may be used to adjust this threshold for specific industries where necessary. Additional analyses will be done to determine if adjustments to the threshold are needed to ensure sufficient coverage or to address competitiveness issues within individual sectors prior to the beginning of the program (e.g., because different Partner jurisdictions may have the same industry but with different sized sources).

3.2. A method will be developed to prevent first jurisdictional deliverers from avoiding coverage, such as by breaking themselves into separate power deliverers such that each delivers electricity with emissions below the threshold.

4. PROGRAM EXPANSION

4.1. Future Program Expansion: The WCI Partners recommend that the scope of the cap-and-trade program be capable of expanding over time (including possibly adjusting applicability thresholds over time). Prior to each compliance period, the Partners will review whether to bring new sources (and if so which ones) into the program.

5. ROLE OF OTHER POLICIES[4]

5.1. The role of other greenhouse gas-reducing policies is to help the WCI Partners achieve their 2020 reduction goal. Those policies will work in concert with the cap-and-trade program and may apply to any source of greenhouse gas emissions.

5.2. Carbon Tax and Other Fiscal Measures:

5.2.1. The WCI Partners agree that individual jurisdictions may use fiscal measures that contribute to achieving overall comparable GHG emission reductions and internalize the price of carbon as expected through the regional cap-and-trade program for transportation and residential/commercial fuels.

5.2.2. British Columbia currently has a carbon tax. By 2012 the Partners will determine the mechanism for integrating the cap-and-trade program with the BC carbon tax.

---

[3] *Thresholds* are levels at which it is determined that a particular entity or facility will have a compliance obligation under the cap-and-trade program.

[4] *Other policies* include complementary policies and alternative policies. A *complementary policy* is used in this context to mean policies other than a cap-and-trade program that aid in the goal of achieving emissions reductions for capped or uncapped sources. *An alternative policy* is a policy that is employed in lieu of a cap-and-trade program for one or more sources.

6. SETTING THE REGIONAL CAP[5]

6.1. The aggregate regional cap for the cap-and-trade program will:

6.1.1. Equal the sum of the Partner allowance budgets (see Apportionment section below).

6.1.2. Include annual caps (with 3-year compliance periods) from the beginning of the program in 2012 through 2020. The annual caps will be set in advance of the program start in 2012 so that the reductions required in each 3-year compliance period through 2020 are predictable.

6.1.3. Decline over time. The regional cap trajectory for covered sectors will be a straight line from the year of initial coverage (2012 for some sources and 2015 for other sources) to 2020.

6.2. 2012: The initial cap will be set at the best estimate of expected actual emissions for those sources covered in the initial year of the program (i.e., 2012). The estimate of expected actual emissions in 2012 will be developed using the best available data (including any available mandatory reporting data) and by accounting for expected changes in emissions by 2012. Population growth, economic growth, voluntary and mandatory emission reductions, and other factors will be considered. The 2012 cap will also recognize actions to reduce greenhouse gas emissions before the start of the program.

6.3. 2015: The regional cap for the second compliance period will be set by adding the best estimate of expected actual emissions in 2015 from transportation fuels and residential, commercial, and industrial fuels (and any other sectors or sources that may be added to the program for the first time in 2015) to the emissions trajectory for the sources first included in the program in 2012.

6.4. 2020: The regional cap for 2020 will be set so that reductions achieved by the cap plus reductions from other greenhouse gas reduction policies will achieve the WCI regional 2020 goal.

6.5. Post-2020 caps: The Partners shall set these regional caps not less than three years in advance.

6.6. Once established, the regional cap for each compliance period will not be adjusted except as necessary to account for:

- Changes in WCI membership,
- Changes in scope or thresholds, or
- Errors discovered in data used to determine the cap, which may become apparent, for example, after the start of mandatory reporting.
- Any adjustments will be made prior to the beginning of the compliance period.

[5] The *regional cap* is the overall limit on total emissions set for the emissions included in the cap-and-trade program.

7. APPORTIONMENT[6]

7.1. Each Partner will have an annual allowance budget within the regional cap from 2012 to 2020. The annual Partner allowance budgets for each year through 2020 will be set prior to the start of the program in 2012.

7.2. The Partners are working on an apportionment methodology based on Partner and regional emission reduction goals and requirements. The apportionment methodology will address factors such as production and consumption of electricity, projected population growth and economic activity, and other factors. The Partners intend to have a recommended apportionment methodology by Fall 2008.

7.3. For years post-2020, the Partners will set allowance budgets not less than three years in advance.

7.4. Once established, each Partner's allowance budget will not be adjusted except as necessary to account for:

- Changes in WCI membership;
- Changes in scope or thresholds;
- Errors discovered in data used to determine the cap or the Partner budgets, which may become apparent, for example, after the start of mandatory reporting.
- Such adjustments will take effect at a regionally coordinated and designated time, such as at the beginning of a compliance period.

7.5. Partners will recognize within their own jurisdictions allowances issued by other Partners so that all WCI allowances are of equivalent use and fungible throughout the WCI region, regardless of which Partner issues the allowances.

7.6. Determination of allowance budgets for new Partners will take into account the following parameters:

- The WCI regional goal;
- Allowance budgets for existing Partners;
- The share of the new Partner's budget that is already included through the WCI's provisions covering imported electricity; and
- The apportionment methodology that is being developed by the Partners (above).

[6] *Allowance apportionment* describes the Partners' budget or share of GHG emission allowances. Allowance budgets must be set for each Partner jurisdiction.

8. DISTRIBUTION OF ALLOWANCES[7]

8.1. Distribution of Allowances by Partners: Once the allowance budget has been established for each Partner, allowances will be issued by each Partner.

8.2. The WCI Partners agree that a minimum percentage of the value of each Partner's allowance budget (for example, through set-asides of allowances, through a distribution of revenues from the auctioning of allowances, or other means) may be dedicated to one or more of the following public purposes that provide benefits across all WCI jurisdictions:

- Energy efficiency and renewable energy incentives and achievement;
- Research, development, demonstrations and deployment (RDD&D) with particular reference to carbon capture & sequestration (CCS); renewable energy generation, transmission and storage; and energy efficiency; and
- Promoting emission reductions and sequestration in agriculture and forestry and other uncapped sources;

8.3. The remaining percentage of Partner allowance budgets will be distributed as each Partner sees fit. When distributing allowances Partners may consider objectives such as:

- Reducing consumer impacts, especially for low-income consumers;
- Providing for worker transition and green jobs;
- Providing transition assistance to industries;
- Adaptation to climate change impacts;
- Recognizing early actions to reduce emissions; and/or
- Promoting economic efficiency.

8.4. In advance of the first compliance period, and at least one year before the beginning of each relevant compliance period thereafter, each Partner will advise the other WCI Partners how it intends to distribute or retire allowances so that Partners' plans can be made public in a coordinated fashion.

8.5. To address competitiveness issues between Partner jurisdictions, the WCI Partners shall consider standardizing the distribution of allowances over time, such as:

- Treating similar emissions-intensive industries operating in more than one Partner jurisdiction, but in the same market, similarly (such as aluminum, electricity, steel, cement, lime, pulp and paper, and oil refining);
- Developing benchmarks to harmonize allocations to similar industries, and;
- Providing a level playing field for new emission sources.

8.6. Partners will allocate or retire all the allowances in their allowance budgets by the end of the applicable compliance period. A Partner will not hold allowances beyond the end of the compliance period.

---

[7] *Allowance distribution* is the Partners' initial distribution of GHG emission allowances into the market.

8.7. The issue of establishing a minimum percentage of allowances subject to auction by each Partner is still under discussion by the Partners. The Partners expect to make a recommendation on this issue by Fall, 2008.

8.8. To the extent Partners decide to auction allowances, Partners will undertake auctions through a coordinated regional auction process by which each Partner will auction allowances throughout the WCI region and receive the proceeds of the auction.

8.9. Credits for Early Reductions: Each Partner has discretion to give credit for early actions, but any credit for early action will come from within the cap and will come out of the individual Partner's allowance budget. Early action credits will not be added to or be on top of the amount of allowances in each Partner's allowance budget.

8.10. Banking: Purchasers and covered entities or facilities will be allowed to bank allowances without limitation, except to the extent that restrictions on the number of allowances any one party may hold are necessary to prevent market manipulation.

8.11. Borrowing: Borrowing of allowances from future compliance periods will not be allowed.

8.12. Compliance Periods: Each compliance period will be three years long.

9. OFFSETS,[8] AND ALLOWANCES FROM OTHER SYSTEMS

9.1. The WCI Partners will include a rigorous offsets program. The primary role of the offsets program is to reduce the compliance costs for the cap-and-trade system, while ensuring the environmental integrity of the cap.

9.2. The WCI Partners will establish a limit on the use of offsets approved/certified by WCI Partners, and/or offsets or allowances from other government-approved GHG emission trading systems. This limit will be expressed as a percentage limit on each covered entity's or facility's compliance obligation that can be satisfied during each compliance period using offsets or allowances from other government-approved GHG emission trading systems. The WCI Partners are considering a limit not greater than ten (10) percent of an individual entity's or facility's compliance obligation (i.e., the number of allowances a covered entity or facility is required to surrender to cover its emissions). The specific limit will be evaluated based on further analysis and consideration of both the cost reduction objective and the desire to ensure a meaningful fraction of emissions reductions occur at WCI covered sources.

9.3. The WCI Partners have identified the following list of project types as a priority for investigation and development to participate in the WCI offset system. Making these project types a priority means the Partners are interested in understanding if they are suitable for the offset system, if they will meet the criteria for environmental integrity, and if adequate protocols /methodologies for

[8] *Offsets* are emission reduction projects undertaken to address emissions not included in a cap-and-trade program. An offset mechanism enables covered entities to offset their own emissions by purchasing emission reduction credits generated through projects that address emissions not covered by the cap.

their quantification and monitoring can be adapted or developed. Priority does not mean these project types are guaranteed to be in an offset system. Project types that reduce emissions that would eventually be covered by the cap-and-trade system would only be eligible until that coverage begins. Project types that reduce emissions covered by the cap-and-trade system would not be eligible to create offsets because the result would be a double counting of the emission reduction. The list is in alphabetical order and does not directly or indirectly represent a ranking or order of preference:

- Agriculture (soil sequestration and manure management);
- Forestry (afforestation/reforestation, forest management, forest preservation/conservation, forest products); and
- Waste management (landfill gas and wastewater management).

9.4. Starting in 2009, the WCI Partners will coordinate to review, develop, and approve, as appropriate, protocols for the project types that meet the necessary criteria for inclusion. The WCI Partners will use offset protocols that are standardized to the extent possible, and make use of (or adapt if needed), existing protocols as appropriate. The WCI Partners will also initiate the establishment of a process during 2009 to coordinate the review and approval other project types and protocols proposed by project developers.

9.5. WCI Partners may approve and certify offset projects located throughout Canada, the United States, and Mexico, where such projects would be subject to comparably rigorous oversight, validation, verification and enforcement as those located within the WCI jurisdictions.

9.6. WCI protocols must meet rigorous criteria to preserve the environmental integrity of the overall cap-and-trade system.

9.7. In the case of offset credits from the Clean Development Mechanism (CDM) and Joint Implementation (JI), the WCI Partners may establish added criteria to ensure similar rigor to WCI approved/certified offset projects or other requirements appropriate to enable use of these offset credits in the WCI program.

9.8. WCI Partners may allow individual regulated entities or facilities to use tradable units (allowances) from other government-regulated GHG emission trading systems that the WCI Partners recognize as meeting similarly rigorous criteria for environmental integrity for compliance purposes. These allowances would be subject to the overall limit described above.

9.9. The WCI Partners are considering a method that restricts the use of offsets from projects located outside WCI jurisdictions for compliance purposes in the WCI cap-and-trade regulatory program.

9.9.1. The use of offsets as a regulatory instrument in the WCI cap-and-trade program will substitute for allowances issued by WCI partner states and provinces for compliance within the cap-and-trade program. Limitations on the use of offsets from projects located outside the WCI would reflect the goal of the regulatory program to achieve reductions in greenhouse gas emissions within the region. Such restrictions would also ensure that WCI partner states and provinces are able to inspect offset projects and enforce any laws relevant to project operations and the use of offsets for compliance. Collateral benefits associated with some offsets projects, such as health, social and environmental benefits would also accrue within WCI partner states and provinces.

9.9.2. WCI Partners have no intention to regulate or restrict the existing voluntary market in offsets, to restrict the sale of offsets from projects located within the WCI states and provinces, or to place restrictions on ownership of offsets projects located within WCI partner states and provinces.

10. REPORTING

10.1. Mandatory measurement and monitoring for all six GHGs will commence in January 2010 for all entities and facilities subject to reporting. Reporting of 2010 emissions will begin in early 2011.

10.2. The entities and facilities subject to reporting are those with annual emissions equal to or greater than 10,000 metric tons of CO_2e. However, in some limited instances the threshold may be based on other parameters, such as throughput or capacity, as long as these thresholds represent the equivalent of, or are lower than, the 10,000-metric-ton threshold.

10.3. Partners may require third-party verification or may carry out government audit programs. (Partners are still discussing whether verification by third parties accredited under a common framework should be required for all reports submitted by entities or facilities covered by the cap.)

10.4. As each Partner collects additional emissions data from entities and facilities required to report, data will be made available to all Partners for review and consideration for inclusion in the cap-and-trade program.

10.5. Nothing in the WCI program design would limit any Partner’s discretion to require reporting earlier, at lower thresholds, or for entities and facilities not covered by the cap-and-trade program.

11. START DATE FOR CAP-AND-TRADE

11.1. The cap-and-trade program will launch January 1, 2012.

12. COMPLIANCE AND ENFORCEMENT

12.1. Each jurisdiction will retain and/or enhance its regulatory and enforcement authority and responsibilities to enforce compliance with the cap-and-trade program within its own Partner jurisdiction.

12.2. Each covered entity or facility will demonstrate compliance with the cap-and-trade program by surrendering sufficient allowances after the end of each compliance period.

12.3. If by the deadline for demonstrating compliance a covered entity or facility does not have sufficient allowances to cover its emissions for the previous compliance period, it shall be required to surrender three allowances for every metric ton not covered by an allowance at the deadline. This does not preclude other penalties allowed under individual state or provincial laws.

12.4. The WCI Partners recognize that during the first compliance period, both they and the entities and facilities covered by the cap-and-trade program will likely encounter issues that arise in the implementation of a new program. Consequently, the Partners are committed to providing appropriate technical and other compliance assistance to the program participants.

12.5. The WCI Partners will ensure accounting systems are in place to prevent using allowances, tradable units, and offsets more than once for compliance.

13. REGIONAL ORGANIZATION AND NEW PARTNERS

13.1. To reduce administrative costs and improve program transparency and consistency, a regional administrative organization will be created to:

- Coordinate the regional auction of allowances;
- Track emissions;
- Monitor and report on market activity, including any potential market manipulation;
- Serve as a forum for Partners to update one another on program progress;
- Coordinate review and adoption of protocols for offsets;
- Coordinate review and adoption of updated reporting protocols;
- Coordinate review and issuing of offset credits; and
- Provide criteria and means to accredit service providers to deliver validation and verification services.

13.2. New Partners will come into the cap-and-trade program at a regionally coordinated and designated time, such as the beginning of the relevant compliance period.

13.3. A new Partner must have adopted an economy-wide greenhouse gas reduction goal for 2020 that reflects a level of effort that is consistent with that of the WCI Partners.

Draft Essential Requirements of Mandatory Reporting for the Western Climate Initiative

July 23, 2008

Introduction

To complete the essential requirements of a model reporting rule, the Western Climate Initiative (WCI) must make numerous decisions about how it wishes to approach, define, and structure the essential requirements that have been identified as necessary to an effective WCI cap-and-trade program. A number of these decisions have already been made by the WCI jurisdictions, but many have not.

The purposes of this paper are to: 1) document the current status of WCI's consideration of essential requirements; 2) identify the decisions that remain to be made; and 3) seek public comment on these essential requirements. As decisions are made to finalize the essential requirements, the WCI will move toward developing a regulatory structure for the essential requirements in future steps.

The paper is divided into 10 categories of essential requirements related to mandatory reporting of GHGs: definitions, pollutants, applicability, timing, confidentiality, report content and submittal, compliance, emissions quantification and monitoring, and verification and quality assurance. For each group of essential requirements, the following information is presented:

- "Discussion and Notes" describes the essential requirements that are proposed to be addressed in the context of future model rule sections.
- "Draft Design of the Regional Cap-and-Trade Program" summarizes the specific recommendations contained in the most current draft design document (July 23, 2008) and/or a previous version (May 16, 2008), if applicable to the essential requirement.
- "Additional Decisions Needed" summarizes the decisions that need to be made about the approach, definition and structure of the essential requirement.

An understanding of existing general reporting requirements for WCI jurisdictions is valuable to the process of determining essential elements for WCI mandatory reporting. Attachment A contains three tables comparing general reporting requirements of existing and imminent programs in WCI jurisdictions and related areas (e.g., The Climate Registry, Regional Greenhouse Gas Initiative, etc.). Table A1 summarizes general requirements related to the scope of the programs (e.g., GHGs reported, sources required to report, thresholds, etc.). Table A2 summarizes the verification and/or quality assurance requirements for each program. Table A3 summarizes the overall reporting requirements (e.g., timing/schedules, reporting procedures, confidentiality, etc.). This information provides a basis for developing WCI's essential elements for reporting, and for identifying early any potential conflicts and/or harmonization between WCI's reporting requirements and jurisdiction reporting requirements.

Definitions

Discussion and Notes

1. This rule section will contain clear and appropriately detailed definitions of key terms used in the monitoring and reporting rule.

2. When source category-specific requirements are considered, there may be hundreds of terms that need definition. The most efficient approach to creating a list is to "borrow" from other jurisdiction's rules. There are a number of precedents to consider for definitions. Terminology defined by The Climate Registry (TCR) could be used, although some definitions might not be sufficiently detailed for regulatory use. If TCR's list is not comprehensive enough for a mandatory reporting rule, then CARB's reporting rule has a very detailed and lengthy list of definitions that may be used. CARB's list combines source category-specific definitions with those common to all source categories in a single list. The definitions established by the U.S. EPA, Canadian agencies, and states like New Mexico should also be considered.

3. Definitions will facilitate communications among WCI jurisdictions and stakeholders by defining common terminology very early in the process of developing the details of essential requirements for model GHG reporting rule language. For example, the term "source categories" is used throughout this paper to indicate groupings of sources and activities; definitions for these types of terms should be agreed upon and articulated by the WCI jurisdictions.

Additional Decisions Needed

1. Using the CARB definitions as a starting point, compile the list of definitions for review by the Reporting Subcommittee.

Pollutants

Discussion and Notes

1. Pollutants – This section will list the pollutants that must be quantified and reported.

2. Conversion factors – The section will specify the 100-year global warming potential factors used to convert other pollutants to CO_2e. The WCI presumably will use the same conversion factors as are used nationally and internationally, such as the IPCC Second Assessment Report, 1995.

Draft Design of the Regional Cap-and-Trade Program (July 23, 2008):

1. Greenhouse gases covered: Carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

Additional Decisions Needed

1. Confirm decision on conversion factors.

Applicability

Discussion and Notes

1. This rule section describes who must comply with the reporting rule. As a minimum, the reporting system must include all activities and sources that will be part of the cap.

2. This rule section will also list any source categories that are not subject to the initial cap but which will be required to report emissions.

3. Thresholds – This section will contain the thresholds for mandatory reporting, stated as metric tons of CO_2 or CO_2e per year, or other appropriate emissions or operational indicators.

4. Sources not included – This section will describe sources or activities in affected source categories that are not subject to reporting requirements.

5. Level of reporting – This rule section will address by source category at what level (i.e. corporate [entity], facility or process level) reporting will be required.

Draft Design of the Regional Cap-and-Trade Program (July 23, 2008):

1. Emissions covered:

    - Electricity generation, including emissions from electricity imported into WCI from non-WCI jurisdictions;
    - Combustion at industrial and commercial facilities;
    - Industrial process emission sources, including oil and gas process emissions;
    - Residential, commercial, and industrial fuel combustion at facilities below the WCI thresholds (as described below in the Point of Regulation section, these emissions will be covered upstream). Coverage of these emissions will begin at the start of the second compliance period;
    - Transportation fuel combustion from gasoline and diesel (as described below in the Point of Regulation section, these emissions will be covered upstream). Coverage of these emissions will begin at the start of the second compliance period.

    Adequate quantification methods will be established for emissions sources prior to including them in the program.

2. Point of Regulation:

- Industrial sources (both process and combustion) with emissions above the threshold: At the point of emission.
- Electricity: First Jurisdictional Deliverer: the generator for sources within WCI jurisdictions and the first entity over which a Partner has regulatory authority that delivers electricity generated outside the WCI into a WCI Partner jurisdiction for consumption in that Partner jurisdiction.
- Residential, commercial, and industrial fuel combustion at facilities with emissions below the threshold: Where the fuels enter commerce in the WCI Partner jurisdictions; generally at a distributor; precise point to be determined and may vary by jurisdiction.
- Transportation fuel combustion: Where the fuels enter commerce in the WCI Partner jurisdictions; generally at the terminal rack, final blender, or distributor; precise point to be determined and may vary by jurisdiction.
- Cogeneration facilities: How to handle emissions associated with cogeneration facilities is still under consideration by the Partners.

3. The entities and facilities subject to reporting are those with annual emissions equal to or greater than 10,000 metric tons of CO_2e. However, in some limited instances the threshold may be based on other parameters, such as throughput or capacity, as long as these thresholds represent the equivalent of, or are lower than, the 10,000-metric-ton threshold.

4. Nothing in the WCI program design would limit any Jurisdiction's discretion to require reporting earlier, at lower thresholds, or for entities and facilities not covered by the cap-and-trade program.

Additional Decisions Needed

1. Complete decisions on which source categories will be subject to mandatory reporting. Select the numeric value and form of applicability thresholds for those source categories.

2. Complete detailed definitions of each source category to address point of regulation issues and further clarify which sources and activities within each source category are covered by the reporting requirement (i.e., activities, sources, and operational boundaries).

3. Determine sources, activities and processes to be excluded from reporting.

4. Determine by source category whether reporting will occur at the corporate (entity), facility, or process level.

Timing

Discussion and Notes

1. Effective Date – This rule section will specify the date or dates when mandatory record keeping and reporting begins for affected source categories. It may be necessary to evaluate the potential use of measurement and monitoring data for years prior to 2010.

2. Reporting Period – This requirement specifies the calendar year or other period within which emissions must be quantified. The Draft Design (July 23, 2008) suggest starting on January 1, thus implying a calendar year reporting period. Consideration may have to be made for some form of more frequent or interim reporting to support the development and implementation of the cap-and-trade program.

3. Report Submission Date – This section will specify when reports must be submitted. To maintain alignment with future cap-and-trade allocations and reconciliation periods, it would seem preferable for reports to be submitted at the same time in all jurisdictions. A key issue is how long after the reporting year ends that reports be due.

Draft Design of the Regional Cap-and-Trade Program (July 23, 2008):

1. Mandatory measurement, monitoring, and reporting for all six GHGs will commence in January 2010 for all entities and facilities subject to reporting. Reporting of 2010 emissions will begin in early 2011.

Additional Decisions Needed

1. Determine whether all jurisdictions are to have the same effective date, reporting year and report submission date, and establish those dates.

2. Determine what the WCI's policy will be on collecting and using data from years prior to 2010.

3. Determine how any jurisdictions that have started reporting early, or plan to do so, will make the transition to the WCI schedule.

4. Determine whether more frequent interim reports are necessary to support the development and implementation of the cap-and-trade program.

5. Establish deadlines for emissions reporting, verification or QA of reported data, and public release of data.

Confidentiality

Discussion and Notes

1. In general, emissions data are not considered confidential although some operational information can be protected, depending on each jurisdiction's legal authority.

2 Stakeholders have offered a range of comments with some favoring a narrow construction of confidentiality to protect the public's right to know, and others favoring a broader construction that would better protect sensitive operational information from competitors.

Additional Decisions Needed

1. Determine policy and procedures pertaining to confidential information and data and the extent of public disclosure.

Report Content and Submittal

Discussion and Notes

1. Content – These sections and subsections will specify the information that each reporting unit will be required to submit. Examples of typical administrative information are facility names, identification numbers, physical addresses, mailing addresses, locations, responsible officials, various operational information, ownership structure, etc. More detailed information will be addressed in the source category-specific requirements.

   Technical content includes such examples as pollutants, quantification methods, and supporting operational and activity information and data. Requirements need to be specific and detailed and some will be source category-specific.

   There are a number of existing reporting rules that could provide potential starting points, however many specific decisions on content will evolve from the choices made for other essential requirements.

2. Submittal – This section will specify who is responsible for submitting the report and to whom, and certifying the accuracy of the information contained in it.

Draft Design Recommendations (May 16, 2008):

1. The WCI has recommended using TCR's central repository for data storage as well as offering flexibility as to where affected sources initially report. Reports could either be submitted directly to jurisdictions (which will then upload the data to TCR's central repository), or be submitted directly through TCR's program framework (which will then download the data to the necessary jurisdictions).

Additional Decisions Needed

1. Determine the specific contents of report to be submitted.

2. Confirm decision on submittal mechanism: direct to TCR or through jurisdictions to TCR.

Compliance

Discussion and Notes

1. Rule violations – This section will discuss the actions that will be considered violations of the rule, for example failure to submit complete reports when required to do so, knowingly submitting false information with a intent to deceive, etc.

2. Enforcement Mechanisms – The WCI will develop consistent administrative practices to respond to non-compliance issues, however specific enforcement actions, such as levying fines and penalties, will likely be carried out by jurisdictions.

3. Records Retention – This section will describe which records must be kept and for how long. More detailed requirements may be included in source-category-specific requirements.

4. Revisions – The rule will describe the process for revising reports that contain inaccurate or missing information and data. The revision process might differ depending on the timing and the circumstances in which the inaccuracies were discovered.

Additional Decisions Needed

1. Determine which actions will be considered violations of the reporting rule.

2. Develop guidelines to promote consistent administrative practices and responses to non-compliance issues among jurisdictions.

3. Determine which records must be maintained for all source categories subject to the reporting rule.

4. Establish procedure and policy for revisions.

Emissions Quantification and Monitoring

Discussion and Notes

1. The essential requirements to the model rule will provide an introduction to quantification, probably in a "General Requirements" section, but will also specify source category-specific quantification requirements.

2. In addition to the technical issues related to reporting, there are also a number of policy-oriented choices to be made. Examples are the degree of coordination with other (non GHG) emissions reporting requirements and *de minimis* requirements.

3. A key factor in determining emissions quantification and monitoring requirements is that the requirements must provide levels of accuracy necessary for an effective cap-and-trade program. It is generally accepted that quantification methods must be more rigorous under mandatory reporting for cap-and-trade, than for some methods allowed for voluntary reporting. For example, while a voluntary program might allow a range of methods, quantification and monitoring requirements for mandatory reporting might include "higher tier" methods that assure the appropriate level of accuracy needed to support a cap-and trade program.

4. Several key issues of concern to stakeholders include: 1) how to deal with combined heat and power (CHP) sources; 2) treatment of biomass combustion; 3) methods for quantifying emissions from imported electricity; and, 4) method for quantifying emissions for waste management.

5. Existing GHG emission quantification and monitoring requirements in the WCI jurisdictions and other relevant programs are currently being summarized and reviewed by the Reporting Subcommittee. This review will determine applicability of existing methods to the WCI reporting requirements for a cap-and-trade program, and provide a basis for evaluating consistency with existing WCI jurisdiction reporting rules.

Draft Design of the Regional Cap-and-Trade Program (July 23, 2008):

1. Adequate quantification methods will be established for emissions sources prior to including them in the program.

Additional Decisions Needed

1. The Reporting Subcommittee will establish a process for selecting and approving general and source category-specific emissions quantification and monitoring methods.

2. Based on the process defined, select the methods, and provide the details for each source category-specific method.

Verification and Quality Assurance

Discussion and Notes

1. This essential requirement will address how reported information will be quality assured.

2. The Reporting Subcommittee is currently writing an issue paper addressing "Third Party Verification" that will inform its recommendations and provide a mechanism for public comment on this issue.

Draft Design of the Regional Cap-and-Trade Program (July 23, 2008):

1. Jurisdictions may require third-party verification or may carry out government audit programs. (Jurisdictions are still discussing whether verification by third parties accredited under a common framework should be required for all reports submitted by entities or facilities covered by the cap.)

Additional Decisions Needed

1. Determine the type of verification and quality assurance program.

2. Based on the type of program recommended, define the specific requirements (e.g., accreditation of verifiers, schedules for completion, etc.).

Comments on this Document

Comments on this document will be solicited in person at the July 29, 2008, WCI stakeholders meeting in San Diego, and we encourage written comments to be submitted by Wednesday, August 13, through the WCI website (www.westernclimateinitiative.org). Also, there will be several other opportunities to submit comments on the essential requirements for mandatory reporting after future drafts are released in the Fall of 2008. We are seeking your opinion on whether we should rely most heavily on conference calls and written comments for stakeholder comments on future drafts of the essential requirements or portions thereof, and have only one or two in-person stakeholder meetings.

Attachment A:

Comparison Matrix of Existing and Imminent General Reporting Requirements for WCI Jurisdictions and Related Programs:

- *Table A1: Scope*
- *Table A2: Verification and Quality Assurance*
- *Table A3: Reporting*

Table A1. Comparison Matrix of Existing and Imminent General Reporting Requirements for WCI Jurisdictions and Related Programs: Scope

Reporting Program/ Jurisdiction	Voluntary, Mandatory, C&T	Coverage (GHGs)	Sources/Sectors		Threshold(s) for Reporting	CO2 from Biomass Provisions	GWPs	De Minimis Provisions
			Included	Excluded				
Canada (EC) (Section 71)	Mandatory, C&T (under development)	CO_2, CH_4, N_2O, SF_6, HFCs, PFCs	Emissions sources are sector dependent	On-site mobile combustion emissions	Section 71 – thresholds are sector dependent *Phase 1, 100kt CO2e	Required, reported separately from other emissions	IPCC Second Assessment Report (1995): • CO2: 1 • CH4: 21 • N2O: 310 • SF6: 23900 • HFCs and PFCs vary by formula	None
Québec	Mandatory	CO_2, CH_4, N_2O, SF_6, HFCs, PFCs	Enterprise, facility, or establishment emitting above threshold provided by an annual public notice related to the Section 46 of Canadian Environmental Protection Act (1999). Sources include stationary fuel combustion, industrial process, venting and flaring, other fugitive emissions, on-site transportation and waste and wastewater	None	Any enterprise, facility, or establishment emitting ≥100,000 metric tons of CO2e	Required	IPCC Second Assessment Report (1995)	None
U.S. EPA	Mandatory (to be proposed September 2008)							
CA (ARB)	Mandatory	CO_2, CH_4, N_2O, SF_6 , HFCs and PFCs as specified by sector	Stationary combustion, process and fugitive sources from facilities that are operational as of Jan 1st, 2008, including: • Cement plants • Petroleum refineries • Hydrogen plants, • Electricity generating facilities • Electricity retail providers • Electricity marketers • Cogeneration facilities • Other facilities emitting ≥25,000 metric tonnes CO2 from general	• Electricity generating facilities solely powered by nuclear, hydroelectric, wind, or solar • Portable equipment • Backup generating units or permitted emergency generators • Hospitals (NAICS 62) • Primary and secondary schools (NAICS 611110)	• ≥25,000 metric tonnes CO2 from stationary combustion sources at petroleum refineries and hydrogen plants, and GSC sources • ≥2,500 metric tonnes CO2 from stationary combustion sources at cogeneration or electricity generation facilities	Calculate and report separately all direct combustion emissions	IPCC Second Assessment Report (1995)	No more than 3% of facility's total CO2e (not to exceed CO2e of 20,000 metric tons)

Table A1 - Continued

Reporting Program/ Jurisdiction	Voluntary, Mandatory, C&T	Coverage (GHGs)	Sources/Sectors		Threshold(s) for Reporting	CO2 from Biomass Provisions	GWPs	De Minimis Provisions
			Included	Excluded				
			from general stationary combustion (GSC) Not required, but may voluntarily report separately facility CO2, CH_4, N_2O emissions from mobile combustion.					
NM	Mandatory	• First year: Direct emissions of CO_2 • Second year: Direct emissions of CO_2 and CH_4. For source types specified in Part 87, also include indirect emissions from all electricity, steam, and heat purchased/consumed at the facility. • Third and subsequent years: all GHGs. For source types specified in Part 87, include indirect (as above).	Part 87 specifies Electrical generators, Petroleum refining and Cement manufacturing. Part 73 gives the state authority to require GHG emissions reporting from all sources with criteria emissions greater than 10 tons/year. Currently requiring all Title V operating permit sources to include GHG direct emissions as specified above. All oil and gas production and processing sources must report GHG emissions for 2010.	Direct emissions from motor and non road vehicles	For Part 87, electrical generating units equal to or greater than 25 MW. For Part 73, authority to require GHG reporting upon request for sources emitting greater than 10 tons of a criteria pollutant or VOC.	Fuel use and fuel type must be reported; biomass is not excluded from reporting.	As specified in reporting procedures, which are published outside of rulemaking and must be as consistent as feasible with other GHG programs.	Reporting procedures may specify simplified or limited reporting requirements for up to 5% of facility emissions.

Table A1 - Continued

Reporting Program/ Jurisdiction	Voluntary, Mandatory, C&T	Coverage (GHGs)	Sources/Sectors		Threshold(s) for Reporting	CO2 from Biomass Provisions	GWPs	De Minimis Provisions
			Included	Excluded				
OR	Mandatory	Direct emissions of CO_2, CH_4, N_2O ,HFCs, PFCs, and SF_6	• Sources required to obtain a Title V Operating permit, including those under OAR Chapter 340, Division 218 • Sources required to obtain an air contaminate discharge permit, including those under OAR Chapter 340, Division 216, referred by activities and sources, and by SIC codes (pg 3-4) • Any source listed below that does not have an air permit and emits ≥2500 t of CO2e: – Solid waste disposal facilities – Wastewater treatment facilities – Electric generating units – Electricity and natural gas T&D systems	Emissions from categorically insignificant activities, indirect emissions, and mobile source emissions (voluntary)		Not specified. (Note: although not specified in the rules, Oregon would follow The Climate Registry General Reporting Protocol (GRP) for reporting biomass emissions.)	IPCC Second Assessment Report (1995)	
WA	Mandatory (under development)	CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6	Stationary sources and mobile source fleets	None	Any source that emits ≥ 10,000 metric tons The owner/ operator of an on-road motor vehicle fleet that emits ≥ 2,500 metric tons	Required, reported separately (not considered in totals)	IPCC Second Assessment Report (1995)	To be included in the department rules

Table A1 - Continued

Reporting Program/ Jurisdiction	Voluntary, Mandatory, C&T	Coverage (GHGs)	Sources/Sectors		Threshold(s) for Reporting	CO2 from Biomass Provisions	GWPs	De Minimis Provisions
			Included	Excluded				
TCR Voluntary Program	Voluntary	CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6	All sectors are encouraged to report. Sectors must report Scope 1 and 2 emissions; scope 3 emissions are voluntary. • Scope 1: Direct emissions from stationary combustion, mobile combustion, physical and chemical processes (12 categories), and fugitive sources • Scope 2: Indirect emissions (e.g., electricity purchases) • Scope 3: Upstream/ downstream emissions	None	None	Required, CO2 reported separately.	IPCC Second Assessment Report (1995)	No concept of de minimis. Simplified techniques may be used for up to 5% of emissions
RGGI	Mandatory, C&T	CO2	Fossil fuel fired EGUs	• EGUs that commenced operation after 2005: <5% of heat input from fossil fuels • EGUs that commenced operation before 2005: <50% of heat input from fossil fuels • Sources that sell less than 10% of electricity generated to the grid. • Sources that sell less than 10% of electricity generated to the grid	Fossil-fuel fired EGUs with nameplate capacity ≥ 25 MW; low emitters excluded	CO2 emissions from biomass unit can be deducted. Excludes biomass mixed with other fuels and old growth timber	Consistent with IPCC	

Table A1 - Continued

Reporting Program/ Jurisdiction	Voluntary, Mandatory, C&T	Coverage (GHGs)	Sources/Sectors		Threshold(s) for Reporting	CO2 from Biomass Provisions	GWPs	De Minimis Provisions
			Included	Excluded				
Climate Leaders	Voluntary	CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6	• Onsite fuel consumption and energy use • Industrial process-related emissions (as applicable) • Onsite waste disposal • Onsite air conditioning/ refrigeration use • Indirect emissions from electricity/steam purchases • Mobile sources			CO2 emissions required, reported separately, not included in tracking progress toward reduction goals	Consistent with IPCC	None, but documentation is needed where emissions cannot be estimated
EU ETS	Mandatory, C&T	CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6	• Mineral oil refineries • Coke ovens • Metal ore roasting and sintering installations • Pig iron and steel • Cement clinker production • Lime production • Glass manufacturing • Ceramic products manufacturing • Pulp and paper production	Emissions from mobile internal combustion engines for transportation purposes	Originally proposed as 25,000 metric tons of CO2 (may be revised in the future)	Required, reported as memo item (not accounted for in total emissions), and amounts of biomass combusted	IPCC Second Assessment Report (1995)	2%, not to exceed 20,000 metric tons
UK ETS	Voluntary, C&T	CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6	Direct emissions from on-site combustion and industrial processes (7 categories), and indirect emissions from electricity generated on the grid		10,000 metric tons CO2e	CO2 from biomass energy excluded	Consistent with IPCC	1% of entity emissions

Table A2. Comparison Matrix of Existing and Imminent General Reporting Requirements for WCI Jurisdictions and Related Programs: Verification and Quality Assurance

Reporting Program/ Jurisdiction	Verification Requirements	Approach to Verification	Requirements for Verifiers	Schedule and Deadlines	Accreditation Procedures
Canada (EC) (Section 71)	Phase 1: No specific requirements for third party verification for 2005 GHG emissions, as long as the information reported is verifiable and verification is retained.				
Québec	Third party verification is not required.	The province performs its own verifications. All the information reported by the facilities is analyzed in relation with the previous year's data. Calculation is verified with the fuels used, production levels, raw materials and emission factors provided by sources. Occasional site visits can be performed.			
U. S. EPA	Verification requirements currently unknown; mandatory reporting rule will not be proposed until September 2008				
CA (ARB)	Operators may use the same verification body for both CCAR and ARB emission data report if operators are already members of CCAR and verification body is accredited by ARB and CCAR. **Annual verification**: Annual submission of the verification opinion for: • Retail providers, marketers, and operators of petroleum refineries and hydrogen plants • Operators of general stationary combustion (GSC) facilities in oil and gas sector • Operators of electric generating and cogeneration facilities that combust fossil fuels and are rated ≥10 MW Verification: • Upon positive verification opinion under full verification requirements, operator may choose less intensive verification services, but full verification shall apply at least once very 3 years • Shall not use the same verification body for more than 6 consecutive years **Triennial verification:** Triennial verification and submission of the verification opinion for: • Cement plants	• Site visit during the first year • Development of verification plan • Development of sampling plan • Data checks • Verification opinion submitted to ARB	Strict accreditation requirements including mandatory years of experience and successful completion of ARB training All verification agreements are subject to conflict-of-interest determination Procedure: • Submit Notice of Verification Services to ARB • Begin services 10 or more days after executive officer receives the notice • Notice include information: staff of the verification team • Documentation of required verification skills of the verification team (A,B,C) Conflict of Interest (COI) Requirements: • ARB will approve verification teams before verification activities take place. Teams must demonstrate acceptable	Verification is optional in 2009 and required in 2010 for all reporting facilities. Schedule: • October 1st for reports due April 1st • December 1st for reports due June 1st Verification body shall submit the opinion to ARB within 6 months of the emissions report, in the same year	Rigorous accreditation requirements consistent with ISO standards and other programs (pre-screening and training)

Table A2 - Continued

Reporting Program/ Jurisdiction	Verification Requirements	Approach to Verification	Requirements for Verifiers	Schedule and Deadlines	Accreditation Procedures
	• Electricity generating or cogeneration facilities that combust pure biomass fuel or geothermal generating facilities • Electricity generating and cogeneration facilities with a capacity ≤10MW • GSC facilities excluding oil and gas sector Verification: • May choose to obtain less intensive verification services for the 2 years following completion of full verification services and prior to the next three-year cycle. • Cannot use the same verification body for more than two consecutive verification cycles.		level of COI and expertise for verifying the facility they contract with. • Term Limit: Verification body to be changed after 6 years of verification services (two cycles). Allowed to resume with client after 3 years off (one cycle). • COI Policy: Verification body and verifier may not provide both consulting and verification services within a 3-year period.		
NM	Third party verification is not required. Owners/operators required to report may choose to register and verify their emissions with TCR or CCAR providing the department has access to the information.				
OR	Use existing verification method: Self-certification with periodic inspections by DEQ and Lane Regional Air Pollution Authority (LRAPA) inspectors.	Verification methodology includes: • Strategic analysis • Risk analysis • Verification • Internal verification report • Verification report			
WA	Verify compliance in accordance with department rules.				
TCR Voluntary Program	Third party verification is required.	• Assess conformance with TCR requirements • Assess completeness to ensure all sources are identified and emissions are quantified • Review methodologies and systems in place to prevent data collection, data handling, and calculation errors. • Implement a sampling plan and conduct site visits • Verify that available information supports emission estimates	Firms submit application and qualification packages to the American National Institute of Standards (ANSI). ANSI conducts site visits COI Requirements: • A key factor in relation to the delivery of verification services is the ability of the Verification Body to be independent and impartial. • The verification body must demonstrate that it undertakes a robust COI assessment for each and every verification	Emission reports due June 30; verification reports due December 15.	TCR has partnered ANSI; ensures consistency with ISO 14065:2007 and ISO 14064-3:2007, as well as TCR calculation and reporting requirements. TCR oversight panel monitors the ANSI accreditation process.

Table A2 - Continued

Reporting Program/ Jurisdiction	Verification Requirements	Approach to Verification	Requirements for Verifiers	Schedule and Deadlines	Accreditation Procedures
			engagement by delivering in a timely manner to the Registry the completed COI Assessment Form (see the Registry's *General Verification Protocol*) and responding to any queries that the Registry or its partner accreditation bodies might have as a result of their review of the Assessment Form. • Where subcontracted verifiers are used, the verification body must assess their competencies against those identified by the verification body in its competency needs evaluation, obtain a signed agreement from the subcontractor in relation to the use of accredited verification processes and procedures, and obtain a signed agreement in relation to the maintenance of confidentiality and a declaration of conformance to COI and impartiality requirements.		
RGGI	Allows first party (i.e., self) verification; third party verification required for offset project sponsors only		Regulatory agencies may accredit independent verifiers. Verifiers must demonstrate knowledge in quantifying GHG emissions and developing and evaluating air pollutant emission inventories. COI Requirements: • Prior to engaging in verification services for an offset project sponsor, the accredited verifier shall disclose all relevant		Regulatory agencies may require training or testing for accreditation.

Table A2 - Continued

Reporting Program/ Jurisdiction	Verification Requirements	Approach to Verification	Requirements for Verifiers	Schedule and Deadlines	Accreditation Procedures
			information to the Regulatory Agency to allow for an evaluation of potential COI with respect to an offset project, offset project developer, or project sponsor. The verifier shall disclose information concerning its ownership, past and current clients, related entities, and any other facts or circumstances that have the potential to create a COI. • Accredited verifiers shall have an ongoing obligation to disclose to the regulatory agency any facts or circumstances that may give rise to a COI with respect to an offset project, offset project developer, or project sponsor. • The regulatory agency may reject a verification report and certification statement from an accredited verifier if the regulatory agency determines that the accredited verifier has a COI related to the offset project, offset project developer, or project sponsor. • The regulatory agency may revoke the accreditation of a verifier at any time given cause.		
Climate Leaders	Third party verification is not required.				
EU ETS	Reports are verified in accordance with the detailed requirements established by member state.	• Assess sources, data, and calculation procedures • Develop a verification plan (including a sampling plan) • Conduct site visits • Prepare verification reports	European Standard EN45011 provides criteria for accreditation of verifiers and for conducting the verification process.	Verification report due March 31 for previous calendar year.	Some member states have a national accreditation body, others have independent accreditation services that certify verifiers, and

Table A2 - Continued

Reporting Program/ Jurisdiction	Verification Requirements	Approach to Verification	Requirements for Verifiers	Schedule and Deadlines	Accreditation Procedures
		(internal and submitted to member state)	COI Requirements: Not specified		others require an exam.
UK ETS	Independent third party verification is required.	Verify the following: • Responsibilities for data collection, aggregation, and quality control • Existence of appropriate tools or procedures to support consistency in data estimation • Methods for systematic data archiving and process documentation • Processes for internal audit, data checking, and quality assurance • Processes for corrective actions • Clearly articulated methods of data interpretation • Processes for periodic review of the data management system	United Kingdom Accreditation Service (UKAS) accreditation (http://www.ukas.com/) COI Requirements: Not specified		UKAS accreditation required

Table A3. Comparison Matrix of Existing and Imminent General Reporting Requirements for WCI Jurisdictions and Related Programs: Reporting

Reporting Program/ Jurisdiction	Year Reporting Commences	Reporting Deadline	Initial Reporting Year Requirements	Reporting Procedures	Record Retention Requirements	Release of Reports	Confidentiality	Noncompliance Penalty	Other Requirements
Canada (EC) (Section 71)	2008 for 2006 emissions.	May 31	Facility and parent company identification and contact information.	Sector-specific	Three years	Minister of Environment will publish GHG totals by gas by facility, unless facility requests confidentiality. Non-confidential data will be published by Statistics Canada subject to laws.	Confidential Information will not be disclosed (written request is required) except in accordance with provisions of CEPA1999 and the access to information act.	Under section 272 of CEPA 1999, may be subject to fines, imprisonment or both (Environment Canada's enforcement and compliance policy).	Administrative information of the operator and source/facility required, as well as a signed statement of certification.
Québec	2008 for 2007 emissions	June 1	None specified.	Requirements include: • Submit separate reports for each facility. • Identify separately activities, processes, or equipment that are the sources of emissions. • Report quantities of fuels, raw materials used and volume of production. • Use forms provided. • Report all data otherwise reported to the EC Minister under public notices given related to Section 46 of the Canadian environmental Protection Act (1999). • Use best data available, and one of these methods: − Emission source sampling;	Minimum of 5 years	Not specified.	Information that is necessary to calculate the quantity of the contaminants emitted, such as data pertaining to production, fuels, raw materials, equipment and processes, is considered confidential.	Failure to submit is liable to a fine of: • $2,000 to $12,000 (natural person) • $5,000 to $25,000 (legal person) Second offenses are doubled.	Facility identification information, emission factors and a conformity report.

Table A3 - Continued

Reporting Program/ Jurisdiction	Year Reporting Commences	Reporting Deadline	Initial Reporting Year Requirements	Reporting Procedures	Record Retention Requirements	Release of Reports	Confidentiality	Noncompliance Penalty	Other Requirements
				– Sampling and CEMS; – Emission estimation model; – Calculation that may include the use of an emission factor published in the scientific literature or documentation specific to the enterprise, facility or establishment; – Mass balance; or – Predictive emission monitoring.					
U.S. EPA	Reporting requirements currently unknown; mandatory reporting rule will not be proposed until September 2008								
CA (ARB)	2009 for 2008 emissions	April 1 : • General stationary combustion (GSC) facilities excluding oil and gas • Electricity generating facilitates and cogeneration facilities not under other operational controls June 1 : • Retail provider	Use methods specified in regulation. For each GHG source specified in the regulation, provide GHG emission estimates, fuel use, and other data identified in the regulation. If during the first year data are not available to implement the full regulatory methods or data reporting requirements, use the best available data for estimating GHG emissions and provide other specified data for those sources with incomplete data.	General requirements include: • Calculate and report each GHG separately for each fuel type used • Monitor and report fuel consumption for the facility and for each process unit or group of units where fuel use is separately metered. • Quantify fuel use with accuracy within ± 5%. • Procedure provided for addressing equipment breakdowns of fuel analytical data monitoring equipment. • Report separately consumption of purchased/acquired electricity, heat, cooling, or steam – no emissions attached.	• Retain reporting records for minimum 5 years • Establish and maintain procedures for records retention • The retained documents including emissions data should be sufficient for verification • Upon request by ARB, all retained documents including data are to be provided within 20 working days • Retain a listing of specific	By statue, all submitted emissions data are public information. Emissions data will be released to the public through web-based reporting and other methods. Other facility information submitted to ARB under the reporting program (e.g., fuel use, process data, etc.) may be designated	All emissions data is public information, any may not be designated as confidential. Reporters may designate non-emission data as confidential during reporting. Third-party requests for submitted data designated as confidential will be handled in accordance with California code of regulations. When requests for confidential data are received, facility operators must provide justification to the ARB for their [illegible]	Failure to submit, knowing submission of false information, late submittal constitute a single separate violation.	Administrative information of the operator and source/facility is required, as well as a signed statement of certification. Web-based interactive tool provided for mandatory GHG facility emissions reporting, facility operator registration, initial QA/QC, reporting progress tracking, verifier relationship tracking, and other functions.

Table A3 - Continued

Reporting Program/ Jurisdiction	Year Reporting Commences	Reporting Deadline	Initial Reporting Year Requirements	Reporting Procedures	Record Retention Requirements	Release of Reports	Confidentiality	Noncompliance Penalty	Other Requirements
		s, • Marketers • GSC facilities within oil and gas sector, • Cement plants • Petroleum refineries • Hydrogen plants		• Obtain a specified fuel analytical data capture rate. • Other requirements are sector dependent.	information for at least 5 years (A-31,32)	as confidential by the facility operator.	confidential data designations to avoid release of the data.		
NM	2009 for 2008 emissions	• July 1 for Part 87 sources. • April 1 or with operating permit emissions report for Part 73 sources.	Direct emissions of CO2	Regulations establish guidelines for development of Reporting Procedures by the department. Procedures must be as consistent as feasible with quantification methods accepted by TCR/CCAR and include: • Recommended calculation methods, conversion factors, and report of supporting data used. • Alternate methods that are available and appropriate. • Means for simplified and limited documentation of CO_2e that collectively account for 5% or less of total facility emissions. • Means to document calculation methods, if different from the proposed tool. • Amounts of fuel use and specifications of	Minimum of 5 years	By statute, all emissions reports are public information. Supporting information may be designated confidential under certain circumstances.		Penalty not to exceed $15,000 per day per violation (NM Air Quality Control Act, section 74-2-12).	• Administrative information of the operator and source/ facility required, as well as a signed statement of certification. • Use reporting tool and procedures provided by the department, except for the persons registering and verifying with TCR or CCAR.

Table A3 - Continued

Reporting Program/ Jurisdiction	Year Reporting Commences	Reporting Deadline	Initial Reporting Year Requirements	Reporting Procedures	Record Retention Requirements	Release of Reports	Confidentiality	Noncompliance Penalty	Other Requirements
				each fuel type, directly related to reported emissions • Calculations for each GHG and means to sum all emissions in CO_2e metric tons, including emissions from regular operation and events such as startup, malfunction. • A listing including percentages of the owners of equity shares of the emissions reported. • Report of the county where facilities are located, for emissions from facilities within the jurisdiction. • For emissions from facilities located on tribal lands, another state or another country, report the tribe, identification of the state or the country.					
OR	2010 for 2009 emissions (2011 for 2010 for sources not under Title V and Air Permits with >2500 metric tons of emissions)	Same as Title V or Air Contaminant Discharge Permit report, or March 15	None	• Any source not required to register and report emissions may do so voluntarily. • GHG emissions pursuant to department approved protocols including estimated annual emissions, activity data, emissions factors, conversion factors, GWP factors and calculation methods.	Minimum 5 years	Not specified	Not specified in these rules, but data would be subject to Oregon Public Records Law.	Not specified in these rules, but would be subject to DEQ enforcement rules.	• Administrative information of the operator and source/facility required, as well as a signed statement of certification. • Registration and reports must be submitted on paper or electronic forms issued by the department.

Table A3 - Continued

Reporting Program/ Jurisdiction	Year Reporting Commences	Reporting Deadline	Initial Reporting Year Requirements	Reporting Procedures	Record Retention Requirements	Release of Reports	Confidentiality	Noncompliance Penalty	Other Requirements
WA	2010 for 2009 emissions. (May phase in largest sources first until Jan. 1st, 2012 when all sources at or above the 10,000 metric tons threshold must be in.)	Oct 31	None	• Requires owner/operator of air contaminant sources of any class to register and report • Reporting consistent with the federal government rules and/or other established protocols. State rules when adopted will clarify.	Not specified	Not specified		Any persons failing to report or pay the required fee may be subject to enforcement penalties.	Administrative information of the operator and source/facility required, as well as a signed statement of certification.
TCR Voluntary Program	First year specified by reporter and may include historical data from as far back as 1990	June 30 data submission required within CRIS	May opt for transitional reporting for up to 2 years (CO2 and for one state at a minimum)	• Protocols currently being developed for various industries • Reporters may opt to report worldwide and scope 3 emissions • Emissions not made public until data verified by third party	Historical data submitted and verified will be held indefinitely unless company requests removal of data from CRIS.	Data visible to public for all reporters at facility level except those that apply for CBI status and roll-up to state level	Data are transparent at the facility level for reporters. Allowances for CBI reasons that allow data to be rolled up at the state level (CO_2e) which must be applied for annually.	None	Administrative information of the operator and source/facility required.
RGGI	2009	March 1		Each CO2 budget source must submit an output monitoring plan. All emissions monitoring information; copies of all reports, compliance certifications, and other submissions and all records made or required under the CO2 Budget Trading Program; copies of all documents used to complete a CO2 budget permit application and other submission under the CO2 Budget Trading Program or to demonstrate compliance with the requirements.	10 years	No specific provisions; intention is for information to be publicly available	Varies by state	Varies by state	• Signed statement of certification required. • Quarterly electronic reports with emissions, operating parameters, and quality assurance test data.

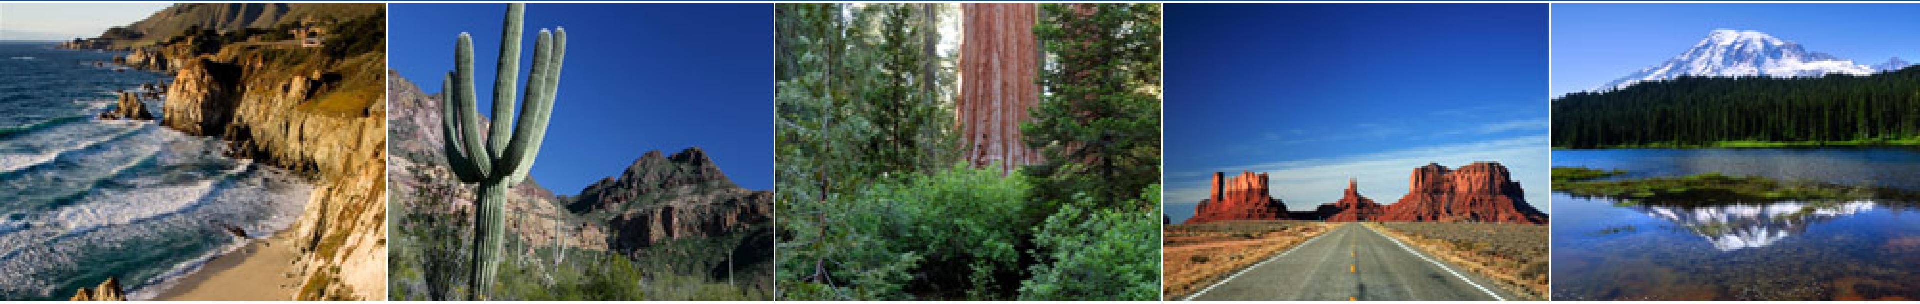
San Diego, California

Western Climate Initiative



WCI Overview and Status

July 29, 2008

San Diego, California

Western Regional Climate Action Initiative (WCI)

Partner

Observer

Initiative Collaboration Includes

Three specific directives:

- Set a regional emissions reduction goal
- Join a multi-state registry to track, manage and credit reductions
- Design a regional multi-sector market-based mechanism

Joint work to:

- Promote clean and renewable energy in the region
- Increase energy efficiency
- Advocate for regional and national climate policies that are in the interest of western states
- Identify measures to adapt to climate change impact

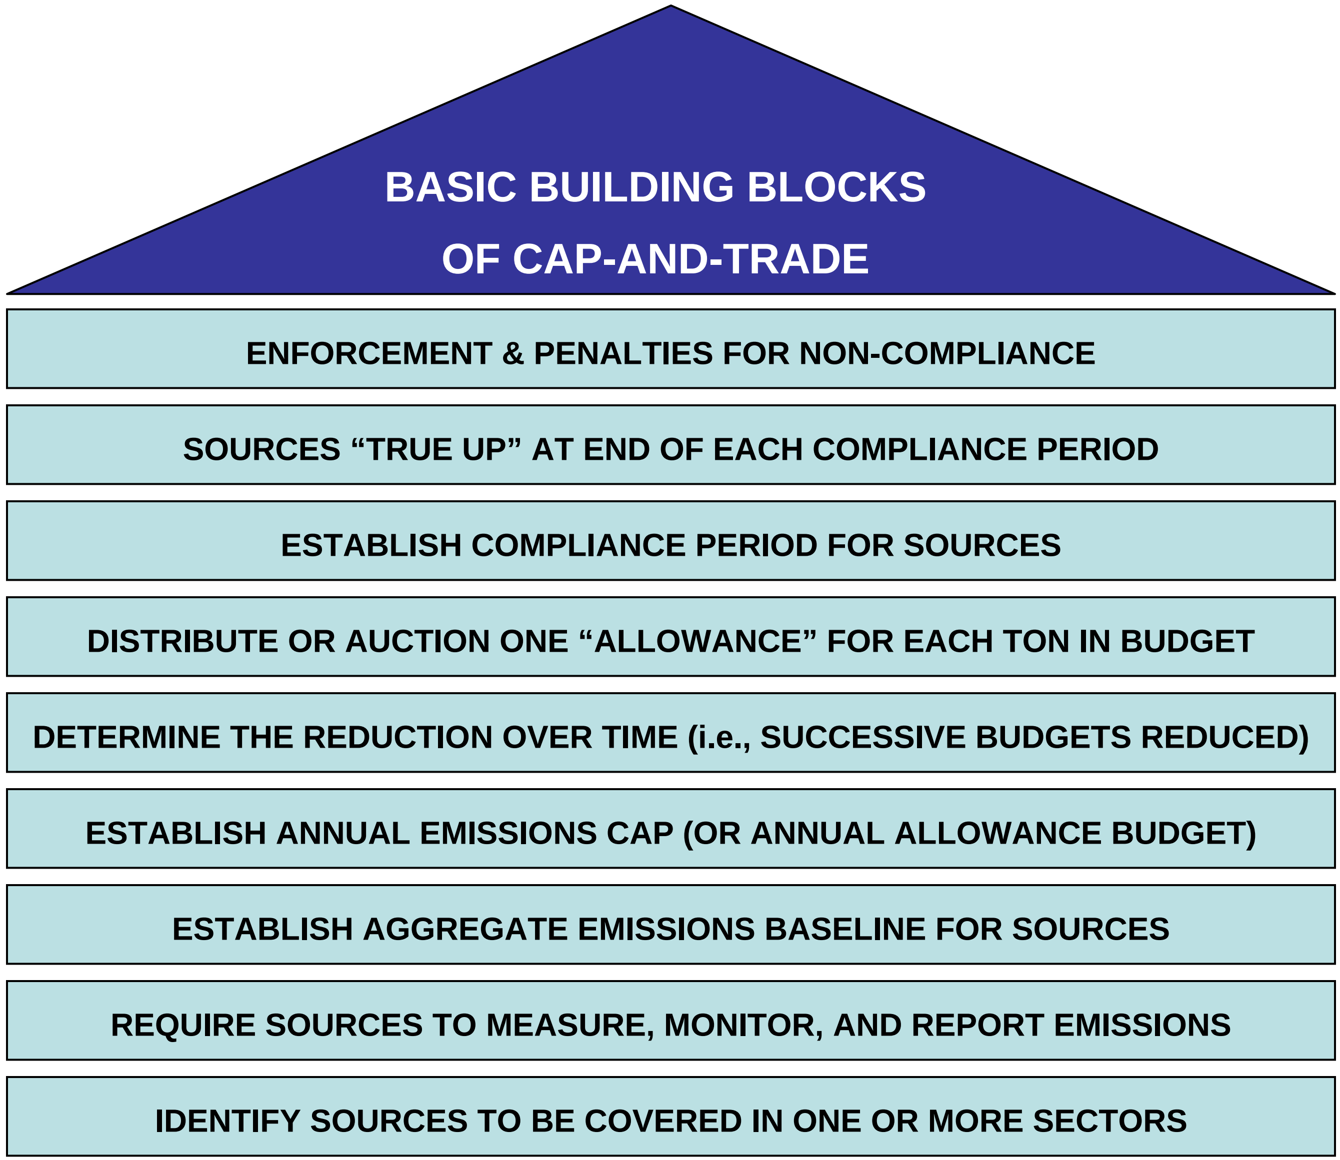
Why Regional Action

- Each WCI partner supports a comprehensive approach to reducing greenhouse gas emissions
- Each has its own reduction goals and is taking steps to implement
- The WCI jurisdictions are particularly vulnerable to climate impacts
- Western US and Canadian partners have a long history of energy efficiencies and renewable energy
- Climate change requires action now – we cannot afford to wait

By leading, we can help ensure the WCI perspective is included in future federal (US and Canadian) action

Why Cap and Trade

- Emission reductions are certain compared to tax
  - Cap sets reduction; tax sets cost
- Lets the market find lowest cost reductions
  - Cost effective for covered sources
- Clean Air Act is largely technology driven
  - Technologies for carbon capture are not widely available
- Cost effective to implement
  - Individual emission permits not required



BASIC BUILDING BLOCKS
OF CAP-AND-TRADE
ENFORCEMENT & PENALTIES FOR NON-COMPLIANCE
SOURCES “TRUE UP” AT END OF EACH COMPLIANCE PERIOD
ESTABLISH COMPLIANCE PERIOD FOR SOURCES
DISTRIBUTE OR AUCTION ONE “ALLOWANCE” FOR EACH TON IN BUDGET
DETERMINE THE REDUCTION OVER TIME (i.e., SUCCESSIVE BUDGETS REDUCED)
ESTABLISH ANNUAL EMISSIONS CAP (OR ANNUAL ALLOWANCE BUDGET)
ESTABLISH AGGREGATE EMISSIONS BASELINE FOR SOURCES
REQUIRE SOURCES TO MEASURE, MONITOR, AND REPORT EMISSIONS
IDENTIFY SOURCES TO BE COVERED IN ONE OR MORE SECTORS

WCI Design Principles

- Equitable, administratively simple, clear compliance path
- Maximize total benefits and avoid localized or disproportionate environmental or economic impacts
- Advance economic, environmental, and public health objectives;
- Real, verifiable, enforceable reductions
- Stimulate investment and reward innovations
- Encourage reductions beyond capped sectors/sources
- Recognition/incentives for early reductions
- Transparent and robust accounting system
- Minimize potential for leakage
- Facilitate links to other systems

WCI Organization

- Scope
  - Gases, Sectors and sources, points of regulation
- Electricity
  - Point of regulation
- Allocations
  - Starting point and 2020 cap
  - Establishing partner allowance budget methodology
- Reporting
  - Required elements including verification
  - Coordination with The Climate Registry and EPA
- Offsets
  - Project types and limits (% and/or geographic)
- Legal Team

Draft Design Recommendations

- Six primary greenhouse gases
- Starting dates and thresholds
  - Reporting
  - Cap and Trade
- Sectors and Points of Regulation
- Cost Containment (in addition to cap and trade)
  - Offsets
  - Banking but no borrowing
  - Three year compliance periods
- Role of other policies
- Program expansion

Draft Design Recommendations (cont.)

- Methodology to develop starting cap
- Distribution of allowances
- Regional organization
  - Shared administrative functions
  - Monitor market
  - Conduct auctions
  - Approve offsets
- Enforcement
  - Three tons for every one ton short
  - Commitment to provide technical assistance

Design issues still to come

- Partner budget - or share - of regional allowances
- Common reporting elements
  - Draft released July 23, 2008
- Specifics around first jurisdictional deliverer
- Implementation schedule, including development of model rule

Timeline

- Draft initial design (policy framework)
  - July 23
- Submit comments on draft design by August 13 (through WCI website)
  - Follow outline of the draft when commenting: Will make it easier to quickly analyze comments
- "Final" design recommendations (policy framework)
  - Expect to release week of September 22

Timeline

- Continued work by WCI Partners to refine design
  - September thru December 2008
  - Further stakeholder involvement during this time period
- 2009 and beyond:
  - Obtain necessary legislative authority
  - Work on model rules and other implementation issues
  - Other complimentary policies of common interest

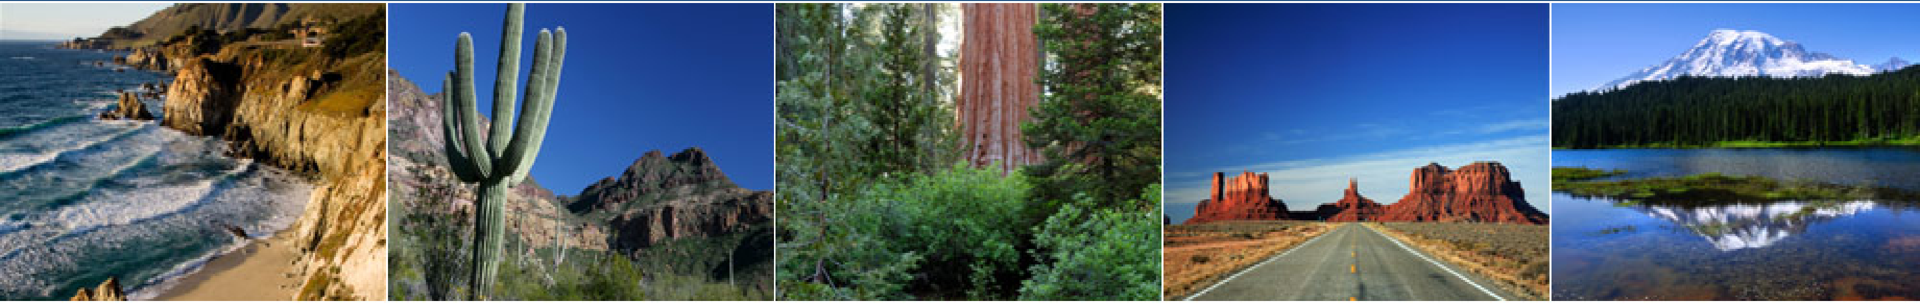
Scope Recommendations

Western Climate Initiative



Scope Recommendations

Michael Gibbs, Cal/EPA

Scope Subcommittee, Chair

July 29, 2008

San Diego, California

Overview

- Mission
- Process
- Recommendations
- Electric Sector

Mission

- Recommend the scope of a proposed cap and trade program:
  - The sectors that fall under the cap.
  - The emissions sources that fall under the cap.
  - The greenhouses gases that fall under the cap.
  - The point(s) of regulation where the cap would be enforced.

Mission (Continued)

- Balance multiple objectives, consistent with the WCI design principles
  - …administratively simple …
  - …minimizes administrative costs…
  - …covers as many sources as is practical…
  - …minimizes the potential for leakage…
  - …facilitates linkage…

Mission (Continued)

- Evaluate:
  - Emissions
  - Ability to measure/calculate emissions at the entity level
  - Administrative feasibility
  - Risk of emission leakage

Process

- Work Plan: October 2007
- Major Options: January 2008
- Workshop: January 2008
- Conference Call: February 2008
- Draft Recommendations: March 2008
- Conference Call: March 2008
- Workshop: May 2008
- Written comments throughout

Recommendations

- Greenhouse gases covered:
  - Carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

Recommendations

- Emissions covered:
  - Electricity generation, including emissions from electricity imported into WCI jurisdictions from non-WCI jurisdictions
  - Combustion at industrial and commercial facilities
  - Industrial process emission sources, including oil and gas process emissions
  - Residential, commercial, and industrial fuel combustion
  - Transportation fuel combustion from gasoline and diesel

Recommendations

- Quantification methods:
  - Adequate quantification methods will be established for emissions sources prior to including them in the program
- Threshold:
  - 25,000 metric tons of CO_2e annually
  - Applies to facilities or entities with a regulatory compliance obligation under the cap-and-trade program
  - Additional analyses to ensure sufficient coverage or to address competitiveness issues

Recommendations

- Points of Regulation: Entities and Facilities
  - Industrial sources (both process and combustion) with emissions above the threshold: At the point of emission
  - Electricity: First Jurisdictional Deliverer
  - Residential, commercial, and industrial fuel combustion at facilities with emissions below the threshold: Where the fuels enter commerce in the WCI Partner jurisdictions
  - Transportation fuel combustion: Where the fuels enter commerce in the WCI Partner jurisdictions

Recommendations

- Future Program Expansion
  - The WCI Partners recommend that the scope of the cap-and-trade program be capable of expanding over time (including possibly adjusting applicability thresholds over time).

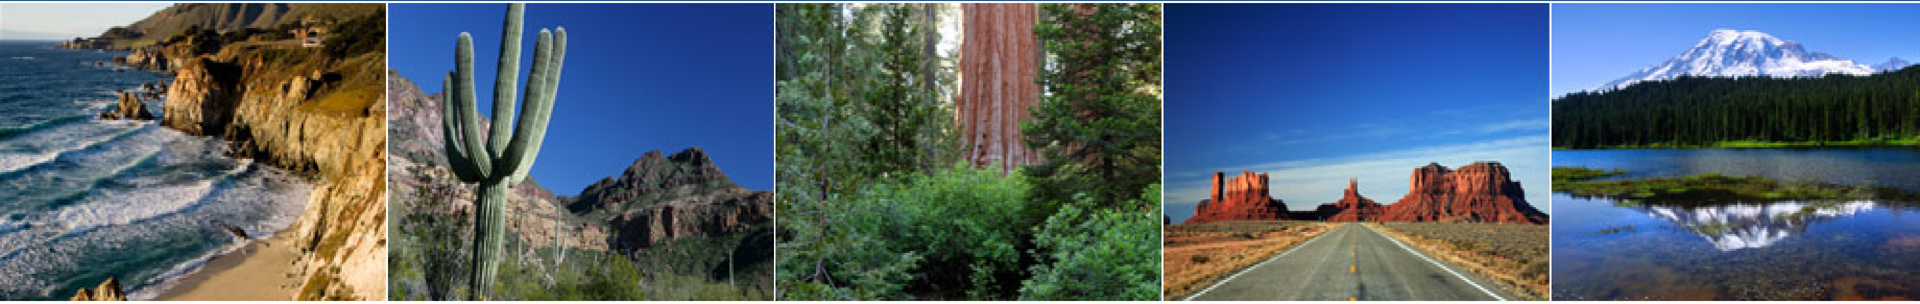
Allocations Recommendations



Draft Allocations Design Recommendations

Steve Owens
Arizona Dep’t of Environmental Quality

July 29, 2008
San Diego, CA

Regional Cap

- The regional cap will be equal to the sum of the Partner allowance budgets.
- The initial regional cap and Partner allowance budgets will be set through 2020.
- 2012: The initial cap will be set at the best estimate of actual emissions for sources covered in the initial year of the program.
- 2015: Expected actual emissions from transportation fuels and residential, commercial & industrial fuels will be added.
- 2020: Cap will set so that reductions achieved by the cap plus reductions from other GHG reduction policies will achieve the WCI regional goal.

Regional Cap

- The regional cap that will decline over time, and each Partner will have an allowance budget within the cap.
- Once established, the regional cap for each compliance period will not be adjusted except as necessary to account for:
  - Changes in WCI membership
  - Changes in scope or thresholds
  - Errors discovered in data used to determine the cap, which may become apparent, for example, after the start of mandatory reporting
- Any adjustments to the regional cap will be made prior to the beginning of the compliance period.
- Post-2020 caps: The Partners will set these regional caps not less than three years in advance.

Partner Allowance Budgets

- The Partners will develop a recommended methodology for calculating the Partner allowance budgets by Fall 2008.
- For post-2020, allowance budgets will be set not less than three years in advance.
- Once established, each Partner’s allowance will not be adjusted except as necessary to account for:
  - Changes in WCI membership
  - Changes in scope or thresholds
  - Errors discovered in data used to determine the cap, which may become apparent, for example, after the start of mandatory reporting

Distribution of Allowances

- Once the allowance budget has been established for each Partner, allowances will be issued by each Partner within its own jurisdiction.
- A minimum percentage of the value of each Partner's allowance budget may be dedicated to one or more of the following public purposes:
  - Energy efficiency and renewable energy incentives and achievement
  - Research, development, demonstrations & deployment with particular reference to carbon capture & sequestration; renewable energy generation, transmission and storage; and energy efficiency
  - Promoting emission reductions and sequestration in agriculture and forestry and other uncapped sources
- The remaining percentage of Partner allowance budgets will be distributed as each Partner sees fit.

Distribution of Allowances (cont.)

- Each Partner will be required to advise the other WCI Partners how it intends to allocate the remaining allowances, so that the WCI can make the Partners' plans public in a coordinated fashion.
- Any Partner that chooses to hold allowances must allocate or retire those allowances by the end of the applicable compliance period.
- The issue of establishing a minimum percentage of allowances subject to auction is still under discussion.
- To address competitiveness issues between WCI jurisdictions, the Partners will consider standardizing the distribution of allowances over time.

Banking, Borrowing & Compliance Periods

- Banking: Purchasers and covered entities will be allowed to bank allowances without limitation, except to the extent that restrictions on the number of allowances any one party may hold are necessary to prevent market manipulation.

- Borrowing: Borrowing of allowances from future compliance periods will not be allowed.

- Compliance Periods: Each compliance period will be three years long.

New Partners

- The determination of allowance budgets for new Partners will take into account:
  - The WCI regional goal
  - Allowance budgets for existing Partners
  - The share of the new Partner's budget that is already included through the WCI's provisions covering imported electricity
  - The apportionment methodology (still being developed)
- New Partners will come into the cap-and-trade program at a regionally coordinated and designated time, such as the beginning of the relevant compliance period.
- A new Partner must have adopted an economy-wide GHG reduction goal for 2020 that reflects a level of effort that is consistent with that of the WCI Partners.

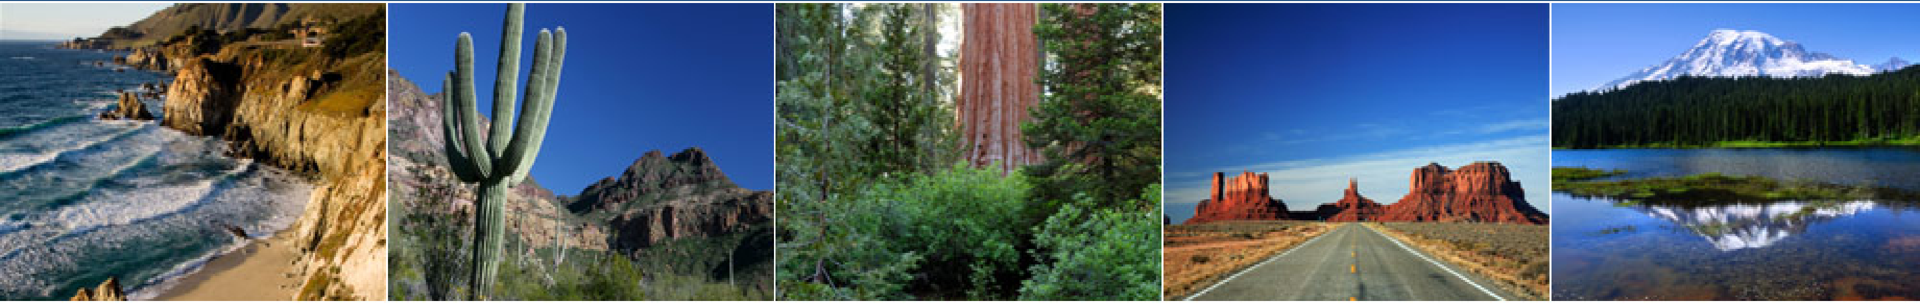
Offsets Recommendations



Offsets Recommendations

Tim Lesiuk
Province of British Columbia
Offsets Subcommittee, Chair

July 29, 2008

San Diego, California

Offsets and Allowances from other systems

- The WCI Partners will include a rigorous offsets system. The primary role of the offsets system is to reduce the compliance costs for the cap-and-trade program, while ensuring the environmental integrity of the cap.
  - *Strong stakeholder support for including an offset program.*
  - *Strong stakeholder desire for offset program to focus on reducing overall cost of targets through reduced compliance costs for emitters, reduced economic impact for consumers, and increased economic opportunities to encourage emission reductions.*
  - *Strong stakeholders concern for environmental integrity and connection between the integrity of the offsets and the integrity of the regional target.*

Offsets and Allowances from other systems

- The WCI Partners will establish a limit on the use of offsets. The WCI Partners are considering a limit not greater than ten (10) percent of an individual entity's or facility's compliance obligation.
  - *Some stakeholders think limiting is counterproductive;*
  - *Some stakeholders think oversupply of offsets could mean less direct emission reductions.*

Offsets and Allowances from other systems

- The WCI Partners have identified the following list of project types as a priority for investigation and development to participate in the offset system.
    - Agriculture (soil sequestration and manure management)
    - Forestry (afforestation/reforestation, forest management, forest preservation/conservation, forest products)
    - Waste management (landfill gas and wastewater management)
  - *Stakeholders have identified many project types the WCI could investigate*
  - *Many stakeholders feel the WCI should identify a list of project types that will be eligible*
  - *Some stakeholders feel project types should be limited*

Offsets and Allowances from other systems

- The WCI Partners will coordinate to review, develop, and approve, as appropriate, protocols for the project types that meet the necessary criteria for inclusion. The WCI Partners will use offset protocols that are standardized to the extent possible, and make use of (or adapt if needed), existing protocols as appropriate. The WCI Partners will also initiate the establishment of a process to coordinate the review and approval of other project types and protocols proposed by project developers.
  - *Stakeholders have advocated for government issued protocols and developer driven protocols.*
  - *Stakeholders strongly support protocols approved before overall program startup.*

Offsets and Allowances from other systems

- WCI Partners may approve and certify offset projects located throughout Canada, the United States, and Mexico, where such projects would be subject to comparably rigorous oversight, validation, verification and enforcement as those located within the WCI jurisdictions.
  - *Stakeholders would like the flexibility to purchase offsets from the lowest cost sources.*
  - *Stakeholders are concerned that the quality of the offsets remain high and consistent with the cap and trade program.*
  - *Stakeholders would like to see the environmental, economic and social co-benefits remain in the WCI jurisdictions.*

Offsets and Allowances from other systems

- WCI design protocols will meet rigorous criteria to preserve the environmental integrity of the overall cap-and-trade program.

Offsets and Allowances from other systems

- In the case of offset credits from the Clean Development Mechanism (CDM) and Joint Implementation (JI), the WCI Partners may establish added criteria to ensure similar rigor to WCI approved/certified offset projects or other requirements appropriate to enable use of these offset credits in the cap-and- trade program.

Offsets and Allowances from other systems

- WCI Partners may allow individual regulated entities or facilities to use tradable units (allowances) from other government-regulated GHG emission trading systems that the WCI Partners recognize as meeting similarly rigorous criteria for environmental integrity for compliance purposes. These allowances would be subject to the overall limit described above.

Offsets and Allowances from other systems

- The WCI Partners are considering a method that restricts the use of offsets from projects located outside WCI jurisdictions for compliance purposes in the WCI cap-and-trade regulatory program.

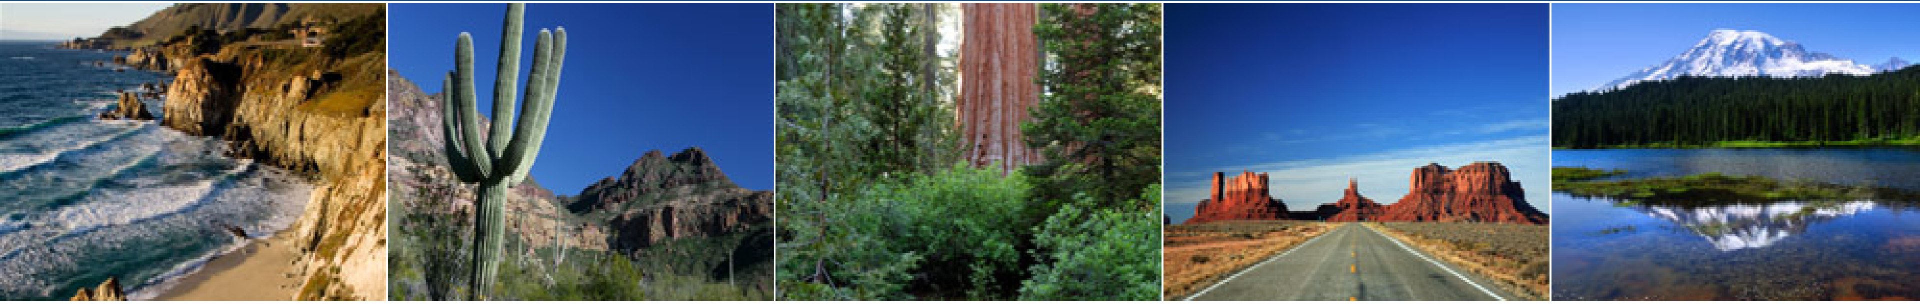
Reporting Recommendations

Western Climate Initiative



Draft Design
Reporting Subcommittee

Jim Norton, Subcommittee Chair

NM Environmental Protection Division Director

July 29, 2008

San Diego, CA

Practical Impacts for Reporting

- Key Elements
  - Consistent, transparent, robust quantification and reporting across sources and states/provinces
  - Broadest possible coverage / inclusion
- Maximum reliance on and linkage with The Climate Registry (TCR) and international reporting programs
  - Anticipate employing TCR quantification protocols and reporting systems and services

Draft Design Recommendations for Reporting

- **10.1:** *Mandatory measurement and monitoring for all six GHGs will commence in January 2010 for all entities and facilities subject to reporting. Reporting of 2010 emissions will begin in early 2011.*

- **10.2:** *The entities and facilities subject to reporting are those with annual emissions equal to or greater than 10,000 metric tons of CO2e. However, in some limited instances the threshold may be based on other parameters, such as throughput or capacity, as long as these thresholds represent the equivalent of, or are lower than, the 10,000-metric-ton threshold.*

Draft Design Recommendations for Reporting – cont.

- **10.3:** *Partners may require third-party verification or may carry out government audit programs. (Partners are still discussing whether verification by third parties accredited under a common framework should be required for all reports submitted by entities or facilities covered by the cap.)*
- **10.4:** *As each Partner collects additional emissions data from entities and facilities required to report, data will be made available to all Partners for review and consideration for inclusion in the cap-and-trade program.*
- **10.5:** *Nothing in the WCI program design would limit any Partner's discretion to require reporting earlier, at lower thresholds, or for entities and facilities not covered by the cap-and-trade program.*

Draft Essential Requirements of Mandatory Reporting

- Purpose of ER Document
  - Document current status of essential requirements
  - Identify remaining decisions
  - Seek public comment

- Scope of ER Document
  1. Definitions
  2. Pollutants
  3. Applicability
  4. Timing
  5. Confidentiality
  6. Report content and submittal
  7. Compliance
  8. Emissions quantification and monitoring
  9. Verification and quality assurance

1. Definitions

- Background
  - Defines Key Terms
  - Facilitates Communications Via Common Terminology
  - Several Jurisdictions Have Definitions
- Additional Decisions Needed
  - Using CARB as a starting point, compile applicable definitions

2. Pollutants

- Background
  - Clearly Defines Pollutants
  - Provides 100-Year Global Warming Potential (GWP) Factors (e.g., IPCC Second Assessment, 1995)
- Draft Design of the Regional Cap-and-Trade Program (7/23/08)
  - GHGs Covered: Section 1.1
- Additional Decisions Needed
  - Determine GWP factors

3. Applicability

- Background
  - Describes Who must Report
    - Sources subject to cap and not subject to cap
    - Sources not subject to reporting
  - Defines Threshold(s)
  - Defines Level of Reporting
    - Entity, facility, process
- Draft Design of the Regional Cap-and-Trade Program (7/23/08)
  - Sources: Sections 1.2.1 through 1.2.6, 1.5
  - POR: Section 2
  - Thresholds: Section 10.2, 10.5
- Additional Decisions Needed
  - Identification of source categories (i.e., which processes)
  - Definitions of sources to address POR issues
  - Sources to exclude from reporting
  - Level of reporting (by source category)

4. Timing

- Background
  - Effective date
  - Reporting period
  - Report submission date
- Draft Design of the Regional Cap-and-Trade Program (7/23/08)
  - Section 10.1
- Additional Decisions Needed
  - Need for uniform dates across jurisdictions?
  - Need for prior years' data?
  - Plan for transitioning to WCI schedule for jurisdictions with existing programs
  - Need for more frequent interim reports to support cap-and-trade program?
  - Deadlines for verification/QA and public release of data

5. Confidentiality

- Background
  - In general, emissions data are not considered confidential
  - Stakeholder comments range from protection of public right-to-know to a broader definition to protect confidential business information
- Additional Decisions Needed
  - Policies and procedures

6. Report Content and Submittal

- Background
  - General requirements (administrative information)
  - Source category-specific requirements
  - Submittal requirements (responsible party)
- Draft Design Recommendations (5/16/08)
  - TCR's central repository
  - Optional submittal directly to TCR or to jurisdictions (who will upload to TCR)
- Additional Decisions Needed
  - Specific contents of report
  - Submittal mechanism

7. Compliance

- Background
  - Rule violations
  - Enforcement mechanisms
  - Records retention
  - Revisions
- Additional Decisions Needed
  - Which actions are violations
  - Guidelines to promote consistent administrative practices among jurisdictions
  - Which records must be retained
  - Procedure and policy for report revision

8. Emissions Quantification and Monitoring

- Background
  - De minimus emissions
  - Accuracy necessary to support a cap-and-trade program
  - Key stakeholder issues: CHP, biomass combustion, methods for electricity imports and waste management
  - First step: review existing methods
- Draft Design Recommendations (5/16/08)
  - Section 1.5
- Additional Decisions Needed
  - Process for selecting and approving methods
  - Select methods and determine details for each source category-specific method

9. Verification and Quality Assurance

- Background
  - Reporting Subcommittee is writing issue paper to inform decision on third party verification or other QA procedures
- Draft Design of the Regional Cap-and-Trade Program (7/23/08)
  - Section 10.3
- Additional Decisions Needed
  - Type of verification and quality assurance program
  - Specific requirements

Next Steps

- Respond to Stakeholder Comments on Essential Requirements (comments due August 13)
- Complete Work Plan
  - Facilitates decision making process on all essential elements
  - Establishes critical path
- Study and Recommend Emissions Quantification and Monitoring Methodologies
- Finalize Essential Requirements Dec 2008
- Welcome Stakeholder Comments Throughout the Process

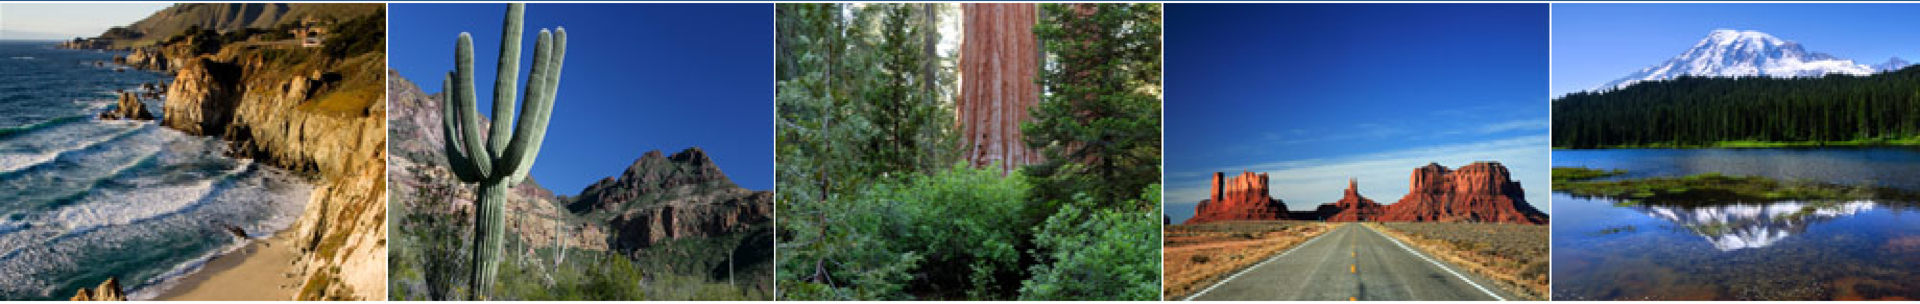
Economic Analysis



Update on Economic Modeling

Economic Modeling Team

July 29, 2008

San Diego, California

Outline of Presentation

- Status
- Quick review of structure of ENERGY 2020
- Updates to Model Inputs
- Comments and questions

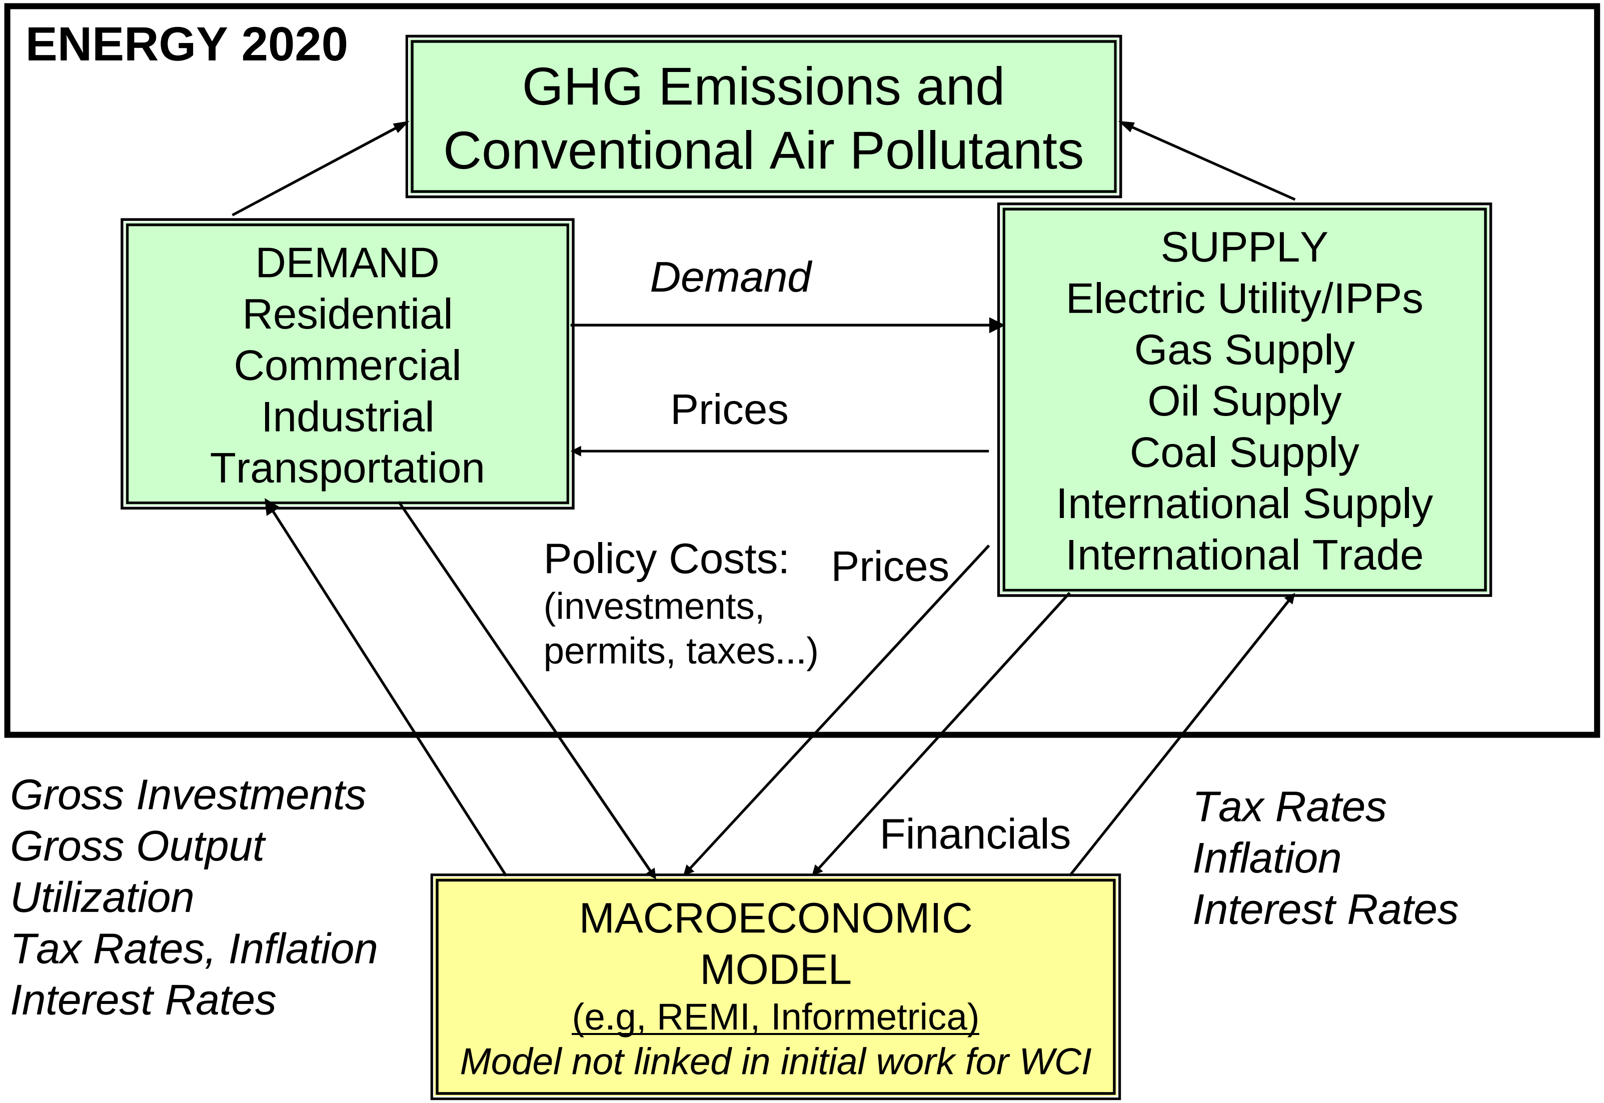
Status

- Model specified
  - Economic and population drivers – partner specific data
  - Energy price forecasts
  - “First Jurisdictional Deliverer”
  - Western Electric Coordinating Council (WECC) area
- Inputs being finalized
  - Cost data
  - Existing policies
    - Renewable Portfolio Standards
    - Energy Independence and Security Act
- Sensitivity analysis requirements being identified
  - Stakeholder conference calls

Status (continued)

- Policy cases being defined
  - Reference case
  - Complementary policies case
  - Cap-and-Trade cases
- Model outputs
  - Emissions
  - Allowance prices
  - Expenditures and costs

ENERGY 2020 Model Structure



Update to Model Inputs

- This “Assumptions Book” catalogs key inputs and assumptions.
- This second draft:
  - Reflects ongoing guidance from WCI.
  - Incorporates widely available and accepted public data sources.
  - Incorporates some partner-specific data.
  - A new section 2 provides a brief overview of the organization of the Assumptions Book. This caused the Analytic Approach section to be renumbered as section 3, and Reference Case Inputs to be renumbered as section 4. Otherwise, the layout of the Assumptions Book is basically unchanged.

4.1 Population and Economic Data

- Section 4.1 now gives specific links to public data sources used for population and economics data (e.g. table below)
- Assumptions (2006-2020): 3% real GDP growth, 2.5% inflation, 5% real discount rate.

Description of Data/Input	Sources	Detailed Reference
Total population, historical and growth over time	US Census Bureau	*Historic (1985-2006):* Regional Economic Information System, Bureau of Economic Analysis, U.S. Department of Commerce. http://www.bea.gov/regional/spi/default.cfm?satable=summary *California:* California population taken from: CEC *California Energy Demand 2008-2018 Staff Revised Forecast*
	Statistics Canada	Statistics Canada Table 051-0001 (based on census data)
	Future	Future annual population growth rates are taken from Regional Forecasts from AEO then applied to the state historical population. Annual Energy Outlook 2007 (February 2007 release). http://www.eia.doe.gov/oiaf/aeo/supplement/suptab_1.xls through suptab_9.xls

4.2 Price Data

- Future energy prices
  - For U.S. states: Have switched from EIA AEO 2007 High Price Case to AEO 2008 High Price Case (see table below)
  - For Canadian provinces: same as U.S. with adjustments for differences in delivered cost
- Also lays out how electric prices are forecast

AEO Price Projections - Imported Crude Oil ($/bbl)

	2005		2010	2020	2030
2007 High Price Case	$49.19		$62.53	$82.60	$92.83
2008 High Price Case	$59.05	*	$69.19	$88.31	$96.42

source: Table C5, AEO 2007 & 2008 (wgt'd average price to refineries)

* $59.05 figure is for 2006

4.5 Electricity Sector Data

- Now gives specific sources of public data used for electric generating capacity and operation data (e.g., table below)
- E3 generation cost projections from 11/07

Input	Sources Used/Available
Plant type	Annual Electric Generator Report: EIA Form 860 (2006) Canadian IPM® Base Case 2004[18] Natural Resources Canada, Canada's Energy Outlook: Reference Case 2006[19] Supplemented by National Energy Board info.
Plant capacity	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Plant historical generation	EIA Form 906/920 (2001-2006) Total generation output by plant type for California from CEC Canada: as above
Plant fuel type	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Plant Heat Rate	EIA Form 906/920 (2001-2006) Canada: as above

Changes in E3 New Generation Cost Estimates

Table shows 2/08 estimates minus 11/07 estimates.

I.e., increase in black and decrease in (red).

Technology	cost basis yr 2005 Total Capital Costs $/kW	Fixed O&M ($/kW-yr)	Variable O&M ($/MWh)	Capacity Factor	Nominal Heat Rate
	2008$	2005	2005		
Biogas	(442)	(31.50)	(1.19)	5%	(2,082)
Biomass	(648)	(14.82)	1.76	5%	6,598
Geothermal	236	(2.08)	(1.20)	0%	NA
Hydro - Small	(9)	(0.86)	2.36	a/	NA
Solar - Thermal	(395)	(14.37)	(1.20)	a/	NA
Wind	21	(8.49)	(1.20)	a/	NA
Coal ST	192	(7.09)	3.12	0%	0
Coal IGCC	221	(10.64)	1.55	0%	0
Coal IGCC w/ CCS	1,026	(12.18)	2.98	0%	0
Gas CCCT	(176)	(2.96)	1.20	0%	0
Gas CT	(13)	(3.60)	2.16	0%	0
Hydro - Large	1,044	4.14	2.67	a/	NA
Nuclear	1,000	(19.12)	(0.73)	0%	0

a/ Capacity factor is at upper end of range in 11/07 E3 estimates.

4.6 Transportation

- The description of transportation sector modeling has been expanded and more data sources provided (e.g., table below).

Input	Sources Used/Available
All tables below are from ***Transportation Energy Data Book*** *(Edition 26, 2007)*[24] *published by the US Department of Energy's Oak Ridge National Laboratory.*	
Average fuel economy	Tables 4.17 and 4.18
New Vehicle Efficiency	Tables 4.7 and 4.8
Scrap/Survival Rates	Tables 3.8, 3.9 and 3.10
Freight Truck Fuel Economy	Tables 5.1 and 5.2
Bus Efficiency	Table 2.13
Rail Efficiency – Passenger	Table 9.10 and 9.11
Rail Efficiency - Freight	Table 9.8
Marine - Freight	Table 9.5
Air Travel	Table 9.2

4.7 Built Environment

- The description of the modeling of the built environment has been expanded and supplemented by new Appendix J (e.g., table below).

Residential Device Standards	
Equipment	**Effective Efficiency Standard**
Gas hot water from 1990 to the final year	59%
Oil hot water from 1990 to the final year	51%
Electric hot water from 1990 to the final year (inc.tank losses)	92%
LPG hot water from 1990 to the final year	59%
Electric air conditioning for 1990	260% COP = 2.6
Electric air conditioning for 1991	261% COP = 2.61
Electric air conditioning for 1992 to 2006	265% COP = 2.65
Electric air conditioning for 2007 to the final year	344% COP = 3.44

Efficiency and Cost Data

- Section 4.7 describes how efficiency choices are made in in the “Built Environment” (residential, commercial and industrial buildings).
- Appendix J presents efficiency and cost data related to the built environment.
- Historic energy use and survey data are used to establish patterns of past & current energy use by sector/end-use.
- Increased requirements for energy services are driven by economic and population changes.
- Additional services can be met using different fuels and at varying levels of efficiency (i.e., Gas or electric water heating, a medium or high efficiency furnace).

Efficiency and Cost Data (cont'd.)

- New investments are assumed to achieve the level of efficiency specified in existing standards (i.e., Residential Device Standards – new gas furnaces must be at least 80% efficient).
- Model recognizes that standards change over time.
- Higher efficiency can be achieved at a cost (i.e., Device Capital Cost in $/mmBtu/Year).
- Capital costs are presented on annualized basis based on the expected life of the investment.
- Upper limit for available efficiency specified as Maximum Device Efficiency (i.e., Natural gas furnaces cannot exceed 97% efficiency).

Efficiency and Cost Data (cont'd.)

- Model evaluates efficiency choice based on energy costs, capital and operating costs within range between minimum standard and maximum efficiency available.
- All standards, maximum efficiency levels, costs and equipment life are specified for each fuel/end-use combination.
- Energy choices are modeled based on both price and non-price factors.
- Non-price factors include market imperfections as well as non-energy considerations (i.e. equipment features, etc.)
- Following slide illustrates model structure used to determine energy demands.

Efficiency and Cost Data (cont'd.)

Example: Additional water heating requirement

- Model would consider fuel choice – ie. natural gas, electricity, LPG, oil, solar, etc.
- Portion which chooses natural gas for water heating can choose any level of efficiency from 59% to 86%
  (see line 1 in table on slide 9 and line 2 in table of Maximum Device Efficiency on page 79 of Assumptions Book)
- The model would compare the cost of the new water heater ($18.50/mmBtu/Year) and the additional O&M costs ($0 in this case) vs. the cost of energy saved over the assumed life of the water heater (15 years).
- For a household using 18 mBtu/year for water heating, moving from 60% to 80% would save about 4.5mBtu/year. The $83.25 cost of this increase (4.5mBtu x $18.50/mBtu/year) would be compared to the value of the energy saved as part of the efficiency decision.

Transportation Choices:

- Transportation choices are conceptually similar to other efficiency choices.
- Economic activity and population changes drive demand for transportation for each geographic area.
- Existing transportation patterns and energy use are established by historic data.
- Consumers can choose between transportation modes (i.e., Rail, marine, trucking for freight;
  Air, train, bus, personal vehicles, etc. for passenger travel).
- Non-price factors including consumer preferences, business requirements and the costs of each transportation mode are represented in model.

Transportation Choices:

- Personal vehicle choices are made in similar manner
- Consumers consider capital and operating costs, fuel choices/costs, and efficiency.
- Costs are presented in the model in terms of capital cost per mile traveled for different vehicle classes (light, medium and heavy passenger vehicles, motorcycles, etc.).
- Larger vehicles with higher capital costs and lower efficiencies therefore have higher cost per vehicle mile traveled.
- Historically non-price factors (i.e., Vehicle size, performance and appearance) have dominated decisions.

4.8 Programs/Policies Incorporated in Reference Case

- This description of "current policies" reflected in the Reference Case is now supplemented by new Appendix I containing state RPS provisions.

State or Prov	Target	Policy
AZ	15% of generation from renewables by 2025	Renewable Energy Standards (formerly known as the Environmental Portfolio Standard) on February 27, 2006. The new rules require regulated electric utilities to generate 15% of their energy from renewable resources by 2025. By 2012, at least 30% of the sta
CA	Major utilities 20% from renewable sources by 2010 on a retail sales basis	California's Investor-Owned Utility, Electric Service Providers, Small and Multi-Jurisdictional Utilities and Community Choice Aggregators to produce at least 20% of their electricity using renewable sources by 2010 based on renewable retail sales. Eligib
MT	10% of generation load to be renewable by 2010; 15% by 2015	Each investor-owned and public utility should: Meet 20% of its load using renewable energy resources by 2020, increasing to 25% by 2025. The legislation contains a cost cap that encourages utilities to invest in renewable generation that is cost competiti
NM	10% of generation by 2011; 15% renewable by 2015; 20% by 2020	Applies to Investor-Owned Utility, Rural Electric Cooperative. IOUs: 15% power generation from renewable sources and 20% by 2020. RECs: 10% by 2020. This legislation expands on NM's current renewable portfolio standard requiring that 10% of the state's en

4.9 (New) Complementary Policies

- Contains a description of policies that make up the Complementary Policies scenario.

  - **Vehicle Miles Traveled –** Assumes that policies will be introduced to reduce VMT in all WCI partner jurisdictions by 2% from BAU levels in 2020.

  - **Energy Efficiency Programs –** Assumes that energy efficiency programs will be undertaken in all WCI partner jurisdictions to reduce energy use (electricity, natural gas, fuel oil and propane) by 1% per year below the reference forecast between 2011 and 2020.

  - **California Clean Cars –** Assumes that all WCI partners will implement the California clean car standards as currently formulated, along with Phase 2 standards currently contemplated by the California ARB.

Changes to Appendices

- Appendix A has been modified to better explain the ENERGY 2020 model.
- Appendix B has been modified to clarify the description of some of the original sources of the default data and how the data have been updated over time.
- New Appendix C now contains Phase 2 data for Arizona, California, New Mexico, and Washington.
- Appendix D (formerly “C”) presents inter-regional transmission capacity based on FERC sources, now supplemented with information supplied by the EMT.
- Appendix E (formerly “D”) presents more description of various datasets used in ENERGY 2020, i.e., the dimensions of the variables that delineate the scope and detail of the model.

Changes to Appendices (cont.)

- New Appendix F contains planned or committed coal capacity additions in the post-2005 period, based on public data sources and a thorough review by the EMT.
- Appendix G (formerly “F”) presents new generation performance and cost assumptions (unchanged - still based on the E3 report for California).
- Appendix H (formerly “G”) presents global warming potential coefficients for the six greenhouse gases (unchanged).
- New Appendix I summarizes Renewable Portfolio Standard provisions among the WCI partners.
- New Appendix J presents efficiency and cost data related to the built environment.

Western Climate Initiative

September 23, 2008

To All Interested Parties:

In February 2007, the governors of Arizona, California, New Mexico, Oregon and Washington kicked off this ambitious effort to design a regional, market-based approach for reducing greenhouse gas emissions. Since that time, the governors of Montana and Utah and the premiers of British Columbia, Manitoba, Ontario, and Quebec have joined in this historic effort and today we are pleased to release our "Design Recommendations for the WCI Regional Cap-and-Trade Program."

Each of our states and provinces recognizes the need to take action now to address the threats posed by global climate change. The design recommendations being released today are an important milestone in our collective effort to respond to the leadership role states and provinces have established on this issue.

While we are pleased to reach this milestone, we recognize that much more remains to be done to move from program design to program implementation. Over the next couple of months, we will prepare a detailed work plan to guide the next phase of the Western Climate Initiative. The work plan will identify the priorities for the coming year and will provide information on how all interested parties can continue to engage in our process.

As we developed these recommendations over the last 18 months, we benefited greatly from the input provided by a wide variety of stakeholders representing business, industry, labor, and environmental groups. The dedication of our state and provincial staff and the assistance of our technical and policy advisors were also critical to our success.

On behalf of the governors and premiers of the Western Climate Initiative, we again thank you for your interest in our work and for your many contributions to date. We look forward to working with you as we move into the next phase of this initiative. We know that together we can meet the challenge of climate change while enhancing overall environmental health and economic vitality throughout the region.

Sincerely,

The WCI Partners

Acknowledgements

Those of us who were honored to represent our states and provinces in designing the WCI cap-and-trade program owe a debt of gratitude to the advisors who helped us throughout the process: Franz Litz, Nicholas Bianco, and Jonathan Pershing of the World Resources Institute, Judi Greenwald, Anna Motschenbacher, Joshua Bushinsky, and Steve Caldwell with the Pew Center on Global Climate Change, Tom Peterson, Jeff Wennberg, Ken Colburn, and June Taylor with the Center for Climate Strategies, and Michael Lazarus with the Stockholm Environment Institute.

Sam Hitz, Tymon Lodder, Jill Gravender and Executive Director Diane Wittenberg from The Climate Registry and Paula Fields with ERG were instrumental in helping develop the essential elements for reporting.

Jill Duggan who heads the United Kingdom's International Emissions Trading office and her colleague, Tim McRae, shared expertise and experiences with the design and implementation of the EU ETS. Similarly, Mr. Litz and Mr. Wennberg worked for New York and Vermont respectively during the design of the Regional Greenhouse Gas Initiative (RGGI) and helped us build upon that experience.

Rob Greenwood and Bill Ross of Ross and Associates provided exceptional facilitation services during the last several negotiating sessions of the WCI, helping us get to success. Lydia Dobrovolny, also with Ross and Associates, provided critical support during the final negotiating sessions.

Karl Hausker, Glen Wood and their colleagues at ICF International and Jeff Amlin at Systematic Solutions, Inc. provided assistance to the WCI Economic Modeling Team as they evaluated a number of important questions related to the costs and benefits of the WCI cap-and-trade program.

Tim Smith with Waggener Edstrom Worldwide developed our communication tools with amazing speed. Deb Kinsley with the Western Governors' Association provided unparalleled service in making all of the arrangements for our Partner meetings and stakeholder workshops. We want to also thank Marcus Schneider and his colleagues at the Energy Foundation who provided the seed money to get this effort underway.

Our biggest thanks go to Pat Cummins with the Western Governors' Association. As our project manager, he kept us on track, on course and within budget. We simply would not have gotten through the process without Pat's assistance and support.

Section 1: Design Recommendations for the WCI Regional Cap-and-Trade Program

The Western Climate Initiative (WCI) jurisdictions are recommending a design for a broad cap-and-trade program as part of a comprehensive regional effort to reduce emissions of global warming pollution to achieve the WCI 2020 regional goal. The recommended design will provide opportunities to obtain low-cost emission reductions through emission trading, allowance banking, and inclusion of an offsets component. The design is also intended to mitigate economic impacts, including impacts on consumers, income, and employment. The design balances all principles adopted by the WCI Partner jurisdictions to maximize total benefits throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts. Finally, the WCI Partner jurisdictions have designed a program that can stand alone, provide a model for, be integrated into, or be implemented in conjunction with programs that might ultimately emerge from the federal governments of the United States and Canada.

1. Scope[1]

1.1. Greenhouse gases (GHGs) covered: Carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

1.2. Emissions covered:

1.2.1. Electricity generation, including emissions from electricity generated outside the WCI jurisdictions (or generated by a federal entity or on tribal lands) that is delivered into a WCI Partner jurisdiction for consumption in that WCI Partner jurisdiction;

1.2.2. Combustion at industrial and commercial facilities;

1.2.3. Industrial process emission sources[2], including oil and gas process emissions;

1.2.4. Residential, commercial, and industrial fuel combustion at facilities with emissions below the WCI thresholds3 (as described below in the Point of Regulation section, these emissions will be covered upstream). Coverage of these emissions will begin at the start of the second compliance period;

---

[1] The *scope* defines the GHG emissions that are included in the cap-and-trade program, including the emission sources and GHG emissions that fall under the cap.

[2] As used here, process emissions include emissions from chemical, biological, and other non-combustion processes. These emissions may be deliberate (e.g., vented), fugitive (e.g., leaked), or accidental.

[3] *Thresholds* are emission levels that determine when a particular entity or facility will have a compliance obligation under the cap-and-trade program.

1.2.5. Transportation fuel combustion (as described below in the Point of Regulation section, these emissions will be covered upstream.) Coverage of these emissions will begin at the start of the second compliance period.

1.2.6. The WCI Partner jurisdictions recommend covering combustion from transportation, residential, commercial, and industrial (including electricity) fuel sources with the expectation that the individual WCI Partner jurisdictions will:

- Mitigate the economic impact on consumers;
- Implement other policies that will reduce GHG emissions from the transportation sector and reduce demand for transportation fuels (such as vehicle standards, smart growth, low carbon fuel standards, transit options, etc.); and
- Address any issues associated with the point of regulation and its implementation.

1.3. For biomass determined by each WCI Partner jurisdiction to be carbon neutral, the carbon dioxide emissions from the combustion of that biomass are not included in the cap-and-trade program, except for purposes of reporting.

1.4. Carbon dioxide emissions from the combustion of pure biofuels, or the proportion of carbon dioxide emissions from the combustion of biofuel in a blended fuel (e.g., B20 or E85), are not included in the cap-and-trade program, except for purposes of reporting.

1.5. Prior to program start, the WCI Partner jurisdictions will assess whether and how to include upstream emissions from biofuel and fossil fuel production, taking into consideration the potential for emissions leakage, the potential role of other policies (such as a low carbon fuel standard), consistent treatment among fuels, and other factors (such as practicality of implementation).

1.6. As described in Section 5, Role of Other Policies, WCI Partner jurisdictions acknowledge that individual jurisdictions may utilize other fiscal measures such as British Columbia's carbon tax, to address transportation fuels and fuel use by residential and commercial sources that contribute to achieving overall comparable GHG emission reductions and internalize the price of carbon as expected through the regional cap-and-trade program.

1.7. Adequate quantification methods will be established for emissions sources prior to including them in the program.

2. Point of Regulation[4]

2.1. Industrial sources (both process and combustion) with emissions above the threshold: The point of regulation will be at the point of emission.

2.2. Electricity: The point of regulation is the First Jurisdictional Deliverer (FJD). For sources within WCI jurisdictions, the FJD is the generator. For power that is generated outside the WCI jurisdictions (or generated by a federal entity or on tribal lands) for consumption within a WCI Partner jurisdiction, the FJD is the first entity that delivers that electricity over which the consuming WCI partner jurisdiction has regulatory authority.

2.3. Residential, commercial, and industrial fuel combustion at facilities with emissions below the threshold: The point of regulation will be where the fuels enter commerce in the WCI Partner jurisdictions, generally at a distributor. The precise point is to be determined and may vary by jurisdiction.

2.4. Transportation fuel combustion: The point of regulation will be where the fuels enter commerce in the WCI Partner jurisdictions, which for liquid fuels is generally at the terminal rack, final blender, or distributor. The precise point is to be determined and may vary by jurisdiction.

3. Thresholds for Coverage Under the Cap-and-Trade Program

3.1. Emission threshold: 25,000 metric tons of carbon dioxide equivalents (CO_2e) annually defines the entities or facilities (e.g., First Jurisdictional Deliverer, fuel distributor, fuel blender) that will have a regulatory compliance obligation under the cap-and-trade program. Mandatory reporting data may be used to adjust this threshold for specific industries where necessary. Additional analyses will be performed to determine if adjustments to the threshold are needed to ensure sufficient coverage or to address competitiveness issues within individual sectors prior to the beginning of the program (e.g., because different WCI Partner jurisdictions may have the same industry but with different sized sources).

3.2. A method will be developed to prevent entities or facilities from avoiding coverage, such as by breaking themselves into separate power deliverers that each deliver electricity with emissions below the threshold.

4. Program Expansion

4.1. Future Program Expansion: The scope of the cap-and-trade program is capable of expanding over time (including possibly adjusting applicability thresholds). Prior to each compliance period, the WCI Partner jurisdictions will review whether to bring new sources into the program and, if so, which ones.

[4] The *point of regulation* is the entity or facility with the compliance obligation, i.e., the requirement to surrender sufficient GHG allowances to cover actual emissions during the compliance period. An *allowance* is the tradable permit to emit one metric ton of GHG emissions in CO_2e. The term *entity* is generally used when the point of regulation is upstream of the point of emissions, to describe a company that has an obligation to surrender allowances to cover the carbon content of the fuel the company is moving through commerce, or when the point of regulation is at the First Jurisdictional Deliverer, to describe a company that has an obligation to surrender allowances to cover the emissions attributable to the generation of power the company is importing. When the point of regulation is at the point where the emissions occur, the term *facility* is generally used. The term *source* is used to refer to emissions from either a facility or an entity.

5. Role Of Other Policies[5]

5.1. The role of other GHG-reducing policies is to help the WCI Partner jurisdictions achieve their 2020 reduction goal and provide other benefits. Those policies will work in concert with the cap-and-trade program and may apply to any source of GHG emissions.

5.2. Carbon Tax and Other Fiscal Measures:

5.2.1. The WCI Partner jurisdictions agree that individual jurisdictions may use fiscal measures that contribute to achieving overall comparable GHG emission reductions and internalize the price of carbon as expected through the regional cap-and-trade program for transportation and residential/commercial fuels.

5.2.2. British Columbia currently has a carbon tax. By 2012, the WCI Partner jurisdictions will determine the mechanism for integrating the cap-and-trade program with the BC carbon tax.

6. Setting the Regional Cap[6]

6.1. The aggregate regional cap for the cap-and-trade program will:

6.1.1. Equal the sum of the WCI Partner jurisdictions allowance budgets (as referenced in Section 7.1).

6.1.2. Include annual caps (with 3-year compliance periods7) from the beginning of the program in 2012 through 2020. The annual caps will be set in advance of the program start in 2012 so that the total number of allowances issued in each 3-year compliance period through 2020 is known.

6.1.3. Decline over time. The regional cap trajectory for covered sectors will be a straight line from the year of initial coverage (2012 for some sources and 2015 for other sources) to 2020.

6.2. 2012: The initial regional cap will be set at the best estimate of expected actual emissions for those sources covered in the initial year of the program (i.e., 2012) as calculated through the Partner allowance budgets as described in 7.2.

[5] *Other policies* include complementary policies and alternative policies. A *complementary policy* is used in this context to mean policies other than a cap-and-trade program that aid in the goal of achieving emissions reductions for capped or uncapped sources. *An alternative policy* is a policy that is employed in lieu of a cap-and-trade program to achieve emissions reductions for one or more sources.

[6] The *regional cap* is the overall limit on total emissions set for the total emissions included in the cap-and-trade program.

[7] The 3-year compliance periods are 2012-2014, 2015-2017, and 2018-2020.

6.3. 2015: The regional cap in 2015 will be set by adding the best estimate of expected actual emissions in 2015 from transportation fuels and residential, commercial, and industrial fuels (and any other sectors or sources that may be added to the program for the first time in 2015) to the emissions trajectory for the sources first included in the program in 2012.

6.4. 2020: The regional cap for 2020 will be set so that reductions achieved by the cap plus reductions from other GHG reduction policies for uncapped sources will achieve the WCI regional 2020 goal.

6.5. Post-2020 caps: The WCI Partner jurisdictions will set these regional caps not less than three years in advance.

6.6. Once established, the regional cap for each compliance period will not be adjusted except as necessary to account for:

- Changes in WCI membership;
- Changes in scope or thresholds; or
- Data found to be incorrect or inaccurate that was used to determine the cap, which may become apparent, for example, after the start of mandatory reporting.

Any adjustments will be made prior to the beginning of the compliance period.

7. Apportionment[8]

7.1. Each WCI Partner jurisdiction will have an annual allowance budget within the declining regional cap from 2012 to 2020. The annual WCI Partner jurisdiction allowance budget for each year through 2020 will be set prior to the start of the program in 2012.

Each WCI Partner jurisdiction's 2020 allowance budget will be derived from its individual WCI Partner jurisdiction goal[9] used for purposes of the program, accounting for other policies described in Section 5.[10]

There are instances in which electricity is generated in one WCI Partner jurisdiction, but consumed in another WCI Partner's jurisdiction, giving rise to the possibility of double-counting emissions. WCI Partner jurisdictions in such situations will agree to an equitable solution in the context of the WCI cap-and-trade program design.

7.2. For 2012, each WCI Partner jurisdiction's allowance budget will be based on the best estimate of expected emissions for sources covered in the cap-and-trade program in the WCI Partner jurisdiction in 2012. The estimate of expected actual emissions in 2012 will be developed using the best available data (including any available mandatory reporting data) and by accounting for expected changes in emissions in 2012. Population growth, economic growth,

---

[8] *Allowance apportionment* describes the Partners' budget or share of WCI region-wide GHG emission allowances. Allowance budgets must be set for each Partner jurisdiction.

[9] Partner goals are those reduction goals or limits that have been established by each individual WCI Partner jurisdiction.

[10] By the end of 2009, Oregon will determine its cap-and-trade specific Partner goal at a level which is at least as stringent as the WCI regional goal.

voluntary and mandatory emission reductions, and other factors will be considered in making the estimate. Each WCI Partner jurisdiction's allowance budget will be adjusted to account for the production and consumption of electricity megawatt hours within each WCI Partner jurisdiction, population growth, and the share of total WCI Partner jurisdictions emissions in 2001 through 2005. Each WCI Partner jurisdiction will make a one-time contribution of 1% of their 2012 budget to be allocated to make these adjustments.

7.2.1. For 2015, each WCI Partner jurisdiction's allowance budget will be set by adding the best estimate of expected actual emissions in 2015 from transportation fuels and residential, commercial, and industrial fuels (and any other sectors or sources that may be added to the program for the first time in 2015) to the emissions trajectory for the sources first included in the program in 2012. The estimate of expected actual emissions in 2015 will be developed using the best available data (including any available mandatory reporting data) and by accounting for expected changes in emissions in 2015 for the sources added to the cap in 2015. Population growth, economic growth, voluntary and mandatory emissions reductions, and other factors will be considered in making the estimate.

7.2.2. From 2015-2020, the trajectory for each WCI Partner jurisdiction's annual allowance budget for covered sectors will be a straight line from the year of initial coverage (2012 for some sources and 2015 for other sources) to 2020.

7.3. For years post-2020, the WCI Partner jurisdictions will set allowance budgets not less than three years in advance.

7.4. Once established, each WCI Partner jurisdiction's allowance budget will not be adjusted except as necessary to account for:

- Changes in WCI membership;
- Changes in scope or thresholds; or
- Data found to be incorrect or inaccurate that were used to determine the cap or the WCI Partner jurisdiction allowance budgets, which may become apparent, for example, after the start of mandatory reporting.

Such adjustments will take effect at a regionally coordinated and designated time, such as at the beginning of a compliance period.

7.5. WCI Partner jurisdictions will recognize within their own jurisdictions allowances issued by other WCI Partner jurisdictions so that all WCI allowances are of equivalent use and fungible throughout the WCI region, regardless of which WCI Partner jurisdiction issues the allowances.

8. Distribution of Allowances[11]

8.1. Distribution of Allowances by WCI Partner jurisdictions: Once the allowance budget has been established for each WCI Partner jurisdiction, allowances will be issued by each WCI Partner within its own jurisdiction. Each allowance will be equal to one metric ton of carbon dioxide equivalent.

8.2. The WCI Partner jurisdictions agree that a portion of the value represented by each WCI Partner jurisdiction's allowance budget (for example, through set-asides of allowances, a distribution of revenues from the auctioning of allowances, or other means) will be dedicated to one or more of the following public purposes which are expected to provide benefits region wide:[12]

- Energy efficiency and renewable energy incentives and achievement;
- Research, development, demonstrations, and deployment (RDD&D) with particular reference to carbon capture & sequestration (CCS); renewable energy generation, transmission and storage; and energy efficiency;
- Promoting emission reductions and sequestration in agriculture, forestry and other uncapped sources; and
- Human and natural community adaptation to climate change impacts.

8.3. The remaining portion of the value represented by each WCI Partner jurisdiction's allowance budgets will be used as that jurisdiction sees fit. WCI Partner jurisdictions may consider objectives such as:

- Reducing consumer impacts, especially for low-income consumers;
- Providing for worker transition and green jobs;
- Achieving emission reductions in communities that experience disproportionate environmental impacts;
- Supporting community-wide efforts funded by local governments to reduce GHG emissions;
- Providing transition assistance to industries;
- Recognizing early actions to reduce emissions; and/or
- Promoting economic efficiency.

8.4. In advance of the first compliance period, and at least one year before the beginning of each relevant compliance period thereafter, each WCI Partner jurisdiction will advise the other WCI Partner jurisdictions how it intends to distribute or retire allowances so that all WCI Partner jurisdictions' plans can be made public in a coordinated fashion.

8.5. If analysis demonstrates that allocations to a particular sector should be treated uniformly by some WCI Partner jurisdictions in order to address competition among like facilities or entities within that sector, and if from that analysis some WCI Partner jurisdictions determine that it is necessary to address those competitiveness issues between the WCI Partner jurisdictions where the facilities or entities operate, those WCI Partner jurisdictions will

---

[11] *Allowance distribution* is the Partners' initial distribution of GHG emission allowances into the market.

[12] This will recognize pre-existing commitments to action and legislative requirements on use of revenue (e.g., through BC's Climate Action Plan and Carbon Tax).

standardize the distribution of allowances as necessary to address competitive impacts sufficiently, in advance of the first compliance period.

- Potential sectors where analysis to consider similar treatment is appropriate include those with process (non-combustion) emissions where the greatest emission reduction potential is associated with large technology changes and high GHG emission intensity, such as aluminum, steel, cement, lime, pulp and paper, and oil refining.
- Some WCI Partner jurisdictions may also decide that based on analysis of competitive factors in the electricity sector, distribution of allowance value or auction revenues in that sector should be standardized between those WCI Partner jurisdictions where competitive issues are recognized.

8.6. A WCI Partner jurisdiction will allocate or retire all the allowances in its allowance budget by the end of the applicable compliance period. Except as provided in Section 8.10, a WCI Partner jurisdiction will not hold allowances beyond the end of the compliance period.

8.7. Recognizing the WCI Partner jurisdictions objective of standardizing treatment of some sectors, and acknowledging the differences in the appropriate use of auctions by sector:

8.7.1. Consistent with applicable state and provincial law, the WCI Partner jurisdictions will auction a minimum of 10% of the allowance budget in the first compliance period beginning in 2012. This minimum percentage will increase to 25% in 2020. The WCI Partner jurisdictions aspire to a higher auction percentage over time, possibly to 100%.

8.7.2. Each WCI Partner jurisdiction has discretion to auction a greater portion of its allowance budget as it sees fit.

8.7.3. If a WCI Partner jurisdiction cannot auction allowances, that Partner jurisdiction will notify the other WCI Partner jurisdictions at least six months before the beginning of auctions scheduled for each compliance period. The fact that a WCI Partner jurisdiction cannot auction allowances shall not preclude the other Partner jurisdictions from doing so.

8.8. To the extent WCI Partner jurisdictions auction allowances, those jurisdictions will undertake auctions through a coordinated regional auction process by which each participating WCI Partner jurisdiction will auction allowances throughout the WCI region and receive their proceeds from the auction.

8.9. By the end of 2009 the WCI Partner jurisdictions will develop a design for the coordinated regional auction process. The WCI Partner jurisdictions will design the auction process to consider and prevent market manipulation.

8.10. To manage the risk of inadvertently setting the program cap higher than intended relative to emissions covered by the program, a reserve or minimum price will be established for a portion of the auctioned allowances. Consistent with applicable state and provincial law, this portion will equal 5% of allowances issued by any WCI Partner jurisdiction. If any of these allowances when offered at auction are not purchased at or above the reserve or minimum price, a fraction of the unsold ones will be retired. The unsold allowances that are not retired may be auctioned in later compliance periods or retained by the individual WCI Partner jurisdictions for use as each sees fit in later compliance periods, as determined in advance by the WCI Partner jurisdictions. Any WCI Partner jurisdiction that does not participate fully in the auction with the reserve or minimum price will retire the same proportion of its allowance budget as those retired by the WCI Partner jurisdictions that participated in the auction. The percentage of the allowance budgets, the reserve price, the fraction of unsold allowances that will be retired, and the fraction of unsold allowances that will be retained by the individual WCI Partner jurisdictions will be determined as part of the auction design.

8.11. Early Reduction Allowances. The program will encourage entities and facilities included under the cap to reduce GHG emissions before the start of the first compliance period in 2012.

8.11.1. Each WCI Partner jurisdiction may issue Early Reduction Allowances for certain emissions reductions at covered entities and facilities within its jurisdiction that are achieved after January 1, 2008 and before January 1, 2012.

8.11.2. By the end of 2009, the WCI Partner jurisdictions will jointly establish criteria to determine which early reductions will be eligible for Early Reduction Allowances. The criteria will ensure that the reductions are voluntary, additional, real, verifiable, permanent and enforceable.

8.11.3. Each WCI Partner jurisdiction that issues Early Reduction Allowances will do so in 2012. Any Early Reduction Allowances issued will be in addition to each WCI Partner jurisdiction's 2012 allowance budget.

8.11.4. These allowances shall be treated like other allowances in the cap-and-trade program.

8.12. Other Early Actions and Set-Asides: Each WCI Partner jurisdiction has discretion to recognize early actions other than those under Section 8.11, or otherwise set-aside allowances for distribution. Recognition for early action or set-asides under this subsection will come from within the cap and will come out of the individual WCI Partner jurisdiction's allowance budget.

8.13. Banking: Purchasers and covered entities or facilities, and parties who otherwise obtain allowances, will be allowed to bank allowances without limitation, except to the extent that restrictions on the number of allowances any one party may hold are necessary to prevent market manipulation.

8.14. Borrowing: Borrowing of allowances from future compliance periods will not be allowed.

8.15. Compliance Periods: Each compliance period will be three years long.

9. Offsets,[13] and Allowances From Other Systems

9.1. The WCI Partner jurisdictions will include a rigorous offsets system. The primary role of the offsets system is to reduce the compliance costs for the cap-and-trade program, while ensuring the environmental integrity of the cap.

9.2. The WCI Partner jurisdictions will limit the use of all offsets, and allowances from other GHG emission trading systems that are recognized by the WCI Partner jurisdictions, to no more than 49% of the total emission reductions from 2012-2020 in order to ensure that a majority of emission reductions occur at WCI covered entities and facilities. Each WCI Partner jurisdiction will have the discretion to set a lower percentage limit. All offsets and non-WCI allowances must meet the rigorous criteria established by the WCI Partner jurisdictions.

The WCI Partner jurisdictions will establish criteria to ensure that all offset projects used to meet a compliance obligation result in a GHG reduction, removal or avoidance that is real, surplus/additional, verifiable and permanent or that meets a comparably rigorous standard as described in Section 9.7 below. Offset projects must also be enforceable by the individual WCI Partner jurisdiction that is issuing the credit and the credit must be verifiable by the individual WCI Partner jurisdiction that is accepting it. The criteria will ensure that the quantification of the GHG reduction, removal, or avoidance is accurate and not double counted. The standards and processes for approving offset projects will be developed and implemented in an open and transparent manner that will be well-defined in advance of the start of the cap-and-trade program.

9.3. The WCI Partner jurisdictions encourage the development of offset–projects located inside WCI jurisdictions for compliance purposes in the WCI cap-and-trade regulatory program in order to capture collateral benefits associated with some offsets projects, such as health, social, and environmental benefits.

9.4. The WCI Partner jurisdictions have identified the following list of project types as a priority for investigation and development to participate in the offset system. Making these project types a priority means the WCI Partner jurisdictions are interested in understanding if they are suitable for the offset system, if they will meet the criteria for environmental integrity, and if adequate protocols/methodologies for their quantification and monitoring can be adapted or developed. Priority does not mean these project types are guaranteed to be in an offset system. Project types that reduce emissions that would eventually be covered by the cap-and-trade system would only be eligible until that coverage begins. Project types that reduce emissions covered by the cap-and-trade system would not be eligible to create offsets because the result would be a double counting of the emission reduction. The list is in alphabetical order and does not directly or indirectly represent a ranking or order of preference:

[13] *Offsets* are emission reduction projects undertaken to address emissions not included in a cap-and-trade program. An offset mechanism enables covered entities to offset their own emissions by purchasing emission reduction credits generated through projects that address emissions not covered by the cap.

- Agriculture (soil sequestration and manure management);
- Forestry (afforestation/reforestation, forest management, forest preservation/conservation, forest products); and
- Waste management (landfill gas and wastewater management).

9.5. Starting in 2009, the WCI Partner jurisdictions will coordinate to review, develop, and approve, as appropriate, protocols for the project types that meet the necessary criteria for inclusion. The WCI Partner jurisdictions will use offset protocols that are standardized to the extent possible and make use of (or adapt if needed), existing protocols as appropriate. The WCI Partner jurisdictions will also initiate the establishment of a process during 2009 to coordinate the review and approval of other project types and protocols proposed by project developers. The WCI Partner jurisdictions will establish rigorous criteria for inclusion of offsets in the WCI program.

9.6. WCI Partner jurisdictions will recognize offsets meeting the WCI criteria within their own jurisdictions regardless of which WCI Partner jurisdiction issued them, so that all WCI offsets are of equivalent use and fungible throughout the WCI region. Offsets not meeting the WCI criteria will not be accepted for compliance purposes.

9.7. WCI Partner jurisdictions may approve and certify offset projects located throughout the United States, Canada, and Mexico where such projects are subject to comparably rigorous oversight, validation, verification, and enforcement as those located within the WCI jurisdictions. WCI Partner jurisdictions will not approve offset credits for GHG reductions in developed countries (Annex 1 countries in UN Framework Convention on Climate Change) for projects that reduce, remove, or avoid emissions from sources that within WCI Partner jurisdictions are covered by the cap-and-trade program.

9.8. The WCI Partner jurisdictions may accept offset credits from developing countries through the Clean Development Mechanism (CDM) of the Kyoto protocol, and the WCI Partner jurisdictions may establish added criteria to ensure similar rigor to WCI approved/certified offset projects or other requirements, such as international offset standards, as appropriate to enable use of these offset credits in the cap-and-trade program.

9.9. The offset protocols used by the WCI Partner jurisdictions will meet rigorous criteria to preserve the environmental integrity of the overall cap-and-trade program.

9.10. WCI Partner jurisdictions do not intend to regulate or restrict the existing voluntary market in offsets, to restrict the sale of offsets from projects located within a WCI Partner jurisdiction, or to place restrictions on ownership of offsets projects located within WCI Partner jurisdictions.

10. Reporting

10.1. Mandatory measurement and monitoring for the six included GHG emissions will commence in January 2010 for all entities and facilities subject to reporting. Reporting of 2010 emissions will begin in early 2011.

10.2. The entities and facilities subject to reporting are those with annual emissions equal to or greater than 10,000 metric tons of CO_2e. Where fuel combustion emissions are covered upstream (e.g., emissions from transportation fuel combustion and emissions from fuel combustion at residential, commercial, and industrial facilities with emissions below the threshold) the reporting threshold will apply to entities (e.g., fuel distributors and blenders) based on the expected combustion emissions from the fuels distributed. In some limited instances the threshold may be based on other parameters, such as throughput or capacity, as long as these thresholds represent the equivalent of, or are lower than, the 10,000-metric-ton threshold..

10.3. WCI Partner jurisdictions will require third party verification of reported emissions from entities and facilities that will be included under the cap.

10.4. Prior to the start of the mandatory reporting program, the WCI Partner jurisdictions will establish the essential requirements for reporting by all entities and facilities required to report in each of the WCI Partner jurisdictions.

10.5. As each WCI Partner jurisdiction collects additional emissions data from entities and facilities required to report, data will be made available to all WCI Partner jurisdictions for review and consideration for possible expansion of the cap-and-trade program.

10.6. Nothing in the WCI program design limits the discretion of any WCI Partner jurisdiction to require reporting earlier, at lower thresholds, or for entities and facilities not covered by the cap-and-trade program.

11. Start Date for Cap-and-Trade

11.1. The cap-and-trade program will launch January 1, 2012.

12. Compliance and Enforcement

12.1. Each WCI Partner jurisdiction will retain and/or enhance its regulatory and enforcement authority and responsibilities to enforce compliance with the cap-and-trade program within its own jurisdiction.

12.2. Each covered entity or facility will demonstrate compliance with the cap-and-trade program by surrendering sufficient allowances by July 1 of the year following the end of each compliance period. To ensure transparency and maintain public confidence, certain data from the emissions reports, allowances, and offsets that are used for compliance will be made public in a timely manner.

12.3. If by the deadline for demonstrating compliance a covered entity or facility does not have sufficient allowances to cover its emissions for the previous compliance period, it shall be required to obtain and surrender three allowances for every metric ton of CO_2e not covered by an allowance at the deadline. This does not preclude other penalties allowed under individual state or provincial laws.

12.4. The WCI Partner jurisdictions recognize that during the first compliance period, both they and the entities and facilities covered by the cap-and-trade program will likely encounter issues that arise in the implementation of any new program. Consequently, the WCI Partner jurisdictions are committed to providing appropriate technical and other compliance assistance to the program participants.

12.5. The WCI Partner jurisdictions will ensure accounting systems are in place to prevent using allowances, tradable units, and offsets more than once for compliance.

13. Regional Organization, New WCI Partner Jurisdictions, and Linkage

13.1. To reduce administrative costs and improve program transparency and consistency, a regional administrative organization will be created to:

- Coordinate the regional auction of allowances;
- Track emissions and provide public information on progress towards the WCI regional goal;
- Monitor and report on market activity, including any potential market manipulation;
- Serve as a forum for WCI Partner jurisdictions to update one another on program progress;
- Coordinate review and adoption of protocols for offsets;
- Coordinate review and adoption of updated reporting protocols;
- Coordinate review and issuing of offset credits; and
- Suggest criteria and means to accredit service providers to deliver validation and verification services.

13.2. New WCI Partner jurisdictions will come into the cap-and-trade program at a regionally coordinated and designated time, such as the beginning of the relevant compliance period.

13.3. Before joining, a new WCI Partner jurisdiction must have adopted an economy-wide GHG reduction goal for 2020 that is at least as stringent as the WCI regional goal.

13.4. Determination of allowance budgets for new WCI Partner jurisdictions will take into account the following parameters:

- The WCI regional goal;
- Allowance budgets for existing WCI Partner jurisdictions;
- The share of the new WCI Partner jurisdiction's budget that is already included through the WCI's regional cap-and-trade program provisions covering imported electricity; and
- The new Partner's individual GHG emissions reduction goal.

13.5. The WCI Partner jurisdictions will seek bilateral and multilateral linkages with other government-approved cap-and-trade systems so that those allowances and allowances issued by WCI Partner jurisdictions would be fully fungible. Until such bilateral or multilateral linkages are established, the use of allowances from other cap-and-trade systems will be limited as described in Section 9.2.

14. WCI Design and Possible Federal Programs

14.1. The WCI Partner jurisdictions have designed a program that can stand alone, provide a model for, be integrated into, or be implemented in conjunction with programs that might ultimately emerge from the federal governments of the United States and Canada. The WCI Partner jurisdictions intend to promote and influence federal GHG emission reduction programs that are consistent with WCI cap-and-trade design principles, and ensure those programs translate into absolute GHG reductions. In the event WCI issues allowances before a federal program in Canada or the United States, WCI Partner jurisdictions will work to ensure that those allowances are fully recognized and valued in the operation of a federal program.

14.2. The approach taken by the WCI Partner jurisdictions builds upon the experience gained by the WCI Partner jurisdictions in developing and implementing climate change action plans and other market-based programs to address air quality issues, including the regional haze and acid rain programs in the United States. Continued leadership in developing a regional cap-and-trade program allows the WCI Partner jurisdictions to take important action now and promote and protect the interests of early actors in the design and implementation of future national and international programs. Taking action now to achieve emission reductions will position WCI Partner jurisdictions to be leaders in the carbon constrained future.

Section 2: Background Report on the Design Recommendations for the WCI Regional Cap-and-Trade Program[14]

The Western Climate Initiative (WCI) is a cooperative effort of seven U.S. states and four Canadian provinces (the "Partners") that are collaborating to identify, evaluate, and implement policies to reduce greenhouse gas (GHG) emissions, including the design and implementation of a regional cap-and-trade program.[15] The Initiative began in February 2007 with the governors of Arizona, California, New Mexico, Oregon, and Washington, who have since been joined by the premiers of British Columbia, Manitoba, Ontario, and Quebec, and the governors of Montana and Utah.[16] Participation in the WCI reflects each Partner's strong commitment to identifying, evaluating, and implementing collective and cooperative actions to address climate change. This Background Report accompanies the Design Recommendations for the regional cap-and-trade program.

The WCI cap-and-trade program is the most comprehensive cap-and-trade program designed to date. Nearly 90 percent of the GHG emissions in the states and provinces will be covered by the cap when it is fully implemented in 2015. It will include more sectors and emissions than either the Regional Greenhouse Gas Initiative (RGGI) in the northeastern United States, which covers the electricity sector only, or the European Union's Emissions Trading Scheme (EU ETS), which does not cover transportation or residential and commercial fuel use. Through its broad scope, the WCI program will reduce costs while reducing emissions across the economy. It will also spur growth in new green technologies, help build a strong clean-energy economy, and reduce dependence on foreign oil.

The Partner jurisdictions are motivated by the impacts of climate change already being felt in the region. Observed trends include rising temperatures leading to warmer, earlier springs and more frost-free days; changing precipitation patterns that include both prolonged drought and increased flooding, as well as shifts in springtime precipitation from snow to rain; changes in water availability due to earlier spring snowmelt, changes in available water volume, and increased evaporation from reservoirs; rising sea levels; and a growing number of large wildfires. Additional impacts expected from unabated climate change include more heat waves, shrinking glaciers and reduced snowpack, reduced biodiversity as invasions of non-native species increase and local habitat moves northward and to higher elevations, and reduced air quality due to elevated levels of ozone and

[14] No statement in this document should be taken to contradict the Design Recommendations released concurrently with this Background Report; any perceived conflict should defer to the Design Recommendations.

[15] The complete text of the February 26, 2007 Memorandum of Understanding can be found in Appendix A.

[16] The states of Alaska, Colorado, Idaho, Kansas, Nevada, and Wyoming participate as observers, as do the province of Saskatchewan and the Mexican border states of Baja California, Chihuahua, Coahuila, Nuevo Leon, Sonora, and Tamaulipas.

particulates. These impacts affect a wide range of economic sectors, from electricity generation to public health, from agriculture to tourism. The cost of inaction is enormous.

The analyses conducted on the WCI design suggest that the region can mitigate the costs of reducing emissions and realize a cost savings through increased efficiencies and reduced fuel consumption. These savings come in addition to the benefits the region will accrue from a cleaner environment and the promotion of investment and innovation to accelerate the transition to a green economy. The WCI cap-and-trade program is a winning proposition for Partner jurisdictions.

The initial phase of the WCI cap-and-trade program will be a time of transition during which WCI Partner jurisdictions will manage risks, protect the economy, and see real reductions in greenhouse gas emissions. Action is needed now to reduce greenhouse gas emissions and to adapt to climate change impacts. Working together, the states and provinces in the WCI are leading the way.

1. Public Comments and Discussion of WCI Recommendations

The process that led to the recommended design of the regional cap-and-trade program was careful and deliberative. At each step of design development, the WCI Partners sought extensive stakeholder input, as described in part 3.1.3, which yielded a great volume of comments on the range of issues confronted by participating WCI Partner jurisdictions. The comments submitted to the WCI Partner jurisdictions have been posted on the WCI website.[17] The WCI Partners carefully reviewed and considered stakeholder comments in order to formulate the design recommendations for the cap-and-trade program.

This section elaborates on the key program design recommendations. Each design element is defined and the design recommendation is summarized. Stakeholder input on the design element is reviewed briefly. Finally, the WCI Partners' recommendation is discussed in light of stakeholder input, the balancing required between disparate stakeholder positions, lessons learned from other cap-and-trade programs, economic analyses, and expert opinion. The design recommendations also rely on the design principles adopted by the WCI Partner jurisdictions and the overarching program goal of ensuring that greenhouse gas (GHG) emissions are reduced within the WCI Partner jurisdictions.

In conjunction with the cap-and-trade program, individual WCI Partner jurisdictions will:

- Mitigate economic impacts on consumers;
- Implement other policies that will reduce GHG emissions from the transportation sector and reduce demand for transportation fuels (such as vehicle standards, smart growth, low carbon fuel standards, and transit options); and

[17] www.westernclimateinitiative.org.

- Address jurisdiction-specific issues associated with the point of regulation and its implementation.
- If any of the design elements differ between the Design Recommendations and the following explanatory text, the Design Recommendations take precedence.

1.1. Scope

1.1.1. Definition

The *scope* defines the GHG emissions that are included in the cap-and-trade program, including the sectors, emissions sources, and greenhouse gases that fall under the cap. The cap is the absolute aggregate limit on GHG emissions.

1.1.2. Design Recommendation

The WCI Partner jurisdictions recommend a multi-sector greenhouse gas cap-and-trade program covering emissions of the six major GHGs: carbon dioxide, methane, nitrous oxide, perfluorocarbons (PFCs), hydrofluorocarbons (HFCs), and sulfur hexafluoride.[18] In the initial compliance period beginning in 2012, the program will cover emissions from electricity, including imported electricity; industrial combustion at large sources; and industrial process emissions[19] for which adequate quantification methods exist. In the second compliance period, beginning in 2015, the program will expand to cover fuels combusted at industrial, residential, and commercial buildings that are not otherwise covered as emissions sources, as well as transportation fuels. The first compliance period of the program will include about half of the economy-wide emissions in the WCI Partner jurisdictions. Starting with the second compliance period, the program will include about 90 percent of emissions. The program is capable of expanding further over time based on new information.

The carbon dioxide emissions from the combustion of biomass that are determined to be carbon neutral will not be covered by the cap-and-trade program emissions cap. Similarly, the carbon dioxide emissions from the combustion of bio-fuels or the bio-fuel component of blended fuels will not be covered by the program emissions cap. However, carbon dioxide emissions from biomass, bio-fuels, and the bio-fuel component of blended fuels will be subject to the program reporting requirements. The WCI Partner jurisdictions are continuing to assess whether and how to include upstream emissions from bio-fuel and fossil fuel production that do not take place within the WCI Partner jurisdictions.

---

[18] The Scope Draft Design Recommendations describes the options considered by the scope subcommittee, the evaluation criteria applied to the options, the data and analytical inputs (including data on emissions, numbers of entities, and potential cost impacts), and the decision process for deciding on the recommendations. Available at www.westernclimateinitiative.org/ewebeditpro/items/O104F16031.PDF.

[19] As used here, process emissions include emissions from chemical, biological, and other non-combustion processes. These emissions may be deliberate (e.g., vented), fugitive (e.g., leaked), or accidental.

Individual jurisdictions may utilize comparable fiscal measures, such as British Columbia's carbon tax, to address transportation fuels and fuel use by residential and commercial sources, and industrial fuels not otherwise covered at the emissions source. Adequate quantification methods will be established for emissions sources before they are included in the program.

1.1.3. Stakeholder Input

Stakeholder comments expressed strong support for the broadest possible coverage of sources and emissions under the cap-and-trade program. Factors identified by stakeholders supporting a broad scope include:

- To provide greater certainty that economy-wide emission reductions will be achieved;
- To reduce compliance costs by covering a broad set of emissions sources with diverse emission reduction opportunities;
- To create a level playing field for all fuels;
- To ensure that carbon is priced throughout the economy; and
- To create a more robust GHG trading market.

Many stakeholders stressed the importance of having reliable measurement, monitoring, and reporting protocols in place in order to include an emissions source in the program. For example, stakeholders from the waste management industry highlighted their view that the quantification protocols for landfill methane emissions cannot currently calculate methane emissions at individual landfills with adequate precision for a cap-and-trade program.

Considerable input was received on whether to include transportation fuels in the cap-and-trade program. Many stakeholders supported including transportation fuels in the program, emphasizing that these fuels are the largest source of GHG emissions across the WCI Partner jurisdictions and for most of the individual jurisdictions. They argued that these fuels need to be included to ensure that the economy-wide emission reduction goals can be achieved. Some stakeholders pointed out that if transportation fuels were omitted from coverage, then they would enjoy a competitive advantage over electricity as a vehicle fuel, since electricity would be covered by the program. Stakeholders also provided analyses indicating that including transportation fuels will reduce the concentration of the carbon trading market by including significant additional participants. Reduced concentration may help protect against market manipulation and provide for a more robust market.

A small group of stakeholders expressed opposition or hesitation to including transportation fuels citing concerns regarding: economic impacts, particularly on low-income communities; administrative complexity; and the lack of technical options for reducing reliance on fossil-carbon-based fuels. Some stakeholders suggested that the demand for transportation fuels has been shown to be highly inelastic, so that there would be little emission reduction achieved by including the fuels in the program. Other stakeholders cited analyses suggesting that the demand for transportation may be inelastic, but the demand for traditional transportation fuels was or is becoming increasingly elastic.

The timing for including transportation fuels in the program was also the subject of considerable input. Some stakeholders said it was best to include the fuels in the first compliance period, in particular to internalize the price of carbon as soon as possible. Others said that a delay in coverage was warranted to allow the point of regulation to be adequately determined and to enable complementary policies to enhance the availability of options for reducing emissions.

Stakeholders also commented on whether and when residential and commercial fuels should be included in the cap-and-trade program. Some stakeholders expressed concerns regarding economic impacts and administrative complexity. Some commented that direct use of natural gas at a residence or business is a more efficient use of that fuel than using it to generate electricity and, for this reason, should be excluded from coverage in the program. It was also argued that energy efficiency programs would be a more effective method of reducing emissions from these fuels. Others stressed the importance of creating a level playing field across all fuels, indicating that natural gas competes with electricity in residential and commercial applications.

The inclusion of industrial process emissions was also the subject of stakeholder input. Stakeholders pointed out that some process emissions are due to chemical reactions that are fundamental to their production processes. They recommended that these “fixed process emissions” be excluded from the program. Similarly, some stakeholders suggested that the process emissions from geothermal electricity generation should be excluded because geothermal electric generation is a low-emitting process.

Issues were also raised by stakeholders related to incorporating combined heat and power (cogeneration) into the program since it has implications in both the industrial and electricity sectors.

1.2. Discussion of WCI Partners’ Recommendation

The WCI Partner jurisdictions have weighed all input carefully and have proposed a program scope that best achieves the program objectives and addresses stakeholder concerns. The WCI Partners are persuaded by the multiple benefits of having as broad a scope as possible, including transportation fuels and fuels for residential, commercial, and small industrial users along with electric sector emissions and industrial emissions. Recognizing that transportation fuels are the largest source of GHG emissions in the region, the WCI Partners have concluded that transportation fuels must be included in order to achieve the objective of reducing emissions not only by 2020, but by 2050. Additionally, the WCI Partners believe that it is important to internalize the cost of carbon throughout the economy and to ensure a level playing field across all fuels. Consequently, the WCI Partners have also concluded that there are important benefits from including transportation fuels and fuels for residential, commercial, and small industrial users.

The timing of the coverage of transportation fuels and fuels for residential, commercial, and small industrial users was considered carefully. While there are benefits of including these fuels starting with the first compliance period, multiple factors necessitated covering them starting in the second compliance period. Electric sector emissions and industrial emissions are traditional emissions sources regulated in the context of clean air regulations. In the WCI Partners' judgment, it is practical to cover these sectors from the start of the program in 2012.

Emissions from fuels for residential, commercial, and small industrial users and transportation fuels are different than those typically dealt with by regulatory agencies under either the U.S. or Canadian Clean Air Acts. The WCI Partner jurisdictions concluded that it is important to have time to develop clear requirements for the entities that will have a regulatory obligation for these emissions, including how to calculate or measure their emissions. In addition, the Partner jurisdictions believe it is important for other policies that will reduce overall consumer demand for these fuels (such as the California clean car standards and strategies to reduce vehicle miles traveled, and to increase the use of low carbon or other "cleaner" fuels) be put in place before these fuels are covered by the cap-and-trade program. The WCI Partner jurisdictions recognize the importance of increased emphasis on energy efficiency to reduce fuel combustion in residential, commercial, and small industrial uses. The WCI Partner jurisdictions also believe it is important to develop strategies to address any potential consumer impacts from covering these emission sources in advance of the second compliance period.

All process emissions with adequate quantification methods will be included in the program. The WCI Partner jurisdictions believe that it is important to incorporate the price of carbon throughout the economy, including in products with fixed process emissions. However, the WCI Partners also recognize that the competitive position of some industrial sources could be affected by this decision. Consequently, the WCI Partners are continuing to evaluate the potential competitive impacts on these sources and will address these impacts if they are found to be significant.

Economic analyses support the recommendation for broad coverage in the cap-and-trade program. The analysis conducted for the WCI Partners is consistent with the body of literature supporting a broad scope, including transportation fuels. In particular, the analysis found that compliance costs can be reduced if the program includes a broad scope.

The WCI Partner jurisdictions recognize the importance of combined heat and power (cogeneration) in the program scope and are continuing to evaluate its implications for the program design.

1.3. Point of Regulation

1.3.1. Definition

The *point of regulation* is the entity or facility with the compliance obligation. The term *entity* is used (a) when the point of regulation is upstream of the point of emissions, to describe a company that has an obligation to surrender allowances to cover the expected emissions from the combustion of the fuel the company is moving through commerce, or (b) when the point of regulation is at the First Jurisdictional Deliverer, to describe a company that has an obligation to surrender allowances to cover the emissions attributable to the generation of power the company is importing. When the point of regulation is at the point where the emissions occur, the term *facility* is generally used. A *compliance obligation* is the requirement to surrender GHG allowances sufficient to cover actual emissions during the compliance period.

1.3.2. Design Recommendation

The WCI Partner jurisdictions are recommending the following points of regulation for the cap-and-trade program:

- For industrial process and combustion sources with emissions above the threshold, the point of regulation is at the facility that has the point of emissions.
- For entities generating and/or delivering electricity with attributed emissions above the threshold, the point of regulation is at the First Jurisdictional Deliverer. This means at the facilities generating power within the WCI Partner jurisdictions and at the first entity over which a Partner has regulatory authority that delivers electricity generated outside the WCI into a WCI Partner jurisdiction for consumption in that Partner jurisdiction.
- For residential, commercial, and industrial fuel combustion at facilities with emissions below the threshold, the point of regulation is where the fuels enter commerce in the WCI Partner jurisdictions, generally at a fuel distributor. The precise point will be determined before the fuels are brought into the program in 2015 and may vary by jurisdiction.
- For transportation fuel combustion, the point of regulation is where the fuels enter commerce in the WCI Partner jurisdictions, generally at the terminal rack, final blender, or distributor. The precise point will be determined before these fuels are brought into the program in 2015 and may vary by jurisdiction.

1.3.3. Stakeholder Input

Stakeholders provided a broad range of comments regarding the preferred points of regulation for the various emissions included in the program. Some stakeholders supported a point of regulation as close to the point of emissions as is practical in order to provide a regulatory obligation on the actual emitter. Other stakeholders supported an upstream point of regulation, particularly for transportation and other fuels in order to provide as broad coverage as possible.

The WCI Partner jurisdictions received a great variety of comments on the point of regulation for the electricity sector. A majority of commenters favored some approach to cover emissions associated with electricity from outside the WCI Partner jurisdictions. However, there was a wide variety of opinions on how best to cover emissions from imported electricity. A specific challenge relative to covering all deliverers of electricity is the need to track the emissions from the point of generation to the point of delivery inside the WCI Partner jurisdictions. Some commenters observed that, considering this challenge, the WCI Partners should start with a generator-based only point of regulation for electricity, then expand to include power imported for consumption into the WCI Partner jurisdictions once the tracking issue was resolved. Some stakeholders suggested that the tracking issues are complex enough that additional technical assessment is necessary to ensure an adequate approach can be successfully deployed.

1.3.4. Discussion of WCI Partners' Recommendation

In selecting the point of regulation for the different covered sources, the WCI Partner jurisdictions considered the experience of prior cap-and-trade programs, the administrative requirements for the covered facilities and entities, the number of facilities and entities that would be included, and especially given the regional nature of the program, the potential for leakage. For industrial facilities, the point of regulation will be at the facility with the source of the emissions, putting the regulatory obligation at the point of emission. Because there are a very large number of small combustion sources in the transportation, residential and commercial sectors, and at small industrial facilities, the Partner jurisdictions decided it would be impractical to regulate at the point of emissions for these sectors. Rather, the WCI Partners found that these emissions can best be covered upstream at the point of entry of the fuel into the region's economy. By starting the inclusion of these fuels in the second compliance period, the Partners have allowed sufficient time to address issues related to defining the precise upstream point of regulation for these sources.

For electricity, the point of regulation will be at the First Jurisdictional Deliverer. The First Jurisdictional Deliverer is the generator of electricity in a WCI jurisdiction, or the first deliverer of electricity that is generated outside the region to be consumed within a WCI Partner jurisdiction. Emissions associated with power that is wheeled through the WCI Partner jurisdictions but not consumed in any of them is not covered by the program. The Partners recognize that there will be challenges to tracking emissions from the source where electricity is generated to the jurisdiction where it will be consumed. However, the WCI Partners also recognize that a significant amount of electricity consumed in the WCI Partner jurisdictions is generated by federal entities, on tribal land, or in non-WCI jurisdictions. Due to the interconnected nature of the electric grid, leakage of electricity emissions to jurisdictions or entities that are not part of the WCI is a significant concern that the First Jurisdictional Deliverer point of regulation is intended to address. Additionally, the Partners determined that this point of regulation can best address leakage while maintaining compatibility with wholesale electricity markets.

The recommendation to put the electricity point of regulation at the First Jurisdictional Deliverer represents a WCI innovation to eliminate emissions leakage. Previous programs—such as the Regional Greenhouse Gas Initiative, which follows a pure generator-based approach—have generally failed to address the leakage potential at all. As a new approach, First Jurisdictional Deliverer will pose some new challenges to implement. Given these challenges, work will continue on the First Jurisdictional Deliverer approach, including additional opportunities for stakeholder input during five stakeholder technical working sessions scheduled through the fall and winter of 2008/09. These meetings will provide the WCI Partners, technical experts, and other stakeholders additional opportunities to work together on key issues associated with the implementation of the First Jurisdictional Deliverer approach.

1.4. Thresholds Triggering a Compliance Obligation under the Cap-and-Trade Program

1.4.1. Definition

Thresholds are annual emission levels that are used to determine whether a particular entity or facility will have a compliance obligation under the cap-and-trade program.

1.4.2. Design Recommendation

The cap-and-trade program will apply an emissions threshold of 25,000 metric tons of CO_2e annually to determine the facilities or entities that will have a regulatory compliance obligation under the program.[20] Additional analyses, including data from mandatory reporting, will be performed to determine if adjustments to the threshold are needed to ensure sufficient coverage or to address competitiveness issues within individual sectors prior to the beginning of the program (i.e., because different Partner jurisdictions have the same industry but with different-sized sources). The WCI Partner jurisdictions will develop a method to prevent entities or facilities from avoiding coverage by breaking themselves into smaller units that individually have emission levels that are below the threshold.

1.4.3. Stakeholder Input

Stakeholders provided a broad range of comments regarding how best to apply emission thresholds. The comments were broadly consistent with the goal of covering the vast majority of emissions while reducing administrative burden by minimizing the number of entities and facilities with a direct compliance obligation. Stakeholders differed in their

[20] The Scope Draft Design Recommendations address the question of thresholds and include a section (Section 4.3) on considerations for setting emissions thresholds. Available at http://www.westernclimateinitiative.org/ewebeditpro/items/O104F16031.PDF.

balancing of these objectives, with some recommending lower thresholds, such as 10,000 metric tons of CO_2e annually, and at least one stakeholder recommending 100,000 metric tons annually. Sector-specific thresholds were also discussed, including thresholds defined in terms of production capacity (such as megawatt (MW) capacity for electric power generation) and other units.

Stakeholders also emphasized the importance of defining how the threshold would be applied, including the definition of "facility" or "entity" that would be used. The definition of facility was discussed particularly with reference to oil and gas production fields that may contain equipment dispersed over large areas. Some stakeholders inquired whether the threshold would be applied prospectively (i.e., prior to the start of the compliance period), annually during a compliance period, or after the end of the compliance period.

1.4.4. Discussion of WCI Partners' Recommendation

The WCI Partner considered a broad range of thresholds for the program, with the objective of covering a large portion of emissions (e.g., 90 percent of the emissions in the covered sectors) with as few facilities and entities as possible. The WCI Partner jurisdictions agree with the objective of minimizing the number of facilities and entities with a direct regulatory obligation to minimize the program's administrative burden for both the complying industries and the program administrators. The WCI Partners reviewed available data from several jurisdictions to assess how many facilities and entities would be expected to have compliance obligations and the portion of total emissions covered for a range of threshold values.[21] Based on this review, the WCI Partners concluded that current data support setting an emission threshold of 25,000 metric tons of CO_2e per year and that this threshold would cover more than 90 percent of emissions.

The WCI Partners recognize that additional data will be valuable for assessing the appropriateness of the threshold level. The comprehensive mandatory emissions reporting will provide more complete data, which will be examined to ensure that the threshold is set to achieve the level of program coverage desired. Of note is that by including residential, commercial, and small industrial fuels in the program at an upstream point of regulation, the threshold becomes less important for ensuring coverage of emissions from these fuels: the emissions at facilities below the threshold are covered upstream. Additionally, as discussed above, the WCI Partners will assess whether the threshold creates competitiveness impacts within industries.

---

[21] For example, The California Air Resources Board found that in California, a threshold of 25,000 metric tons of CO2 covered about 94 percent of emissions from stationary sources. A threshold of 10,000 metric tons of CO2 increased coverage to only 96 percent of emissions, but nearly doubled the number of regulated sources. See the Staff Report: Initial Statement of Reasons for Rulemaking, available online at http://www.arb.ca.gov/regact/2007/ghg2007/isor.pdf.

1.5. Program Expansion

1.5.1. Definition

Program expansion allows the cap-and-trade program to incorporate additional sectors, greenhouse gases, or facilities or entities under the cap, or to include a new Partner in the cap-and-trade-program.

1.5.2. Design Recommendation

The WCI Partner jurisdictions have designed a cap-and-trade program that is capable of expanding over time (including possibly adjusting applicability thresholds over time). Prior to each compliance period, the WCI Partner jurisdictions will review whether to bring new sources into the program, and if so, which ones.

1.5.3. Stakeholder Input

The great majority of stakeholders commenting suggested broad coverage to the extent practicable. Some also expressed a desire to bring all of the states and provinces that are part of the western interconnected electrical grid into the program.

1.5.4. Discussion of WCI Partners' Recommendation

A provision that allows for expansion over time is responsive to public comments calling for broad coverage of the cap-and-trade program. The scope of the program will expand from its initial coverage of industrial combustion and process sources and electricity sources in the first compliance period. In the second compliance period, transportation fuels will be included, along with residential, commercial, and industrial fuels serving facilities not covered by the program in the first compliance period. In addition, the program emissions threshold has been set initially at 25,000 metric tons of CO_2e annually, but will be revisited based on the mandatory emissions data to be reported by emissions sources region-wide, and additional facilities or entities may be brought into the program. Finally, the WCI Partner jurisdictions would like any states, provinces or tribes that have committed to making GHG emission reductions comparable to the WCI regional reduction goal to become Partners in the WCI.

1.6. Role of Other Policies

1.6.1. Definition

Other policies include complementary policies and alternative policies. A *complementary policy* is used in this context to mean policies other than a cap-and-trade program that aid in the goal of achieving emission reductions inside or outside the capped sectors. *An* *alternative policy* is a policy that is employed in lieu of a cap-and-trade program for one or more sectors.

1.6.2. Design Recommendation

The role of other GHG-reducing policies is to help the WCI Partner jurisdictions achieve their 2020 reduction goal and provide other benefits. Those policies will work in concert with the cap-and-trade program and may apply to any source of GHG emissions.

In addition, the WCI Partner jurisdictions have agreed that individual jurisdictions may use fiscal measures that contribute to achieving overall comparable GHG emission reductions and internalize the price of carbon as expected through the regional cap-and-trade program for transportation and residential/commercial/small industrial fuel users. British Columbia currently has a carbon tax on these fuels. By 2012, the WCI Partner jurisdictions will determine the mechanism for integrating the cap-and-trade program with British Columbia's carbon tax.

1.6.3. Stakeholder Input

Many stakeholders emphasized the importance of complementary measures, especially for the residential, commercial, and transportation sectors. Others expressed concern that complementary measures would not provide the same level of certainty in emissions reductions from these sectors as would coverage under the cap.

1.6.4. Discussion of WCI Partners' Recommendation

The WCI Partner jurisdictions recognize that it will take numerous policies working in concert with cap-and-trade to achieve the regional reduction goal. The WCI economic analysis supports this point. It also makes sense: for example, codes that require energy efficient buildings complement the inclusion of electricity and residential, commercial, and small industrial fuel use under the cap.

In addition to aiding in the achievement of reductions at sources covered by the cap, complementary policies are needed for reductions at sources not covered by the cap-and-trade program. For example, during the first compliance period, the WCI Partners are recommending that complementary policies be instituted to reduce fuel demand in the transportation residential, and commercial sector, and by small industrial fuel users. This will help ensure consumers have real choices about the cars they drive, the fuels they use, and energy efficient appliances and buildings when these fuels are included in the cap-and-trade program in 2015.

The WCI Partner jurisdictions also agree that other policies, such as British Columbia's carbon tax, can be used as an alternative to cap-and-trade if designed to achieve comparable emission reductions and to internalize the cost of carbon for transportation fuel and fuel use by residential, commercial, and small industrial sources, as expected through the cap-and-trade program.

1.7. Setting the Regional Cap for the Cap-and-Trade Program

1.7.1. Definition

The *regional cap* is the overall GHG emissions limit set for the facilities and entities covered by the cap-and-trade program. The cap declines over time to the desired reduction limit in 2020. For the WCI Partner jurisdictions, the program is designed to achieve their 2020 emissions goal.

1.7.2. Design Recommendation

The WCI Partner jurisdictions are recommending the following with respect to the aggregate regional emissions cap:

- The aggregate regional cap for the cap-and-trade program will (a) represent the sum of the WCI Partner jurisdictions allowance budgets; (b) include annual caps with three-year compliance periods, and (c) decline over time to reach the 2020 cap level.
- The initial 2012 regional cap will be set based on the best estimate of expected actual emissions. Among the factors that will be considered in making these estimates are population growth, economic growth, voluntary and mandatory emission reductions, and other factors including reporting data that is available when the cap is set. Of particular importance is that the voluntary emission reductions recognized through the issuance of Early Reduction Allowances be reflected in the estimates for the 2012 allowance budgets for each WCI Partner, and consequently the region as a whole (see Part 1.10 for a discussion of the Early Reduction Allowances). A mechanism will be developed that reconciles the 2012 allowance budgets for each Partner with the Early Reduction Allowances issued by each Partner.
- The 2015 regional cap will be set by adding the best estimate of actual emissions in 2015 from transportation fuels and residential, commercial, and industrial fuels (and any other sectors or sources that may be added to the program in 2015) to the emissions cap trajectory for the sources first included in the program in 2012.
- The 2020 regional cap will be set so that reductions achieved by the cap plus reductions from other GHG reduction policies will achieve the WCI 2020 regional emissions goal.
- Annual regional caps for calendar years 2012 through 2020 will be established before the start of the program in 2012 so that the total number of allowances issued in each three-year compliance period through 2020 will be known.
- The annual regional caps will only be adjusted for changes in WCI membership, changes in program scope or applicability thresholds, or to correct for data discovered

to be incorrect or inaccurate. Any adjustments will be made before the beginning of a compliance period.

1.7.3. Stakeholder Input

A number of stakeholders cautioned against beginning the cap-and-trade program with a cap that over-allocates emissions allowances, with some recommending use of actual, historic emissions as opposed to estimates of future emissions that rely on best available data. Many stakeholders expressed concern that setting the regional cap at the level of emissions expected in 2012 will encourage emitters to increase their emissions prior to the setting of the regional cap in order to increase the allowances in the system. Some stakeholders expressed support for setting the initial cap far ahead of the 2012 program start, so that the program reduces emissions in the first year and does not penalize early actions or create a "perverse incentive" for higher emissions before the program starts. Stakeholders were not unanimous on whether the cap should decline in a uniform straight line from the start of the program, or begin without a reduction and decline at an accelerating rate over time. Many stakeholders stressed the importance of having good emissions data for setting the cap to avoid over-allocation and to ensure more robust reductions from the program.

1.7.4. Discussion of WCI Partners' Recommendation

Recognizing that good emissions data will not be available before it is time to set the 2012 cap, the WCI Partner jurisdictions have accounted for the need to project actual emissions in the first year of the program. This projection will take into account population growth, economic growth, voluntary and mandatory emissions reductions, and other factors. Some WCI Partner jurisdictions will have limited emissions reporting in place prior to the recommended start of the WCI reporting in 2010; this reporting data will also be considered. The 2015 cap will bring in additional sectors under the cap, and the initial cap for these sectors will be established in a similar manner, with the reporting data playing a larger role.

The recommended approach for setting the 2012 emissions cap does not provide an incentive to increase emissions through 2012. The estimate for 2012 will be completed at the latest in 2010. Consequently, there is no opportunity to increase emissions prior to 2012 to influence the estimate of the 2012 emissions cap. Also, to provide an incentive to reduce emissions before the start of the program in 2012, the WCI Partner jurisdictions are recommending Early Reduction Allowances, which will provide allowances for certain voluntary reductions made during a specific period prior to 2012.

To guard against over-allocation, the WCI Partner jurisdictions have also recommended that the first five percent of the auctioned allowances have a minimum reserve price. If allowances are not purchased at or above the minimum reserve price, a portion will be retired, auctioned in a subsequent period, or distributed in a subsequent period. This mechanism will serve to remove "extra" allowances from the market. This auction provision is detailed below in Part 1.9.

The WCI Partner jurisdictions are recommending that the annual regional caps from 2012 to 2020 follow a straight-line declining trajectory, recognizing that the total amount of allowances will increase in 2015 when transportation and other fuels are added to the program. It should be noted that the end point for 2020 will not change when those fuels are added. All caps will be established in advance of the start of the program in 2012 so that the reductions accomplished from the program will be known well in advance. Setting the caps in advance will also allow the WCI Partner jurisdictions to ensure the 2020 reduction goal will be met.

The economic modeling analysis suggests that the cap-and-trade program can achieve reductions from capped sectors consistent with the regional reduction goal with modest economic benefits. The cost per metric ton of allowances is expected to remain below $25 through 2020 with complementary policies, banking, and offsets. WCI's economic modeling found that the savings from reduced fuel expenditures under a cap-and-trade program with complementary policies could exceed the cost of additional investments in energy efficiency. The overall effect on the economy (e.g., the effect of the WCI program on state GDP, employment, and income) remains to be analyzed via additional macroeconomic modeling; however, prior modeling studies of other proposed cap-and-trade programs found that the economy can continue to grow robustly under well-designed climate policies.

1.8. Allowance Apportionment to WCI Partners

1.8.1. Definition

Allowance apportionment describes the individual Partner share of the overall "budget" of GHG emission allowances under a regional cap. An allowance budget must be set for each Partner jurisdiction.

1.8.2. Design Recommendation

The WCI Partner jurisdictions are recommending the following concerning the establishment of individual WCI Partner allowance budgets:[22]

- Each WCI Partner will have an annual allowance budget within the regional cap. All annual allowance budgets through 2020 will be established before the start of the program in 2012. The sum of the individual Partner's allowance budgets will equal the regional cap.

---

[22] The Allocation Options paper describes the advantages and disadvantages of different allocation options and the relevant design principles. Available at http://www.westernclimateinitiative.org/ewebeditpro/items/O104F14628.pdf.

- Each WCI Partner's 2012 allowance budget will be based on the best estimate of expected emissions for sources covered in the cap-and-trade program in the WCI Partner's jurisdiction in 2012, developed using the best available data and by accounting for expected changes in emissions in 2012. Population growth, economic growth, voluntary and mandatory emissions reductions, and other factors will be considered. Of particular importance is that the voluntary emission reductions recognized through the issuance of Early Reduction Allowances be reflected in the estimates for the 2012 allowance budgets. A mechanism is needed, and will be developed, that reconciles the 2012 allowance budgets for each Partner with the Early Reduction Allowances issued by each Partner.
- There will be a one-time adjustment in 2012 to each WCI Partner jurisdiction's allowance budget to account for the production and consumption of electricity megawatt hours within each WCI Partner jurisdiction, population growth, and the share of total WCI Partner jurisdictions emissions in 2001 through 2005. Each WCI Partner jurisdiction will make a one-time contribution of one percent of its 2012 budget to make these adjustments.
- For 2015, each WCI Partner jurisdiction's allowance budget will be set by adding the best estimate of expected actual emissions in 2015 from transportation, residential, and commercial fuels, and small industrial fuel users (and any other sectors or sources that may be added to the program for the first time in 2015) to the emissions trajectory for the sources first included in the program in 2012. The estimate of expected actual emissions in 2015 will be developed using the best available data (including available mandatory reporting data) and by accounting for expected changes in emissions in 2015 for the sources added to the cap at that time. Population growth, economic growth, voluntary and mandatory emissions reductions, and other factors will be considered in making the estimate.
- Each WCI Partner jurisdiction's 2020 allowance budget will be derived from its individual WCI Partner jurisdiction goal used for purposes of the program.[23] Reductions from other greenhouse gas reduction policies will also be considered.
- In order to avoid the double counting of emissions associated with electricity that is generated in one WCI Partner jurisdiction but consumed in another Partner jurisdiction, the affected WCI Partner jurisdictions will negotiate an equitable solution for apportioning those allowances.
- For years post-2020, the WCI Partner jurisdictions will set allowance budgets not less than three years in advance, based on future reduction limits or goals and using at least three years of reporting data for covered sectors.
- Individual WCI Partner jurisdiction allowance budgets will be established before the start of the program in 2012 and will only be adjusted for changes in WCI membership, changes in program scope or applicability thresholds, or to correct for errors discovered in the data.

[23] Partner goals are those reduction goals or limits that have been established by each individual WCI Partner jurisdiction for the cap-and-trade program.

1.8.3. Stakeholder Input

Stakeholders provided a wide diversity of comments on potential ways to apportion allowances among Partners, with little consensus on key issues particularly for the electricity sector. Many argued for emissions to be apportioned based on load while others were equally passionate that emissions be apportioned based on historical emission levels. The comments reflected the stakeholders' view of how the apportionment method selected might affect their potential to receive free allocation.

Several stakeholders called for WCI to recognize the voluntary market for Renewable Energy Credits (RECs) via a set-aside of allowances to reward or incentivize renewable investment at the regional or state and provincial level.

1.8.4. Discussion of the WCI Partners' Recommendation

The WCI Partners' recommendation for the establishment of individual WCI Partner jurisdiction allowance budgets reflects the special or unique circumstances in each state and province, including the mix of industries; the production and consumption of electricity and the source of that electricity; and expected growth in the economy and population. The WCI Partner jurisdictions agreed to make a one-time adjustment to take these factors into account. The formula for determining how to distribute the allowances associated with this adjustment will be part of the work plan for 2009 and beyond for the WCI Partner jurisdictions.

Nothing in this design precludes any individual WCI Partner jurisdiction from setting aside some amount of allowances to reward or incentive renewable energy. See Part 1.10 for the discussion on set-asides.

1.9. Allowance Distribution by Partners

1.9.1. Definition

Allowance distribution is the Partners' initial issuance of GHG emission allowances.

1.9.2. Design Recommendation

The WCI Partner jurisdictions are proposing the following approach to allowance distribution by the WCI Partners:[24]

[24] The Allocation Options paper describes the advantages and disadvantages of different allocation options and the relevant design principles. Available at http://www.westernclimateinitiative.org/ewebeditpro/items/O104F14628.pdf.

- Generally, allowance distribution will be done independently by each WCI Partner jurisdiction.
- In some cases, the WCI Partner jurisdictions have agreed to consider standardizing allowance distribution across specific sectors if analysis demonstrates uniform treatment is necessary to address competitiveness issues. This uniform treatment, if deemed necessary, will be implemented prior to the first compliance period.
- The WCI Partner jurisdictions have agreed that a portion of the *value* represented by each Partner's allowance budget (for example, through set-asides of allowances, a distribution of revenues from the auctioning of allowances, or other means) be dedicated to specific purposes that will benefit all of the WCI Partner jurisdictions. Those purposes are: energy efficiency; research, development, demonstrations, and deployment (RDD&D); agricultural and forestry sequestration; and adaptation to climate change impacts.
- The WCI Partner jurisdictions are recommending a number of other potential uses for the remaining allowance value. They are: reducing consumer impacts, especially for low-income consumers; providing for worker transition and green jobs; achieving emission reductions in communities that experience disproportionate environmental impacts; supporting community-wide efforts funded by local governments to reduce GHG emissions; providing transition assistance to industries; recognizing early actions to reduce emissions; and/or promoting economic efficiency.
- For the first compliance period, the WCI Partner jurisdictions will auction a *minimum* of 10 percent of the allowance budget, and to increase the minimum percentage to reach 25 percent in 2020. WCI aspires to reach higher auction percentages over time, possibly to 100 percent.
- Each WCI Partner jurisdiction may auction a greater percentage of its allowance budget at its discretion.
- Some jurisdictions may not have the legal authority to auction allowances and that will not prevent the other Partner jurisdictions with authority from doing so.
- Each WCI Partner will advise the other WCI Partners of its allocation methods before the program start, and at least one year in advance of the start of each subsequent compliance period.
- The WCI Partner jurisdictions have recommended that auctioning be coordinated through a regional auction platform. The design of the auction will be completed before the cap-and-trade program begins in 2012 and will consider how to prevent market manipulation under the auctions.
- To counter any potential oversupply of allowances in the emissions trading market, the WCI Partner jurisdictions recommend that the first five percent of the allowances auctioned during the first and second compliance period have a reserve price. Should some of the allowances not sell at the reserve price, the Partners may retire a fraction of the allowances or retain them to be auctioned in later compliance periods, as agreed to by the WCI Partners in advance.

1.9.3. Stakeholder Input

There were widely differing opinions about how the Partners should distribute allowances. Some commenters called for 100 percent free allocation to covered facilities and entities, while others favored a 100 percent auction of all allowances. Still others favored a hybrid with some distribution for free, such as to retail providers of electricity with the rest auctioned. Most stakeholders who advocated for 100 percent auction pointed to the Regional Greenhouse Gas Initiative (RGGI), which ultimately decided to auction nearly 100 percent of the allowances in that system. They expressed concern over the creation of windfall profits from the distribution of free allowances to covered facilities and entities. Some stakeholders asked that the approach for distributing allowances take into account competitiveness issues that may arise between similar industries and between industrial sectors under the cap-and-trade program. No common ground was found in the widely varying stakeholder views. A number of stakeholders commented on the use of auction revenue. A variety of uses and purposes were suggested.

1.9.4. Discussion of the WCI Partners' Recommendation

In making their recommendation on allowance distribution, the WCI Partners considered the following:

- Auctions are an efficient methodology to distribute allowances and some level of auction is necessary for price discovery, which may help to minimize price volatility, especially in the beginning of the program.
- The WCI Partner jurisdictions aspire to eventually achieve a nearly 100 percent level of auction.
- Unlike RGGI, which covers just the electricity sector in the Northeast and is a deregulated market, within the WCI most of the electric sector is vertically integrated and rate regulated. Auctions are not needed to address potential windfalls under these conditions, and the allowances that are provided will be used for public purposes.
- Like RGGI, the WCI Partners believe that the decision on the maximum amount of auctioned allowances is best left to that states and provinces. The RGGI states agreed to use a percentage of the value of the allowances for consumer benefit and strategic energy purposes. The decision to auction allowances was made by each participating state after consultation with stakeholders and legislators in part as the method to assure those uses were realized. The WCI Partner jurisdictions have recommended that the allowance value be used for purposes similar to RGGI. The allowance value could be from auction revenues, direct allocation of allowances for specific uses, through set-asides, or other means as determined by the individual states and provinces.

- In addition to electricity, the first compliance period covers industrial emission sources. Many industrial facilities face domestic and international competition from facilities that are not covered by climate policies. For those facilities that are unable to pass along compliance costs in the face of this competition, there is a substantial risk of emissions leakage: the emissions would shift to outside of the WCI Partner jurisdictions without reducing emissions overall. The related issue of job leakage or outsourcing, even to other parts of the United States or Canada, is a legitimate concern that needs to be considered by each state and province. As a regional program, the primary mechanism for addressing this leakage risk is through the judicious distribution of allowances to facilities to ensure that they have an incentive to reduce emissions, but are not disadvantaged competitively.
- If the WCI Partner jurisdictions had designed a federal program for either the US or Canada, the auction percentage would have been much higher because of the guaranteed national scope of the program and the additional policy levers available at the federal level, including the ability to address international competition.
- There is uncertainty regarding the status of future international climate agreements and which countries might be signatories to them, particularly China and India. Depending on the outcome, the portion auctioned in a federal program could be higher as the leakage issues are addressed through those international agreements.
- The WCI economic modeling found that combining cap-and-trade with a portfolio of complementary policies will make the program more cost-effective. Using some portion of allowance value for the uses recommended in the WCI design will help realize that cost-effectiveness.[25]

1.10. Early Reduction Allowances and Other Early Actions or Set-Asides

1.10.1. Definition

Early Reduction Allowances refers to rewarding certain greenhouse gas reductions that occur at facilities or entities covered by the cap-and-trade program prior to the start of the program and after a set starting date. *Early actions* refer more generally to activity that reduces emissions that may not qualify for Early Reduction Allowances. *Set-asides* are allowances that are allocated for specific purposes by individual WCI Partner jurisdictions.

1.10.2. Design Recommendation

The program will encourage entities and facilities included under the cap to reduce greenhouse gas emissions after January 1, 2008 and before the start of the first compliance period in 2012 through the issuance of Early Reduction Allowances. These allowances will be in addition to the WCI Partner jurisdictions' 2012 allowance budgets. By the end of

[25] This will recognize pre-existing commitments to action and legislative requirements on use of revenue (e.g., through BC's Climate Action Plan and Carbon Tax).

2009, the WCI Partner jurisdictions will jointly establish criteria to determine which early reductions will be eligible for these allowances. The criteria will ensure that the reductions are voluntary, additional/surplus, real, verifiable, permanent, and enforceable. Each WCI Partner jurisdiction that issues Early Reduction Allowances will do so in 2012. These Early Reduction Allowances will be treated like other allowances in the cap-and-trade program.

For all other early actions and all types of set-asides, each WCI Partner jurisdiction will have the discretion to determine which early actions it will recognize or whether and for what purposes allowances will be set-aside. Recognition for early action and other set-asides will come from within the cap and out of the individual WCI Partner jurisdiction's allowance budget.

1.10.3. Stakeholder Input

There was a general level of support for granting recognition for early actions through the award of allowances. Some commenters favored awarding those allowances through set-asides coming out of individual WCI Partner allowance budgets. However, most commenters preferred that allowances be issued in addition to each WCI Partner's allowance budget as the only meaningful way to recognize GHG emission reductions that are taken prior to program launch.

1.10.4. Discussion of WCI Partners' Recommendation

The recommendation allows for the award of Early Reduction Allowances to facilities and entities that will be covered by the program that reduce their emissions on or after January 1, 2008 and before January 1, 2012. The WCI Partner jurisdictions will develop the additional criteria for determining which reduction activities will be eligible for Early Reduction Allowances. All Early Reduction Allowances will be allocated to the facilities and entities that have made reductions that are eligible for these allowances in 2012 only. Entities that will be covered by the program in 2015 may be eligible for these allowances and will also receive them in 2012.

The WCI Partner jurisdictions believe that the granting of Early Reduction Allowances provides an additional incentive for facilities and entities that will be covered by the cap-and-trade program to reduce emissions prior to the program start. Awarding these allowances will not result in an over-allocation of allowances because the Early Reduction Allowances will apply to reductions of emissions that would have otherwise been included in each Partner's 2012 allowance budget. This design recommendation is consistent with the Northeast NO_x Budget Cap-and-Trade Program, as well as the subsequent U.S. Environmental Protection Agency (EPA) NO_x SIP-Call Program.

The WCI Partner jurisdictions also recognize that there are specific purposes for which allowance set-asides may be warranted. For example, a WCI Partner jurisdiction with hydro power may want to set-aside allowances for use during low water years. Alternatively, a WCI Partner jurisdiction may want to recognize early reduction activities that do not qualify for Early Reduction Allowances. Each Partner will have the discretion to create set-asides for specific purposes; any allowances used for these purposes will come from the Partner's allowance budget.

1.11. Banking, Borrowing and Compliance Periods

1.11.1. Definitions

Banking of emissions allowances and offset credits means that holders of the allowance or offset credit may use the allowance or credit that is received or purchased in one compliance period for sale or use in a subsequent compliance period. *Borrowing* means using allowances from a future compliance period to cover a compliance obligation in a current compliance period.

1.11.2. Design Recommendation

Emission allowances will not expire. Parties who own emission allowances will be allowed to hold, or "bank," the allowances without limitation, except to the extent that restrictions on the number of allowances any one party may hold are necessary to prevent market manipulation.

Borrowing of allowances will not be permitted.

Each compliance period will cover three specific years: 2012–2014 is the first compliance period; 2015–2017 is the second compliance period, and 2018–2020 is the third compliance period. The compliance periods will not be rolling periods. Each will start on January 1 of the first year of the compliance period.

1.11.3. Stakeholder Input

Stakeholders who commented on these issues generally favored allowing unlimited banking of allowances. Some commenters expressed concern that extensive banking could lead to manipulation of the market. Borrowing attracted some favorable comments, but also a number of negative comments. Nearly all commenters favored a multi-year compliance period.

1.11.4. Discussion of WCI Partners' Recommendation

Banking of allowances can encourage early compliance. Banking of allowances can reduce volatility over time by providing liquidity in the market. It can also give facilities and entities a stake in the continued operation of the program in that banked allowances are a financial asset. In the economic analysis conducted for the WCI program design, banking moderated allowance prices more than any other program design element, including offsets, thereby reducing the costs of the program. Banking has been used in the U.S. Acid Rain cap-and-trade program, as well as the NO_x budget trading program in the Eastern United States.

The WCI Partner jurisdictions have recommended that banking of allowances be allowed without limit, except to the extent that limits on banking prove necessary to prevent market manipulation. This is an issue that the WCI Partner jurisdictions will analyze prior to the start of the program.

Borrowing of allowances will not be allowed in the WCI cap-and-trade program. Borrowing creates a risk of undermining the program because the practice creates a debt, and could result in facilities and entities with a large debt asking for relief. Such relief may result in an over-allocation of allowances, a breaking of the emissions cap or exemptions from the program's coverage. No U.S. cap-and-trade system to date has allowed borrowing.

The three-year compliance period will allow covered facilities and entities to manage planned or emergency changes in operations over the short term, as well as low water years that might affect the generation of hydro electricity.

1.12. Offsets and Allowances from Other Cap-and-Trade Systems

1.12.1. Definition

Offsets are GHG emission reductions, GHG emissions avoided, or GHG removals from the atmosphere, measured in metric tons of CO_2e. Offsets are achieved by *offset projects*. *Offset credits* (also measured in metric tons of CO_2e) are issued for offsets that are achieved by offset projects that meet certain criteria. Offset credits can be traded, and can be used for compliance purposes, or as part of voluntary actions. When used within a cap-and-trade program, offset credits used for compliance purposes come from emission sources or sinks not covered by the cap.

Emission allowances from other cap-and-trade systems are regulatory instruments used to limit GHG emissions. These emission allowances are issued by appropriate government regulatory authorities and are used for compliance purposes.

1.12.2. Design Recommendation

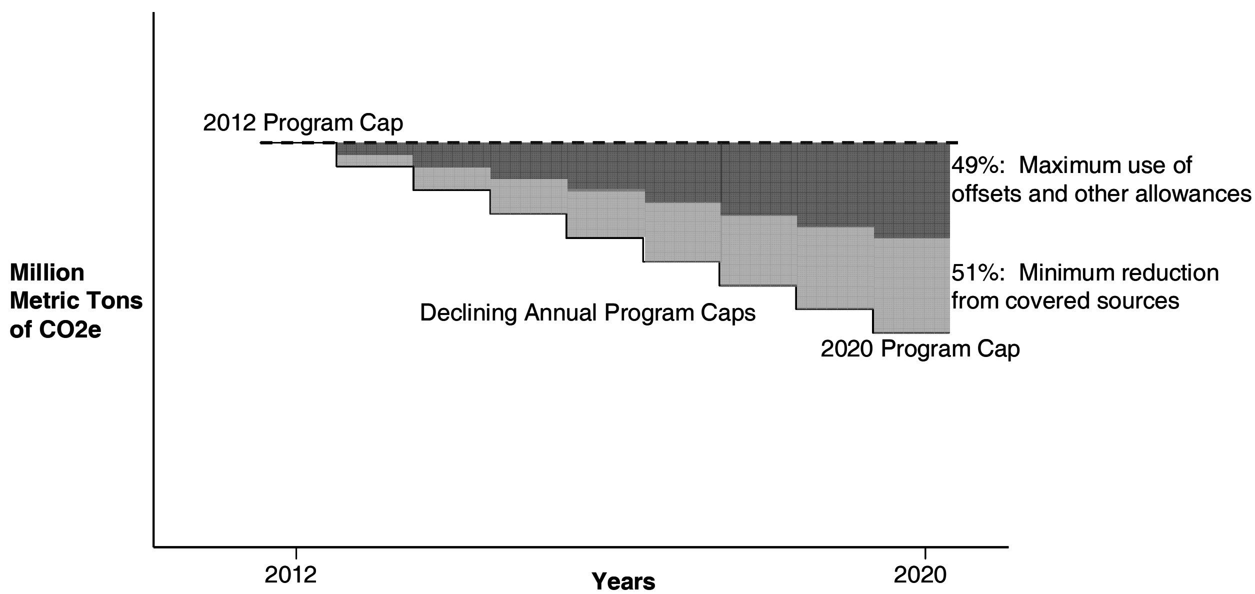
The WCI Partners are recommending a rigorous offset program. The purpose of the offset program is to reduce compliance costs while encouraging emission reductions, innovation, and technology development for sources and sinks not covered by the cap-and-trade program. In order to achieve these goals, the WCI Partners recommend the following offset program design features:[26]

---

[26] The Offsets Options Paper describes how, in developing its recommendation, the Offsets subcommittee defined a range of options, including whether to have offsets, and whether to limit their quantity, location, and type. Available at http://www.westernclimateinitiative.org/ewebeditpro/items/O104F14585.PDF . WCI

- The WCI Partner jurisdictions will establish standards and processes for issuing offset credits, accepting offset credits from the Clean Development Mechanism (CDM), and recognizing emission allowances from other GHG trading systems. The offset credits issued or recognized by the WCI Partner jurisdictions and emission allowances from other GHG trading systems recognized by the WCI Partner jurisdictions can be used for compliance purposes in the WCI Partner jurisdictions cap-and-trade program. The standards and processes will be developed and implemented in an open and transparent manner that will be well-defined in advance of the start of the cap-and-trade program.
- The WCI Partner jurisdiction will limit the use of all offsets and allowances from other GHG emission trading systems that are recognized by the WCI Partner jurisdictions to no more than 49 percent of the total emission reductions from 2012-2020. This limit will ensure that a majority of emission reductions occur at WCI covered entities and facilities. The 49 percent limit is conceptually illustrated in Figure A.

Figure A: Illustration of the 49 Percent Offsets Limit



This illustration shows how the limit on the use of all offsets and allowances from other systems is limited to 49 percent of total emission reductions starting from the 2012 program emissions cap. For simplicity, this illustration does not show the expansion of the program scope in 2015.

held an Offsets Public Workshop to help inform its recommendation. Workshop materials are available at http://www.westernclimateinitiative.org/WCI_Meetings_Events.cfm . The Offsets subcommittee defined criteria and objectives for the offsets program. See the Offsets Draft Design Recommendations for details. Available at http://www.westernclimateinitiative.org/ewebeditpro/items/O104F16589.PDF

- Each WCI Partner jurisdiction will have the discretion to set a lower limit on the use of offsets and allowances from other trading systems.
- The WCI Partner jurisdictions will jointly establish criteria to ensure that all offset projects used to meet a compliance obligation result in a GHG reduction, removal or avoidance that is real, surplus/additional, verifiable and permanent. The criteria will be used to ensure that the quantification of the GHG reduction, removal, or avoidance is accurate and not double counted.
- In addition, offset projects must be enforceable by the individual WCI Partner jurisdiction that is issuing the credit and the credit must be verifiable by the individual WCI Partner jurisdiction that is accepting it.
- The standards and processes for approving offset projects will be developed and implemented in an open and transparent manner that will be well-defined in advance of the start of the cap-and-trade program.
- Offset credits will not be approved for projects that reduce, remove or avoid emissions from sources covered by the WCI cap-and-trade program.
- The WCI Partner jurisdictions have identified the following list of project types as a priority for investigation and potential participation in the offset program:
    - Agriculture (soil sequestration and manure management);
    - Forestry (afforestation/reforestation, forest management, forest preservation/conservation, forest products); and
    - Waste management (landfill gas and wastewater management).
- Starting in 2009, the WCI Partner jurisdictions will jointly coordinate to review, develop and approve protocols for the project types that meet the necessary criteria for inclusion. At the same time, WCI Partner jurisdictions will initiate the establishment of a process to coordinate the review and approval of other project types and protocols proposed by project developers.
- WCI Partner jurisdictions will recognize offsets meeting the WCI criteria within their own jurisdictions regardless of which WCI Partner jurisdiction issued them. Offsets not meeting the WCI criteria will not be accepted for compliance purposes.
- The WCI Partner jurisdictions are recommending the following geographical parameters for offsets:
    - WCI Partner jurisdictions may approve, certify, and issue offset credits for projects located throughout the United States, Canada, and Mexico where such projects are subject to comparably rigorous oversight, validation, verification and enforcement as those located within the WCI jurisdictions.
    - WCI Partner jurisdictions will not accept offset credits for GHG reductions in developed countries (Annex 1 countries in the UN Framework Convention on Climate Change) for projects that reduce, remove, or avoid emissions from sources that within WCI Partner jurisdictions are covered by the cap-and-trade program.

- The WCI Partner jurisdictions may accept offset credits from developing countries through, for example, the Clean Development Mechanism (CDM) mechanism of the Kyoto Protocol, and the WCI Partner jurisdictions may establish added criteria to ensure similar rigor to WCI approved/certified offset projects or other requirements appropriate to enable use of these offset credits in the cap-and-trade program.
- The WCI Partner jurisdictions encourage the development of offset projects located inside WCI Partner jurisdictions for compliance purposes in the WCI cap-and-trade regulatory program in order to capture collateral benefits associated with some offsets projects, such as health, social, and environmental benefits.

1.12.3. Stakeholder Input

Stakeholders generally supported a rigorous offset program. Underlying the support for an offset program is the recognition that all offsets used for compliance purposes must be of the highest quality. Stakeholders referenced issues that have arisen in previous offset programs, including the CDM, to highlight the importance of developing and applying project protocols that ensure that reductions are real, surplus/additional, verifiable, permanent, and enforceable.

Stakeholders were divided on whether the use of offsets for compliance purposes should be limited either in quantity or location. Some stakeholders suggested that there is no need to limit the use of high quality offsets because they reflect real emission reductions. Some stakeholders objected to the use of any offsets, pointing out the existing disproportionate environmental impacts experienced in some communities. Many stakeholders expressed a strong preference for a limitation on the use of offsets to ensure that a majority of reductions are made at covered facilities or entities. Many others favored no limitation provided the offsets meet rigorous criteria.

Many stakeholders expressed support for specific types of offsets. Many stakeholders also commented that the offset limitation should be applied to the reductions that are required, not to the compliance obligation of a facility or entity. Finally, some stakeholders recommended that the location of offset projects be limited to within WCI partner jurisdictions in order to assure enforcement and verification or so that the environmental co-benefits of the projects would be realized within the WCI jurisdictions. Others argued that any reduction in greenhouse gases in the world is important to combat climate change and thus the location of the project should not matter.

1.12.4. Discussion of WCI Partners' Recommendation

The WCI Partners believe that the program as designed will result in a rigorous offset program. The Partners recognize that issues have been raised regarding the quality of offsets from previous programs and the Partners propose to learn from past efforts, to build on their strengths and avoid their weaknesses. Toward this end, the Partners will develop and implement the offset program in an open and transparent manner that incorporates stakeholder input and involvement.

In making the recommendations in the program design, the WCI Partner jurisdictions considered the following:

- Offsets are an important tool to manage the risks of unexpectedly high compliance costs. Multiple analyses, including the economic analysis conducted for the WCI Partner jurisdictions, highlight the role that offsets can play in reducing the risks of high compliance costs.
- The quality of the offset project matters. It must be real, additional/surplus, permanent, verifiable, and enforceable.
- The criteria and protocols for offsets are critically important and will be developed by the WCI partner jurisdictions jointly.
- The manner in which greenhouse gases, especially carbon dioxide, mix in the atmosphere means that a reduction in any location is important to address global climate change.
- The wording of the Initiative signed by the Governors and Premiers calls for a design of a market program that will reduce greenhouse gases in the WCI Partner jurisdictions collectively "and to achieve related co-benefits."
- Co-benefits include the innovation that comes from moving toward a low carbon economy, which the cap incentivizes.
- The majority of emission reductions - at least 51 percent - will come from facilities and entities covered by the WCI program. This will help initiate the transformation to a low- carbon future within the WCI jurisdictions.
- Any WCI Partner jurisdiction that sets a limit lower than 49 percent will reduce the use of offsets and allowances from other systems from its portion of the total.
- Offset projects in developed countries (including Canada and the United States) that reduce emissions from sources that would be covered by the cap-and-trade program were they in the WCI Partner jurisdictions are not eligible to create offset credits. The WCI Partners have excluded offset credits from these projects in developed countries to avoid providing an incentive to delay the adoption of policies to reduce GHG emissions.
- Offset projects located outside the WCI jurisdictions that are subject to comparably rigorous oversight, validation, verification, and enforcement as those located within the WCI jurisdictions should help reduce compliance costs.
- The WCI Partner jurisdictions recognize that flexibility to use the limited amount of offsets and allowances from other systems any time throughout the period of 2012-2020 may help contain compliance costs. Therefore, the offset program may

incorporate flexibility to use offsets and non-WCI allowances across the three compliance periods, which each WCI Partner jurisdiction could use at its discretion.

- The WCI economic modeling analysis found that offsets contribute to managing the risk of high compliance costs in combination with banking and complementary policies. However, the analysis indicated that limiting the use of offsets and allowances from other programs to 49 percent of the reductions achieved by the program should provide adequate cost moderation.

The WCI Partner jurisdictions will establish eligible WCI offset project types, as well as requirements, methodologies and measurement and verification protocols, in advance of the program start. This approach will help ensure that project developers clearly understand the requirements for achieving acceptable reductions before the project begins. The WCI Partner jurisdictions will also develop a process by which offset project developers can propose additional offset project types for approval.

The WCI Partners did not include a recommendation to limit offset projects to WCI Partner jurisdictions in order to provide opportunities for additional low-cost reductions within the system, to support emission reductions on a global scale, and because of concerns that such a limitation may not withstand legal challenges.

1.13. Cost Containment

1.13.1. Definition

Cost containment is keeping the costs of program as low as possible, consistent with program objectives. There are a variety of cost containment mechanisms that can help manage the cost of compliance for covered entities in a cap-and-trade program. The cap-and-trade program is itself a form of cost containment, since emission trading minimizes costs. Offsets, described above, are a cost containment mechanism. Temporal flexibility, including banking, borrowing, and the length of the compliance period, is another.

1.13.2. Design Recommendation

The WCI Partner jurisdictions are recommending a broad scope and the inclusion of offsets as described above. They also recommend that purchasers and covered entities be allowed to bank allowances, without restrictions on the amount of allowances that may be banked or on how long they may be banked. WCI Partner jurisdictions recommend that borrowing of allowances from future compliance periods not be allowed. The WCI Partners recommend the compliance periods be three years long.

1.13.3. Stakeholder Input

Stakeholder input generally favored the inclusion of the cost-containment features of a broad cap-and-trade program, some offsets component, and unlimited banking. Stakeholder comment generally did not favor borrowing. In addition, some stakeholders called for an emergency clause, allowance price cap, or exit ramp in the event of a significant economic crisis attributable to the cap-and-trade program.

1.13.4. Discussion of WCI Partners' Recommendation

The WCI Partner jurisdictions have made a number of design decisions that will contain costs.

- The broad scope affords numerous opportunities to contain costs through emission trading.
- Temporal flexibility allows firms greater flexibility in compliance. Such flexibility can reduce allowance price volatility.
- Unlimited banking will help address price volatility.
- Complementary programs will also contain costs, and the program encourages their use.
- Offsets will also help contain costs.

The WCI Partner jurisdictions did not include borrowing for the reasons noted in Part 1.11. An allowance price cap was also not included because of the potential to exceed the cap and not meet the emission goal in 2020. The WCI Partners hope to link this program to other similarly rigorous programs, possibly including the EU ETS. It is the understanding of the WCI Partner jurisdictions that the EU will not link to a system with a price cap. Finally, the WCI Partner jurisdictions did not include an escape clause because each WCI Partner jurisdiction has its own laws on emergency action that must be considered in the development of any such recommendation.

1.14. Reporting

1.14.1. Definition

Reporting describes the required monitoring and measurement of GHG emissions by facilities and entities, and how these emissions will be reported.

1.14.2. Design Recommendation

The WCI Partner jurisdictions recommend that mandatory measurement and monitoring for the six included GHGs commence January 2010 with reporting of the 2010 calendar year emissions beginning in early 2011. The entities and facilities subject to reporting are those with annual emissions equal to or greater than 10,000 metric tons of CO_2e. Where fuel combustion emissions are covered upstream (e.g., emissions from transportation fuel combustion and emissions from fuel combustion at residential, commercial, and industrial facilities with emissions below the threshold) the reporting threshold will apply to entities (e.g., fuel distributors and blenders) based on the expected combustion emissions from the fuels distributed. However, in some limited instances the threshold may be based on other parameters, such as throughput or capacity, as long as these thresholds represent the equivalent of, or are lower than, the 10,000-metric-ton threshold.

WCI Partner jurisdictions will require third-party verification of reported emissions from entities and facilities that will be included under the cap.

Prior to the start of the mandatory reporting program, the WCI Partner jurisdictions will establish the essential requirements for reporting by all entities and facilities required to report in each of the WCI Partner jurisdictions. Essential requirements will include specifics regarding:

- Applicability and Boundaries
- Definitions
- Timing
- Report Content and Submittal
- Pollutants and Equivalence Factors
- Compliance
- Verification/Audit/Quality Assurance
- Emissions Quantification and Monitoring

As each WCI Partner jurisdiction collects additional emissions data from entities and facilities required to report, certain data will be made available to all WCI Partner jurisdictions for review and consideration for possible expansion of the cap-and-trade program.

Each WCI Partner jurisdiction will maintain discretion to require reporting at lower thresholds or from entities and facilities outside of the cap-and-trade program.

1.14.3. Stakeholder Input

Stakeholders said they want a reporting system that is fair, easy to manage, and not costly for reporters or WCI Partner jurisdictions. Stakeholders generally supported a transparent and robust accounting system for consistent and accurate reporting of emissions across sectors and jurisdictions. There was substantial support for the WCI Partner jurisdictions' efforts to harmonize WCI reporting and future federal greenhouse gas reporting, and there was concern regarding the burdens of having to report differently to multiple programs. Stakeholders overwhelmingly supported beginning reporting before cap-and-trade commences, in order to have accurately measured emissions as a basis for allocating allowances. Stakeholders were generally split on the topic of third-party verification.

Additional opportunities for stakeholder input will be available during the fall of 2008 as the essential requirements for reporting continue to be developed and the final draft is released in December of 2008.

1.14.4. Discussion of WCI Partners' Recommendations

Comprehensive mandatory and accurate reporting is especially important to a cap-and-trade program because of its focus on actual emissions performance and emission allowance trading. The WCI Partner jurisdictions' recommendations are consistent with the overwhelming stakeholder support for beginning reporting before cap-and-trade commences, and with the general support for the development of uniform WCI-wide reporting rules to maximize administrative simplicity and cost effectiveness.

The WCI Partners recognize the burdens that would be created by multiple widely divergent reporting programs, and will seek to harmonize reporting across WCI Partner jurisdictions. The WCI Partner jurisdictions will encourage federal reporting program development to consider the need for flexibility and accommodation of the needs of regional cap-and-trade programs already far along in their development.

The WCI Partner jurisdictions recommend a reporting threshold lower than the threshold for inclusion in the cap-and-trade program for several reasons. First, reporting must be at a lower level to ensure that accurate, verified emissions data support the exclusion of a sub-threshold entity or facility from the obligation to hold allowances. Second, reporting down to a threshold of 10,000 metric tons of CO_2e is needed to determine whether the threshold for inclusion in the cap-and-trade program is set at the appropriate level to include a high proportion of emissions. Third the lower reporting threshold is required to monitor potential leakage to facilities or entities below the threshold of the cap-and-trade program. Finally, a threshold of 10,000 metric tons of CO_2e is being considered in potential legislation for a U.S. federal cap-and-trade program.

The WCI Partner jurisdictions have considered the advantages and disadvantages of third-party verification and jurisdictional audit and quality assurance. The WCI Partner jurisdictions note that in a cap-and-trade program, every metric ton of emissions translates into a financial obligation or benefit, whereas in existing air pollutant reporting and compliance, errors in emissions data can be inconsequential if they do not affect whether a compliance limit has been exceeded. For those facilities and entities with compliance obligations, there are no inconsequential emissions totals. A high degree of accuracy and reliability for this emissions data is needed for market transparency and credibility, as well as for potential linkage to other emissions trading programs.

1.15. Enforcement

1.15.1. Definition

Enforcement is the means of assuring covered entities' compliance with the cap-and-trade program.

1.15.2. Design Recommendation

The WCI Partner jurisdictions recommend that if a covered entity or facility does not have sufficient allowances at the end of a compliance period, the entity or facility shall be required to surrender three allowances for every excess metric ton of CO2e to the jurisdiction to which they have the compliance obligation within three months of the end of each compliance period. This does not preclude other penalties allowed under individual state or provincial laws. Each WCI Partner jurisdiction will retain its existing regulatory and enforcement authority and responsibilities.

1.15.3. Stakeholder Input

Stakeholders generally recognized the importance of having an enforcement mechanism. A number of stakeholders noted a preference for financial penalties or a combined policy that calls for a violator to surrender required allowances and pay a fine. Additionally, some stakeholders requested greater flexibility during the first compliance period while regulated sources become familiar with the program. Stakeholders also highlighted the importance of transparency in the enforcement process, specifically recommending that information be made public regarding the use and origin of offset credits for compliance.

1.15.4. Discussion of WCI Partners' Recommendation

In any cap-and-trade program, participants must be accountable for their emissions and must comply with requirements for monitoring, reporting, and holding adequate emissions allowances. The enforcing jurisdiction must provide certainty through well-recognized and automatic penalties for non-compliance. Previous well-designed cap-and-trade programs have had compliance rates over 99 percent. [27]

The enforcement mechanism recommended by the WCI Partner jurisdictions is the same as the NO_x Budget Program in the northeastern United States. The Partners did not recommend a financial penalty because the price of allowances will be set by the market. It will be impossible to assure a set penalty amount will be higher than the cost of allowances.

---

[27] Recommendations for Designing a Greenhouse Gas Cap-and-Trade System for California, available online at http://climatechange.ca.gov/publications/market_advisory_committee/2007-06-29_MAC_FINAL_REPORT.PDF.

However, each WCI Partner jurisdiction may establish additional penalties, including civil and criminal penalties for intentional violations of program requirements. Such penalties provide an additional level of deterrence to ensure that the financial incentives associated with the cap-and-trade program are not abused and to increase confidence in the integrity of the market and the value of an allowance.

The WCI Partner jurisdictions also recommend that certain data from the emissions reports, allowances, and offsets that are used for compliance be made public in a timely manner to ensure transparency and maintain public confidence.

1.16. Regional Organization

1.16.1. Definition

A *regional organization* centralizes the execution of administrative tasks for the WCI Partner jurisdictions. It has no authority beyond that of the individual WCI Partner jurisdictions.

1.16.2. Design Recommendation

The WCI Partner jurisdictions will create a regional administrative organization to:

- Coordinate the regional auction of allowances;
- Track emissions and provide public information on progress towards the WCI regional goal;
- Monitor and report on market activity, including any potential market manipulation;
- Serve as a forum for WCI Partners to update one another on program progress;
- Coordinate review and adoption of protocols for offsets;
- Coordinate review and adoption of updated reporting requirements and emissions measurement methods;
- Coordinate review and issuance of offset credits; and
- Suggest criteria and means to accredit service providers to deliver validation and verification services.

1.16.3. Stakeholder Input

Stakeholders generally emphasized the need for coordination across the region to ensure consistency in the program.

1.16.4. Discussion of WCI Partners' Recommendation

The regional organization recommendation is designed to help the WCI Partner jurisdictions achieve the necessary coordination. Each jurisdiction will retain its regulatory authority and enforcement responsibilities. By centralizing administrative tasks and coordinating WCI Partner activities, the regional organization will help reduce administrative costs and improve program transparency and consistency. RGGI has such an organization and it has thus far been successful in facilitating consistent implementation of RGGI's cap-and-trade program across the RGGI states.

1.17. Other Issues Raised by Stakeholders

A few stakeholders have also raised issues around market manipulation. The WCI Partners will continue to examine this issue and are committed to taking steps as the program is further designed to minimize the potential for manipulation. Evidence from existing and past allowance systems has not revealed compelling evidence that market manipulation through collusion or other market gaming situations has occurred. Price distortions did occur where there was not full price disclosure or when trading was thin, causing price volatility.

2. Overview of Cap-and-Trade

A cap-and-trade program sets a clear, mandatory, enforceable limit on GHG emissions and then allows the market to identify the least-cost ways to achieve the limit. The state or provincial government sets an absolute aggregate limit (or "cap") on GHG emissions from a sector or multiple sectors. Tradable emissions "allowances," or limited authorizations to emit,[28] are then distributed in an amount that equals the total emissions permitted by the cap, which may decline over time. These allowances can be distributed by auction, free allocation, or a combination of the two. The government specifies which entities or facilities must surrender allowances to cover their emissions at the end of a pre-determined period of time, which is called the "compliance period."

After allowances are issued by governments, they can be bought and sold ("traded"). The limit on the total number of allowances, combined with the requirement to surrender allowances to cover emissions, makes allowances valuable and scarce. Allowance trading occurs because participants face different costs for reducing emissions. Trading allowances reveals a market price for them. The price is an incentive to facilities and entities with emissions to either invest in reductions that will let them sell allowances or avoid the cost of buying them. For some participants, implementing new, low-emitting technologies may be relatively inexpensive. Those participants will buy fewer allowances or sell surplus allowances to participants that face higher emission control costs. A participant will choose to buy more allowances when the cost of an allowance is lower than the cost of reducing its emissions. By giving participants a financial incentive to control emissions and the flexibility to determine how and when emissions will be reduced, the capped level of emissions is achieved in a manner that minimizes the cost of emissions reductions.

[28] Emission allowances are not considered property rights but are a limited authorization to emit.

Emissions trading programs have been successfully implemented in the United States and other countries to control other types of emissions, such as acid rain pollutants like sulfur dioxide (SO_2), in an environmentally sound, cost-effective manner.[29]

When designed properly, cap-and-trade programs provide certainty on the level of emissions reductions achieved and help ensure these reductions are attained at the lowest cost. The cap creates a firm limit on GHG emissions. By letting individual sources choose when and how to reduce emissions, cap-and-trade minimizes the cost of emission reduction. It also stimulates the development of new technological solutions that can enable lower-cost reductions now and in the future.

Cap-and-trade programs may also cost governments less to implement than command-and-control programs in which governments specify various performance, operational, or emission requirements based upon technology.[30] The state or province needs only (1) to ensure that covered sources accurately report their emissions and, at the end of each compliance period, surrender a number of allowances equal to their emissions; and (2) to provide some market oversight to ensure fair competition.

When designed properly, cap-and-trade programs can be particularly useful in the effort to address climate change and can aid more traditional policies in achieving emissions reductions. Greenhouse gas emissions come from many different kinds of sources with widely varying options for achieving emission reductions, affording numerous opportunities for mutually advantageous trading. Also, the location of a given emissions reduction does not matter with respect to climate change. A GHG cap-and-trade program is environmentally effective because a ton of carbon dioxide (CO_2) or other greenhouse gas emitted from one source has the same global warming effect as a ton emitted from any other.[31]

---

[29] Estimated savings for Phases I and II of the Acid Rain Program were more than $1 billion in 1995 dollars. The cost savings estimated in comparison to command-and-control approaches were estimated to be about 44-55 percent of the total compliance costs. *See for example* Carlson, C. P., D. Burtraw, M. Cropper, and K. L. Palmer. 2000. Sulfur dioxide control by electric utilities. *Journal of Political Economy* 108 (6):1292-1326. Ellerman, A. D., P. L. Joskow, R. Schmalensee, J. Montero, E. M. Bailey. 2000. *Markets for Clean Air: The US Acid Rain Program*. Cambridge: Cambridge University Press.

[30] For example, the U.S. acid rain program requires a staff of approximately 50 people to track all emissions data, allowance transfers, and compliance for over 4000 sources, including auditing of all hourly emissions data, tracking several thousand allowance transfers per year, annual compliance determination, and annual program assessment. See *Recommendations for Designing a Greenhouse Gas Cap-and-Trade System for California*. Recommendations of the Market Advisory Committee to the California Air Resources Board, June 2007, p. 73 and 99. Available online at www.pewclimate.org/docUploads/2007-06-29_MAC_FINAL_REPORT.pdf

[31] From a climate change perspective, because GHGs are chemically stable and persist in the atmosphere for a decade or longer and become well mixed throughout the atmosphere, the location of the reduction does not matter. Still, there may be other important policy reasons to consider the location of GHG reductions.

2.1. The Reasons for a Regional Cap-and-Trade Program

The reasons for coordinating regionally to design and implement a cap-and-trade program are compelling. A vast body of literature makes the case for a GHG cap-and-trade system that maximizes coverage of emissions and minimizes the costs of achieving a given GHG emissions level. Cap-and-trade has been applied successfully in the United States and Canada and in other regions to reduce other pollutants, and a number of countries have implemented such a system for GHGs under the Kyoto Protocol of the UN Framework Convention on Climate Change. In the absence of U.S. and Canadian federal engagement in these efforts, many U.S. states and Canadian provinces are moving ahead on their own and/or in cooperation with neighboring states and provinces to reduce GHG emissions.[32]

Because of their broader coverage, regional cap-and-trade programs perform better than individual state or provincial programs can in terms of realizing cost savings from trade, maintaining competitiveness and avoiding emissions leakage. Emissions leakage occurs when economic activity and associated emissions shift out of the jurisdiction covered by the policy in order to avoid the costs of compliance. The regional program levels the competitive playing field across the participating jurisdictions, thereby reducing the risk of emissions leakage.

Regional cap-and-trade programs can be more efficient and effective than state-by-state and province-by-province efforts because they cover more emissions sources and provide greater opportunities for mutually beneficial transactions. Administrative and technical support functions can also be shared among the participating jurisdictions, lowering the overall costs of implementation. Regional cap-and-trade programs can also help move the United States and Canada toward federal-level policies by acting as laboratories for program design and implementation. RGGI, for example, has advanced the debate in the United States around a number of cap-and-trade design issues, including allowance auctioning and offsets. WCI jurisdictions hope that their own analyses, deliberations, decisions, and implementation experiences will help to accelerate the development of U.S., Canadian, and global GHG markets.

2.2. Lessons from the European Union

The European Union (EU) developed a cap-and-trade program to meet its GHG reduction obligation under the Kyoto Protocol. The EU Emissions Trading Scheme (ETS) covers carbon dioxide emissions from certain sectors, including power generation, certain industrial process sources, and all large industrial combustion facilities. Proposed in 2001, the EU ETS began its three-year "learning phase" in 2005. The goal of the learning phase was to

---

[32] In addition to the states and provinces participating in the WCI, ten Northeast states (Connecticut, Delaware, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Rhode Island, and Vermont) have joined to form Regional Greenhouse Gas Initiative (www.rggi.org), which is a cap-and-trade program for CO_2 from electrical utilities, and six Mid-Western States (Iowa, Illinois, Kansas, Michigan, Minnesota, and Wisconsin) and one Canadian Province (Manitoba) have signed on to the Mid-Western Greenhouse Gas Reduction Accord (www.midwesternaccord.org) to design a cap-and-trade program for their region.

develop the infrastructure and experience to successfully implement a cap-and-trade program during the second trading period, which started in 2008, and not to achieve significant reductions in GHG emissions, per se.[33]

A number of lessons can be drawn from the EU ETS. In particular, the EU ETS learning phase demonstrated:

- The importance of accurate emissions data to create an effective trading system that results in sufficient emissions reductions and to ensure that the appropriate number of allowances is distributed;
- That cost containment measures such as banking and multi-year compliance periods tend to reduce market volatility;
- Suppliers quickly factor the price of emissions allowances into their business decisions under a cap-and-trade program;
- The relationship between allowance allocation, allowance markets, and electricity regulation must be understood and addressed to avoid unintended consequences; and
- The linkage of 28 separate trading programs in the EU ETS provides a valuable prototype for a globally linked carbon market.

2.3. Lessons from Other Emission Trading Programs[34]

The United States has implemented six emissions trading programs since the late 1970s: the early U.S. EPA emissions trading programs,[35] the federal Lead-in-Gasoline, Acid Rain, and Mobile Source trading programs; the northeast regional NOx Budget Trading Program, and the Los Angeles Air Basin RECLAIM program. From an examination of the literature and experiences with these programs, there are important lessons and recommendations that emerge:

---

[33] For a full examination of the EU ETS, see Ellerman, D. A. and P. Jaskow. 2008. *The European Union's Emissions Trading System in Perspective.* Pew Center on Global Climate Change. Available online at: www.pewclimate.org/docUploads/EU-ETS-In-Perspective-Report.pdf

[34] *See for example* www.epa.gov/airmarkets.usca; Aulisi, A., A. E. Farrell, J. Pershing, and S. Vandeveer. 2005. *Greenhouse Gas Emissions Trading in U.S. States. WRI White Paper.* Available online at http://pdf.wri.org/nox_ghg.pdf. Ellerman, A. D., P. L. Joskow, and D. Harrison, Jr. 2003. *Emissions Trading in the U.S*. Pew Center on Global Climate Change. Available online at www.pewclimate.org/global-warming-in-depth/all_reports/emissions_trading. *Climate Change 101: Cap and Trade*. Pew Center on Global Climate Change and Pew Center on States. Available online at www.pewclimate.org/docUploads/Cap&Trade.pdf.

[35] The early EPA programs included four programs—collectively referred to as EPA Emissions Trading or EPA ET—are related by the common objective of providing sources with flexibility to comply with traditional source-specific command-and-control standards while maintaining environmental objectives focused primarily on local air quality. They included netting, offsets, bubbles, and banking. *See* Ellerman, A. D., P. L. Joskow, and D. Harrison, Jr. 2003. *Emissions Trading in the U.S*. Pew Center on Global Climate Change.

- Emission trading has successfully reduced emissions and the costs of achieving those reductions without compromising environmental goals.[36]
- The inclusion of a broad and diverse set of emission sources under the cap will lower costs, achieve the environmental objective, and accelerate innovation, making cap-and-trade particularly applicable for reducing greenhouse gas emissions.
- A common set of rules and guidelines are required for monitoring and reporting emissions to ensure market transparency and compliance.
- Rigorous monitoring of emissions is critical to making the probability of detecting non-compliance high. Penalties for non-compliance must be strict and sure.
- There are some elements of a multi-jurisdictional cap-and-trade program that must be the same between implementing jurisdictions; these include certain elements of measurement and reporting of emissions, the schedule for distributing allowances to covered entities or facilities, compliance and reconciliation periods, the use of banking and/or borrowing, the acceptance of offsets and allowances from other trading programs, and compliance and enforcement.
- Other elements of a multi-jurisdictional cap-and-trade program do not need to be the same across implementing jurisdictions: it is not critical that the states and provinces allocate allowances within their jurisdictions in the same manner and jurisdictions may include varying levels of auction in their allowance distribution.

2.4. WCI Design Principles

To attain the Western Climate Initiative's regional GHG reduction goal, the WCI Partner jurisdictions committed to designing a cap-and-trade system that:

- Is equitable, administratively simple for government and private participants, minimizes administrative costs, and has a clear compliance path;
- Maximizes total benefits in jurisdictions throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts;
- Requires all reductions to be real, verifiable, enforceable, and permanent, and surplus/additional;
- Stimulates investment, especially in low carbon technologies, and rewards innovations that will lead to long-term, permanent greenhouse gas reductions;
- Covers as many sources as is practical, while encouraging pollution reductions beyond the capped sources and sectors;

[36] When compared to a policy that would have forced scrubbing to achieve the same level of emissions (required for acid rain mitigation), cost savings of the Acid Rain Program were estimated to be $1.6 billion per year in 1995 dollars. *See* Carlson, C. P., D. Burtraw, M. Cropper, and K. L. Palmer. 2000. Sulfur dioxide control by electric utilities. *Journal of Political Economy* 108 (6):1292-1326.

- Provides appropriate recognition and incentives for early emissions reductions;
- Assures a transparent and robust accounting system that will measure and report emissions rigorously and consistently across all sectors and throughout the region;
- Minimizes the potential for leakage; and
- Facilitates linkage to similarly rigorous regional and international greenhouse gases reduction markets and encourages other states, provinces, and countries to join the market.

2.5. Statement on the Overall Policy Design

The WCI Partners are proposing the most expansive cap-and-trade program in U.S. history, covering more sectors than the EU ETS in a broad, multi-sector greenhouse gas cap-and-trade program. As designed, the program will cover approximately 90 percent of the region's GHG emissions. Recognizing that federal mandatory GHG reduction programs might emerge in the United States and/or Canada, the WCI Partner jurisdictions have designed a program that can stand alone, provide a model for, be integrated into, or be implemented in conjunction with future federal programs. The WCI Partner jurisdictions intend to promote and influence federal GHG emission reduction programs that are consistent with the WCI cap-and-trade design principles and to ensure those programs translate into absolute GHG reductions. In the event WCI issues allowances before a federal program in Canada or the United States, the WCI Partner jurisdictions will work to ensure, but cannot guarantee, that those allowances are fully recognized and valued in the operation of a federal program.

3. Process to Date and Continued Work

3.1. Setting the Regional Goal

The WCI Partner jurisdictions issued their regional GHG reduction goal on August 22, 2007 to achieve an aggregate reduction of 15 percent below 2005 levels by 2020.[37] The WCI regional goal is consistent with the state and provincial goals of the WCI Partner jurisdictions and does not replace the existing goals of the individual WCI Partner jurisdictions. Several metrics were used to establish this goal, including:

- The aggregation of GHG emissions and emissions goals of the WCI Partner jurisdictions;
- Currently available state and provincial emissions inventories, including gross emissions estimates, across all sectors, for the six GHGs reported to the United Nations Framework Convention on Climate Change by the U.S. Environmental Protection Agency in the US Greenhouse Gas Inventory and by Environment Canada in the Canada National Inventory Report: carbon dioxide (CO_2), methane (CH_4), nitrous

[37] *See* Western Climate Initiative Statement of Regional Goal. Available online at www.westernclimateinitiative.org/ewebeditpro/items/O104F13006.pdf.

oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6); and[38]

- Where available, consumption-based (or "load-based") emissions estimates for the electricity sector, reflecting the emissions associated with generating the electricity delivered to consumers in each state or province regardless of whether the electricity was generated in state/province or out of state/province.

The WCI Partner jurisdictions also committed to doing their share to reduce regional GHG emissions sufficiently over the long term to significantly lower the risk of dangerous threats to the climate. Current science suggests that this will require worldwide reductions in carbon dioxide emissions of 50 to 85 percent below 2000 levels by 2050.[39]

3.2. The Work of the Subcommittees

Five WCI subcommittees were formed to work toward a cap-and-trade program design that all WCI Partner jurisdictions can embrace and recommend for implementation in their jurisdiction. The five subcommittees and their purposes were:

- Reporting. Recommend the GHG emissions reporting system needed to support the WCI cap-and-trade program.
- Electricity. Recommend the point of regulation for the electricity sector.
- Scope. Recommend what other sectors and sources to include in the cap-and-trade program in addition to the electricity sector and the appropriate point of regulation for each sector.
- Allocations. Recommend how to apportion emissions allowances among the WCI Partner jurisdictions and how WCI Partner jurisdictions should distribute allowances to achieve jurisdictional and regional goals.
- Offsets. Recommend whether and how emissions offsets should be included.

Each subcommittee was chaired by a representative of one of the WCI Partner jurisdictions, composed of staff from WCI Partner and observer jurisdictions, and had support from various consultants and advisors working under contract to the Western Governors' Association. During the development of the draft program design, the subcommittees met regularly by conference call and at times held face-to-face meetings. All subcommittees incorporated stakeholder involvement and feedback to help design the program.

---

[39] IPCC. 2007. *Climate Change 2007: Synthesis Report; Summary for Policymakers.* Available online at: www.ipcc.ch/pdf/assessment-report/ar4/syr/ar4_syr_spm.pdf

In addition to these five subcommittees, an Economic Modeling Team (EMT) was established to prepare the work plan for, select, and oversee the work of a contractor to evaluate the potential economic impact of the cap-and-trade program. This effort is on-going and includes outreach to stakeholders to receive advice and data to bolster the assumptions and inputs that underlie the modeling exercise.

3.3. Stakeholder Process for the Design Recommendations

Throughout the WCI cap-and-trade design process, there have been many opportunities and methods for stakeholder input on a regional level. These opportunities supplemented and did not replace extensive stakeholder consultations at the state and provincial level. In addition, states and provinces have and are continuing to conduct extensive stakeholder consultations. The decisions reached throughout the design process have benefited greatly from stakeholder input.

The regional stakeholder process for the Design Recommendations included a number of important avenues for the sharing of information and input. Among them:

- Stakeholder Workshops. Five regional stakeholder workshops were held to allow face-to-face interaction between stakeholders and WCI Partner jurisdictions and staff. Three of these workshops were comprehensive and included subcommittee-specific sessions to explore the subject areas within each subcommittee's purview. The other two addressed offsets and electricity point-of-regulation specifically. The workshops are noted in the table below.
- Stakeholder Conference Calls. Over the course of the design effort, the WCI Partner jurisdictions held regional stakeholder conference calls to update stakeholders on progress toward a cap-and-trade design and to answer stakeholder questions.
- Review and Comment in Writing. At regular intervals throughout the process, the WCI Partner jurisdictions and the subcommittees released written work for review and comment by stakeholders.
- The Website.[40] The WCI website served as a repository for information on the design effort. The website included information on upcoming stakeholder calls and workshops, and also provided a way to submit comments to the WCI Partner jurisdictions.

The table below details the various stakeholder events along with the work products released by WCI leading up to the release of the Design Recommendations accompanying this document. As noted above, the activities outlined in the table are in addition to the individual outreach to stakeholders conducted by each individual WCI Partner jurisdiction.

[40] The Western Climate Initiative website can be accessed at www.westernclimateinitiative.org.

Part 1, Cap-and-Trade Program Design, summarizes stakeholder input on the cap-and-trade program design elements.

3.4. Continued Work

The Design Recommendations released along with this document represent the final high-level design elements for the cap-and-trade program. Many of the design aspects will require further development. The WCI Partner jurisdictions' next task will be to develop a work plan that identifies and prioritizes those items and develop a schedule for their completion. The work plan will be shared with stakeholders once it is complete. The work plan will include opportunities for stakeholders to advise, comment, and participate in the further development of the cap-and-trade program.

4. Economic Analysis

4.1. Insights from Prior Analyses of Climate Policies

The potential economic impacts of climate protection policies have been the subject of considerable analysis and debate for more than a decade. Recognizing that significant reductions in GHG emissions are required globally to prevent the most serious climate change impacts, studies have examined how to design climate policies to minimize economic impacts. One of the important recommendations from the recent work has been that market-based policies, such as cap-and-trade programs, can reduce emissions at a lower cost than can be achieved through traditional regulation. This conclusion is grounded in economic theory as well as empirical evidence from past cap-and-trade program experience. Specifically, comprehensive carbon pricing through a cap-and-trade program takes advantage of the diverse opportunities to reduce emissions throughout the economy and provides incentives for continued innovation.

Recent efforts, therefore, move past the basic question of whether to use market-based policies, such as a cap-and-trade program, and onto the question of how to best design a

---

[48] Meeting agenda and presentations are available online at www.westernclimateinitiative.org/WCI_Meetings_Events.cfm.

[49] The Draft Design Recommendations are available online at www.westernclimateinitiative.org/ewebeditpro/items/O104F18808.PDF.

cap-and-trade program. To inform the design of this program, the WCI Partner jurisdictions examined program guidance,[50] U.S. analyses of the Lieberman-Warner Climate Security Act and California AB32, and Canadian analyses by Environment Canada and British Columbia. These analyses consistently demonstrated that several program design features can have an important impact on compliance costs:

- Flexibility in the timing of GHG reductions reduces the overall costs of cumulative GHG abatement. Multiple-year compliance periods and allowance banking have been identified as effective approaches for providing flexibility.
- Allowing offset credits to be used for program compliance can lower the compliance cost of meeting emission reduction targets.
- A broad scope that covers more sectors in a cap-and-trade program can lower compliance costs by providing maximum opportunities to pursue low-cost emission reductions.

Studies have also shown that innovation in advanced, low-carbon technologies (such as carbon capture and storage for electric power generation) can have a substantial impact on compliance costs, particularly after 2020. Consequently, providing incentives for technology development and demonstration is important for minimizing costs.

Complementary policies have also been examined as a means for addressing market barriers that would otherwise hinder the exploitation of low-cost GHG emission reduction opportunities (e.g., via improved energy efficiency). Thus, complementary policies can lower the overall cost of reducing GHG emissions. Analysts differ in their treatment of complementary policies, however. Some analysts allow for cost savings to be realized from complementary policies such as building codes, appliance standards, vehicle standards, and energy efficiency programs. A recent McKinsey analysis of GHG abatement costs in the United States provides one view of the potential for gains from complementary policies.[51] McKinsey found significant opportunities to reduce GHG emissions while also saving money through investments in energy efficiency. The existence of opportunities to reduce GHG emissions at "negative cost" even in the absence of a cap-and-trade program suggests that complementary policies, such as energy efficiency standards and programs, can lead households and businesses to exploit such opportunities.

Other analysts start with the presumption that markets function efficiently, so that there is little or no opportunity for these complementary policies to lead to overall savings.[52] Under these assumptions, any climate policies must impose economic costs. This divergence of views on the potential to realize savings from complementary policies is one of the primary

[50] See, for example, U.S. Environmental Protection Agency, *A Guide to Designing a Cap and Trade Program for Pollution Control*, Office of Air and Radiation, Washington, D.C., EPA430-B-03-002, June 2003, available online at: www.epa.gov/airmarkt/resource/cap-trade-resource.html.

[51] Creyts, J., et al. (McKinsey). 2007.

[52] See generally Stavins, Robert et al. 2007. "Too Good to Be True? An Examination of Three Economic Assessments of California Climate Change Policy." AEI-Brookings Joint Center Working Paper No. 07-01.

factors that causes some studies to show a small net savings to the economy from climate policies, while others show a small net cost. What is important to recognize is that in virtually all analyses, well defined cap-and-trade programs with the cost-saving features listed above have been found to be consistent with continued robust economic growth in the U.S. and Canada. By coupling a cap-and-trade program with complementary policies, the WCI Partners expect to use the market to capture cost-effective reduction opportunities and drive innovation, while targeted complementary policies address barriers that might otherwise limit the adoption of least-cost emission reductions.

4.2. WCI Economic Analysis

In order to examine the economic impacts of WCI program design options, WCI Partner jurisdictions contracted with ICF International and Systematic Solutions, Inc. (SSI) to perform economic analyses using ENERGY 2020,[53] a multi-region, multi-sector energy model. The workings of the model and the inputs to the model were the subject of multiple stakeholder conference calls and were discussed at two WCI stakeholder workshops. Appendix B presents the results of the analysis.

To help inform the program design process, the analysis examined the implications of key design decisions, including: program scope, allowance banking, and the use of offsets. Due to time and resource constraints, the modeling was limited to the eight WCI Partner jurisdictions in the Western Electric Coordinating Council (WECC) area, thereby excluding from the analysis three Canadian provinces, Manitoba, Quebec, and Ontario. Future analyses are planned that will integrate these provinces so that a full assessment of the WCI Partner jurisdictions can be performed.

The results of the analysis provided the following insights into the program design:[54]

- Complementary Policies: The analysis demonstrated that energy efficiency programs, vehicle emissions standards, and programs to reduce vehicle miles traveled (VMT) are important for achieving emission reductions. The manner in which these policies are represented in ENERGY 2020 results in overall savings being realized from these policies. Resources from the cap-and-trade program (e.g., from the auctioning of emission allowances) can fund these complementary programs.
- Banking: The analysis demonstrated that the ability to bank allowances is critical for reducing compliance costs. Throughout all the cases examined, emission allowances

[53] More about the ENERGY 2020 model can be found online at www.energy2020.com/energy.htm.

[54] Like all analyses of climate policies, this analysis relies on a model to explore alternative policy choices and provide insights about how the economy might respond to different types and forms of regulation. The insights derived from the studies do not depend on perfectly accurate projections of the future or precise estimates of economic variables. Rather, modeling studies assess the relative impacts of policy alternatives, to estimate the likely economic effects of policies and to identify preferred policy choices. For a review of how economic models can be used in policymaking, see: Peace, Janet and John Weyant. 2008. "Insights Not Numbers: The Appropriate Use of Economic Models." White Paper prepared for the Pew Center on Global Climate Change, available at http://www.pewclimate.org/white-paper/economic-models-are-insights-not-numbers

were estimated to be banked in early years when allowance prices were below $10/metric ton, and used when allowance prices rose in later years.

- Offsets: The analysis demonstrated that under certain circumstances, offsets provide an effective mechanism for limiting compliance costs. In the analysis performed to date, offsets were assumed to be available at $20/metric ton. As allowance prices were estimated to rise to this level, offsets were estimated to be used in combination with allowance banking to reduce compliance costs.

Overall, the analysis found that the WCI Partner jurisdictions can meet the regional goal of reducing emissions to 15 percent below 2005 levels by 2020 with a small overall savings due to reduced energy expenditures exceeding the direct costs of GHG emission reductions.[55] The savings are focused primarily in the residential and commercial sectors, where energy efficiency programs and vehicle standards are expected to have the most significant impacts. Energy-intensive industrial sectors are estimated to have small net costs overall (less than 0.5 percent of output). When offsets are included in the analysis, allowance prices are estimated to increase from $6/metric ton in 2015 to about $24/metric ton in 2020. If offsets are not included, or if they cost substantially more than $20/metric ton, then the allowance price is estimated to be higher. To date the analysis has included a simplified representation of the potential supply of offsets. Additional work is being considered to develop a better estimate of the supply of offsets under various offset program policies.

The analysis examined the sensitivity of the results to various assumptions. The analysis suggests a net savings whether future energy prices are higher or lower than in the Reference Case. It also suggests a net savings with higher electricity power generation costs. If the program scope were narrowed to exclude transportation fuels and residential and commercial fuels, the overall impacts would be similar, but allowance prices may be expected to be higher because the program is focused on a smaller group of sources. If the program causes a substantial increase in natural gas prices, then the overall impact is estimated to be a small net cost to the economy. However, the program is not expected to lead to increases in natural gas prices. As discussed with stakeholders during the WCI economic analysis conference calls, it is worthwhile to explore many additional sensitivities to better understand the implications of various analytical assumptions and inputs. However, time and resources did not allow additional sensitivities to be examined for this report.

These WCI modeling results are generally consistent with the findings of prior modeling studies of both U.S. and Canadian programs. Offsets and allowance banking provide compliance flexibility that reduces allowance prices. The analysis suggests that offsets are particularly important during the years approaching 2020, but may play a minor role in the early years of the program when allowance prices are expected to be less than $10/metric ton. The overall net savings that are found are consistent with studies that assume that complementary policies, such as energy efficiency programs and vehicle standards, can

[55] Reduced energy expenditures are caused by improved energy efficiency.

result in economic savings. While the overall costs and savings from emission reductions and reduced fuel expenditures are small, potential impacts on specific energy-intensive industrial sectors warrant additional examination. In particular, the results reinforce the need to consider strategies for mitigating economic impacts on industries facing competition from facilities that are not included in climate policies.

In considering the results of the WCI analysis, it is worth highlighting several important assumptions:

- It is assumed that no new nuclear power or hydropower generation capacity will be built prior to 2020. Therefore, the analysis does not include any increase in this power as a result of the cap-and-trade program.
- It is assumed that no carbon capture and storage for electric power generation will be built prior to 2020. Consequently, the analysis does not include the benefits of this carbon-sequestering technology.
- It is assumed that no new coal-fired power plants are built in the WECC states and provinces through 2020 beyond those that are already planned.
- It is assumed that plug-in hybrid electric vehicles will not be produced in any significant quantity prior to 2020. Thus, the model does not include an increase in this low carbon transportation alternative as a result of the cap-and-trade program.
- For the U.S. states, the requirements of the Energy Independence and Security Act (EISA) are assumed to be part of the Reference Case against which the cap-and-trade program is evaluated. For the Canadian provinces, lighting, equipment, and appliance standards as set out by the Canadian Standards Association as well as the federal "ecoENERGY" Renewable Fuels Strategy are included in the Reference Case.

Finally, the analysis does not examine the potential macroeconomic impacts of the costs and savings estimated with ENERGY 2020. The WCI Partner jurisdictions are planning to continue the analysis so that macroeconomic impacts, such as income, employment, and output, can be assessed. Once completed, the macroeconomic impacts can be compared to previous studies of cap-and-trade programs considered in the United State and Canada.

4.3. Benefits of Cap-and-Trade Not Fully Represented in Economic Models

Economic models are by necessity simplified representations of the real-world economy, including the characteristics of and relationships among the households and firms that constitute the economy. The simplified nature of these models means that they may not fully capture all of the advantages of market-based climate policies, such as cap-and-trade programs, compared to prescriptive standards (i.e. command-and-control or direction regulation). The aspects of the real-world economy that are imperfectly represented in models are described below along with the implications for how well modeling studies capture the true advantages of market-based climate policies.

Heterogeneity: In direct regulation, all facilities in an industry are required to achieve a given level of performance or emission reduction. Modeling tools typically represent the industry as a single "model facility" or as a sector with demand and supply elasticities. In reality, industry is actually heterogeneous with different facilities facing different costs for reducing emissions. An important benefit of cap-and-trade is that it allows the low cost facilities to do more than the high cost facilities—i.e. the market directs the least-cost emissions reductions. The existing modeling tools may not fully capture this benefit of cap-and-trade, thus underestimating the relative cost-effectiveness of cap-and-trade compared to other policies.

Diffuse Behavioral Change: The price signal from a market program such as cap-and-trade will create consumer behavior change throughout the economy that is diffuse and not necessarily captured by existing modeling tools. These behavior changes are responses to persistent price signals that are not reflected in elasticities and are not part of "model facility" engineering cost studies. For example, bottom-up energy models may show that efficient lighting will be installed at a given allowance price, but it may not show that the consumer will also use the lights more efficiently. Existing modeling tools may not fully reflect these effects.

Induced Innovation: The price signal from a market program such as cap-and-trade will induce technological innovation in a way that is not adequately included in models.

Errors in Direct Regulation Cost Estimates: When direct regulations are promulgated, the costs of complying with the regulations will likely be estimated incorrectly, either too high or too low. When a portfolio of direct regulations is being developed, the mix and stringency of the regulations will be incorrectly estimated as a result. If the cost estimates are too high for a regulation, that regulation will not be strict enough. If the cost estimate is too low, that regulation may be too strict. Market programs such as cap-and-trade do not suffer from this problem, as the market sorts out who should do what to achieve the total emission reduction needed. Existing modeling tools presume that the costs of control are known in advance and are correct. Consequently, the benefit of avoiding these cost estimating errors is not captured by the models, thereby under-estimating the benefits of using market programs.

Appendix A: Western Regional Climate Action Initiative Agreement

Note: This agreement was subsequently signed by: Premier Gordon Campbell, British Columbia, Premier Gary Doer, Manitoba, Governor Jon Huntsman, Utah, Governor, Brian Schweitzer, Montana, Premier Jean Charest, Quebec, and Premier Dalton McGuinty, Ontario

Janet Napolitano **Bill Richardson**

WESTERN REGIONAL CLIMATE ACTION INITIATIVE

WHEREAS, western states are experiencing the effects of a hotter, drier climate, including prolonged droughts, excessive heat waves, reduced snow packs, increased snowmelts, decreased spring runoffs, altered precipitation patterns, more severe forest and rangeland fires, widespread forest diseases, and other serious impacts; and

WHEREAS, scientific consensus has developed that increasing emissions of human-caused greenhouse cases (GHGs), including carbon dioxide, methane and other GHGs, that are released into the atmosphere are affecting the Earth's climate; and

WHEREAS, the Western Governors Association (WGA) has declared that climate change could have severe economic and environmental impacts on the Western States in coming decades; and

WHEREAS, the WGA also has declared that action is needed to reduce GHG emissions and that many of these actions can have significant economic and environmental benefits for the Western States, including increased energy efficiency, increased renewable energy generation, improved air quality, cost savings, job growth, increased state revenues, and reduced water pollution; and

WHEREAS, we support the development of national, regional, tribal, state and local programs to reduce GHG emissions; and

WHEREAS, we support national, regional, tribal, state and local level policies on global climate change that are consistent with efforts to develop cost-effective alternative energy sources and more efficient use of energy; and

WHEREAS, we recognize the need for collaboration among states to develop climate change policies that provide consistent approaches to recognize and give credit for actions to reduce GHG emissions; and

WHEREAS, we have already adopted or committed to adopt clean tailpipe standards for passenger vehicles that will result in major reductions in GHG emissions and other pollutants; and

WHEREAS, we support market-based policies to reduce GHG emissions in the most cost-effective manner; and

WHEREAS, we have set goals to significantly reduce GHG emissions from our respective states; and

WHEREAS, we welcome expanding the partners to this initiative to other states, tribes, Canadian provinces and Mexican states and offer monitoring status to any state, tribe or province interested in observing the initiative;

NOW, THEREFORE, we, the undersigned Governors, jointly establish the Western Regional Climate Action Initiative and agree to collaborate in identifying, evaluating and implementing ways to reduce GHG emissions in our states collectively and to achieve related co-benefits. This collaboration shall include, but is not limited to:

- Setting an overall regional goal, within six months of the effective date of this initiative, to reduce emissions from our states collectively, consistent with state-by-state goals;

- Developing, within eighteen months of the effective date of this agreement, a design for a regional market-based multi-sector mechanism, such as a load-based cap and trade program, to achieve the regional GHG reduction goal; and

- Participating in a multi-state GHG registry to enable tracking, management, and crediting for entities that reduce GHG emissions, consistent with state GHG reporting mechanisms and requirements.

In addition, we commit to continue our independent and collaborative efforts to reduce GHG emissions through:

- Promoting the development and use of clean and renewable energy within the region;

- Increasing the efficiency of energy use within our jurisdictions;

- Advocating regional and national climate policies that reflect the needs and interests of western states, tribes and provinces; and

- Identifying measures in our states, tribes and provinces to adapt to the impacts of climate change.

We will direct our staffs and the appropriate state agencies to meet as soon as is practicable to develop a work plan to move forward with this initiative.

DONE, in five (5) duplicate originals, this 26th day of February, 2007, in Washington, D.C.

Governor Christine O. Gregoire
State of Washington

Governor Theodore R. Kulongoski
State of Oregon

Governor Janet Napolitano

Appendix B: Economic Modeling Results

Introduction

This appendix presents data from the economic modeling performed for WCI, including the model inputs and outputs for the cases examined. The focus here is on the data and assumptions used as model inputs and the model outputs. The main body of the Background Document discusses the policy implications of the model results.

This appendix is organized as follows:

- Cases Analyzed: describes the cases presented in this appendix.
- ENERGY 2020: provides a brief technical discussion of the model used.
- Assumptions: lists the primary assumptions used in the model.
- Outputs: defines the model outputs that are presented for the cases.
- Summary Results: provides a brief table of key model outputs.
- Reference Case: presents the results of the Reference Case.
- Cap-and-Trade Policy Cases: presents the results of the cap-and-trade policy cases.
- Sensitivity Cases: presents the results of three sensitivity cases.

As discussed below, additional detail on the ENERGY 2020 model and the model inputs and assumptions used in this analysis are presented in the *Assumptions Book for ENERGY 2020* posted on the WCI website.[1]

Cases Analyzed

This appendix presents three groups of cases. The first group is the Reference Case which reflects expectations in the absence of the WCI policies to reduce greenhouse gas emissions.

The second group is the Cap-and-Trade Policy Cases. These cases examine the primary alternatives for the cap-and-trade program, including whether to allow the use of offsets and whether to have a narrow or broad scope. The narrow scope includes stationary sources (including process emissions) and the electric sector. The broad scope also includes transportation fuels and residential/commercial fuels. The cases presented are:

- broad scope without offsets;
- broad scope with offsets; and
- narrow scope with offsets.

For all three Cap-and-Trade Policy cases, complementary policies are included along with the cap-and-trade program, including clean car standards, programs to reduce vehicle miles traveled, and energy efficiency programs. These complementary policies are defined below.

The third group of cases is the Sensitivity Cases. The purpose of the sensitivity cases is to assess the impacts of various assumptions and inputs on the model results. These assumptions can affect both the Reference Case and the Policy Cases. While a large number of

[1] The WCI website is: www.westernclimateinitiative.org.

assumptions and sensitivities are of interest, this analysis focuses on three sensitivities that were identified as most important by WCI partner jurisdictions and stakeholders.

- High Energy Prices and High Generation Costs: This sensitivity includes both higher energy prices and higher power generation costs as a set of conditions that could occur together in the future. This sensitivity was performed for both the Reference Case and the Policy Case with the broad scope and offsets.
- Low Energy Prices: This sensitivity uses energy prices that are lower than those used in the Reference Case. This sensitivity was performed for both the Reference Case and the Policy Case with the broad scope and offsets.
- High Natural Gas Prices: This sensitivity was designed to examine the impact of higher natural gas prices that may be induced by policies that are undertaken to reduce greenhouse gas emissions. Consequently, this sensitivity was applied to the Policy Case with broad scope and offsets. The results of this Policy Case are compared to the Reference Case with the standard natural gas price assumptions because the presumption is that policies are inducing the natural gas prices to increase.

Additional sensitivity analyses are warranted, and many important and worthwhile issues were identified by stakeholders during the conference calls and workshops that covered this work. However, due to time and resource constraints, additional sensitivities are not included at this time. Future work is anticipated that will enable additional sensitivity analyses to be performed.

ENERGY 2020

ENERGY 2020 was used to perform this analysis. A description of ENERGY 2020 is in the *Assumptions Book for Energy 2020* posted on the WCI website.[2] Additional documentation is available on the California Air Resources Board (ARB) website.[3] The following is a brief summary.

ENERGY 2020 is an integrated multi-region energy model that provides all-fuel demand and supply sector simulations. ENERGY 2020 can be linked to a detailed macroeconomic model to determine the economic impacts of energy/environmental policy and the energy and environmental impacts of national economic policy. However, the macroeconomic analysis was not performed for this study.

The model simulates demand by three residential categories (single family, multi-family, and agriculture/rural), over 40 NAICS commercial and industrial categories,[4] and three transportation services (passenger, freight, and off-road). There are approximately six end-uses per category and six technology/mode families per end-use.[5] The technology families

[2] The WCI website is: www.westernclimateinitiative.org.

[3] The posting on the ARB website is at: http://www.arb.ca.gov/cc/scopingplan/economics-sp/models/models.htm.

[4] NAICS is the North America Industrial Classification System which was developed jointly by the U.S., Canada, and Mexico to provide new comparability in statistics about business activity across North America.

[5] End-uses include Process Heat, Space Heating, Water Heating, Other Substitutable, Refrigeration, Lighting, Air Conditioning, Motors, and Other Non-Substitutable (Miscellaneous). Detailed modes include: small auto, large

correspond to six fuels groups (oil, gas, coal, electric, solar and biomass) and 30 detailed fuel products. The transportation sector contains 45 modes including various type of automobile, truck, off-road, bus, train, plane, marine and alternative-fuel vehicles. More end-uses, technologies, and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical, locale-specific data. The load duration curves for electricity demand are dynamically built up from the individual end-uses to capture changing conditions under consumer choice and combined gas/electric programs.

Each energy demand sector includes cogeneration, self-generation, and distributed generation simulation, including mobile-generation, micro-turbines, and fuel-cells. Fuel-switching responses are rigorously determined. The technology families (which can be split, as an option, to portray specific technology dynamics) are aggregates that, within the model, change building shell, economic-process and device efficiency and capital costs as price or other information that the decision makers see, change. ENERGY 2020 utilizes the historical and forecast data developed for each technology family to parameterize and disaggregate the model.

The supply portion of the model includes endogenous detailed electric supply simulation of capacity expansion/construction, rates/prices, load shape variation due to weather, and changes in regulation.[6] The model dispatches plants according to the specified rules whether they are optimal or heuristic and simulates transmission constraints when determining dispatch. A dispatch routine selects critical hours along seasonal load duration curves as a way to determine system generation. Peak and base hydro usage is explicitly modeled to capture hydro-plant impacts on the electric system.

ENERGY 2020 supply sectors include electricity, oil, natural gas, refined petroleum products, ethanol, land-fill gas, and coal supply. Energy used in primary production and emissions associated with primary production and its distribution is included in the model. The supply sectors included in a particular implementation of ENERGY 2020 will depend on the characteristics of the area being simulated and the problem being addressed. If the full supply sector is not needed, then a simplified simulation determines delivered-product prices.

ENERGY 2020 includes pollution accounting for both combustion (by fuel, end-use, and sector) and non-combustion, and non-energy (by economic activity) for SO_2, NO_2, N_2O, CO, CO_2, CH_4, PMT, $PM_{2.5}$, PM_5, PM_{10}, VOC, CF_4, C_2F_6, SF_6, and HFC at the state and provincial level by economic sector.

Assumptions

This section presents an overview of the major assumptions used in the modeling analysis. The *Assumptions Book for ENERGY 2020* presents a detailed list of the model inputs, including links to the data sources used to assemble the input data.

---

auto, light truck, medium-weight truck, heavy-weight truck, bus, freight train, commuter train, airplane, and marine. Each mode type can be characterized by gasoline, diesel, electric, ethanol, NG, propane, fuel-cell, or hybrid vehicles.

[6] ENERGY 2020 includes a complete, but aggregate representation of the electric transmission system.

- Geographic Coverage: This phase of the analysis covers the area of the Western Electricity Coordinating Council (WECC), which includes eight WCI partners: British Columbia, Washington, Oregon, California, Arizona, New Mexico, Utah, and Montana. By covering the entire WECC, the impacts of the WCI programs and policies on electricity generation in the non-WCI WECC states and provinces can be examined. Future analyses are planned that will incorporate the WCI partners that are not in the WECC, including Manitoba, Ontario, and Quebec.
- Sectors and Sources: This phase of the analysis includes energy use in all sectors, as well as most industrial process emissions. Landfill methane emissions and non-energy agriculture emissions are included in the total emissions estimates, but emission reductions are not estimated for these sources.[7] The analysis is based on gross emissions, so that forestry emissions and sinks are excluded.
- WCI Population and GDP Forecast: The model is driven by forecasts provided as input that include population growth and economic growth by detailed sector. Table B-1 shows the population growth forecast and Table B-2 shows the economic growth forecast.

Table B-1: Population Forecast for Eight WCI Partners, Selected Years (Millions)

Jurisdiction	2006	2010	2015	2020	Annual Growth
Arizona	6.2	7.0	7.9	8.8	2.5%
British Columbia	4.3	4.5	4.7	4.9	0.9%
California	37.4	39.1	41.5	44.1	1.2%
Montana	0.9	1.0	1.1	1.2	1.6%
New Mexico	2.0	2.2	2.3	2.5	1.8%
Oregon	3.7	3.9	4.1	4.3	1.1%
Utah	2.6	2.7	3.0	3.2	1.6%
Washington	6.4	6.8	7.3	7.7	1.4%
WCI	**63.5**	**67.2**	**71.9**	**76.7**	**1.4%**
Source: Assumptions Book for ENERGY 2020					

[7] Examples of non-energy agriculture emissions are methane emissions from livestock, carbon and N_2O emissions from agricultural soils, and methane emissions from livestock manure management.

Table B-2: Regional Gross Product Forecast for Eight WCI Partners, Selected Years (Billions of 2007 US dollars)

Jurisdiction	2006	2010	2015	2020	Annual Growth
Arizona	237	271	322	363	3.1%
British Columbia	266	294	326	358	2.1%
California	1,800	2,066	2,458	2,782	3.2%
Montana	33	37	42	47	2.5%
New Mexico	77	87	103	117	3.0%
Oregon	159	186	227	259	3.6%
Utah	98	111	129	146	2.9%
Washington	302	345	410	462	3.1%
WCI	**2,972**	**3,396**	**4,018**	**4,534**	**3.1%**
Source: Assumptions Book for ENERGY 2020					

- Emission Reduction Options: The model simulates decisions by energy users for each end use, including: fuel choice; investment in end use efficiency (e.g., by purchasing devices that are more efficient than the minimum required by standards); and end use utilization (how much the device is used). End-use specific choices are simulated as needed, such as mode choice for freight movement and passenger transportation. Choices are simulated based on costs (increased capital costs versus the value of fuel saved) as well as non-price attributes (convenience, acceptance of the technology). Past purchasing behavior is used to calibrate the non-price choice parameters for each end use.
- Energy Independence and Security Act of 2007 (EISA): The Reference Case, Policy Cases, and Sensitivity Cases include the requirements in the EISA, including the CAFÉ standards, appliance and lighting energy efficiency standards, and the renewable fuels standard (RFS). These requirements are assumed to be implemented fully in the WCI partner jurisdictions in the United States. For British Columbia and other Canadian provinces, lighting, equipment and appliance standards as set out by the Canadian Standards Association[8] as well as federal "ecoENERGY" Renewable Fuels Strategy[9] are incorporated.
- Renewable Portfolio Standards: All cases incorporate the individual Partner's already-adopted Renewable Portfolio Standards (RPS). See Appendix I of the *Assumptions Book for ENERGY 2020* for details.

---

[8] http://www.oee.nrcan.gc.ca/regulations/home_page.cfm

[9] This strategy requires 5% average renewable content based on the gasoline pool that is produced or imported, starting in 2010, and 2% average renewable content in diesel fuel and heating oil (distillate) by 2012. The Canada Gazette indicates that the 2% renewable content in diesel fuel and heating oil is equivalent to 5% renewable content in on-road diesel use. (See http://canadagazette.gc.ca/partI/2006/20061230/html/notice-e.html#i3)

- WCI Fuel Prices: The model is also driven by forecasts of fuel prices (oil, coal, natural gas). The model calculates electricity prices internally. Table B-3 shows the fuel price forecast used in the Reference Case. This forecast is taken from the Energy Information Agency's Annual Energy Outlook 2008 high price series. State- and province-specific prices are derived in the model from the prices shown in this table.

Table B-3: Fuel Price Forecast

	2006	2010	2015	2020
World Oil Price (2007 US$/barrel)	64.32	76.22	86.92	97.90
Natural Gas Wellhead Price (2007 US$/mmBtu)	6.93	7.50	7.13	7.29
Coal Prices (2007 US$/ton)	25.33	26.91	24.78	24.29
Source: EIA Annual Energy Outlook 2008 high price series.				

- First Jurisdictional Deliverer: All cases incorporate a proxy to represent First Jurisdictional Deliverer. Consequently, emissions from electricity imported into the WCI partner jurisdictions from outside the WCI partner jurisdictions are included in the analysis.
- Allowance Banking: The model enables allowances to be banked when allowance prices are low, and for allowances to be used from the bank when allowance prices are high. Attachment 1 discusses the parameters used to model allowance banking.
- Coal Plants: The cases allow no new coal plants to be built by 2020 in the WECC beyond those already planned and committed. See Appendix F of the *Assumptions Book for ENERGY 2020* for the list of coal plants that are assumed to be planned and committed.
- Nuclear Plants: The cases assume no new nuclear plants to be built by 2020 in the WECC.
- Carbon capture and storage: Carbon capture and storage is assumed not feasible for electric power generation through 2020.
- Hydropower: The cases assume no new hydropower capacity built in the WECC by 2020.
- Plug-in hybrids: The cases assume that plug-in hybrid and electric vehicles are not available in significant numbers through 2020.
- Electrical Generation Costs: The modeling effort relies on estimates of power generation capital costs, operating costs, and heat rates developed for a recent study for the California Public utilities Commission (see Table B-4).
- Macroeconomic estimates: This phase of the analysis does not include macroeconomic analysis.

Table B-4: Summary of Power Generation Cost Inputs

Technology	Total Capital Costs $/kW	Fixed O&M ($/kW-yr)	Variable O&M ($/MWh)	Capacity Factor	Nominal Heat Rate
Biogas	$2,623	107.5	0.01	85%	11,566
Biomass	$3,836	50.18	2.96	85%	15,509
Geothermal	$3,575	154.92	-	90%	-
Hydro - Small	$2,530	13.14	3.3	50%	-
Solar - Thermal	$2,840	49.63	-	40%	-
Wind	$1,983	28.51	-	37%	-
Coal ST	$2,671	25.91	4.32	85%	8,844
Coal IGCC	$3,087	36.36	2.75	85%	8,309
Coal IGCC with CCS	$5,127	42.82	4.18	85%	9,713
Gas CCCT	$878	11.04	2.4	90%	6,917
Gas CT	$794	11.4	3.36	5%	10,807
Hydro - Large	$2,530	13.14	3.3	50%	-
Nuclear	$4,999	63.88	0.47	85%	10,400
<5MW CHP	$1,952	11.04	2.4	40.5%	9,700
>5MW CHP	$1,259	11.04	2.4	85%	9,220

Cost Basis Year = 2005. All estimates are 2008 U.S. dollars.
Source: E3 GHG Calculator v2b, tab "Gen Cost". Available at: http://www.ethree.com/GHG/GHG%20Calculator%20v2b.zip

Outputs

The model results include estimates of energy use, GHG emissions, electricity generation, fuel prices, and costs. The following are brief explanations of the model results that are shown for the cases analyzed.

- Greenhouse Gas (GHG) Emissions: GHG emissions are presented in millions of metric tons of carbon dioxide equivalent ($MMTCO_2e$). Emissions for the eight WCI partner jurisdictions included in the analysis are presented by major sector.
- Compliance Summary: The Compliance Summary shows how GHG emissions are reduced to achieve the WCI partners' regional emissions goal of a 15% reduction from 2005 levels by 2020. The Compliance Summary shows a Compliance Total, which is the calculated emissions minus offsets used and adjusted for any allowances that are banked or that are used from the bank. The running total of emission allowances banked is also reported. The Compliance Total also considers changes in emissions in the non-WCI WECC power sector. The WCI cap-and-trade policies and complementary policies will affect GHG emissions from power generated in the non-WCI WECC states and provinces.

The change in these emissions are also included in the Compliance Total. To make this calculation, emissions associated with power imported into the WCI jurisdictions are estimated at 70 million tons per year. This estimate is preliminary, and is based on an assessment of recent power flows and emissions factors. Given the uncertainty in the estimate of these emissions, as well as the imperfect manner in which the First Jurisdictional Deliverer (FJD) policy is represented in the model, the reduction in emissions from the non-WCI WECC power sector counted toward the Compliance Total is limited to no more than 45 million tons in any year. Using this limit, the potential emission reduction from the non-WCI WECC power sector may be underestimated, thereby making the model evaluate a more stringent program than may be required in some cases. The Compliance Total is compared to 2006 emissions calculated in the model to estimate the emission reduction. In all the cases presented below, the compliance total shows approximately a 15% reduction in total economy wide emissions in 2020 relative to 2006. As discussed above, the estimates include only the eight WCI partner jurisdictions in the WECC.

- Total Energy Use: Total energy use is reported by fuel type and by major sector in units of TBtu/year.
- Electric Sector: Outputs for the electric sector include:
  - Generation Capacity in units of megaWatts (MW) by generation type. Note that estimated generation capacity grows due to capacity additions, but capacity retirement is not calculated. Consequently, generation capacity does not decline in the model outputs.
  - Generation Output in units of gigaWatt-hours per year (GWh/year) by generation type. The generation output is for the eight WCI partner jurisdictions in the WECC.
  - Electricity Sales in units of GWh/year, including electricity imports into the eight WCI partner jurisdictions in the WECC.
- Transportation Sector: Outputs for the transportation sector include vehicle miles traveled for passenger and freight vehicles, as well as miles traveled per passenger. The fleet average efficiency is reported for four vehicle types in miles per gallon.
- Fuel Prices: Fuel prices are reported for electricity, natural gas, coal, fuel oil, LPG, gasoline, and diesel in 2007 dollars per million Btu (2007 $/mmBtu). The prices include the forecasted energy prices (presented in Table B-3 above for the reference case and other tables below for the sensitivity cases) as well as the costs of delivering the fuels to market. The prices reported for the cap-and-trade policy cases also include the calculated allowance price, reflecting the appropriate carbon content of the fuel.
- Costs and Savings: Costs and savings are reported in millions of 2007 dollars per year ($M/Yr). Fuel Expenditures are reported by major sector, showing changes in expenditures from the Reference Case. These estimates of fuels expenditures do not include the value of the calculated allowance price, so a separate table of total allowance value is presented (equal to emissions times the allowance price). The allowance values reported by sector do not consider that the full allowance value may not be passed

through to consumers. Consequently, the allowance value by sector is reported as "potential" allowance value, recognizing that a portion of the allowance value may be borne by producers and not passed through to consumers. Total Costs are also reported by major sector, which are the sum of changes in fuel expenditures and changes in investment costs. Investment costs increase as more efficient devices, buildings, and processes are purchased in response to the limit on GHG emissions. The investment costs are annualized using a 5% real discount rate over the life of the equipment. The annualize costs are counted each year over the life of the equipment. The estimates of Total Costs include both the change in fuel expenditures and the change in investment costs. As shown in the tables below, the fuel expenditure savings typically offset most or all of the increased investment costs.

Results are shown only for the total of the eight WCI partners included in the analysis. State and province specific results are not included.

Reference Case

This section presents the results of the Reference Case. This case represents the future through 2020 in the absence of the WCI cap-and-trade program and related complementary GHG emission reduction policies. Table B-5 through Table B-10 show model outputs for:

- GHG emissions;
- energy use;
- electric sector results;
- transport sector results;
- fuel prices; and
- fuel expenditures.

Each table shows total results for the eight WCI Partners in the WECC. The three Canadian provinces not included in this analysis (Manitoba, Quebec, and Ontario) will be included in future modeling efforts.

Each table shows results for 2006 (the first year simulated by ENERGY 2020), 2010, 2015, and 2020. The growth rate reported for 2006-2020 is the average annual rate of exponential growth between the 2006 level and the 2020 level.

Table B-5: Reference Case Greenhouse Gas Emissions: Eight WCI Partners

GHG Emissions *(MMTCO2E)*	2006	2010	2015	2020	Growth Rate 2006-2020

Cap-and-Trade Policy Cases

This section presents the results of three Cap-and-Trade Policy Cases:

- Broad Scope, with complementary policies and without offsets
- Broad Scope, with complementary policies and with offsets
- Narrow Scope, with complementary policies and with offsets

The narrow scope includes of the following:

- Electricity generation, including emissions from electricity imported into WCI jurisdictions from non-WCI jurisdictions
- Combustion at industrial and commercial facilities
- Industrial process emission sources, including oil and gas process emissions

The broad scope includes the emissions in the narrow scope plus the following:[10]

- Residential, commercial, and industrial fuel combustion at facilities with emissions below the WCI thresholds
- Transportation fuel combustion from gasoline and diesel

The banking of allowances is included in all three Policy Cases to simulate how allowances issued or auctioned in one year may be used in a later period. When allowance prices are low, allowances would likely be saved for use in a later year – which is referred to as being banked. When prices are high, allowances would be used from previous year, which is referred to as withdrawn from the bank. Attachment 1 explains how the model simulates banking and withdrawing of allowances.

Offsets are limited to 5% of the compliance obligation. The supply of offsets is modeled using an S-shaped curve that defines the portion of the offset limit that would be used as a function of allowance price. The analyses presented here limit the use of offsets to 5% of the annual compliance obligation, with an expected price of $20 per MTCO2e. Figure B-1 shows how the model simulates the use of offsets. At an allowance price of $20 per MTCO2e, approximately 58% of the offset limit is estimated to be used.

The Offsets Subcommittee is defining a process to develop offset supply curve data reflecting the availability and price of offsets under various offset policy assumptions. When available, those data would enable a more precise assessment to be conducted of the implications of policies that include offsets as a design feature.

The complementary policies have a substantial impact on the estimated emissions and costs. This analysis incorporates three broad sets of policies across all eight WCI partner jurisdictions in the analysis:

- Clean Car Standards, equivalent to California's Pavley I and II. These standards reduce emissions by about 30 MMTCO2E in 2020 compared to the Reference Case.

[10] For purposes of modeling the broad scope of the cap-and-trade program, the eight WCI partner jurisdictions included in the analysis are modeled with the broad scope starting in 2012. Note that British Columbia plans to use its carbon tax as an alternative policy for covering transportation fuels and residential/commercial fuels. This modeling effort, however, treats British Columbia the same as the other seven WCI partner jurisdictions included in the analysis.

- Programs that reduce total Vehicle Miles Traveled (VMT) by 2% from the forecast reference case by 2020. These programs reduce emissions by about 4 MMTCO2E when considered in addition to the Clean Car Standards.
- Aggressive energy efficiency programs that achieve a 1% reduction in the annual rate of electricity and natural gas demand growth. These programs reduce emissions by about 74 MMTCO2E in 2020 across all sectors.

We recognize that the WCI partner jurisdictions have climate action plans that reflect the specific opportunities and needs of the individual jurisdictions. In particular, they typically include policies that extend beyond the three included in this analysis. Based on the available time and resources for this study, as well as the focus on overall results for the WCI partner jurisdictions as a whole, the analysis is limited to reflecting these broad policies at this time.

By themselves the three complementary policies included in the analysis accomplish about 108 MMTCO2E of GHG reductions in 2020, which is about half of the reductions required from the Reference Case estimates in this analysis. Table B-11 shows the estimates for the transportation policies.

The complementary policies are modeled in conjunction with the cap-and-trade policies under the expectation that the cap-and-trade program can provide resources needed for supporting the VMT programs and the energy efficiency programs. In particular, the value of emission allowances (whether auctioned or provided for free) can be directed to support these programs.

Figure B-1: Assumed Offset Supply Curve

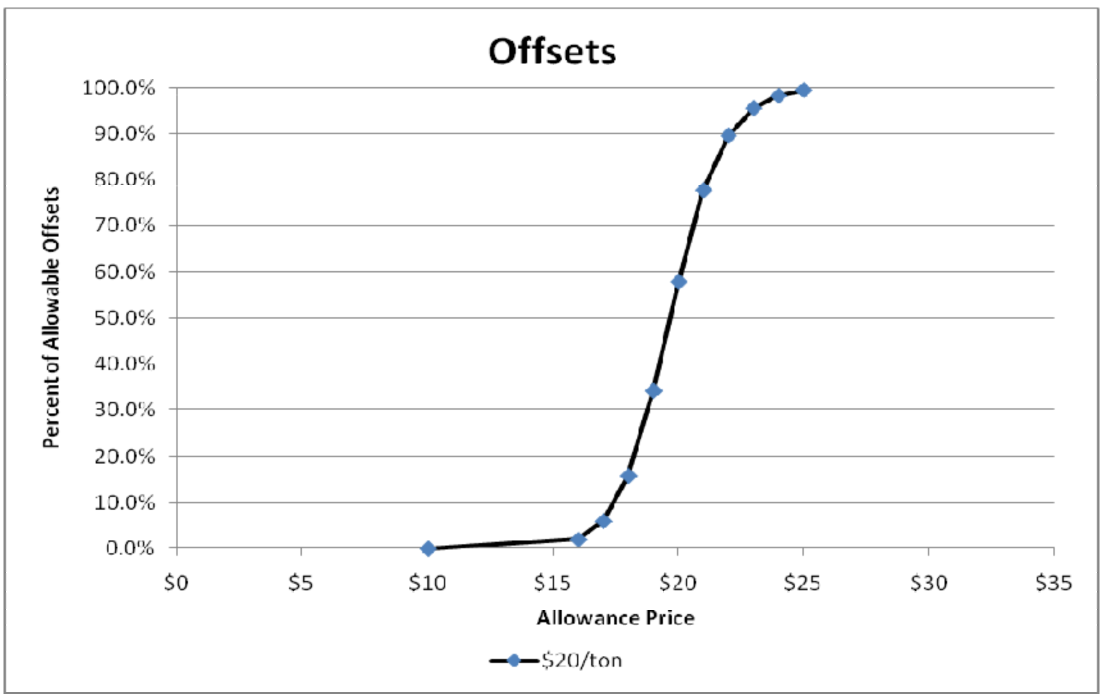

Table B-11: Impact of Transportation Complementary Policies in 2020 Compared to the Reference Case: Eight WCI Partners

	Clean Car Standards	Clean Car Standards and VMT Reduction
Change in GHG Emissions (million tons)	-30.1	-34.2
Change in Annual Vehicle Miles Traveled/Person	112	-65
Change in Annual Fuel Expenditures (million 2007$)	($11,943)	($13,549)
Change in Vehicle Capital Expenditures (million 2007$)	$10,325	($5,549)
Net Cost (Savings) (million 2007$)	($1,618)	($19,098)
Net cost does not include the cost of VMT Reduction programs.		

Table B-12 through Table B-19 show model outputs for these quantities:

- GHG emissions and compliance summary;
- energy use;
- electric sector results;
- transport sector results;
- fuel prices;
- fuel expenditures;
- potential allowance value; and
- costs.

Each table shows results for 2020 for eight WCI Partners, i.e., the seven states and British Columbia. As discussed above, the other three Canadian provinces will be included in future modeling efforts. For each policy case, the three columns indicate the Cap-and-Trade value for the quantity described in the left-most column, the difference between the Cap-and-Trade value and the Reference Case value, and the percentage difference between the two values.

Table B-16 shows fuel prices as a percent difference from Reference Case prices. Table B-19 shows the cost estimates, which only meaningful as incremental differences between the Cap-and-Trade value and the Reference Case value.

Total	**(23,525)**	**(22,080)**	**(11,422)**
These costs do not include costs of VMT Reduction programs, Energy Efficiency programs, nor Potential Allowance Value.			

Sensitivity Cases

This section presents the results of three sensitivity cases. These cases consider alternatives to the energy prices and generation costs assumed in the Reference Case. The cases discussed here are:

- High Energy Prices and High Generation Costs
- Low Energy Price Case
- High Natural Gas Price Case

Other cases are also of interest, but time did not allow for development of input data for them to be modeled in a meaningful way.

For the first two of these sensitivity cases, it was necessary to produce a new Reference Case as well as a policy case. In these cases the policy is compared to its appropriate sensitivity Reference Case.

For all the sensitivity cases, the WCI policy case is for the broad scope with offsets. The sensitivities are variations of the assumptions embedded in the Reference Case, not variations of cap-and-trade policy design.

High Energy Prices and High Generation Costs

The purpose of this sensitivity is to examine the implications of energy prices being higher than assumed in the Reference Case. There has been considerable stakeholder comment that the energy prices in the Reference Case may be too low. Additionally, some stakeholders have commented that the power generation cost assumptions maybe too low, indicating that the recent increases in commodity prices have had an impact on these costs.

This sensitivity includes both increased energy prices and increased power generation costs as a set of conditions that could occur together in the future. The high energy cost case assumes that energy prices start at current 2008 prices and increase in real terms by 50% by 2020, as shown in Table B-20. The high power generation cost case assumes that capital and operation and maintenance (O&M) costs are 30% higher than in the Reference Case.

Table B-20: Fuel Price Forecast:
High Energy Prices and High Generation Costs Sensitivity Case

	2006	2010	2015	2020
World Oil Price (2007 US$/barrel)	64.21	120.37	143.52	166.67
Natural Gas Wellhead Price (2007 US$/mmBtu)	5.97	11.12	13.26	15.40
Coal Prices (2007 US$/ton)	28.98	41.47	48.52	55.90

Low Energy Price Case

The purpose of this sensitivity is to examine the implications of energy prices being lower than assumed in the Reference Case. While there has not been stakeholder comment suggesting that energy prices may be lower, it is prudent to examine the implications of lower prices. The low energy price case uses the mid-price case from the Annual Energy Outlook 2008 (Table B-21).

Table B-21: Fuel Price Forecast: Low Energy Price Sensitivity Case

	2006	2010	2015	2020
World Oil Price (2007 US$/barrel)	$64.21	$71.60	$57.88	$57.74
Natural Gas Wellhead Price (2007 US$/mmBtu)	$5.97	$7.11	$6.09	$6.25
Coal Prices (2007 US$/ton)	$25.37	$26.66	$23.53	$22.33
Source: EIA Annual Energy Outlook 2008 mid-price series.				

High Natural Gas Price Case

The purpose of this sensitivity is to examine the implications of natural gas prices being higher than assumed in the Reference Case. There has been considerable stakeholder comment that efforts to reduce GHG emissions may increase the demand for natural gas. Consequently, the price of natural gas may increase as a result of the policies that are implemented to reduce emissions.

In the cases examined above, the demand for natural gas declines overall as a result of the complementary policies and the cap-and-trade program. Consequently, the policies examined in this analysis would not be expected to lead to an increase in natural gas prices. Nevertheless, this sensitivity was performed to examined the implications of higher natural gas prices.

To perform this sensitivity, the high natural gas price shown in Table B-20 was used with the cap-and-trade policy. The results were compared to the original Reference Case with the Reference Case natural gas prices. So, the natural gas prices are higher in the cap-and-trade case than in the Reference Case.

Results

Table B-22 through Table B-29 show model outputs for 2020: Each table shows results for eight WCI Partners, i.e., the seven states and British Columbia. The other three provinces will be included in future modeling efforts.

For each policy case, the three columns indicate the relevant Reference Case value (because each policy case has a different Reference Case), Cap-and-Trade value for the quantity described in the left-most column, and the difference between the Cap-and-Trade value and its Reference value.

Table B-26 shows fuel prices as a percent difference from Reference prices. Table B-29 shows the costs, which are only meaningful as incremental differences between the Cap-and-Trade value and the appropriate Reference Case.

Other Industry	$1,917	$2,782	$5,806
Passenger Transportation	($21,999)	($20,845)	($19,589)
Freight Transportation	($298)	($1,362)	($423)
Agriculture	($546)	($287)	($131)
Total	**($30,514)**	**($16,245)**	**$7,880**
These costs do not include costs of VMT Reduction programs, Energy Efficiency programs, nor Potential Allowance Value.			

Summary Results

Table B-30 presents summary results for the cases presented above. The GHG emissions are reported for the eight WCI partner jurisdictions included in the analysis. Fuel Expenditures and Total Costs (Savings) are relative to the appropriate Reference Case. The potential value of allowances is shown assuming that the full allowance value is passed through to consumers. Total Costs (Savings) include Fuel Expenditures and annualized investment costs. All emissions are in MMTCO2E and all costs are in 2007 dollars.

Table B-30: Summary Results for 2020: Eight WCI Partners

Case	**GHG Emission** (MMTCO2E)	**Offsets Used** (MMTCO2E)	**Allowance Price** (2007 $)	**Change in Fuel Expenditures** ($M/Yr)	**Potential Allowance Value** ($M/Yr)	**Total Costs (Savings)** ($M/Yr)
Reference Case	992.8	--	--	--	--	--
Cap-and-Trade Policy Cases						
Broad Scope, No Offsets	859.2	--	$63	(32,296)	39,516	(23,525)
Broad Scope, With Offsets	877.9	31.8	$24	(31,012)	15,150	(22,080)
Narrow Scope, With Offsets	847.8	18.2	$71	(22,794)	16,092	(11,422)
Sensitivity Cases						
High Price	833.3	12.7	$18	(42,736)	10,521	($30,514)
Low Price	857.0	34.1	$56	(22,598)	35,642	($16,245)
High Natural Gas Price	865.4	26.6	$20	(6,525)	12,434	$7,880
Fuel Expenditures and Total Costs (Savings) are changes from Reference Case values. Potential Allowance Value calculated as emissions times allowance price. Total Costs (Savings) do not include costs of VMT Reduction programs, Energy Efficiency programs, nor Potential Allowance Value.						

Attachment 1: Banking

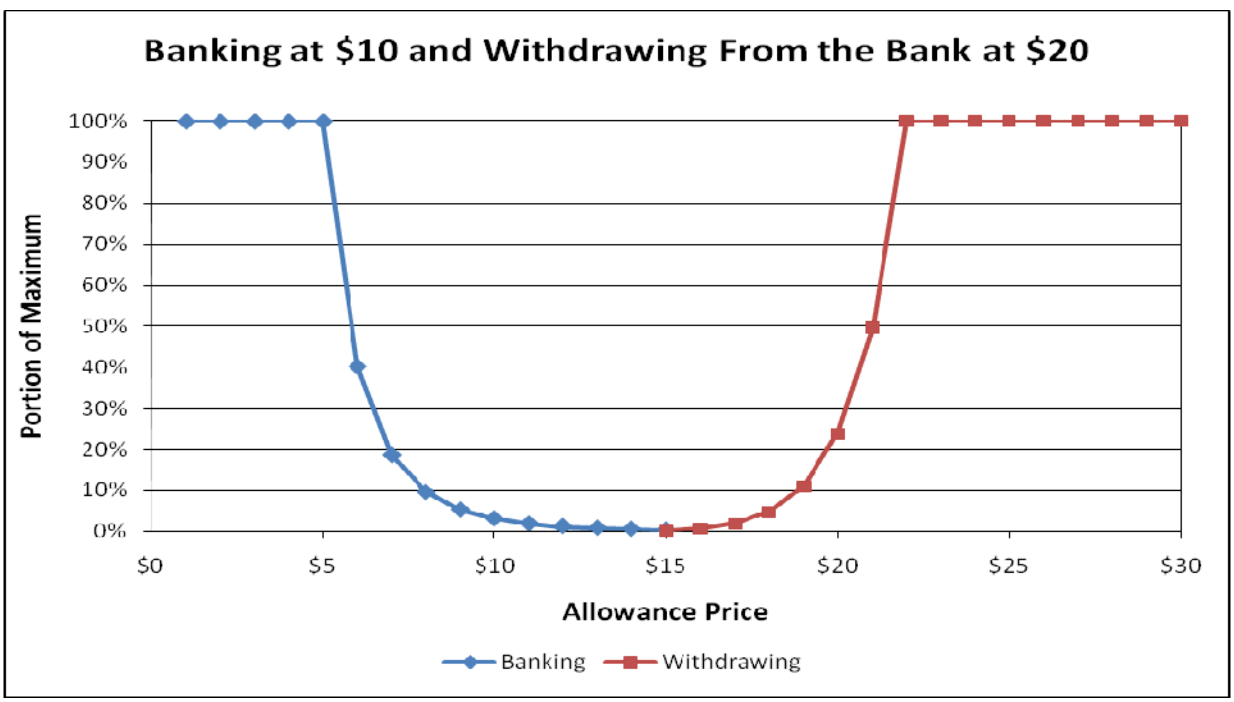
The purpose of banking is to enable allowances issued or auctioned in one year to be used in a later period. When allowance prices are low, allowances would likely be banked. When prices are high, allowances would be withdrawn from the bank. The model does not have the ability to optimize the banking behaviour in the market. Rather, banking is simulated using the following model input parameters:

- The price below which allowances are put into the bank.
- The maximum portion of emission allowances in a given year that can be banked.
- The price above which allowances are withdrawn from the bank.
- The maximum portion of the allowances in the bank in a given year that can be withdrawn.

Figure A-2 shows the banking and withdrawing curves used the cases presented here. The curves shown in the figure set the price below which allowances are banked at $10/ton. The price above which allowances are withdrawn from the bank is set at $20/ton.

The curves in the figure indicate the portion of the allowable banking and redeeming amounts that are simulated to be used. The recommended program design sets no limits on the amounts that can be banked. However, bounds are set in the model to better simulate behavior, particularly in the early years of the program when allowances prices are simulated to be low. The maximum amount put into the bank in a single year is limited to 10% of total allowances available in that year. The maximum amount withdrawn from the bank in a single year is limited to 30% of the allowances in the bank.

Figure B-2: Banking Curves



Attachment 2: Detailed Cap-and-Trade Policy Results

This attachment shows the detailed results for two of the cap-and-trade program model runs:

- Broad Scope, with complementary policies and with offsets; and
- Narrow Scope, with complementary policies and with offsets.

Total	217,237	240,856	241,656	257,859	1.2%

Table B-45: Cap-and-Trade Program Potential Allowance Value: Eight WCI Partners Narrow Scope with Complementary Policies and Offsets

Allowance Value (M$)				
Sector	**2006**	**2010**	**2015**	**2020**
Residential	$0	$0	$0	$0
Commercial	$0	$0	$521	$1,925
Energy Intensive Industry	$0	$0	$3,176	$12,293
Other Industry	$0	$0	$524	$1,873
Passenger Transportation	$0	$0	$0	$0
Freight Transportation	$0	$0	$0	$0
Agriculture	$0	$0	$0	$0
Total	**$0**	**$0**	**$4,221**	**16,092**
Potential allowance value is calculated as the allowance price times the emissions in the sector. The full allowance value may not be incurred in each sector depending on the manner in which allowances are distributed and the ability to pass allowance costs to customers.				

Table B-46: Cap-and-Trade Program Annualized Costs (Savings): Eight WCI Partners Narrow Scope with Complementary Policies and Offsets

Annualized Cost (M$/Yr) (Change from Reference Case)				
Sector	**2006**	**2010**	**2015**	**2020**
Residential	$0	$331	($1,771)	($3,327)
Commercial	$0	($37)	($3,144)	($4,760)
Energy Intensive Industry	$0	$1,109	$5,237	$12,674
Other Industry	$0	$258	$1,085	$3,250
Passenger Transportation	$0	($5,326)	($15,073)	($19,005)
Freight Transportation	$0	($0)	$0	$0
Agriculture	$0	($3)	($194)	($254)
Total	**$0**	**($3,668)**	**($13,859)**	**($11,422)**
These costs do not include costs of VMT Reduction programs, Energy Efficiency programs, nor Potential Allowance Value.				

Appendix C: General Q & A

Western Climate Initiative

Q: What is the Western Climate Initiative announcing today?

The Western Climate Initiative (WCI) Partners today announced their proposed design of a regional market-based cap-and-trade program. This program is an important component of a comprehensive regional effort to reduce the pollution that causes global warming to 15 percent below 2005 levels by 2020.

Q: What are the market design elements being released by the WCI?

The WCI partners are recommending a multi-sector cap-and-trade program to reduce the pollution that causes global warming to 15% below 2005 levels by 2020. This program includes the following design parameters:

- A limit on the emissions from all major sources of global warming pollutants;
- Include under the cap all electricity-related emissions, including those associated with electricity imported from outside the WCI partner jurisdictions;
- Ensure that all regulated entities use a consistent reporting methodology; and
- Mitigate economic impacts on consumers and regulated entities by allowing flexibility in how and when the reductions are made (e.g., banking of allowances and the limited use of offsets).

Q: How was the WCI market design developed?

The release of the WCI design recommendations is the culmination of 18 months of extensive analysis, stakeholder consultation and deliberation by the WCI Partners. We will continue to consult with and seek input from the broad range of stakeholders who contributed to this process.

Q: What are the next steps?

The release of this market design program marks the culmination of 18 months of extensive analysis, stakeholder consultation and deliberation by the WCI Partners. This proposal will now be further developed by each WCI Partner with the objective of taking the steps necessary to implement the program.

The timeline agreed to by the WCI Partners is that each will begin reporting emissions in 2011 for emissions that occur in 2010. The first phase of the cap-and-trade program will begin on January 1, 2012, with a three-year compliance period. The second phase will begin in 2015, when the program is expanded to include transportation fuels and residential, commercial and industrial fuels.

Q: What emissions sources are subject to the cap under the WCI agreement?

The WCI cap-and-trade program covers the largest emitters from each state and province, including energy (electricity generation, natural gas and heating fuels), industrial emissions and transportation emissions.

Q: How will emissions allowances be distributed under the WCI agreement?

Each WCI Partner jurisdiction will have an emission allowance budget under the cap-and-trade program that is consistent with its jurisdiction-specific emissions goal for 2020. Each Partner has the flexibility to decide how best to allocate its allowance budget within its jurisdiction.

For instance, a Partner could "give" allowances to the emitters operating within its jurisdiction, "auction" the allowances to willing buyers, or provide for some combination of the two. The WCI design calls for a minimum auction level of 10% at the start of the program, increasing to at least 25% by 2020. Each jurisdiction may auction a higher percentage if it so chooses. In addition, the WCI Partners have agreed to use a portion of the allowance value for purposes with region-wide benefits, such as energy efficiency and low-carbon technology development.

Q: How will compliance be determined under the WCI agreement?

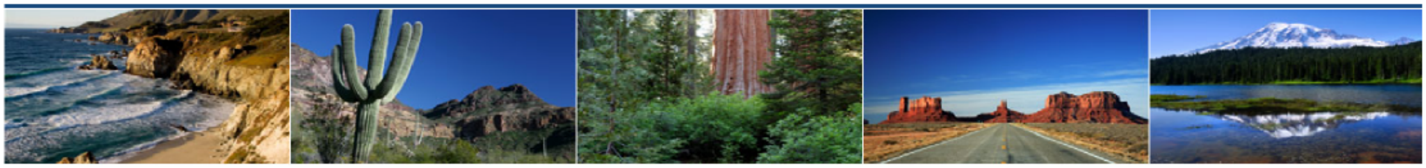
The bedrock of a cap-and-trade system is a rigorous emissions reporting requirement. The regulated sources are required to ensure the data are accurate and complete. Each WCI partner will require third party validation of reported emissions from entities and facilities that will be included under the cap.

The WCI agreement is consistent with previous well-designed cap-and-trade programs that have had compliance rates of over 99 percent. At the end of each compliance period, facilities and entities with emissions are required to submit the same number of emission allowances to the government as the emissions they had during that compliance period. If the facility or entity does not have sufficient emission allowances to cover its emissions, a "penalty" of three allowances will be assessed for each one they are short.

Q: What are offsets? How are they handled under the WCI agreement?

Offsets are reductions in greenhouse gas emissions from outside of the capped sectors, such as forestry and agriculture. Offset credits may be used, provided they meet rigorous criteria to ensure that emission reductions are real, verifiable, surplus/additional, permanent and enforceable. Offset credits may be traded. The WCI program limits the use of offsets for compliance purposes to ensure that a majority of the required emission reductions is achieved in the sources covered by the cap-and-trade program.

Western Climate Initiative



September 30, 2008

To All Interested Parties:

Today, the WCI Reporting Subcommittee is releasing their “Essential Requirements of Mandatory Reporting for the Western Climate Initiative, Second Draft.” This document builds on the draft recommendations released in July, incorporates reporting elements from the Design Recommendations for the WCI Regional Cap-and-Trade Program (released September 23, 2008), and identifies additional decisions to be made.

As noted in the draft recommendations released in May, completion of the essential requirements for mandatory emissions reporting is scheduled for December 2008. As noted in this current draft, we have many additional decisions that will need to be made in order to complete the essential requirements, and we intend to provide additional opportunities for stakeholder input and comment as the work proceeds.

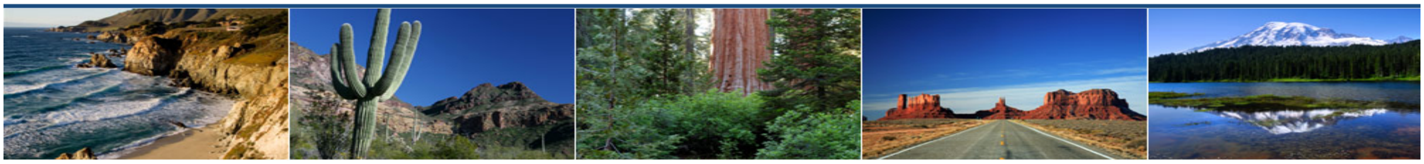
Stakeholder comments on the reporting-related elements of the July Draft Design document and the initial draft of the Essential Requirements are summarized in Attachment D of this Second Draft. Stakeholder comments have been very helpful in shaping the decisions made to date, and we look forward to receiving your comments on this current document and its Attachments. Additional opportunities for public comment will be provided as future drafts of the Essential Requirements for Reporting are completed. These future drafts will include increasing level of detail and the final document will address all the Essential Requirements.

You are invited to participate in a stakeholder conference call to discuss the present draft on October 7 at 11 AM Mountain Time. The call-in number is 800-868-1837 (direct dial 404-920-6440), access code 659-537#. We ask that written comments be submitted through the WCI Website (www.westernclimateinitiative.org) by Tuesday, October 14.

Sincerely,

Jim Norton, Chair
WCI Reporting Subcommittee
State of New Mexico

Western Climate Initiative



Essential Requirements of Mandatory Reporting
for the Western Climate Initiative,
Second Draft

September 30, 2008

Introduction

The "Design Recommendations for the WCI Regional Cap-and-Trade Program" (September 23, 2008) state that "prior to the start of the mandatory reporting program, the WCI Partner jurisdictions will establish the essential requirements for reporting by all entities and facilities required to report in each of the WCI Partner jurisdictions." To complete the essential requirements for reporting rules, the Western Climate Initiative (WCI) must make numerous decisions about how it wishes to approach, define, and structure the elements that have been identified as necessary to an effective WCI cap-and-trade program. A number of these decisions have already been made by the WCI, but many have not. This paper documents the current status of the essential requirements of mandatory reporting, and is an update to the document previously issued on July 23, 2008, addressing continuing work being conducted by the WCI Partners and the Reporting Subcommittee (RSC). Also, this paper strives to incorporate responses to comments made by Stakeholders on the July 23 version (see Attachment D).

The purposes of this paper are to: 1) document the current status of WCI's consideration of essential requirements; 2) identify the decisions that remain to be made; and 3) seek public comment on these essential requirements. As decisions are made to finalize the essential requirements, the WCI will move toward developing a regulatory structure for the essential requirements in future steps.

The paper is divided into nine categories of essential requirements related to mandatory reporting of GHGs: definitions, pollutants, applicability, timing, confidentiality, report content and submittal, compliance, emissions quantification and monitoring, and verification and quality assurance. For each group of essential requirements, the following information is presented:

- "Discussion and Notes" describes the essential requirements that are proposed to be addressed in the context of future model rule sections.
- "Design Recommendations for the WCI Regional Cap-and-Trade Program" summarizes the specific recommendations contained in the most current design document (September 23, 2008) and/or previous draft versions (July 23, 2008 or May 16, 2008), if applicable to the essential requirement.
- "Recommendations for Reporting" summarizes the specific recommendation being made by the RSC pertaining to reporting, if applicable to the essential requirement.
- "Additional Decisions Needed" summarizes the decisions that need to be made concerning the approach, definition and structure of the essential requirement, and any options, if applicable to the essential requirement.

Comments on this document should be submitted in writing by Tuesday, October 14, through the WCI Website (www.westernclimateinitiative.org). Please note that relative to the previous version (released July 23, 2008), most of the new material is contained in the Attachments. Also, there will be other opportunities to submit comments on the essential requirements for mandatory reporting after future drafts are released in the Fall of 2008.

Definitions

Discussion and Notes

1. This rule section will contain clear and appropriately detailed definitions of key terms used in the monitoring and reporting rule.

2. When source category-specific requirements are considered, there may be hundreds of terms that need definition. The most efficient approach to creating a list is to "borrow" from other jurisdiction's rules. There are a number of precedents to consider for definitions. Terminology defined by The Climate Registry (TCR) could be used, although some definitions might not be sufficiently detailed for regulatory use. If TCR's list is not comprehensive enough for a mandatory reporting rule, then CARB's reporting rule has a very detailed and lengthy list of definitions that may be used. CARB's list combines source category-specific definitions with those common to all source categories in a single list. The definitions established by the U.S. EPA, Canadian agencies, and states like New Mexico should also be considered.

3. Definitions will facilitate communications among WCI jurisdictions and stakeholders by defining common terminology very early in the process of developing the details of essential requirements for model GHG reporting rule language. For example, the term "source categories" is used throughout this paper to indicate groupings of sources and activities; definitions for these types of terms should be agreed upon and articulated by the WCI jurisdictions.

Recommendations for Reporting

1. The Reporting Subcommittee recommends the partial list of definitions shown in Attachment A. We will add to the list as required during on-going development of the Essential Requirements for Mandatory Reporting. In general, we will include definitions that are necessary to understanding specific essential reporting requirements and avoid definitions that are not absolutely essential. For example, we will not define terms that are used in their common English context (e.g., fence line, unit) or that explain acronyms or chemical formulae.

Additional Decisions Needed

1. Using the CARB, Environment Canada, and TCR definitions as a starting point, compile the list of definitions for review by the Reporting Subcommittee.

2. Continue to develop definitions.

Pollutants

Discussion and Notes

1. Pollutants – This section will list the pollutants that must be quantified and reported.

2. Global warming potential (GWP) factors – The section will specify the 100-year GWP factors used to convert other pollutants to CO_2e. The WCI presumably will use the same GWP factors as are used regionally and internationally, such as the IPCC Second Assessment Report, 1995, updating that list only for new GHGs as identified in the IPCC Third Assessment Report, 2001.

Design Recommendations for the WCI Regional Cap-and-Trade Program (September 23, 2008):

1. Greenhouse gases (GHGs) covered: Carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride.

Recommendations for Reporting:

1. According to the Intergovernmental Panel on Climate Change (IPCC), the global warming potential (GWP) of a GHG is defined as the ratio of the time-integrated radiative forcing from the instantaneous release of 1 kilogram (kg) of a trace substance relative to that of 1 kg of a reference gas. The reference gas used is CO_2. It is recommended that the values listed in the table below be used to be consistent with other statewide and national GHG inventories. (This table is the same as contained in the TCR General Reporting Protocol, Version 1.1, May 2008.) Operators would use these values when converting emissions of GHGs to carbon dioxide equivalent values (CO_2e) for purposes of estimating de minimis or other emissions as specified in these essential requirements.

Additional Decisions Needed

1. In order to remain consistent with international practice, and in the event that more recent GWP values are adopted as standard practice by the international community (e.g., when reporting under the United Nations Framework Convention on Climate Change [UNFCCC]), then a mechanism for updating the GWPs would need to be developed.

Global Warming Potential Factors for Required Greenhouse Gases

Common Name	Formula	Chemical Name	GWP
Carbon dioxide	CO_2		1
Methane	CH_4		21
Nitrous oxide	N_2O		310
Sulfur hexafluoride	SF_6		23,900
Hydrofluorocarbons (HFCs)			
HFC-23	CHF_3	trifluoromethane	11,700
HFC-32	CH_2F_2	difluoromethane	650
HFC-41	CH_3F	fluoromethane	150
HFC-43-10mee	$C_5H_2F_{10}$	1,1,1,2,3,4,4,5,5,5- decafluoropentane	1,300
HFC-125	C_2HF_5	pentafluoroethane	2,800

Common Name	Formula	Chemical Name	GWP
HFC-134	$C_2H_2F_4$	1,1,2,2-tetrafluoroethane	1,000
HFC-134a	$C_2H_2F_4$	1,1,1,2-tetrafluoroethane	1,300
HFC-143	$C_2H_3F_3$	1,1,2-trifluoroethane	300
HFC-143a	$C_2H_3F_3$	1,1,1-trifluoroethane	3,800
HFC-152	$C_2H_4F_2$	1,2-difluoroethane	43*
HFC-152a	$C_2H_4F_2$	1,1-difluoroethane	140
HFC-161	C_2H_5F	fluoroethane	12*
HFC-227ea	C_3HF_7	1,1,1,2,3,3,3- heptafluoropropane	2,900
HFC-236cb	$C_3H_2F_6$	1,1,1,2,2,3-hexafluoropropane	1,300*
HFC-236ea	$C_3H_2F_6$	1,1,1,2,3,3-hexafluoropropane	1,200*
HFC-236fa	$C_3H_2F_6$	1,1,1,3,3,3-hexafluoropropane	6,300
HFC-245ca	$C_3H_3F_5$	1,1,2,2,3-pentafluoropropane	560
HFC-245fa	$C_3H_3F_5$	1,1,1,3,3-pentafluoropropane	950*
HFC-365mfc	$C_4H_5F_5$	1,1,1,3,3-pentafluorobutane	890*
Perfluorocarbons (PFCs)			
Perfluoromethane	CF_4	tetrafluoromethane	6,500
Perfluoroethane	C_2F_6	hexafluoroethane	9,200
Perfluoropropane	C_3F_8	octafluoropropane	7,000
Perfluorobutane	C_4F_{10}	decafluorobutane	7,000
Perfluorocyclobutane	c-C_4F_8	octafluorocyclobutane	8,700
Perfluoropentane	C_5F_{12}	dodecafluoropentane	7,500
Perfluorohexane	C_6F_{14}	tetradecafluorohexane	7,400
Source: Intergovernmental Panel on Climate Change (IPCC) Second Assessment Report published in 1995, unless no value was assigned in that document. In that case, the GWP values are from the IPCC Third Assessment Report published in 2001 (those marked with *). GWP values are from the Second Assessment Report (unless otherwise noted) to be consistent with international practices. Values are 100-year GWP values.			

Applicability

Discussion and Notes

1. This rule section describes who must comply with the reporting rule. As a minimum, the reporting system must include all activities and sources that will be part of the cap.

2. This rule section will also list any source categories that are not subject to the initial cap but which will be required to report emissions.

3. Thresholds – This section will contain the thresholds for mandatory reporting, stated as metric tons of CO_2 or CO_2e per year, or other appropriate emissions or operational indicators.

4. Sources not included – This section will describe sources or activities in affected source categories that are not subject to reporting requirements.

5. Level of reporting – This rule section will address by source category at what level (i.e. corporate [entity], facility or process level) reporting will be required.

Design Recommendations for the WCI Regional Cap-and-Trade Program (September 23, 2008):

1. Emissions covered:

    - Electricity generation, including emissions from electricity generated outside the WCI jurisdictions (or generated by a federal entity or on tribal lands) that is delivered into a WCI Partner jurisdiction for consumption in that WCI Partner jurisdiction;
    - Combustion at industrial and commercial facilities;
    - Industrial process emission sources*, including oil and gas process emissions;
      *As used here, process emissions include emissions from chemical, biological, and other non-combustion processes. These emissions may be deliberate (e.g., vented), fugitive (e.g., leaked), or accidental.
    - Residential, commercial, and industrial fuel combustion at facilities with emissions below the WCI thresholds* (as described below in the Point of Regulation section, these emissions will be covered upstream). Coverage of these emissions will begin at the start of the second compliance period;
      * Thresholds are emission levels that determine when a particular entity or facility will have a compliance obligation under the cap-and-trade program.
    - Transportation fuel combustion from gasoline and diesel (as described below in the Point of Regulation section, these emissions will be covered upstream). Coverage of these emissions will begin at the start of the second compliance period.

2. For biomass determined by each WCI Partner jurisdiction to be carbon neutral, the carbon dioxide emissions from the combustion of that biomass are not included in the cap-and-trade program, except for purposes of reporting.

3. Carbon dioxide emissions from the combustion of pure biofuels, or the proportion of carbon dioxide emissions from the combustion of biofuel in a blended fuel (e.g., B20 or E85), are not included in the cap-and-trade program, except for purposes of reporting.

4. Prior to program start, the WCI Partner jurisdictions will assess whether and how to include upstream emissions from biofuel and fossil fuel production, taking into consideration the potential for emissions leakage, the potential role of other policies (such as a low carbon fuel standard), consistent treatment among fuels, and other factors (such as practicality of implementation).

5. Adequate quantification methods will be established for emissions sources prior to including them in the [cap-and-trade] program.

6. Point of Regulation*
   * The point of regulation is the entity or facility with the compliance obligation, i.e., the requirement to surrender sufficient GHG allowances to cover actual emissions during the compliance period. An allowance is the tradable permit to emit one metric ton of GHG emissions in CO_2e. The term entity is generally used when the point of regulation is upstream of the point of emissions, to describe a company that has an obligation to surrender allowances to cover the carbon content of the fuel the company is moving through commerce, or when the

point of regulation is at the First Jurisdictional Deliverer, to describe a company that has an obligation to surrender allowances to cover the emissions attributable to the generation of power the company is importing. When the point of regulation is at the point where the emissions occur, the term facility is generally used. The term source is used to refer to emissions from either a facility or an entity.

- Industrial sources (both process and combustion) with emissions above the threshold: The point of regulation will be at the point of emission.
- Electricity: The point of regulation is the First Jurisdictional Deliverer (FJD). For sources within WCI jurisdictions the FJD is the generator. For power that is generated outside the WCI jurisdictions (or generated by a federal entity or on tribal lands) for consumption within a WCI Partner jurisdiction, the FJD is the first entity that delivers that electricity over which the consuming WCI partner jurisdiction has regulatory authority.
- Residential, commercial, and industrial fuel combustion at facilities with emissions below the threshold: The point of regulation will be where the fuels enter commerce in the WCI Partner jurisdictions, generally at a distributor. The precise point is to be determined and may vary by jurisdiction.
- Transportation fuel combustion: The point of regulation will be where the fuels enter commerce in the WCI Partner jurisdictions, generally at the terminal rack, final blender, or distributor. The precise point is to be determined and may vary by jurisdiction.

7. The entities and facilities subject to reporting are those with annual emissions equal to or greater than 10,000 metric tons of CO_2e. Where fuel combustion emissions are covered upstream (e.g., emissions from transportation fuel combustion and emissions from fuel combustion at residential, commercial, and industrial facilities with emissions below the threshold) the reporting threshold will apply to entities (e.g., fuel distributors and blenders) based on the expected combustion emissions from the fuels distributed. In some limited instances the threshold may be based on other parameters, such as throughput or capacity, as long as these thresholds represent the equivalent of, or are lower than, the 10,000-metric-ton threshold.

8. Nothing in the WCI program design limits the discretion of any WCI Partner jurisdiction to require reporting earlier, at lower thresholds, or for entities and facilities not covered by the cap-and-trade program.

Recommendations for Reporting:

1. GHG emissions from combustion of biofuels and biomass will be included in the reporting requirements, and reported separately from other fuel combustion types.

Additional Decisions Needed

1. Complete decisions on which source categories will be subject to mandatory reporting. Select the numeric value and form of applicability thresholds for those source categories.

2. Complete detailed definitions of each source category to address point of regulation issues and further clarify which sources and activities within each source category are covered by the reporting requirement (i.e., activities, sources, and operational boundaries).

3. Determine sources, activities and processes to be excluded from reporting.

4. Determine by source category whether reporting will occur at the corporate (entity), facility, or process level.

Timing

Discussion and Notes

1. Effective Date – This rule section will specify the period when mandatory record keeping and reporting begins for affected source categories. An issue is whether or not to use measurement and monitoring data for years prior to 2010.

2. Reporting Period – This requirement specifies the calendar year or other period within which emissions must be quantified. The Design Recommendations (September 23, 2008) suggests starting on January 1, thus implying a calendar year reporting period. Consideration may have to be made for some form of more frequent or interim reporting to support the development and implementation of the cap-and-trade program.

3. Report Submission Date – This section will specify when reports must be submitted. To maintain alignment with future cap-and-trade allocations and reconciliation periods, it is preferable for reports to be submitted at the same time in all jurisdictions. A key issue is how long after the reporting year ends that reports be due.

Design Recommendations for the WCI Regional Cap-and-Trade Program (September 23, 2008):

1. Mandatory measurement and monitoring for the six included GHG emissions will commence in January 2010 for all entities and facilities subject to reporting. Reporting of 2010 emissions will begin in early 2011.

2. For 2012, each WCI Partner jurisdiction's allowance budget will be based on the best estimate of expected emissions for sources covered in the cap-and-trade program in the WCI Partner jurisdiction in 2012. The estimate of expected actual emissions in 2012 will be developed using the best available data (including any available mandatory reporting data) and by accounting for expected changes in emissions in 2012.

3. Each covered entity or facility will demonstrate compliance with the cap-and-trade program by surrendering sufficient allowances by July 1 of the year following the end of each compliance period.

Recommendations for Reporting

1. Mandatory measurement, and monitoring will begin in all Partner jurisdictions on January 1, 2010.

2. The reporting period is the calendar year, beginning with 2010 emissions to be reported in 2011.

3. To spread out the reporting and verification workload in the early years of reporting, reporting deadlines will be staggered for emissions occurring in the calendar years 2010 and 2011. Some source categories will submit their reports April 1, three months after the end of the reporting period, and the remainder will report on May 1, four months after the end of the reporting period. Electrical generating units; facilities which only contain stationary combustion sources of GHGs; and transportation and residential, commercial, and industrial fuels will report on April 1. All other source categories, including facilities and other reporting entities with a combination of stationary combustion and non-combustion sources, will report on May 1.

4. For the reporting periods 2010 and 2011, facilities and other reporting entities that are subject to verification requirements will complete the verification process no later than five months following their reporting deadline (i.e., September 1 or October 1).

5. Requirements for reporting of pre-2010 emissions will not be specified in the Essential Requirements. Jurisdictions cannot adopt retrospective requirements for measurement and monitoring, but some jurisdictions may have pre-existing reporting requirements that can be used in obtaining the "best available data" for pre-2010 emissions.

Additional Decisions Needed

1. Establish report submission and verification deadlines for the 2012 and subsequent reporting periods.

2. Determine whether more frequent interim reports are necessary to support the development and implementation of the cap-and-trade program.

3. Establish a timetable for the public release of reported data.

Confidentiality

Discussion and Notes

1. In general, emissions data are not considered confidential although some operational information can be protected, depending on each jurisdiction's legal authority.

2 Stakeholders have offered a range of comments with some favoring a narrow construction of confidentiality to protect the public's right to know, and others favoring a broader construction that would better protect sensitive operational information from competitors.

Design Recommendations for the WCI Regional Cap-and-Trade Program (September 23, 2008):

1. As each WCI Partner jurisdiction collects additional emissions data from entities and facilities required to report, data will be made available to all WCI Partner jurisdictions for review and consideration for possible expansion of the cap-and-trade program.

2. Each covered entity or facility will demonstrate compliance with the cap-and-trade program by surrendering sufficient allowances by July 1 of the year following the end of each compliance period. To ensure transparency and maintain public confidence, certain data from the emissions reports, allowances, and offsets that are used for compliance will be made public in a timely manner.

Additional Decisions Needed

1. WCI is considering whether WCI-wide policy and procedures pertaining to emissions data and public disclosure are needed in addition to existing policy and procedures of individual WCI jurisdictions.

Report Content and Submittal

Discussion and Notes

1. Content – These sections and subsections will specify the information that each reporting unit will be required to submit. Examples of typical administrative information are facility names, identification numbers, physical addresses, mailing addresses, locations, responsible officials, various operational information, ownership structure, etc. More detailed information will be addressed in the source category-specific requirements.

   Technical content includes such examples as pollutants, quantification methods, and supporting operational and activity information and data. Requirements need to be specific and detailed and some will be source category-specific.

   There are a number of existing reporting rules that could provide potential starting points; however, many specific decisions on content will evolve from the choices made for other essential requirements.

2. Submittal – This section will specify who is responsible for submitting the report and to whom, and certifying the accuracy of the information contained in it.

Draft Design Recommendations (May 16, 2008):

1. The WCI has recommended using TCR's central repository for data storage as well as offering flexibility as to where affected sources initially report. Reports could either be submitted directly to jurisdictions (which will then upload the data to TCR's central repository), or be submitted directly through TCR's program framework (which will then download the data to the necessary jurisdictions).

Recommendations for Reporting: Upon further consideration and discussion, the May 16, 2008 design recommendation is revised as follows:

1. The WCI recommends using a version of TCR's Climate Registry Information System (CRIS), modified to support mandatory reporting, to collect and manage WCI's regional database of emissions information. In addition, jurisdictions may use the CRIS Common Reporting Framework to meet their individual jurisdictional database needs for emission collection, verification, and compliance.

2. Emission reports must be submitted to the appropriate jurisdiction or their agent, where verification and compliance will be conducted.

3. All jurisdictional databases will transfer or ensure the transfer of verified emissions and related information into the regional database.

Additional Decisions Needed

1. Determine the specific contents of report to be submitted.

Compliance

Discussion and Notes

1. Rule violations – This section will discuss the actions that will be considered violations of the rule (e.g., failure to submit complete reports when required to do so, knowingly submitting false information with a intent to deceive, etc.).

2. Enforcement Mechanisms – The WCI will develop consistent administrative practices to respond to non-compliance issues; however specific enforcement actions, such as levying fines and penalties, will likely be carried out by jurisdictions.

3. Records Retention – This section will describe which records must be kept and for how long. More detailed requirements may be included in source category-specific requirements.

4. Revisions – The rule will describe the process for revising reports that contain inaccurate or missing information and data. The revision process might differ depending on the timing and the circumstances in which the inaccuracies were discovered.

Design Recommendations for the WCI Regional Cap-and-Trade Program (September 23, 2008):

1. Each WCI Partner jurisdiction will retain and/or enhance its regulatory and enforcement authority and responsibilities to enforce compliance with the cap-and-trade program within its own jurisdiction.

Additional Decisions Needed

1. Determine which actions will be considered violations of the reporting rule.

2. Develop guidelines to promote consistent administrative practices and responses to non-compliance issues among jurisdictions.

3. Determine which records must be maintained for all source categories subject to the reporting rule.

4. Establish procedure and policy for revisions.

Emissions Quantification and Monitoring

Discussion and Notes

1. The essential requirements to the model rule will provide an introduction to quantification, probably in a "General Requirements" section, but will also specify source category-specific quantification requirements.

2. In addition to the technical issues related to reporting, there are also a number of policy-oriented choices to be made. Examples are:

   a. The degree of coordination with other (non-GHG) emissions reporting requirements;
   b. De minimis requirements; and
   c. Procedures for missing data.

3. A key factor in determining emissions quantification and monitoring requirements is that the requirements must provide levels of accuracy necessary for an effective cap-and-trade program. It is generally accepted that quantification methods must be more rigorous under mandatory reporting for cap-and-trade, than for some methods allowed for voluntary reporting. For example, while a voluntary program might allow a range of methods, quantification and monitoring requirements for mandatory reporting might include "higher tier" methods that assure the appropriate level of accuracy needed to support a cap-and-trade program. Attachment B explains the relative accuracy of several general types of GHG emissions quantification and monitoring methods, and Attachment C contains a preliminary assessment of the adequacy of GHG emissions quantification methods for various source categories.

4. Several key issues of concern to stakeholders include the following:

   a. How to deal with combined heat and power (CHP) sources;
   b. Treatment of biomass combustion;
   c. Methods for quantifying emissions from imported electricity; and
   d. Methods for quantifying emissions for waste management.

5. Existing GHG emission quantification and monitoring requirements in the WCI jurisdictions and other relevant programs are currently being summarized and reviewed by the Reporting Subcommittee. This review will determine applicability of existing methods to the WCI reporting requirements for a cap-and-trade program, and provide a basis for evaluating consistency with existing WCI jurisdiction reporting rules.

Draft Design of the Regional Cap-and-Trade Program (July 23, 2008):

1. Adequate quantification methods will be established for emissions sources prior to including them in the program.

Additional Decisions Needed

1. Select the methods, and provide the details for each source category-specific method.

2. Determine if a de minimis reporting level will be allowed, and if so, then determine its level and the method(s) for estimating de minimis emissions.

3. Specify procedures for missing data. These may be source-category specific.

4. We are considering requiring reporting of emissions as estimated by best practice estimates for some specified emissions source categories in cases where accurate methods are not currently available and are not prescribed in the Essential Requirements.

Verification and Quality Assurance

Discussion and Notes

1. This essential requirement will address how reported information will be quality assured.

2. ISO 14064-3 and ISO 14065 are international standards for GHG verification and accreditation, respectively. In an effort to promote international consistency of GHG reporting and verification, many GHG reporting and market programs, including EU ETS, UK ETS, and TCR have based their verification programs on these standards. In addition, California's mandatory reporting regulation is based on ISO standards. WCI also intends to design its verification and accreditation programs to be consistent with ISO 14064-3 and ISO 14065 (as much as possible).

Design Recommendations for the WCI Regional Cap-and-Trade Program (September 23, 2008):

1. WCI Partner jurisdictions will require third party verification of reported emissions from entities and facilities that will be included under the cap.

Recommendations for Reporting

1. The Reporting Subcommittee will evaluate and modify the existing California regulation to lay out a standardized approach to verification that will assure integrity in the reported GHG data and a consistent quality of verifications across all WCI partners. Key areas of focus will be accreditation of verifiers, core verification services, and conflict of interest requirements. The WCI verification requirements will also ensure an enforceable verification program with direct oversight.

Additional Decisions Needed

1. Define the specific requirements for third-party verification by reporting entities and facilities.

2. Determine the level of quality assurance required for entities and facilities that are required to report, but will not be included in the cap.

Approach

The Reporting Subcommittee will add to the definitions list as required during on-going development of the Essential Requirements for Mandatory Reporting. In general, we will include definitions that are necessary to understanding specific essential reporting requirements and avoid definitions that are not absolutely essential. For example, we will not define terms that are used in their common English context (e.g., fence line, combustion, unit) or that explain acronyms or chemical formulae.

Partial List of Definitions

"Stationary combustion unit" means any boiler, heater, furnace, kiln, turbine, internal combustion engine, incinerator or other non-mobile source device that combusts any solid, liquid, or gaseous fuel for purposes of producing useful heat or energy for industrial, commercial, or institutional use; or for purposes of reducing the volume of waste by removing combustible material. [1]

"Facility" means any property, plant, building, structure, stationary source, stationary equipment or grouping of stationary equipment or stationary sources located on one or more contiguous or adjacent properties, in actual physical contact or separated solely by a public roadway or other public right-of way, and under common operational control.[2]

"Carbon dioxide equivalent" or "CO_2 equivalent" or "CO_2e" means a measure for comparing carbon dioxide with other GHGs, based on the quantity of those gases multiplied by the appropriate global warming potential (GWP) factor and commonly expressed as metric tons of carbon dioxide equivalent.

"Continuous emissions monitoring system" or "CEMS" means the total equipment required to obtain a continuous measurement of a gas concentration or emission rate from combustion or industrial processes.

"Greenhouse gas", "greenhouse gases" or "GHG" means carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), hydrofluorocarbons (HFCs), and perfluorocarbons (PFCs).

"Global warming potential" or "GWP factor" means the radiative forcing impact of one mass-based unit of a given greenhouse gas relative to an equivalent unit of carbon dioxide over a given period of time.

---

[1] The intent is to require any collection of stationary combustion units, located at any facility, that collectively emit 10,000 tons of CO_2e on an annual basis, to report emissions. In other words, the requirement applies to any individual stationary combustion unit, or any collection of units, whether or not they are located at a source-specific category facility addressed by this rule. Biomass-fueled units are included but would be reported separately.

[2] Some special "facilities," such as oil or gas production fields, will have separate definitions.

“Hydrofluorocarbons” or “HFCs” means a class of GHGs primarily used as refrigerants, consisting of hydrogen, fluorine, and carbon.

“Perfluorocarbons” or “PFCs” means a class of greenhouse gases consisting on the molecular level of carbon and fluorine.

The uncertainty in the greenhouse gas (GHG) emissions reported to WCI will be evaluated by the product of the uncertainties of the various components or methods used to estimate the emissions (e.g., direct measurements of flue gas; parametric measurements of fuel flow, feed water flow and steam flow; equipment manufacturer data; etc.). Accuracy is the inverse of uncertainty; that is, a high level of accuracy is the same as a low level of uncertainty. The quantification methods required for GHG emissions reporting under the WCI cap-and-trade program should have a high level of accuracy to ensure that all emissions reported across all source categories are equal, and that each ton reported is, in fact, a ton.

This document explains the relative accuracy of several general types of GHG emissions quantification and monitoring methods: continuous emissions monitoring systems (CEMS), parametric monitoring (i.e., measuring something other than fuel or gas, such as a catalytic feed rate), and material balance. This comparison provides a basis for comparing the accuracy of various source-specific methods, and determining their adequacy for use in reporting emissions under the WCI cap-and-trade program. Also, this document provides some initial conclusions regarding the relative accuracy of methods available to estimate and monitor emissions for non-combustion emissions from several source categories. This information will be updated in the future based on a continuing analysis of accuracy of existing quantification and monitoring methods.

Types of GHG Emissions Quantification and Monitoring Methods

Direct measurement of CO_2 emissions, such as collected with a CEMS maintained to specifications, can provide a high level of measurement accuracy. On the other hand, parametric monitoring would generally provide less accuracy as compared to CEMS, although often sufficient to support cap-and-trade programs. For example, pipeline quality natural gas has a relative consistent carbon composition, so measuring the flow of natural gas to a combustor is a good predictor of the CO_2 emissions from the combustor. However, the carbon content of coal, refinery gas, or field gas can be highly variable (i.e., greater than 10%) making fuel flow an inaccurate CO_2 emissions predictor for these fuels without taking special care.

A material balance approach to estimating coal combustion emissions can provide greater accuracy than parametric monitoring for these sources. In a material balance method, the carbon content of the incoming coal and of the discarded ash are measured on a frequent basis and used in conjunction with mass flow measurements to determine the carbon emitted as CO_2. Also, the accuracy of emission quantification and monitoring methods can vary depending upon the GHG being measured or estimated. For example, continuous fuel flow measurements can be fairly accurate for determining CO_2 content, but not at all accurate for determining CH_4 or N_2O content.

Relative Accuracy of Source-Specific Methods

The relative accuracy of existing GHG quantification and monitoring methods is being evaluated on a source category-specific basis, especially for the source categories (combustion and noncombustion) that are candidates for inclusion in the WCI cap-and-trade program. Accuracy of annual emissions will be affected by the required frequency of measurement and the variability of the parameter(s) to be measured. Several metrics are being used to determine if source-specific methods support accurate reporting of GHG emissions, including:

1. Relative accuracy compared to CEMS measurements
2. Whether or not other cap-and-trade programs (e.g., European Union) require, recommend, or allow use of the method for a particular source category.

Based on the preliminary information on existing methods collected and examined to date, several source categories have been judged to have inadequate quantification methods for some of their non-combustion emissions to support including those emissions in the WCI cap-and-trade program at this time. It should be noted that facilities in these source categories could be subject to the program if they had sufficient combustion emissions to exceed cap-and-trade thresholds.

For now, this assessment is qualitative, and based on engineering judgment, in order to expedite the identification of source categories for which no accurate methods currently exist. A more detailed assessment of methods for other source categories will be necessary in order to select specific methods, when more than one method exists for estimating emissions. In addition to this qualitative assessment, the fact that some source categories are not included in other cap-and-trade programs, such as the European Union, factor into the recommendation to not require allowance obligations for these source categories in the WCI cap-and-trade program. For example, the following emission sources do not appear to have quantification and monitoring methods accurate enough to support inclusion in a cap-and-trade program:

- Landfills – The generation of CH_4 in landfills is based on several site-specific factors, including waste composition, moisture content, temperature, availability of nutrients, waste density, and waste particle size. Historical estimation methods, such as the method published by the U.S. EPA in AP-42, rely on a "first order decay" equation that includes several parameters with high uncertainty, such as the methane generation potential, which can vary by as much as ±50% from the default values provided in the methods. We consider this method to be highly uncertain, especially as compared to a CEMS method. It should be noted that the Solid Waste Industry for Climate Solutions (SWICS) has proposed to replace default values with new values for landfill gas collection system efficiencies and methane oxidation in cover soils, and use new carbon storage factors for carbon sequestration.
- Municipal and Industrial Wastewater Treatment Plants- The generation of CH_4 and N_2O in large open lagoons is very difficult to measure, so the emissions are normally estimated using imprecise models and emission factors. The models attempt to predict the methane and nitrous oxide byproducts from microbial processes that are highly influenced by unknown factors in the lagoons, including temperature, waste digestibility, trace nutrient levels, oxygen and nitrogen levels, and microbial species.

As stated above, this information will be updated in the future based on a continuing analysis of accuracy of existing quantification and monitoring methods.

Source Category	*Accurate method*	*Method available, may need improved accuracy*	*Method under review*	*Identification/ development of accurate method underway*
Electricity Generation, Cogeneration (CHP)	●			
Electricity Importers (retail providers, marketers)				WCI Electricity Subcommittee
Stationary Fossil Fuel Combustion Sources: Fossil fuel combustion in equipment at industrial sources (e.g., cement plants, refineries, etc.)	●			
Biomass Combustion Sources: Biomass combustion in equipment at industrial sources.	●			
Liquid Transportation Fuels: Combustion of fuel in on- and off-road vehicles, regulated at point where fuel enters into commerce that may vary by jurisdiction (e.g., distribution terminal/rack, licensed fuel wholesalers)	●			
Residential, Commercial, Industrial (RCI) Fuels: Combustion of fuel (NG, fuel oil, other) in the RCI sector, regulated at point when fuel enters into commerce (e.g., local distribution company [LDC] for NG, distribution terminal/rack)	●			
Petroleum refineries	●			
Hydrogen production	●			
Noncombustion Emissions (Combustion Emissions for these Sources are Included in "Stationary Combustion Sources" Above)				
Oil and gas production & gas processing				WRAP/TCR
Natural gas distribution systems				CCAR
Cement production	●

Responses to July 2008 Draft Design document and Draft Essential Requirements for Reporting

Thirty-eight commenters responded regarding reporting[3]. Most were from potential reporters, with a few from other categories (environmental groups, NGOs and consulting companies, and municipalities). Many comments addressed only a few topics, but several provided comments on all reporting topics presented in the July documents. A few provided very detailed recommendations in the form of regulatory language.

1) Highlights

Stakeholders were asked to recommend effective mechanisms for stakeholder involvement in the ongoing development of the Essential Requirements this year. The few comments received were supportive of frequent conference calls, perhaps supplemented by in-person meetings at the jurisdiction level or focused on specific topics or source sectors.

One significant emerging issue is that many potential reporters are calling for uniformity with the forthcoming US EPA mandatory GHG reporting regulation. This is likely driven by concern over the burden of having to measure, monitor, and report differently to two separate programs.

A few commenters have noted the need for development of a transaction tracking system in addition to the emissions reporting system.

Many industry commenters said that the 10,000 metric ton CO2e reporting threshold was too low or had not been adequately justified.

Although there were few comments on the issue of oil and gas production emissions, it is notable that both industry and environmental group commenters recommended aggregation of field facilities into larger reporting entities.

Most of those commenting on the issue of annual versus more frequent reporting recommended annual reporting. Most advocated uniform reporting timelines across WCI, but some were concerned about possible conflicts with existing reporting rules.

Most who commented on Global Warming Potential values to be used in calculating CO2 equivalents recommended using IPCC values, and some specified use of the 1995 IPCC Second Assessment Report values. None recommended use of other values.

Several commenters expressed concern that ancillary data other than emissions should be confidential. For some industries where emissions are from fuel combustion, the close relationship of emissions to fuel use may lead to claims of confidentiality for emissions data.

Commenters remain divided on whether reporting should be direct to TCR or through jurisdictions.

[3] Excluding multiple submissions of identical coalition or group comments by group members.

Many commenters recommended that quantification methods be consistent with existing industry protocols or federal, state or provincial reporting programs. Some called for simplified methods for small emitters, or de minimis provisions and specific exclusions for insignificant emission points. There were also recommendations for flexibility in quantification methods allowed to be used.

The requirement for third party verification remains a significant issue. Most commenters on this topic were from industry, and most opposed it. They argued that use of defined protocols, self-certification, and opportunity for agency audit should be sufficient. Some recommended exempting certain categories, such as certified CEMs, Title V sources, or sources not selling credits.

2) Detailed summary

Comments are summarized below by topic. Number in parentheses indicates number of commenters on each topic, or making a specific recommendation.

Mechanisms for Stakeholder Input to Further Development of Reporting Requirements (6)

- Frequent conference calls focused on specific topics (2)
- Supplement by in-person meetings at the jurisdiction level (1) or focused on specific topics or industries (2)
- Engage industry associations (1)

General (17)

- Consistency across WCI and between jurisdictional and federal levels (5)
- WCI reporting should be identical or equivalent to EPA mandatory GHG reporting system, or use data from EPA system with no separate WCI reporting (4)
- Need transactional tracking system in addition to emissions reporting (2)
- Support draft design on reporting (1)
- Reporting system as close as possible to TCR (2)
- Support current WCI draft design for reporting (1)
- Recommend industry protocol for solid waste management sector reporting (1)

Definitions (9)

- Harmonize across US regulatory frameworks (1)
- Support use of CARB as starting point (3)
- Start with TCR GRP instead of CARB definitions, which are too specific to CARB program (1)
- Also use forthcoming EPA reporting rule definitions, harmonize with federal programs (2)
- For effective stakeholder comment, give full text of referenced definitions, (1)
- Detailed recommendations for changes to CARB definitions (1)
- Source category definitions must include details on POR and activities included (1)

<u>Applicability (29)</u>

- Threshold of 10,000 metric tons CO2e is too low and/or lacks justification, will burden small companies (7)
- Reporting threshold should be same as cap and trade threshold (4)
- Reporting threshold should be 50,000 metric tons (1)
- Support threshold of 10,000 metric tons CO2e (2)
- Reporting thresholds should be industry-specific (1)
- Exclude specific sources:
  - methane vented and fugitive emissions from oil and gas sources because quantification inaccurate (1)
  - landfills because quantification inaccurate (1)
  - emergency engines and emergency generators (1)
  - indirect emissions (1)
  - sources, activities and processes associated with aviation fuel because in federal jurisdiction only (1)
- Include specific sources:
  - oil and gas field emissions (3)
  - transportation fuels and natural gas distribution (1)
  - biomass emissions (1)
- For oil and gas E&P, develop unique definition of reporting entity that will aggregate small facilities, such as by production field (4)
- Minimize exclusions (1)
- Reduce burden on small companies by phase-in or by providing assistance (1)
- Unclear on status of landfills and wastewater treatment plants (1)
- Be flexible in determining reporting level, vary this as appropriate for source/sector (1)
- Watch out for complexity of boundary issues, see EU ETS for examples (1)
- Point of regulation for RCI fuel use and transportation fuels should be uniform across WCI (2)
- Support policies to incentivize CHP (1)
- Distinguish between biogenic and anthropogenic CO2 emissions (1)
- Support reporting at corporate or facility level, not process level (1)

<u>Timing (14)</u>

- Report annually (6)
- Report monthly or quarterly, for efficient market functioning (1)
- Set uniform deadlines across WCI (4)
- Recommend specific reporting deadlines, 6-8 mos. after end of emissions year (5)
- Concern about conflict with existing jurisdictional deadlines (2)
- Set deadlines consistent with TCR (1) or Climate Leaders and other programs (1)
- Historical data to set cap should be collected in consistent manner (1)
- Move first reporting ahead one year and allow submission of "best available information", as in CARB rule (1)
- Support 2010 as first emissions year to be reported (1)
- Pre-2010 emissions reporting should be voluntary (1)

<u>Pollutants and GWPs (6)</u>

- Use 100-yr GWP values consistent with US and international reporting (5), such as IPCC (4), specifically from IPCC Second Assessment Report, 1995 (3)
- Formally adopt policy for calculating CO2 equivalents (1)

<u>Confidentiality (8)</u>

- Some ancillary data (energy consumption, wholesale power sales and purchases, production rate, specific fuel use) should be confidential (5)
- Facility-level reports should be confidential (1)
- Emissions data or total emissions should be public (3)
- Confirm public "right to know" for GHG emissions reports (1)
- Protect confidential information in accordance with federal and jurisdictional law ((1)

<u>Report Content and Submittal (11)</u>

- Report through jurisdictions for upload to TCR (4)
- Report directly to TCR (2)
- Support reporter option on reporting to TCR vs jurisdictions (1)
- Minimize reporting of ancillary information not needed for cap and trade (2)
- Consider streamlined reporting for small entities (1)
- Be consistent with EPA mandatory GHG reporting (2)
- Reporting fees to be borne by jurisdiction (1)

<u>Compliance (3)</u>

- Use federal Acid Rain and Title V programs as examples (1)
- Assume compliance would be according to existing state law (1)
- Identifies several additional issues to be decided (1)

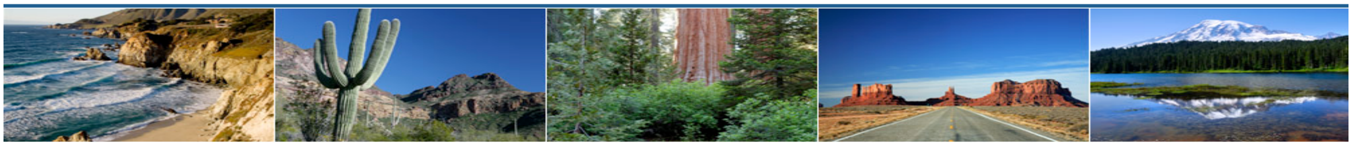
<u>Quantification (13)</u>

- Rely on existing sector-specific methods (API Compendium, WRI/WBCSD, EU ETS, Canadian and US federal programs, forest products industry protocol) (5)
- Be consistent with EPA mandatory federal reporting (2)
- Methods for landfills (1) and for methane fugitive and process emissions from oil and gas (1) are unreliable, inadequate for cap and trade
- Treat CHP like any other emissions source (1)
- For small combustion sources at oil and gas sources, use standardized emission factors (1)
- For biomass and high GHG fuels (LNG and tar sands), do not use arbitrary emission factors unsupported by analysis (1)
- De minimis emissions should be set at 3%, also use list of de minimis activities as in Title V program (1)
- Level of accuracy should be based on significance and materiality of emissions (1)
- Allow for flexibility and avoid dictating specific methods (1)
- Share with stakeholders the process for selecting and approving methods (1)

<u>Verification (21)</u>

- No third party verification for all sources (8)
- No third party verification, use defined protocols and self-certification with agency audit authority, for:
  - power plant CEMs (1)
  - sources not selling credits (1)
  - Title V reporters (2)
  - sources subject to permitting (3)
  - small emitters (1)
- Support third party verification (2)
- Support CARB approach of multiyear verification cycle with one full verification and several less intensive verifications per cycle (1)
- Common approach and consistent standards for verification (2)
- If allow jurisdictional audit, set minimum standards for compliance assurance such as budget and staff levels, audit rates (1)
- Need accreditation process for verifiers to ensure program integrity (1)

Western Climate Initiative



ELECTRICITY SUBCOMMITTEE
TECHNICAL WORKING SESSION

SALT LAKE CITY, UT
October 16, 2008

10:00 a.m. to 4:15 p.m.

Location:
Utah Department of Environmental Quality
Building #2 (North Building)
168 North 1950 West
Salt Lake City

AGENDA

1.	**10:00**	**Introductions**
2.	**10:20**	**Review of Plan for Technical Working Sessions and Agenda for the Day** **David Van't Hof, Chair, WCI Electricity Subcommittee**
3.	**10:40**	**Presentation and Discussion of Leakage Issue Based on Imports and Exports Information** **Snuller Price, E3**

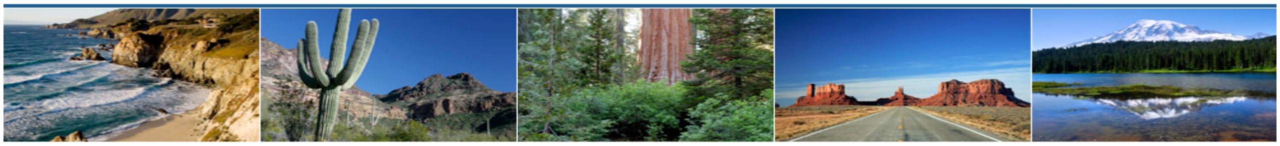
Western Climate Initiative



ELECTRICITY TECHNICAL WORKING SESSION

Operational Reliability and Liquidity Issues – Background Paper for WCI December 2 Workshop[1]

Introduction

Stakeholders for the electricity sector have asked the Western Climate Initiative (WCI) to address how a cap-and-trade market should be structured to handle electricity operational reliability and market liquidity. They have asked these issues in two roles, as one of the largest sectors participating in the cap-and-trade market and as entities with specific technical challenges in providing service to customers. The WCI Electricity subcommittee plans to provide recommendations to the WCI Partners on these technical issues and is seeking stakeholder input. This paper is designed to serve as a springboard for the December 2 Technical advisory workshop and subsequent written comments. The paper includes issues identified so far, open questions, and a range of sample solutions which WCI could employ to address operational and liquidity issues in the market design.

These issues may not be uniform across the WCI. With respect to operational reliability, while all system operators must conform with the North American Electric Reliability Corporation (NERC) and regional reliability standards, the exact procedures and products used to maintain operational reliability may be different among and between vertically integrated utilities and more de-regulated systems. Operational reliability and liquidity issues may also be different for (Western Electricity Coordinating Council (WECC) and the Eastern Canadian Provinces that are WCI members, since they have different grids with different rules and regulatory structures. We will need to identify what issues are in common and which need to be tailored to each grid's structure. Finally, we should identify which issues are appropriate for WCI-wide guidelines and which are relevant only to some jurisdictions.

---

[1] *The lead author of this paper is Karen Griffin of the California Energy Commission. Generous assistance and comment on an early draft was provided by Udi Helman (California Independent system Operator), Bud Beebe (Sacramento Municipal Utility District, Mark Meldgin (Pacific Gas and Electric)) and Jessica Verhagen British Columbia). It also draws on stakeholder comments in California's proceedings on implementing AB 32 and so benefits from views of public and private utilities, power marketers, independent generators, and consumer and environmental representatives.*

Operational Reliability Description

Operational reliability is a system attribute provided mostly by generation at the behest of the balancing authority. It is the balancing authority's[2] ability to balance real-time supply and demand for energy while respecting physical and security constraints on generation and transmission operations and maintaining sufficient operating reserves to meet applicable control performance standards. While the immediate focus of this paper is on short-term reliability, there is also some discussion of longer-term reliability issues, as reflected in multi-year grid planning and resource adequacy assessments.

A fundamental complication of operational reliability in power systems is that electricity cannot, for the most part, be stored. Some generating units must be able to run when called upon to balance energy supply and demand and support grid reliability. In the current WECC grid, most units operated specifically for grid reliability purposes are fossil-fired and they emit greenhouse gases (GHG). (The WECC exception is hydropower, which plays a significant reliability role in the northwest and California). Under a cap-and-trade system, the owners of fossil-fired units will need to acquire and surrender allowances to cover their GHG emissions. Retrofitting these units with carbon reducing technologies is not yet a commercial feasible approach. Their only options to meet a tightening allowance cap are to buy allowances or not generate. For plants not owned by a utility, these units must be able to obtain allowances and recover the costs either through bilateral contracts or spot market revenues.

Some reliability issues may present problems over time for obtaining allowances, but may be fairly well defined and can be planned for. Other reliability issues, such as emergency purchases or dispatch instructions, may be difficult to plan for. Separating operational reliability into such constituent pieces may help us to craft targeted solutions without having unintended consequences on power system operations and markets.

Operational Reliability Issues Which Have Been Raised by Stakeholders

1. To what extent do non-utility generators have an opportunity to recover the full costs of acquiring allowances needed to operate in real time, including those generators with "must-run" contracts to ensure grid reliability? How many contracts executed before entities could reasonably anticipate a carbon price will still be in place in 2012? Existing contracts with no re-openers do not allow generators to recover costs of allowances. Is this a generic issue for implementing cap-and-trade or do concerns about operational reliability require specific remedies?

2. Plans to increase renewables across the WCI necessarily include new dispatchable gas plants as well as possible repowering of existing dispatchable thermal resources to counter balance for the variability of wind and solar generation. Will allowances be available for these new plants and

[2] A balancing authority may be a utility or it may be an independent system operator.

existing/repowered capacity needed for such support? On the one hand, if we are reducing greater use of baseload MWh, there would still be room for plants producing fewer hours of energy. On the other hand, fossil plants kept available on line for renewable integration may be operating at less efficient levels with higher emissions. Is this just an example of how to handle new entry and exit and hence belonging to a wider policy discussion at the Partner level before being addressed on a technical level?

3. In terms of longer-term reliability, how can the electricity sector align its resource acquisition timelines to take into account the trajectory of reductions needed to meet the carbon reduction goals? Does the carbon reduction trajectory affect the speed with which jurisdictions increase their auction percentages? Grid reliability may be threatened if either allowance prices or other policies compel high-emitting plants which are also necessary for grid reliability to shut down before resources which provide comparable attributes are brought on line.

   The lead times present for electricity sector infrastructure are substantial. To the extent that renewables require new transmission lines to be delivered to load centers, multi-year delays may be possible for getting these renewables online. Such delays threaten the ability of large amounts of renewables to be counted on for accomplishing reductions in the early years of a cap and trade. With a linearly declining cap, this would cause reliability problems for the grid towards the end of the first, and possibly second compliance periods, as generators face substantial penalties for operating without available allowances. While the sector will be under a multi-sector cap and trade, adequate availability of "excess" allowances from other capped sectors has not been evaluated.

4. Will there be pressures to over-procure allowances? To assure grid reliability, load serving entities (LSEs) will typically "over-procure" energy and capacity for the peak demand periods of the summer months. To the extent that allowances will be held in similar conservative fashion by LSEs as a hedge to assure availability of capacity, these "allowance banks" may well challenge market liquidity. Generation capacity must meet instantaneous expected and real demand at all times and there is requirement for "capacity reserve" that is very infrequently needed.

5. How will we prevent wholesale market suppliers in the WCI from withholding power if they contend that allowances are not available at a reasonable price and, conversely, how do we prevent allowance price spikes from translating into windfall profits for all market participants? [See the appended SMUD example.] Or, is this issue any different from the ones the market already faces: a coal/hydro/nuclear/renewable generator faces the same situation if the price of natural gas jumps. The market doesn't consider profits sustained in an open market to be "windfall" profits when non-natural gas generators see increased profit because the price of natural gas increases.

6. May generators be held hostage to speculators when they need allowances to cover reliability dispatch? Without careful allowance market monitoring, it may be difficult in such circumstances to distinguish between strategic physical withholding to affect wholesale energy prices and market-driven speculative price increases. Are multiyear compliance periods and banking adequate to deal with short term acute demand? Is the demand anticipated to be relatively small compared to the overall supply of allowances? Is this a generic issue which should be addressed by the monitoring and market oversight committees, or is there something unique to the electricity sector?

7. With respect to longer-term adequacy, does the electricity sector need special allocation rules to deal with very large swings in system reliance on fossil-fired generation due to variability in hydro generation output, such as those which occur in California in low and high water years, as illustrated in the following paragraphs? Are there other predictable swings in GHG emissions caused by resource trade-offs in other WCI jurisdictions?

   Hydro variability in the West is substantial. In California, hydro generation variability averaged 25 percent per year between 1990 and 2004. That is, on average, from one year to the next, the amount of hydro generation was either 25 percent above or below the previous year. For the Northwest, that variability averaged 16 percent, and when the two regions are combined, the annual variability averaged 13 percent. By splitting this timeframe into 5 three year time windows, and comparing those time windows to the typical annual combined generation over this time period, the three year windows were on average 8 percent higher or lower than the historical average. This all goes to show that even with 3 year compliance periods, hydro variability will still tend to be either above or below the historical average by an amount that is significant enough to cause a shortage or surplus of allowances.

   Currently, as a mechanism to deal with the variability of hydroelectricity, utilities will hedge for dry hydro conditions by procuring more fossil generation than may actually be necessary to meet load. If procuring fossil generation also means procuring allowances in order to operate, this may challenge liquidity of the market. As an example, in the 1970's, gasoline lines occurred as a result of the need for everyone to have a full tank of gasoline in case they were to run out. Risk adverse utilities will likely prefer to have allowances on hand, rather than risk shutting customers off.

8. Will operational reliability concerns play a bigger role in the early years of GHG allowances, until the challenges of incorporating intermittent resources into the system are overcome? For example, if we initially have a system with high wind penetration, causing substantial variability in output that represents challenges for operational reliability, but that is augmented later with solar, price-responsive demand response and storage capability that mitigate the variability but without increasing GHG emissions.

9. What parallels should we look at for how others have handled similar problems (RGGI? NOx credits in SCAQMD, EU ETS power sector??)

10. Is operational reliability more or less an issue for the vertically integrated utilities compared to those portions of WCI, such as ISOs, which operate using market rules and tariffs?

11. Who (as exactly as we can identify) is responsible for assuring grid reliability? This is reasonably well understood for the current system, but responsibility for grid reliability as it is affected by allowance availability should be clarified prior to its challenge. (This may have a relationship to the time constants for action stated above, e.g., ISO or other Balancing Authority for day ahead and instantaneous, and LSE's or "Government" for assuring sufficient capacity availability over long time-frames.) It may be good to explore various key entities in this regard (six month actions, one year actions, three year or one Compliance Period actions, Power plant development time frames, transmission development time frames). Vertically Integrated LSE's, market dependent LSE's, Power Marketers, Merchant Generators, Electricity Consumers. In this regard, is forced DSM (i.e., directed curtailment) an acceptable "Reliability Enhancer?"

    Examples of issues which might arise include:

    - If a Generator, near the end of a compliance period, had no allowances, and their availability was uncertain (illiquid market) would they bid? Would they bid and/or run if told to by, what, LSE?, ISO?, BA? What entity is responsible for this decision, and which entities are responsible for dealing with the outcome?
    - If a generator has a contract (like a futures contract) for allowances to cover their position, but the contractually obligated company cannot get allowances because (pick one or more) they go bankrupt, the allowances are all gone or held by price independent entities (like say an LSE that "must hold" some reserve amount above their apparent need), Who pays fine? Who comes up with "pay-back" allowances from next allowance vintage?
    - What is the price elasticity of all of the individual capped sectors? Are there specific inelastic incompatibilities within sectors? (At 30 $/ton a manufacturer can switch from natural gas to electricity to heat my plastic, but electricity sector can't absorb that load for 30$/ton.) Electricity rate structures are not responsive enough to prevent this type of dislocation.
    - Effect of commodity inventory buffers and their effect on allowance purchase (and timing) decisions. For instance, natural gas in the pipeline

offers a physical storage buffer (with known response time and limitations) therefore the gas market has some time to respond to changing demand. What, for instance, are aluminum supplier inventory response time issues and effect on decision time for (HFC) GHG allowance and electricity demand adjustments in response to carbon price signals? What, for instance, are Portland Cement inventory options to contribute to GHG allowance liquidity in short-term? Would market "know" when coal combustion had used more allowances than would be compatible with reliable grid capacity to the end of a compliance period?

Liquidity Description

Liquidity measures the capability for an asset, such as an emission credit, to be bought or sold quickly without causing a significant movement in price and with minimum loss of value. Some literature suggests that liquidity is largely a question of how we design the allowance contract. If there are more players, if the emissions certificate is more uniform, if there is price transparency, if it is fungible with other carbon markets so that it can be easily traded, then the market will be more liquid. These do not seem to be electricity-specialized issues.

Almost everyone favors the liquidity which comes from greater participation of entities in the cap market in order to provide lower cost allowances, but stakeholders are split on the potential for liquidity to morph into speculation and market manipulation. In this debate, "good" liquidity is when there are many buyers and sellers, and when both small and large participants can buy or sell allowances in the amounts they want at the time they want. "Bad" liquidity happens when the allowance market is dominated by "speculators" who want to profit from their buying and selling expertise regardless of the impact it has on the ability of the actual system to provide reliable power. Obviously, these are over-simple generalizations to show the bookends of the debate.

One complication that permeates these conversations is the multi-sector nature of the envisioned cap-and-trade program. Additional capped sectors should increase allowance liquidity, however without quantification of the temporal, operational, and size characterization of interacting sectors, it is guesswork to judge the potential allowance market liquidity issues posed with a linearly decreasing cap with real reductions of significant size over the decade.

Liquidity Issues Which Have Been Raised by Stakeholders

1. Is it correct that the GHG allowance/offset market will probably be liquid if people have confidence that, when they sell at some price, they can reverse, and buy back some time later, at roughly the same price? On a graph of price vs. quantity, in other words, a supply function for GHG allowances/offsets that is flatter, rather than steeper, may lead to a more liquid market. If, in contrast, a small shift in demand for GHG

allowances/offsets would cause a large change in the price, people might tend to hold their allowances, out of fear of selling allowances just before some change, like dry hydro that would cause a jump in allowance prices.

2. Hydro swings may be important for liquidity as well as operational reliability. The WCI electricity sector is larger than California; it includes more hydro, and is subject to bigger hydro swings. For example, consider 1992, which was a dry year throughout the WCI (though not as dry as 2001 or 1977). Hydroelectric generation in the WCI in 1992 was about 30 million MWh below the median of the last several years. Using gas CCs to make up the shortfall would create a need for about 12 million more allowances or offsets. Would that cause liquidity issues?

3. Are there criteria for identifying when there is a minimum critical amount of liquidity, rules to prevent market manipulation, staged processes, safety valves, monitoring standards which can be set? What specific recommendations could we make for consideration in a WCI approach? Is there evidence that rules tried so far have been successful or unsuccessful? If intermediaries are found to introduce more problems than they solve, what metrics do other markets use to determine the tipping point at which intermediaries harm rather than help the market?

4. What are the key principals that an allowance market needs to have to draw in good liquidity?

Brainstorming List of Possible Solutions: Operational Reliability

For any issue which is deemed to be significant, the WCI Electricity Committee may recommend a possible solution for Partners to consider. The following list is a starter list of ideas to be explored if there is a need to do so. These could be considered either for a WCI-wide guideline or be recommended for consideration by individual partners if the issue is relevant to them.

1. Allowance set aside for reliability. This introduction of a ‘conditional bank’ of allowances to compensate for either overly wet or overly dry compliance periods may be necessary to ensure that adequate allowances exist in order to ensure reliability. Such conditional banks may also need to be considered for temperature variability. Would it have to be accounted for within each partner’s budget?

2. Set a “de minimus” reliability exemption, e.g., for emergency transactions, under the argument that those are likely to have little impact on GHG emissions but could prove extremely difficult to appropriately assign allowance obligations, especially across WCI boundaries.

3. Make the cost of allowance automatic pass-through to customers; don’t include the price of allowances in bids.

4. Let the market set the price of reliability (i.e., incorporating the cost of high allowance prices) – if prices spike in shortage or emergency conditions, that is sending a valid signal about the worth of reliability and the need for non-GHG emitting resources to provide reliability services.

   An example of market pricing is the ISO's MRTU design which will have some mechanisms to do this. One is called "scarcity pricing" and would raise spot prices for energy, regulation and reserves when the system is short of any of those. Similarly, in periods when there is oversupply of wind (likely at night in California), the ISO is exploring mechanisms to send the right price signal for resources to curtail.

5. The balancing authority/utility acquires allowances for generation it directs be turned on for reliability.

6. In order to cut down on the potential for hoarding of allowances, introduce a vintaging element and limit maximum lifetimes for allowances. . While there is general agreement that banking of allowances is desirable, some confusion may develop between legitimate banking activities and 'hoarding' with the intent of harming market liquidity.

7. Do nothing extra; because we determine that the existing flexible compliance rules handle the issue adequately

Brainstorming – Possible Solutions: Liquidity

1. Are the flexible compliance measures already adopted sufficient or is there some additional proposal needed for either operational reliability or liquidity?

2. How could we structure the allowance auction to encourage "good" liquidity, restricting the amount of allowances purchased by an entity, restricting allowance auction to covered entities and allowing intermediaries to function in the secondary market?

3. Any market established for trading carbon allowances should have transparency as a first principle. Possibilities to ensure transparency include public disclosure of allowance ownership after auctions and at regular reporting intervals (quarterly?). Such disclosures will be necessary to ensure that entities cannot 'corner the market'. Of potentially equal importance would be a regular reporting requirement for entities to show that they hold allowances sufficient to cover generation that already occurred. Again here quarterly or bi-annual reporting may be sufficient to ensure that significant deficits are not introducing the potential for unnecessary volatility, and would help prevent the possibility of running out of allowances due to imperfect information.

4.

Operational Reliability Issue #4 - example: Fuel price differential

It is well known that coal and gas fuels have a significant difference in price. Given coal's relative abundance in the United States, in particular as compared to gas, it is likely that this cost difference will continue and, if anything, will increase over time. Because of this significant fuel price differential, coal generators have a much easier time acquiring allowances than gas generators, but they need two to three times as many allowances per MWh produced. Because of the very large difference in marginal operating costs, until carbon prices reach fairly high levels, such as $50 to $60 per ton or more, gas will not displace coal generation. Additionally, coal plants are less economic to maneuver than gas fired turbines; they don't like to be shut-down for the night, so coal based bids will likely be more resistant to being forced out of bidding than just the fuel price spread would indicate. As a result, to the extent that prices remain below the $50 to $60 per ton for any significant amount of time in a compliance period, it is possible for coal generators to consume more allowances than that which is compatible with maintaining an amount of gas generation compatible with current reliability needs.

Consider the simple scenario (no offsets, no allowances from other sectors); coal generation, natural gas generation, and other generation are available and are needed to meet capacity at some time. The allowance cap is insufficient to allow all coal and natural gas generation to run at design annual capacity. Why can't coal, running baseloaded, buy more allowances (and retire them) than is compatible with any fossil fueled generation having allowances to cover operation in, say, the last month of the compliance period?

Western Climate Initiative: Electricity Leakage Analysis

October 16, 2008
Electricity Subcommittee Technical Working Session
Salt Lake City, Utah

Snuller Price, E3

Agenda

- E3 and PLEXOS Background
- Research Objective and Approach
- Summary of 2020 Simulated Dispatch
- Analysis Results
  - Coverage
  - Contract Shuffling
  - Leakage
- Next Steps and Possible Refinements
- Question and Answer

E3 Background

Energy and Environmental Economics, Inc.

- **E3 Overview**
  - E3 is an electricity consulting firm founded in 1993 in San Francisco.
  - Clients span local, state and federal government, small and large public and investor-owned electric utilities, and energy technology companies
  - Approximately 20 staff in energy economics, policy, and resource planning
- **Related Projects**
  - California GHG Modeling of electricity sector for AB32
  - IRPs and Energy Plans in the Northwest; Idaho State Energy Plan, IRP for PNGC Power, Lower Valley Energy, Umatilla Electric Cooperative
  - Long-line transmission, British Columbia – California Renewable Energy Partnership, Load Resource Balance in the Western Interconnection: Towards 2020 for Western Electric Industry Leaders (WEIL)

PLEXOS Solutions

- Software, consulting, and information services company located in Sacramento, CA
- Company utilizes PLEXOS software for regional analyses
  - Advanced linear and mixed integer programming algorithm for “operations quality” unit commitment and dispatch
  - Simultaneous (versus sequential) optimization of generation, transmission, system, emission, and storage constraints
- Four principles, each w/ 20+ years resource planning experience
- Worked with E3 on the CPUC GHG modeling
- Currently engaged to provide renewable integration study for CAISO
- Performed similar study recently for 3 CA IOUs

Plexos Solutions

Investigation of 3 related questions

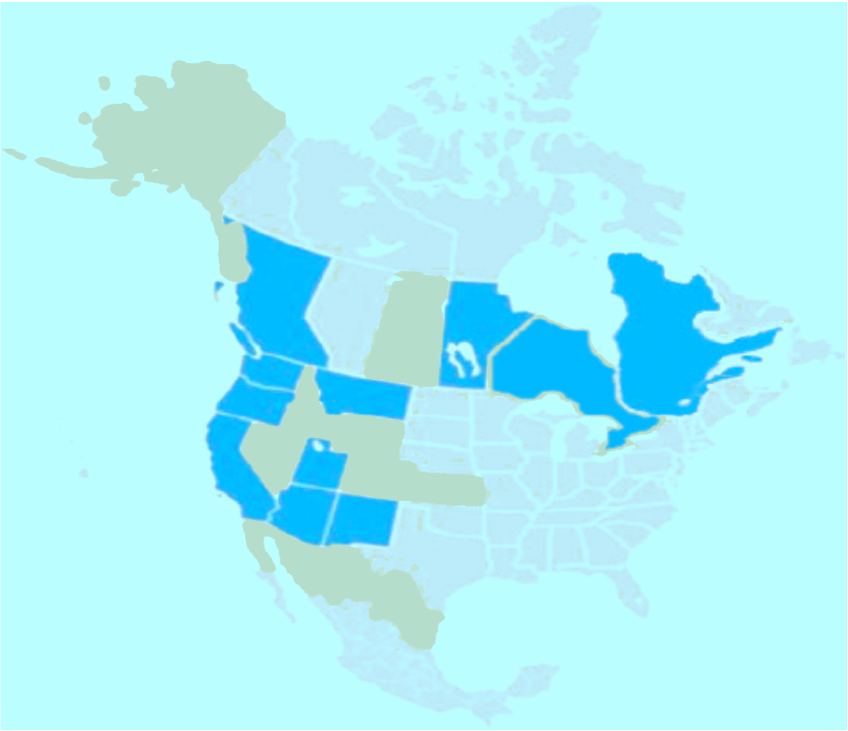
- Coverage
  - How well does the system cover the actual CO2 emitted by the electricity sector in WCI states?
- Contract Shuffling
  - What is the potential to reduce CO2 in the WCI by 'shuffling' ownership or contracts to outside the WCI?
- Leakage
  - What is the potential to change *generator operations* to reduce CO2 in the WCI but increase it outside?
  - What is the potential to change *new generation investment* choices to reduce CO2 in the WCI but increase it outside?

Analysis Limitations

- One month project that leverages prior analysis
- Analysis based on a single snapshot of 2020 WECC case
  - Estimate of 2020 generation and loads
  - Production Simulation yields 2020 GHG emissions
- Given time constraints, we also make recommendations on possible improvements to the analysis

Jurisdictions Included in Analysis

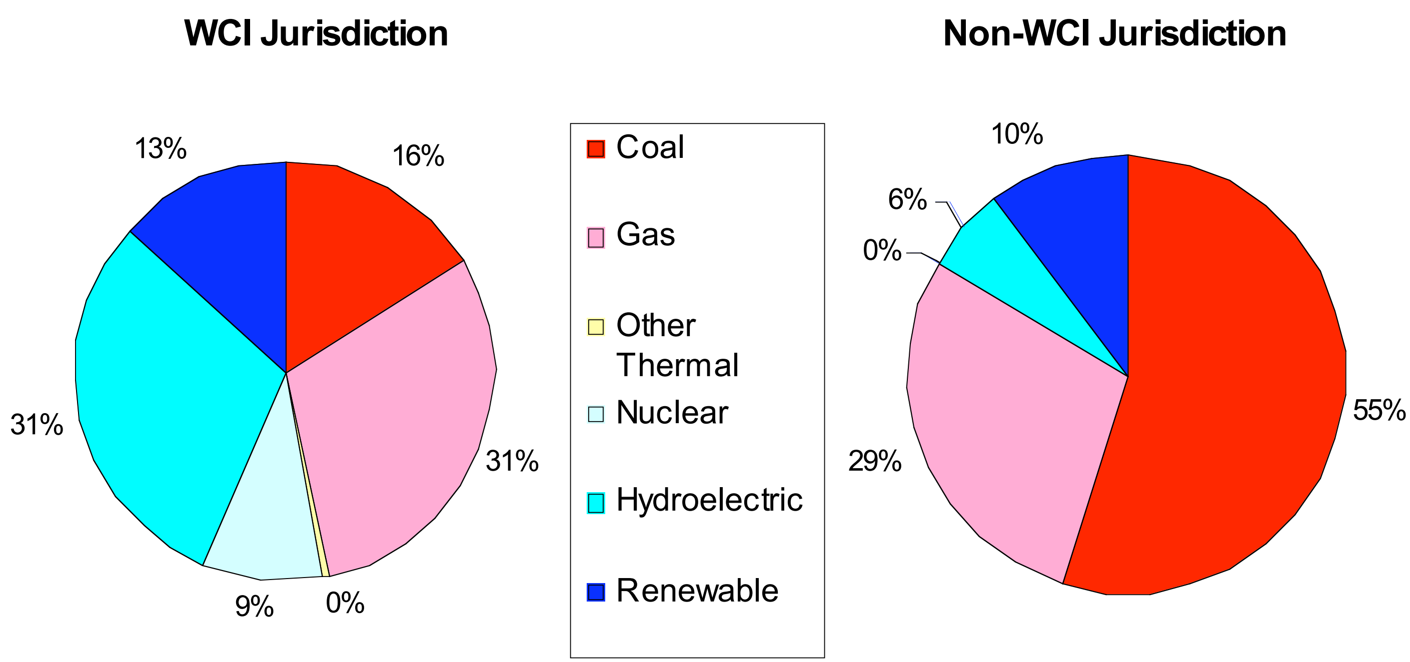
- Analysis focuses on the 8 western states and provinces
  - BC, WA, OR, CA, AZ, NM, UT, MT
- PLEXOS 2020 simulation does not include the 3 eastern province members



WCI Point-of-Regulation Recommendations for Electricity Sector

- Implement First Jurisdictional Deliverer
  - Generation within WCI is monitored at the smokestack
  - Specified imports buy CO_2 at actual rate
    - Specified: owned generation, or long-term contract
  - Unspecified imports buy CO_2 at the ‘deemed rate’
    - ‘Deemed rate’ is a pre-defined emissions intensity applied to system power imported to WCI (lbs CO_2/MWh)
    - Unspecified: Market purchases of power or short-term contract from trading point

2020 Generation by Jurisdiction

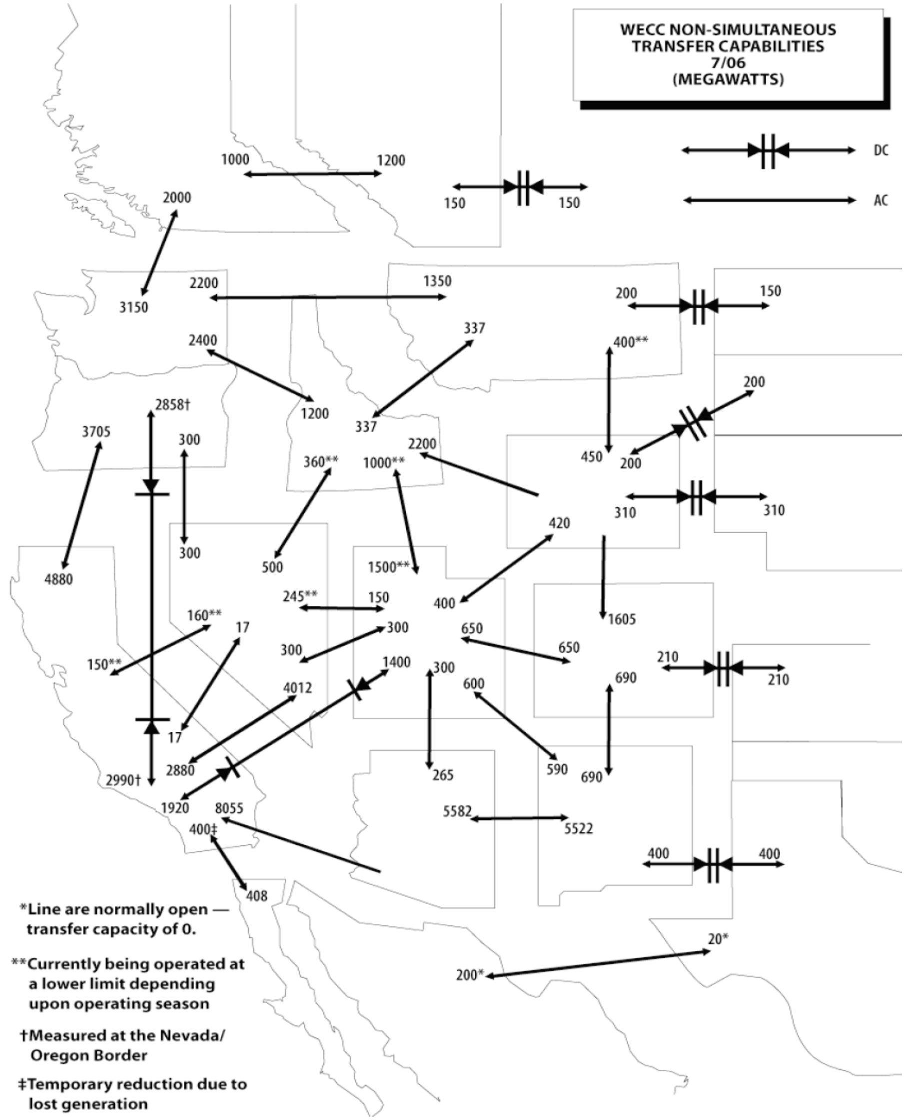


Generation (GWh)

	WCI	Non-WCI	Tribal Lands	TOTAL
Coal	126,675	146,510	42,556	*315,741*
Gas	233,015	77,355	0	*310,371*
Other Thermal	3,257	0	0	*3,257*
Nuclear	72,512	0	0	*72,512*
Hydroelectric	232,532	16,661	0	*249,193*
Renewable	103,298	27,653	0	*130,951*
TOTAL	*771,289*	*268,180*	*42,556*	*1,082,024*

Resulting Transmission Flows

- PLEXOS database contains a full model of high voltage transmission system in the WECC
- Results are based on a zonal simulation of the WECC with transmission flows between regions
- Results provide hourly flows on each major line in the WECC



Coverage Results

"Coverage" is measured as the share of emissions attributable to WCI consumption that is captured by the market design

1. Coverage Analysis

- Two bookends
  - ‘Source-based’ emissions: emissions from smokestacks within WCI
  - ‘Consumption-based’ emissions: best estimate of actual emissions based on generation assignment to states and provinces
- Ratio of source-based to consumption-based emissions provides estimate of coverage for source-based method
- FJD regulation of imports improves coverage

Consumption-Based Methodology

- Use 2020 PLEXOS Simulation
- Assign coal, hydro, and nuclear units by state based on LSE ownership / contracts
  - For LSEs that serve multiple states we apportion their fuel mix based on share of sales in each state
  - For BPA resources we assign based on share of customer requirements in each state
  - For WAPA resources we assign known specific projects to states or to the state in which the resource resides without better information
  - Assigns renewables to geographic jurisdiction (WCI & non-WCI)
- Remaining generation is natural gas, which is assigned to states based on the remaining load served using the average natural gas emissions rate

Emissions Coverage

- Source-based regulation would cover approximately 74% of WCI emissions

Regulation based on Consumption
MMT CO2

	WCI States	Non-WCI States	TOTAL
Coal	179	129	*309*
Gas	110	10	*119*
Other	4	0	*4*
TOTAL	*293*	*139*	*432*

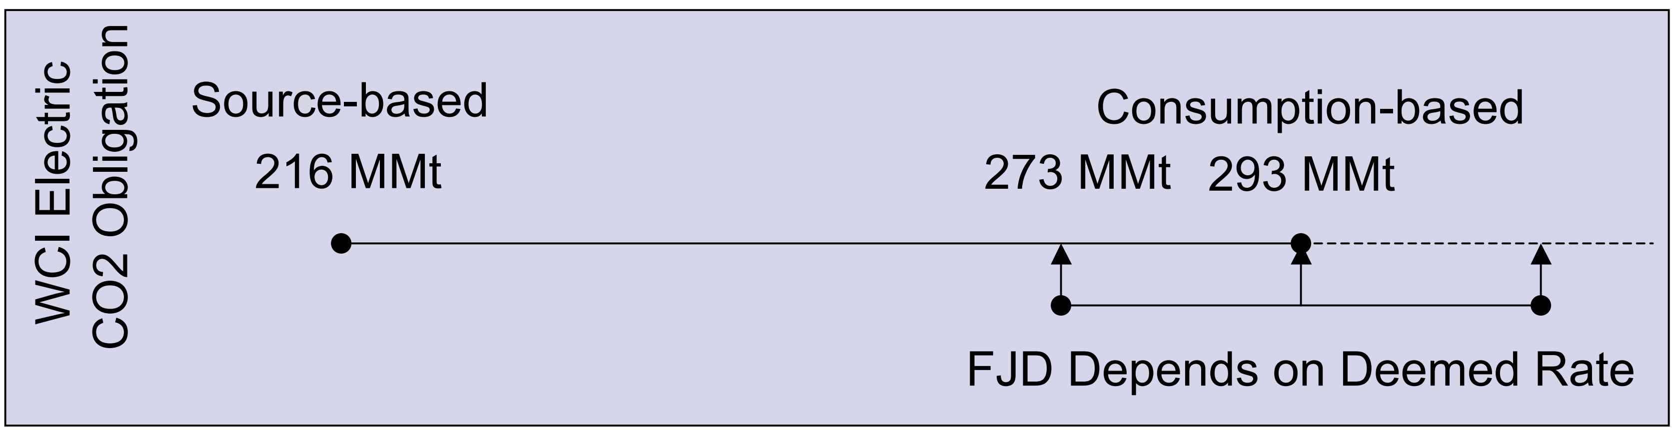
Regulation at the Source
MMT CO2

	WCI	Non-WCI	Tribal Lands	TOTAL
Coal	122	145	41	*309*
Gas	90	30	0	*119*
Other	4	0	0	*4*
TOTAL	*216*	*175*	*41*	*432*

216 MMT ÷ 293 MMT = 74%

First Jurisdictional Deliverer

- Regulation of imported electricity improves coverage
- Apply actual emissions intensity of specified generation (known contracts and ownership of generation in non-WCI states)
- Remaining imports: apply deemed emissions rate
  - High deemed rate can lead to more than 100% coverage
  - Low deemed rate can lead to less than 100% and more opportunities for leakage and incentive for shuffling



Coverage Analysis Conclusions

- Regulation of imports is necessary because a source-based point of regulation (i.e. ignoring imports) would only include approximately 74% of WCI electricity sector CO2
- Coverage analysis also provides an upper bound on contract shuffling

Contract Shuffling Results

Contract shuffling is an action that reduces WCI CO_2 obligations without any change in operations

2. Contract Shuffling Analysis

- Evaluate unconstrained shuffling
- Evaluate shuffling to specified imports
  - Potential is limited by non-WCI hydro
- Evaluate shuffling to unspecified imports
  - Potential is limited by deemed emissions intensity for system power
  - Evaluate regional exceptions

Unconstrained Contract Shuffling

- Contract shuffling is measured as the difference between pre-WCI consumption-based emissions and WCI regulated emissions
- The difference between the consumption-based CO2 emissions and source-based CO2 and is the upper bound for shuffling
- If all fossil-based imports were shuffled to zero carbon resources, 26% of the WCI carbon emissions could be shuffled (77 MMt CO2)

Unconstrained Contract Shuffling Potential
MMT CO2

	WCI States	Non-WCI States	Change in CO2
Coal	57	-57	*0*
Gas	20	-20	*0*
Other	0	0	*0*
TOTAL	*77*	*-77*	*0*

Contract Shuffling to Specified Imports

- Non-WCI hydro and renewables are the only source for shuffling to zero-carbon specified imports
  - Assumes renewables are not available for shuffling due to RPS targets
- Idaho contains most non-WCI, non-Federal hydro
- Maximum potential shuffling from hydro of 20 MMTCO2 if all non-WCI hydro was shuffled to coal (2,200lbs/MWh)

Hydroelectric Generation (GWh)

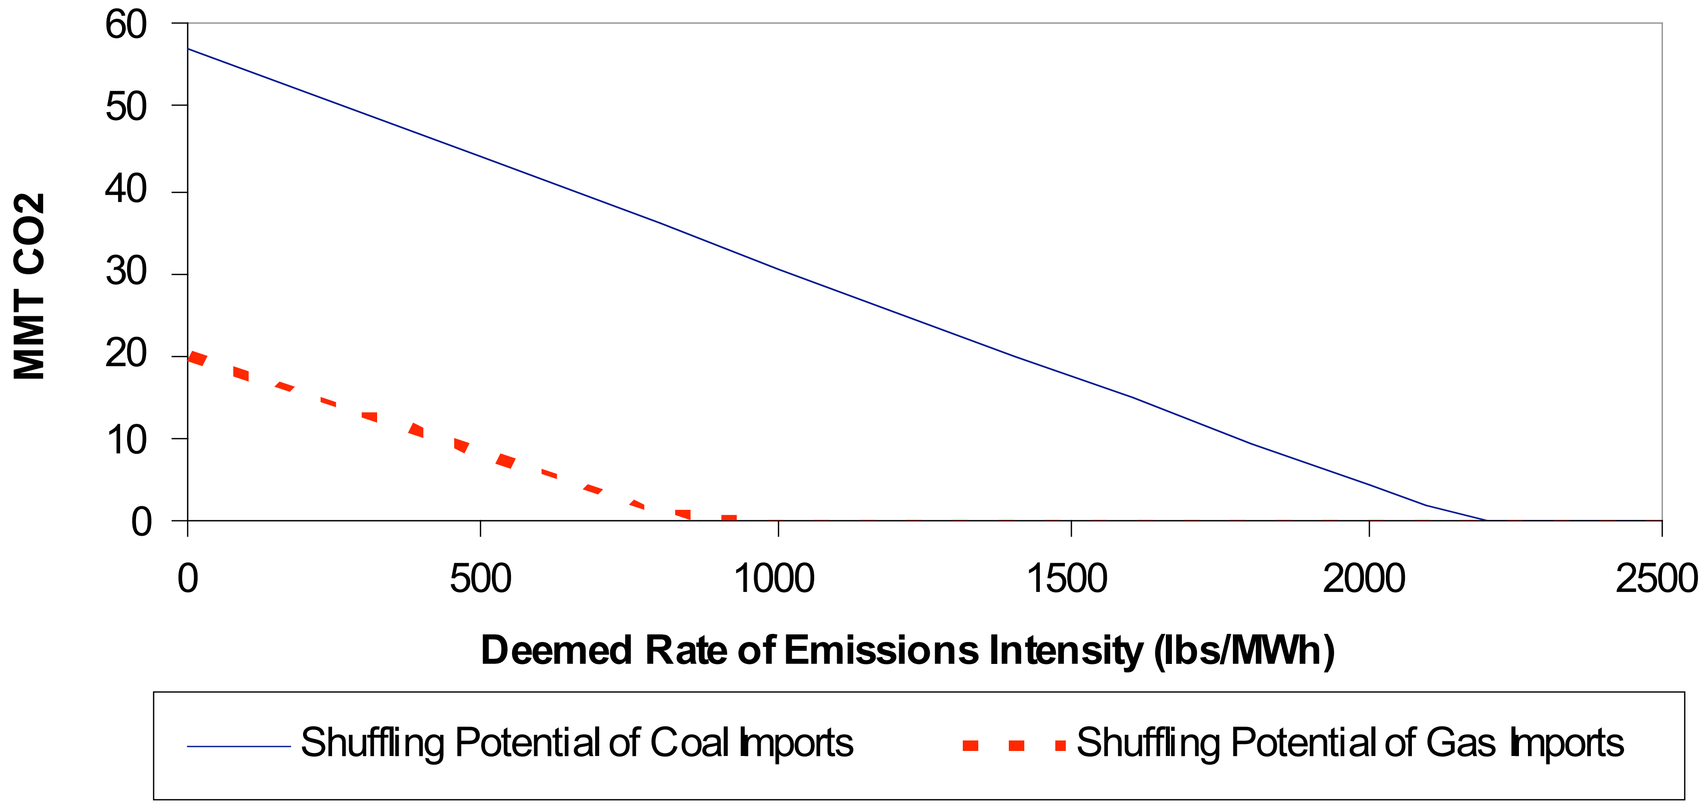
	AB	CO	ID	WY	TOTAL
Federal Hydro	0	1984	3672	1280	6936
Non-Federal Hydro	2051	1380	8835	561	12827
Total	*2051*	*3364*	*12507*	*1841*	19764

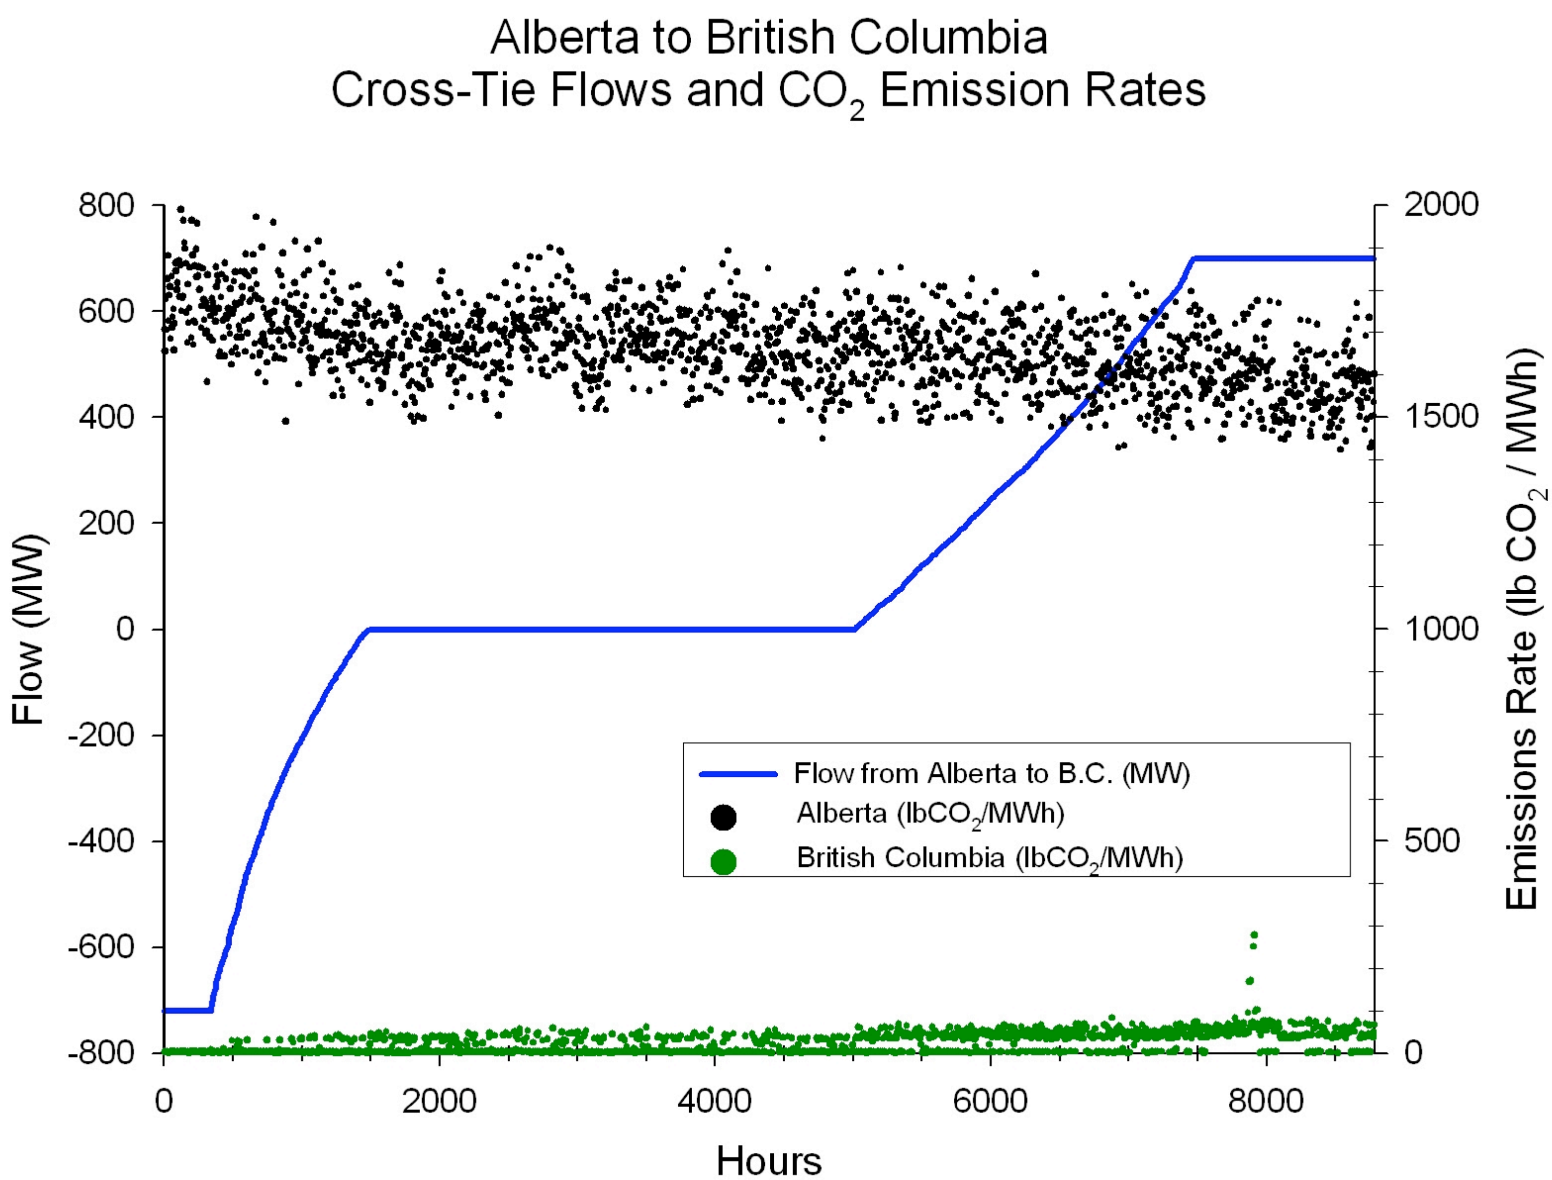
MMT CO2 - Maximum Shuffling

	AB	CO	ID	WY	TOTAL
Federal Hydro	0	2	4	1	7
Non-Federal Hydro	2	1	9	1	13
Total	2	3	12	2	20

Contract Shuffling to System Power

- Deemed emissions rate limits contract shuffling





Alberta to British Columbia

Flow from Alberta to B.C. (MW)
Alberta (lbCO_2/MWh)
British Columbia (lbCO_2/MWh)

Shuffling Analysis Conclusions

- Ability to shuffle to specified imports is relatively small, limited by non-WCI hydro generation and federal control
- Rules for specified imports could capture most remaining coal imports
- Deemed emissions rate can limit economic incentive to shuffle remaining imports in most cases
  - Alberta to BC intertie may require separate deemed emissions intensity

Leakage Results

Leakage is a change in operations or investment which reduces WCI CO_2 emissions while increasing non-WCI CO_2 emissions

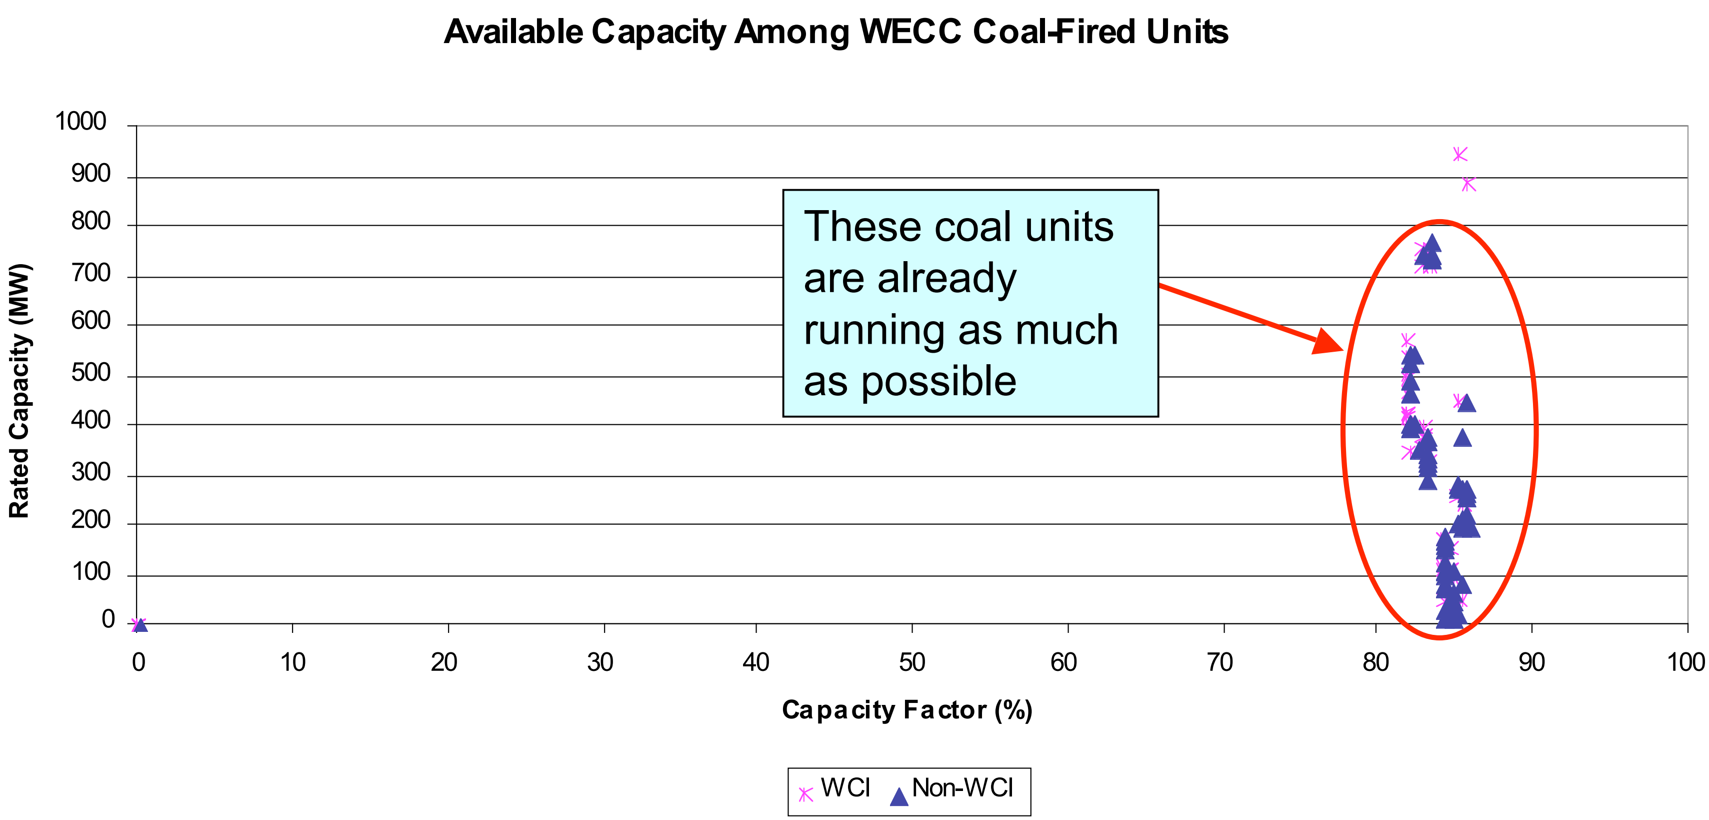
3. Leakage Analysis

- Two types of leakage:
  - Change in power plant operations
    - For example, increase generation of non-WCI coal and decrease WCI generation
  - Change in new power plant investment in non-WCI regions to avoid CO2 obligations
    - For example, build new coal plant in a non-WCI state and import generation into WCI

Inherent Barriers to Leakage

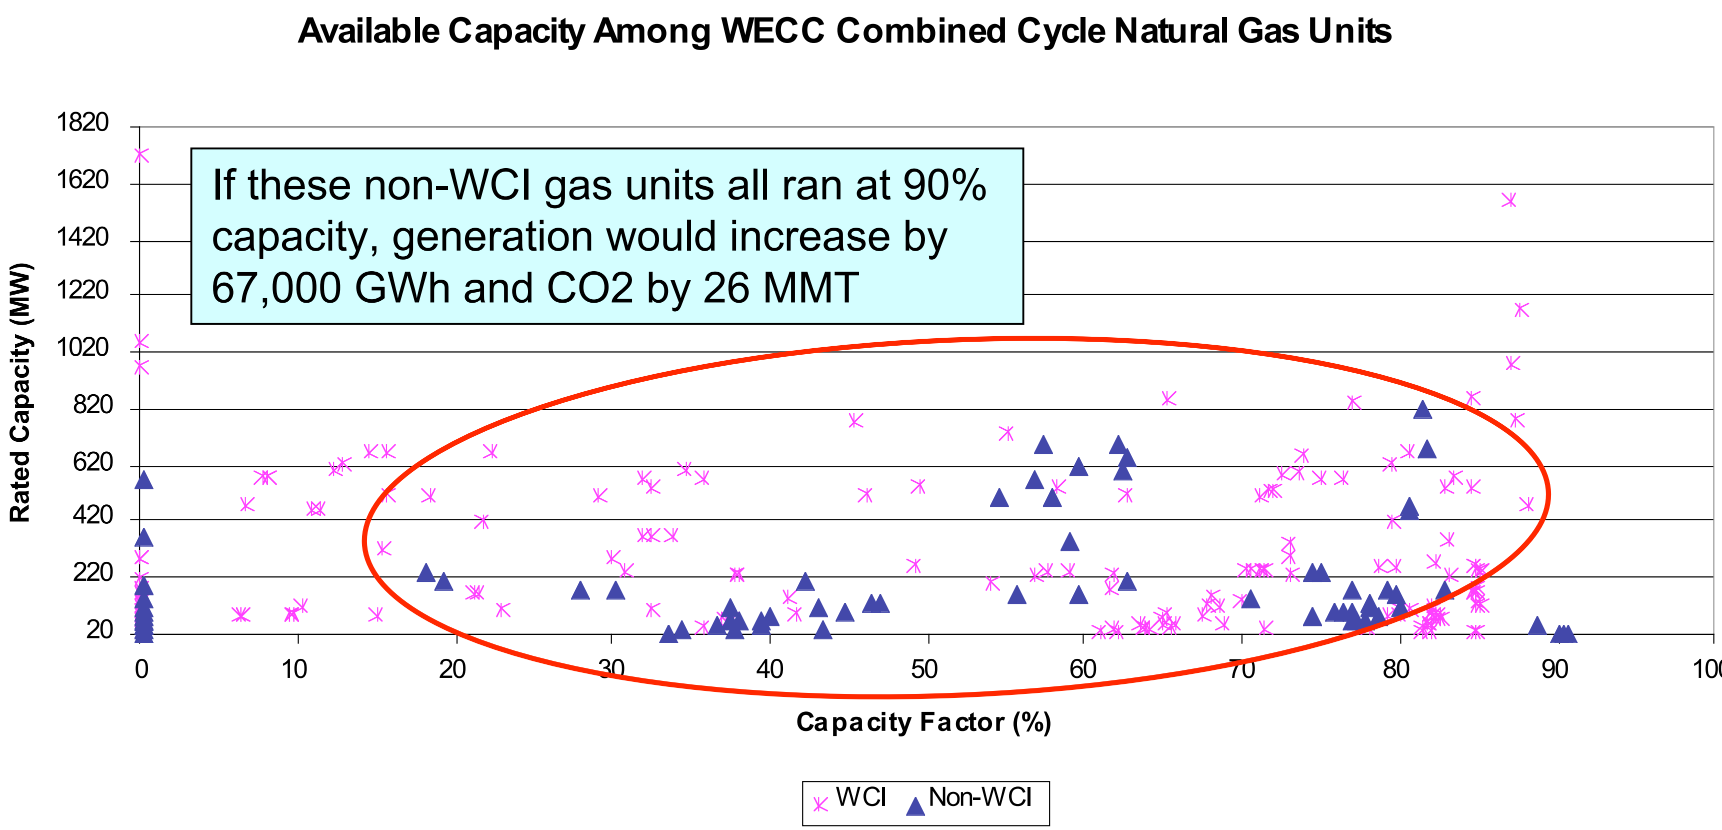
- For existing non-WCI power plants to increase operation:
  - Requires available non-WCI generation capacity
  - Requires transmission capacity to import electricity
- For new power plant construction to create leakage:
  - Requires transmission capacity to import electricity
  - Requires shuffling; either sale of electricity into WCI as system power to get the deemed emissions rate (e.g. unspecified merchant generation), or shuffling to lower carbon resource such as hydro

Leakage Potential from Change in Coal Operations is Extremely Limited



Since coal operates near the maximum technical capacity factor, there is limited potential for leakage through increased coal usage.

Some Potential for Non-WCI Gas to Increase Output

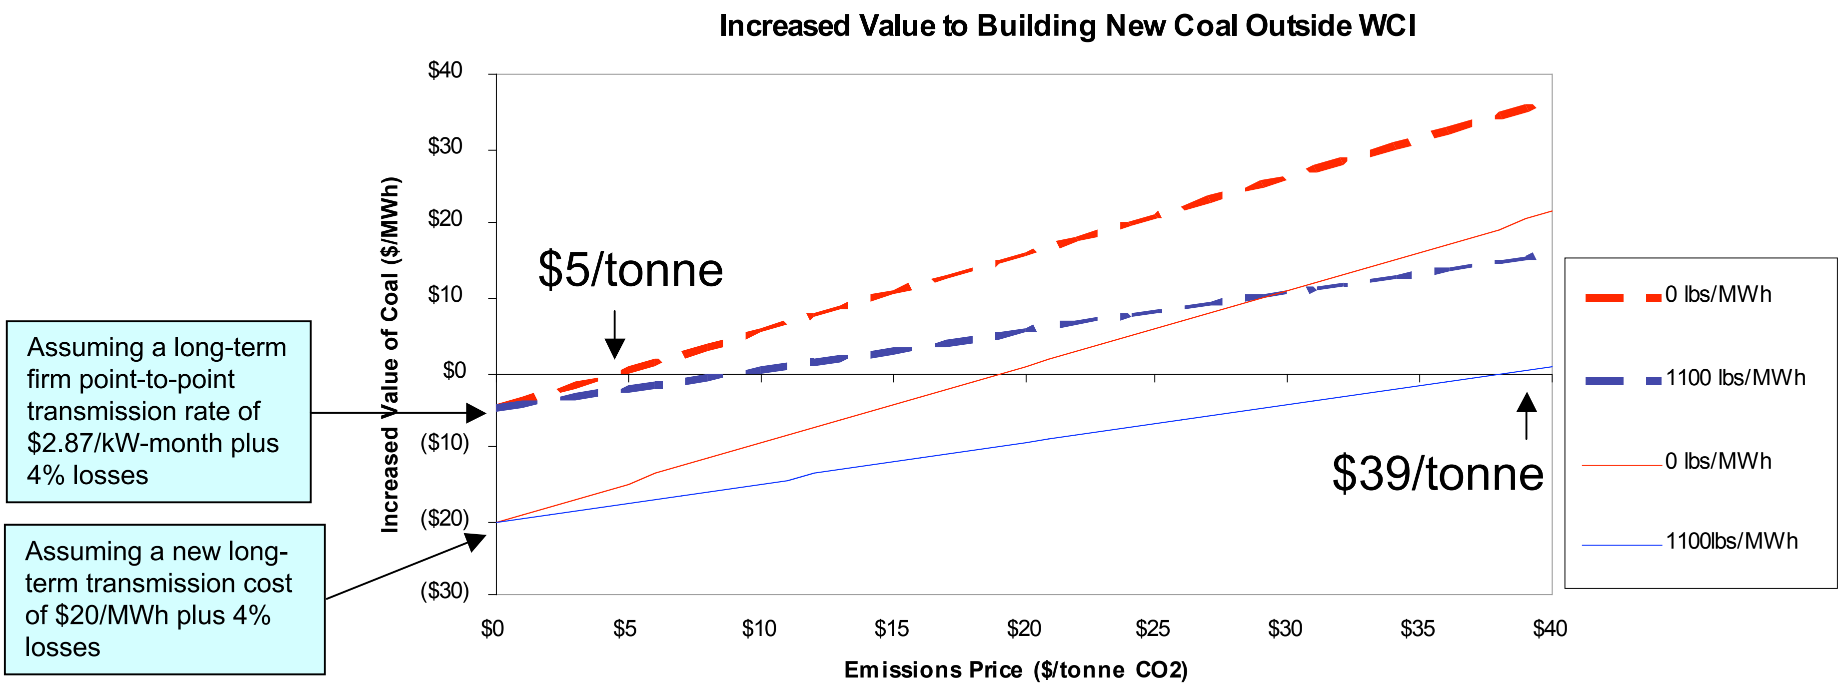


However, FJD with a deemed emissions rate at least as high as combined cycle gas reduces the potential for leakage to natural gas

Leakage through New Construction

- Will WCI carbon regulation tip the economics towards more new coal generation in non-WCI jurisdictions?
- Analysis compares economics of a new coal plant within WCI to a non-WCI jurisdiction including CO2 price differential, transmission cost and losses
- Three situations for new non-WCI coal generation:
  - Signs long-term contract (i.e. specified generation) – no leakage if owner must purchase CO2 allowances under reporting rules for specified generation
  - New plant is able to sell into WCI as system power at the FJD deemed emissions rate
  - New plant is able to sell into WCI as zero-carbon

Economic Pressure for New Coal



- CO2 price changes incentive for new non-WIC coal – but the cost of new transmission and the deemed emissions factor for imports are also important
- **Economics may not be the primary constraint for new projects**

Leakage Analysis Conclusions

- Limited leakage potential for changes in operation of coal generation
- Some leakage potential for changes in operation of combined cycle generation
  - Limited by deemed emissions rate under FJD
- Some leakage potential to new non-WCI coal investment at CO2 prices above \$5 - \$39/tonne
  - Limited by rules for specified generation under FJD
  - Limited by non-economic factors for new construction

Summary

Findings

- Regulation of CO_2 from electricity imports is necessary to increase coverage above ~74% of WCI electricity sector CO_2
- Contract shuffling potential is limited under FJD
  - ~13 MMT CO_2, assuming no shuffling potential from non-WCI federal hydro or renewables
  - Regionally specific deemed emissions rates may reduce contract shuffling potential, i.e. Alberta to BC
- Leakage potential is limited under FJD
  - Potential to increase non-WCI coal operations is approximately zero
  - Potential to increase non-WCI gas operations is small and limited by deemed rate
  - Potential for leakage through new coal investment outside of WCI is limited by FJD rules on specified generation and other factors

WORLD RESOURCES INSTITUTE

To: Western Climate Initiative Electricity Subcommittee

From: Franz Litz and Nicholas Bianco, World Resources Institute

Date: October 14, 2008

Re: Initial Considerations for the Development of a "First Jurisdictional Deliverer" Definition

---

This brief memorandum examines some of the issues presented in developing a regulatory definition of "first jurisdictional deliverer" (FJD) for purposes of considering those issues together with expert stakeholders. After providing some background, we consider the purpose of a regulatory definition, and provide an example from the source-based cap-and-trade context. Next, the specific issues presented by the FJD approach are identified. Finally, some possible definitions are outlined for consideration and comment.

We would like to emphasize that this memorandum represents some initial thinking on defining the term "first jurisdictional deliverer" by the authors using past experience as a guide. This memorandum is not a product of the WCI Electricity Subcommittee, nor has it been approved or otherwise adopted by the Subcommittee. It is designed to stimulate thinking and engender discussion on the part of subcommittee members and the expert stakeholders who are part of the Technical Advisory Group (TAG).

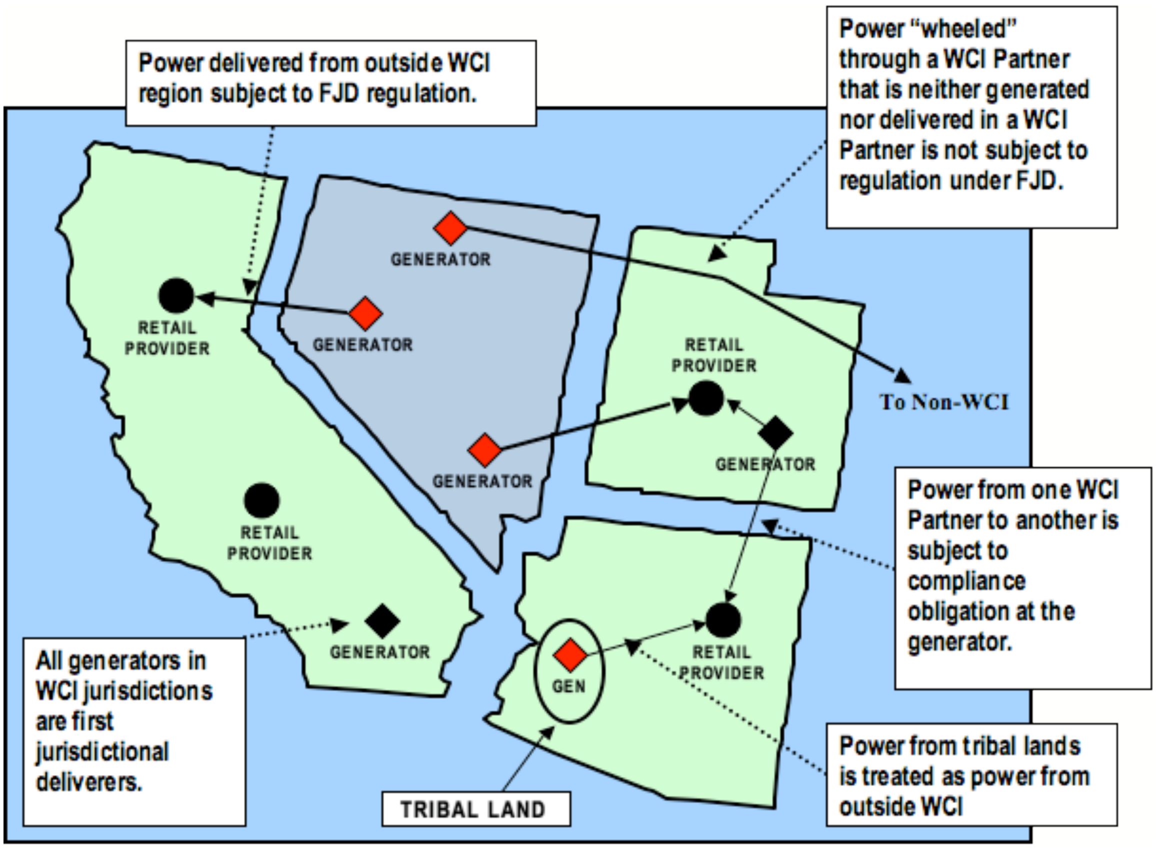
Background

The Western Climate Initiative Partner jurisdictions issued their "Design Recommendations for the WCI Cap-and-Trade Program" on September 23, 2008. The Design Recommendations included the following statement concerning the point of regulation for the electricity sector:

> *2.2 Electricity: First Jurisdictional Deliverer: For sources within WCI jurisdictions the point of regulation will be at the generator.*

For power imported into WCI jurisdictions, the point of regulation will be at the first entity that delivers electricity that is generated outside the WCI jurisdictions (or generated by a federal entity or on tribal lands) for consumption within a WCI Partner jurisdiction and over which the WCI partner jurisdiction has regulatory authority.

The WCI Electricity Subcommittee has undertaken a series of technical working sessions for electricity sector experts and stakeholders to begin developing a plan for implementing the FJD approach to covering the electricity sector. Among the tasks that the Subcommittee faces is settling on a definition for the "First Jurisdictional Deliverer". This memorandum aims to be helpful in this regard.



The figure above depicts a portion of the WCI region and very generally those circumstances in which the first jurisdictional deliverer approach is to be applied to cover electricity emissions. First jurisdictional deliverers include GHG-emitting electricity generators in WCI partner jurisdictions, as well as the first entity to deliver electricity generated outside the WCI partner jurisdictions. Power "wheeled" through a WCI partner jurisdiction but originating in a non-WCI partner jurisdiction and destined for final delivery in another non-WCI jurisdiction is not subject to regulation under the approach.

Purpose of a Regulatory Definition

A regulatory definition for First Jurisdictional Deliverer will help identify what entity or entities are subject to the requirements of the WCI cap-and-trade program requirements for the electricity sector. Because the factual circumstances that lead to the delivery of electricity (with associated CO_2 emissions) will vary, the definition must be broad enough to capture all potential factual circumstances. Failure to capture all possible circumstances results in a potential loophole in coverage and difficulty in enforcement. At the same time, a regulatory definition should result ideally in one party being held responsible for the delivery of electricity exceeding the applicable threshold.

Example of Regulatory Definitions

Before developing a regulatory definition for FJD, it is helpful to consider how the the terms “owner” and “operator” were defined in the generator-based program launched recently by the participating states of the Regional Greenhouse Gas Initiative (RGGI). Under RGGI, all of the owners and operators of an electric generating unit with a nameplate capacity of 25 megawatts are subject to the requirements of the program.[1]

RGGI defines “owner” to mean

> *(1) any holder of any portion of the legal or equitable title in a CO_2 budget unit;or*
>
> *(2) any holder of a leasehold interest in a CO_2 budget unit, other than a passive lessor, or a person who has an equitable interest through such lessor, whose rental payments are not based, either directly or indirectly, upon the revenues or income from the CO_2 budget unit;or*
>
> *(3) any purchaser of power from a CO_2 budget unit under a life-of-the-unit contractual arrangement in which the purchaser controls the dispatch of the unit;or…*

[1] http://rggi.org/docs/model_rule_corrected_1_5_07.pdf

RGGI defines "operator" to mean:

> *Any person who operates, controls, or supervises a CO_2 budget unit or a CO_2 budget source and shall include, but not be limited to, any holding company, utility system, or plant manager of such a unit or source.*

It should be noted that the RGGI definitions are taken from the federal model cap-and-trade rule used for the NO_x SIP Call program, and now used for the federal Clean Air Interstate Rule.[2]

A few important observations can be made about these definitions developed by EPA with the Northeast states:

(1) The program initially casts a net wide enough to implicate all possible entities associated with the covered generating unit. Indeed, in many cases it is clear that a unit may have multiple owners and another operator—meaning more than one entity is on the regulatory "hook".

(2) Yet in practice there is little doubt who is responsible for compliance. The RGGI model rule, like the federal rules that came before, calls for a single entity to step up and assume responsibility for a specific unit's emissions by becoming the "authorized account representative".

(3) In essence, these existing regulatory definitions allow the private sector entities to determine which entity will carry out the responsibilities under the cap-and-trade program for a given generating unit. As long as there is an authorized account representative, the regulatory agency has no need to enforce against the other owners and/or operators.

It may also be helpful to consider the definitions under consideration by the California Air Resources Board (CARB) for its emissions reporting regulation. While emissions reporting is in this case a broader exercise than identifying the responsible party for compliance purposes, the attached excerpt from the California reporting rule may be helpful in considering appropriate terms.

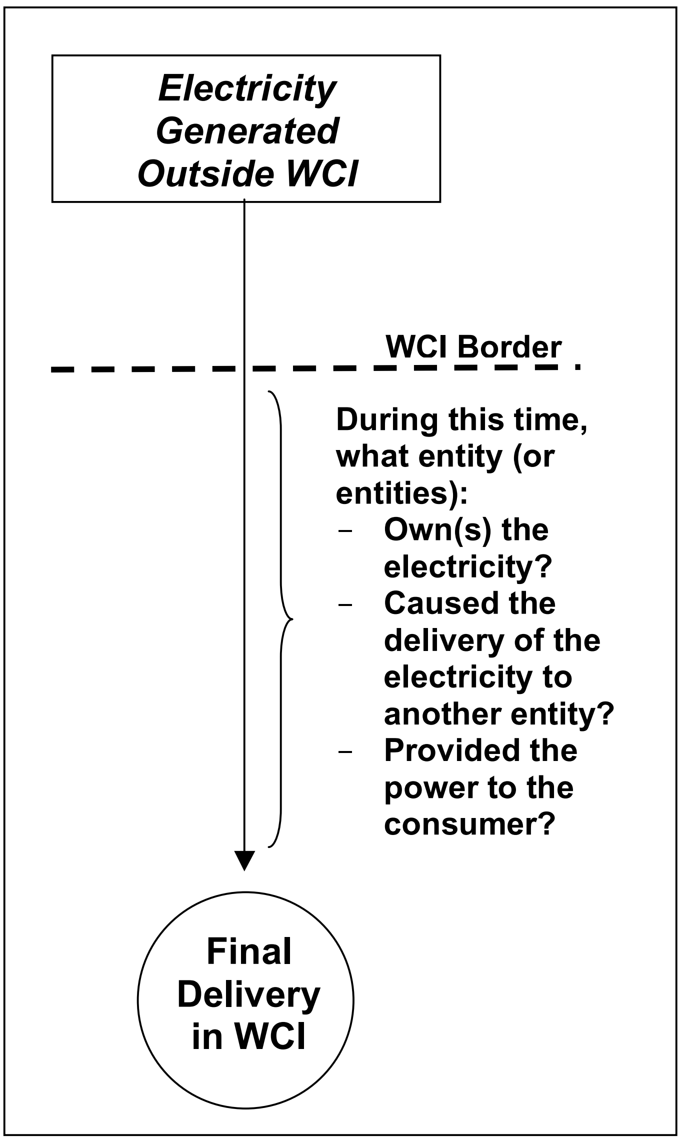
Considerations for an FJD Definition

The first jurisdictional deliverer approach will be able to borrow from the generator-based experience to define that part of the FJD universe that closely resembles the generator-based approach—the FJDs that are generators within the WCI. The

[2] See 40 CFR Part 96.

new challenge presented by the FJD approach is to develop a definition that also encompasses that part of the FJD universe that delivers electricity generated outside the WCI region. Yet, even in defining FJDs that are not generators, casting a wide definitional net while simultaneously ensuring that one entity steps up to meet the requirements of the program may prove a useful analog.

The FJD definition must take into account the entities that are responsible for delivering power generated outside the region for consumption in the region. It is helpful to consider what entities own the electricity commodity and what entities cause the resource to move to its delivery point in a WCI jurisdiction. The adjacent figure asks a number of these questions. The questions can perhaps be pared down to a version of the owner/operator definitions, i.e. the owners of the electricity delivered and the "operators" or "conveyors" in the electricity chain of custody. These conveyors may include power brokers that arrange for sales of the electricity from one owner to another, or the retail provider that ultimately delivers the electricity to the consumer.

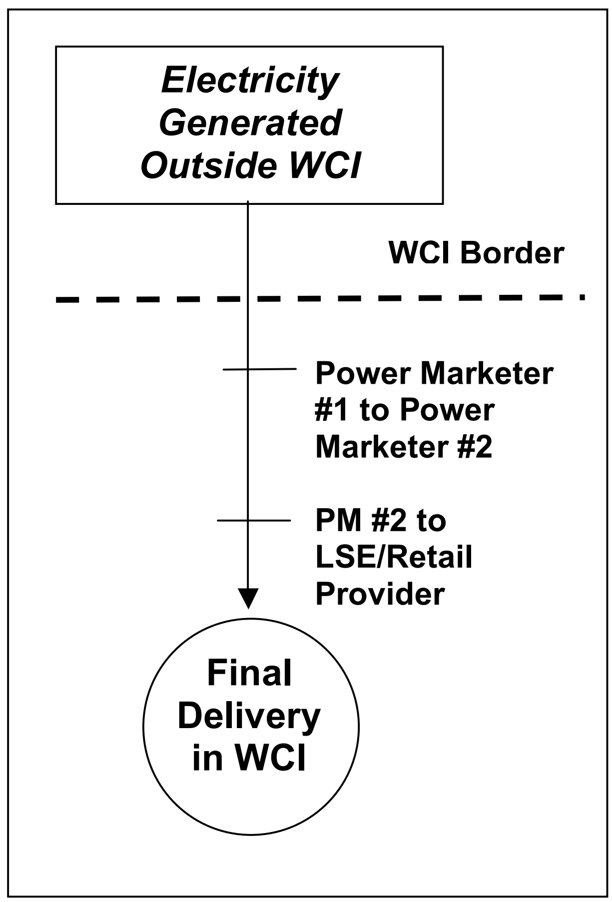


It may also be helpful to consider how these deliverers of electricity from outside WCI are different from the owner and operators of generating units inside WCI. In the case of generating units, the program regulates the emissions of actual physical assets. In contrast, regulating entities that deliver is a less tangible exercise. The potential for "gaming" to prevent these less tangible entities from being subject to a compliance obligation raises issues for defining FJD.

For example, while a generating unit cannot be divided physically in two to reduce its emissions below the applicability threshold, one must consider the potential for power transactions to be split in such a way to spread deliveries across multiple FJDs so as to remain below the applicability threshold of 25,000 metric tons per annum. The potential for dividing deliveries suggests that the definition of FJD might be broad enough to capture entities further down the chain of deliveries where those deliveries will ultimately have to be aggregated, such as the retail provider. Thus, if a retail provider accepts deliveries of electricity from numerous small FJDs that fall below the threshold, the retail provider would trigger applicability because the sum of its uncovered emissions exceeds the 25,000-metric-ton applicability threshold.

Similarly, where the entity that first delivers power into a WCI jurisdiction claims it is non-jurisdictional, such as in the case of a federal power authority, then the definition of FJD must be broad enough to capture the next entity in the chain of custody that is jurisdictional. This may mean that the regulatory definition of FJD must be broad enough to capture every entity in the delivery chain, since in some cases the first jurisdictional entity will be the retail provider.

The fact that the definition is broad enough to capture more than one entity for the same power delivery should not raise concerns, however. Just as in the case of a traditional generator-based program, where there are often numerous entities that trigger coverage under the “owner” and “operator” definitions, the broad definition is necessary to draw out one responsible party for each relevant delivery. That one entity will vary depending on the circumstances, but the private actors will ensure that one party is on the regulatory “hook” for a specific set of power deliveries.



Consider the example in the adjacent figure, depicting a chain of delivery that exceeds the 25,000 ton threshold for applicability. Here, power marketer (PM) #1 has brought the electricity into the WCI partner jurisdiction and has delivered that electricity to PM #2. If both PM #1 and PM #2 fall within the definition of FJDs, then they are both potentially liable for the emissions under the WCI cap-and-trade program. Which of them will step up to satisfy the compliance obligation?

The answer to the question may depend on a private arrangement between PM #1 and PM #2. So long as the emissions reported along this chain of delivery are "covered" with allowances by one of the two FJDs, then the regulator will not have reason to enforce. This is directly analogous to the arrangements among parties that are owners and/or operators of stationary power plants in a generator-based cap-and-trade program.

Another possible answer is that they are both liable to meet the compliance obligation. If this were the approach of the regulator, then the practical effect would be to ensure that no transactions of this type occur, because liability would proliferate as the electricity is passed along the chain of custody. PM #1 would not deliver the power to PM #2 without assuming the regulatory obligation, because that obligation attaches to PM #1 whatever PM #1 does. PM #2 might accept the power delivery, but will understand that it too has an obligation to cover the emissions attributable to the power it received from PM #1 unless PM #1 follows through with its obligation. Provided the regulator pursues an enforcement strategy that seeks to compel compliance by PM #1, the FJD will always be the first entity in the delivery chain over which the WCI partner has jurisdiction.

Now consider that PM #1 may turn out to be non-jurisdictional. In such a case, PM #1 and PM #2 may simply agree that PM # 2 will assume the obligation to comply with the cap-and-trade program. Alternatively, PM #2 may accept delivery of the electricity knowing that PM #1 has not assumed the compliance obligation attached to the delivery. Because PM #2 is also liable for those obligations, it moves to comply with the cap-and-trade program. The net effect is that PM#2 turns out to be the first entity in the delivery chain over which the WCI partner has jurisdiction, assuming PM #1 claims that it is non-jurisdictional turn out to be true.

What if I am an entity further along the chain of delivery after PM #1 and PM #2? I may be another power marketer or a broker or the retail provider and LSE. My behavior will depend on whether I will be subject to liability if I accept delivery of electricity for which the deliverer is unable to demonstrate upstream compliance. To capture large numbers of smaller transactions below the emissions threshold, the LSE or retail provider might be required to aggregate all "uncovered" power deliveries for the relevant compliance period.

<u>Possible Definitions</u>.

The following are first-cut possible definitions designed to provide for thoughtful discussion that the Subcommittee can draw from in the eventual drafting of definitions.

Owner. Any of the following persons:

(1) with respect to a [CO2 budget unit]

(a) any holder of any portion of the legal or equitable title in a CO_2 budget unit; or

(b) any holder of a leasehold interest in a CO_2 budget unit, other than a passive lessor, or a person who has an equitable interest through such lessor, whose rental payments are not based, either directly or indirectly, upon the revenues or income from the CO_2 budget unit; or

(c) any purchaser of power from a CO_2 budget unit under a life-of-the-unit contractual arrangement in which the purchaser controls the dispatch of the unit; or

(2) with respect to electricity generated outside of [the WCI region] and delivered for consumption within WCI any holder of any portion of the legal or equitable title in the electricity; or….

Operator. Any person who operates, controls, or supervises a [CO_2 budget unit or a CO_2 budget source] and shall include, but not be limited to, any holding company, utility system, or plant manager of such a unit or source.

Marketer. Any person who controls, brokers, or arranges for the delivery of electricity that originated outside of [the WCI region] for delivery and consumption in a [WCI partner jurisdiction].

To give effect to these definitions, the electricity component of the cap-and-trade program would have to require that:

(1) with respect to each covered electric generating unit, one authorized representative of the owners and operators of the unit will be designated, and that representative will be responsible for meeting all requirements of the program; and

(2) with respect to each electricity delivery [meeting certain conditions related to its compliance status when it enters the WCI jurisdiction], one authorized representative of the owners and marketers of the power delivered will be designated, and will be responsible for meeting all requirements of the program.

Closing Thoughts

This memorandum seeks to identify preliminary issues related to defining what entities will be first jurisdictional deliverers (FJDs) under a WCI electricity cap-and-trade program. Recognizing that no "first pass" gathers all issues or adequately addressed them, we have attempted to reduce thoughts to paper to help the WCI partner jurisdictions, and its expert stakeholders, move toward identification of additional issues and ultimately to available solutions.

REGULATION FOR THE MANDATORY REPORTING OF GREENHOUSE GAS EMISSIONS

California Air Resources Board

Key Definitions and Reporting Requirements Related to Electricity Imports and Exports

From section 95102 - Definitions

(1) “Asset controlling supplier” means any entity that operates electricity generating facilities or serves as an exclusive marketer for certain generating facilities even though it does not own them.

(2) “Asset owning supplier” means any entity owning electricity generating facilities that delivers electricity to a transmission or distribution line.

(3) “Busbar” means the power conduit of an electricity generating facility that serves as the starting point for the electricity transmission system.

(4) “California eligible renewable resource” means an electricity generating facility that the California Energy Commission has certified as an eligible renewable energy resource that may be used by a retail seller of electricity to satisfy its California Renewables Portfolio Standard Program procurement requirements, consistent with Public Utilities Code sections 399.11 through 399.16 and Public Resources Code sections 25740 through 25751.

(5) “Cogeneration facility” means an industrial structure, installation, plant, building, or self-generation facility, which may include one or more cogeneration systems configured as either a topping cycle or bottoming cycle plant.

(6) “Cogeneration system” means individual cogeneration components including the prime mover (heat engine), generator, heat recovery, and electrical interconnection, configured into an integrated system that provides sequential generation of multiple forms of useful energy (usually mechanical and thermal), at least one form of which the facility consumes on-site or makes available to other users for an end-use other than electricity generation.

(7) “Distributed emissions” means CO_2 emissions from fuel combustion at cogeneration facilities distributed between energy stream outputs including thermal energy, electricity generation and potentially other product outputs

(8) "Electricity generating facility" means generating facility.

(9) "Electricity transaction" means the purchase, sale, import, export or exchange of electric power.

(10) "Entity" means a person, firm, association, organization, partnership, business trust, corporation, limited liability company, company, or government agency.

(11) "Exchange agreement" means a commitment between electricity market participants to swap energy for energy. Exchange transactions do not involve transfers of payment or receipts of money for the full market value of the energy being exchanged, but may include payment for net differences due to market price differences between the two parts of the transaction or to settle minor imbalances.

(12) "Facility" means any property, plant, building, structure, stationary source, stationary equipment or grouping of stationary equipment or stationary sources located on one or more contiguous or adjacent properties, in actual physical contact or separated solely by a public roadway or other public right-of way, and under common operational control, that emits or may emit any greenhouse gas. Operators of military installations may classify such installations as more than a single facility based on distinct and independent functional groupings within contiguous military properties.

(13) "Final point of delivery" means the last point of delivery for a given electricity transaction.

(14) "Generating facility" means a facility that generates electricity and includes one or more generating units at the same location.

(15) "Generating unit" means any combination of physically connected generator(s), reactor(s), boiler(s), combustion turbine(s), or other prime mover(s) operated together to produce electric power.

(16) "Gross generation" means the total electrical output of the generating unit, expressed in megawatt hours (MWh) per year.

(17) "Kilowatt hour" or "kWh" means the electrical energy unit of measure equal to one thousand watts of power supplied to, or taken from, an electric circuit steadily for one hour. (A watt is a unit of electrical power equal to one ampere under pressure of one volt, or 1/746 horsepower).

(18) “Long-term power contract” means a power contract with a term of five years or more.

(19) “Marketer” means a purchasing/selling entity that is not a retail provider, and that is the purchaser/seller at the first point of delivery in California for electric power imported into California, or the last point of receipt in California for power exported from California.

(20) “Multi-jurisdictional retail provider” means a retail provider that provides electricity to end users in California and in one or more other states.

(21) “Nameplate generating capacity” means the maximum rated output of a generator under specific conditions designated by the manufacturer, expressed in megawatts (MW) or kilowatts (kW).

(22) “Net power generated” means the gross generation minus station service or unit service power requirements, expressed in megawatt hours (MWh) per year. In the case of cogeneration, this value is intended to include internal consumption of electricity for the purposes of a production process, as well as power put on the grid.

(23) “NERC E-tag” means North American Electric Reliability Corporation (NERC) energy tag representing transactions on the North American bulk electricity market scheduled to flow between or across control areas.

(24) “Null power” means any electricity produced by a renewable energy electricity generating facility from which a Western Renewable Energy Generation Information System (WREGIS) or a Nevada Tracks Renewable Energy Credits (NVTREC) certificate has been unbundled and sold separately.

(25) “NVTREC” means Nevada Tracks Renewable Energy Credits.

(26) “Operational control” for a facility subject to this article means the authority to introduce and implement operating, environmental, health and safety policies. In any circumstance where this authority is shared among multiple entities, the entity holding the permit to operate from the local air pollution control district or air quality management district is considered to have operational control for purposes of this article.

(27) "Operator" means the entity having operational control of a facility, or other entity, from which an emissions data report is required under this article. For purposes of reporting electricity transactions as required in

section 95111, “operator” means a retail provider, marketer, or facility operator.

(28) “Pacific Northwest” or “PNW” means Washington, Oregon, Idaho, Montana, and British Columbia.

(29) “Point of delivery” means a point on an electric system where a power supplier delivers electricity to the receiver of that energy. This point can be an interconnection with another system or a substation where the transmission provider’s transmission and distribution systems are connected to another system.

(30) “Point of receipt” means a point on an electric system where an entity receives electricity from a supplier. This point can be an interconnection with another system or a generator busbar.

(31) “Point source” means any separately identifiable stationary point from which greenhouse gases are emitted.

(32) “Power” means electricity, except where the context makes clear that another meaning is intended.

(33) “Power contract” means an arrangement for the purchase of electricity. Power contracts may be, but are not limited to, power purchase agreements and tariff provisions.

(34) “Prime mover” means the type of equipment such as an engine or water wheel that drives an electric generator. “Prime movers” include, but are not limited to, reciprocating engines, combustion or gas turbines, steam turbines, microturbines, and fuel cells.

(35) “Purchasing/selling entity” means an entity that is eligible to purchase or sell energy or capacity and reserve transmission services.

(36) “Qualifying facility” means a cogeneration or small power production facility that meets ownership, operating, and efficiency criteria established by the Federal Energy Regulatory Commission (FERC) pursuant to the Public Utility Regulatory Policies Act.

(37) “Renewable energy” means energy from sources that constantly renew themselves or that are regarded as practically inexhaustible. Renewable energy includes, but is not limited to, energy derived from solar, wind, geothermal, hydroelectric, wood, biomass, tidal power, sea currents, and ocean thermal gradients

(38) "Retail provider" means an entity that provides electricity to retail end users in California and is an electric corporation as defined in Public Utilities Code section 218, electric service provider as defined in Public Utilities Code section 218.3, public owned electric utility as defined in Public Resources Code section 9604, community choice aggregator as defined in Public Utilities Code section 331.1, or the Western Area Power Administration.

(39) "Self-generation facility" means a facility dedicated to serving a particular end user, usually located on the user's premises. The facility may either be owned directly by the end user or owned by an entity with a contractual arrangement to provide electricity to meet some or all of the user's load.

(40) "Source" means greenhouse gas source, as defined in this section.

(41) "Southwest" or "SW" means Arizona, Nevada, Utah, Colorado, and western New Mexico.

(42) "Specified source of power" or "specified source" means a particular generating unit or facility for which electrical generation can be confidently tracked due to full or partial ownership or due to its identification in a power contract including any California eligible renewable resource.

(43) "Supplemental firing" means an energy input to the cogeneration facility used only in the thermal process of a topping cycle plant, or in the electricity generating or manufacturing process of a bottoming cycle plant.

(44) "Thermal host" means the user of the steam or heat output of a cogeneration facility.

(45) "Topping cycle plant" means a cogeneration facility in which the energy input to the facility is first used to produce useful power output, and at least some of the reject heat from the power production process is then used to provide useful thermal output.

(46) "Unspecified source of power" or "unspecified source" means electricity generation that cannot be matched to a particular generating facility. Unspecified sources of power may include power purchased from entities that own fleets of generating facilities such as independent power producers, retail providers, and federal power agencies and power purchased from electricity marketers, brokers, and market

(47) “Useful power output” means the electric or mechanical energy made available for use, exclusive of any such energy used in the power production process.

(48) “Useful thermal output” means the thermal energy made available in a cogeneration system for use in any industrial or commercial process, heating or cooling application, or delivered to other end users, i.e., total thermal energy made available for processes and applications other than electrical generation.

(49) “Waste-derived fuel” means a fuel typically derived from waste(s) and generally used as a substitute for conventional fossil fuels. Waste-derived fuels can include fossil fuels such as waste oil, plastics, or solvents; biomass such as dried sewage or impregnated saw dust; or fractions of both fossil fuels and biomass such as municipal solid waste or tires.

(50) “WREGIS” means Western Renewable Energy Generation Information System.

From section 95111
Data Requirements and Calculation Methods for Electricity Generating Facilities, Retail Providers and Marketers.

(a) ***Electricity Generating Facilities.*** The operator of an electricity generating facility specified in section 95101(b) shall include the following information in the greenhouse gas emissions data report for each report year and shall meet the requirements specified in sections 95111(c)-(i) as applicable to the facility when calculating emissions for inclusion in the report.

(1) For each facility, operators shall include:

(A) ARB designated facility identification number (ID), nameplate generating capacity in megawatts (MW), and net power generated in the report year in megawatt hours (MWh);

(B) Fuel consumption by fuel type, reporting in units of million standard cubic feet for gases, gallons for liquids, short tons for non-biomass solids, and bone dry short tons for biomass-derived solid fuels;

(C) Average high heat value by fuel type, reporting in units of MMBtu per unit of fuel as specified in section 95111(a)(1)(B), if measured, based on values measured by the operator or the fuel supplier as specified in section 95125(c)(1)(A)-(C). If high heat value is not measured by the operator or available from the fuel supplier, then the operator shall report steam produced in MMBtu. The operator may elect to convert pounds of steam into MMBtu using the method provided in section 95125(h)(1)(B). The operator shall include boiler efficiency, if known;

(D) Average carbon content, as a percent, by fuel type, if measured, based on values measured by the operator or the fuel supplier as specified in section 95125(d);

(E) CO_2, N_2O, and CH_4 emissions from stationary combustion in metric tonnes as specified in section 95111(c)-(d) by fuel type;

(F) Process CO_2 emissions from acid gas scrubbers or acid gas reagent used in the combustion source, if applicable, in metric tonnes;

(G) Fugitive CH_4 emissions from coal storage from coal-fired facilities, if applicable, in metric tonnes;

(H) Fugitive emissions of HFC related to the operation of cooling units that support power generation, if applicable, in kilogram

(I) Fugitive CO_2 emissions from geothermal facilities, if applicable, in metric tonnes;

(J) Fugitive SF_6, in kilograms, emitted from equipment that is located at the facility and that the operator is responsible for maintaining in proper working order. Operators of multiple facilities or operators subject to the requirements in section 95111(b)(2)(A) may aggregate SF_6 emissions for all sources or any subset of sources;

(K) For facilities located inside California, wholesale sales (MWh) exported directly out-of-state, if known, that are additional to electricity transactions reported as specified in section 95111(b)(2)(E). Sales shall be aggregated by counterparty and measured at the busbar. The operator shall report the region of destination as Pacific Northwest (PNW) or Southwest (SW).

(2) For each generating unit operators shall include:

(A) Generating unit ID designated by ARB, nameplate generating capacity (MW), and net power generated (MWh);

(B) Fuel consumption by fuel type reporting in units of million standard cubic feet for gases, gallons for liquids, short tons for non-biomass solids, and bone dry short tons for biomass-derived solid fuels;

(C) CO_2, N_2O, and CH_4 emissions from fuel combustion in metric tonnes as specified in section 95111(c)-(d) by fuel type;

(D) For units of facilities located inside California, wholesale sales (MWh) exported directly out-of-state by generating unit if applicable and as specified in section 95111(a)(1)(K).

(3) ***Aggregation of Multiple Units.*** If a facility lacks the necessary metering or monitoring equipment to measure data individually for each generating unit, the operator may report data on an aggregated basis for multiple units that combust the same fuel type.

(4) ***Cogeneration Facilities.*** Operators of generating facilities with cogeneration systems subject to the requirements of this article shall also meet the requirements of section 95112.

(5) ***Out-of-State Facilities.*** Operators of out-of-state generating facilities that are not subject to any of the mandatory reporting requirements of this article may voluntarily submit a greenhouse gas emissions data

report that meets applicable requirements in this article for generating facilities.

(6) ***Asset Owning/Asset Controlling Suppliers*.** An asset owning or asset controlling supplier may voluntarily request that ARB assign a supplier-specific ID to the supplier's fleet of generating facilities if the supplier's sales of renewable energy account for 50 percent or more of their total sales of electric energy for the report year or if power purchased by the supplier from unspecified sources does not exceed 20 percent of the supplier's total sales of electric energy for the report year. An asset owning or asset controlling supplier that chooses this option shall:

(A) Meet the requirements in this article as applicable for each generating facility in the supplier's fleet;

(B) Include in its greenhouse gas emissions data report the list of the generating facilities in its fleet along with the ARB designated facility ID;

(C) If wholesale power purchased by the supplier accounts for more than 10 percent of total electric energy sold by the supplier for the report year, the supplier shall include in its greenhouse gas emissions data report wholesale power purchased (MWh) from specified and unspecified sources and wholesale power sold from specified sources according to the specifications in section 95111(b)(1)(A)-(B);

(D) Retain for verification purposes documentation that the power sold by the supplier originated from the supplier's fleet of facilities and either that the fleet is under the supplier's operation control or that the supplier serves as the fleet's exclusive marketer;

(E) Provide the supplier-specific ID to retail providers who purchase unspecified power from the supplier's fleet.

(b) ***Retail Providers and Marketers*.**

(1) ***General Requirements for Retail Providers and Marketers*.** Retail providers and marketers shall meet the following general requirements in preparing their greenhouse gas emissions data report for each report year. Retail providers and marketers shall include electricity transactions associated with both renewable and nonrenewable energy sources of power.

(A) When reporting electricity transactions, retail providers and marketers shall:

1. Specify the amount of electricity in MWh;
2. For electricity from specified sources, specify the amount of electricity as measured at the busbar;
3. For electricity from unspecified sources, specify the amount of electricity as measured at the first point of receipt for which the reporting entity has information;
4. For electricity from specified sources, specify the facility name, the ARB designated facility ID, and the generating unit ID for the unit generating the power, if applicable;
5. Specify region of origin and region of destination;
6. Retail providers shall aggregate and specify electricity transactions by counterparty;
7. Marketers shall aggregate and specify electricity transactions by power supplier;
8. Specify the amount of electricity (MWh) that is null power when applicable;
9. Specify electricity received under exchange agreements as purchases and electricity delivered under exchange agreements as wholesale sales.

(B) If the region of origin for an electricity transaction cannot be documented, the retail provider or marketer shall designate the region as unknown.

(C) ***Power Wheeled Through California.*** When reporting power transactions involving imports into California or exports out of California, the retail provider or marketer shall exclude the amount of power imported into California that terminates in a location outside of California, as measured at the first California point of delivery.

(D) ***California Department of Water Resources (DWR).*** The California Department of Water Resources shall include all applicable information identified in this article for retail providers, including the amount of power used by DWR itself.

(E) ***Multi-jurisdictional Retail Providers.*** Multi-jurisdictional retail providers shall include information required for retail providers in this article for the service territory that includes California end-use customers.

(F) ***Western Area Power Administration (WAPA).*** The Western Area Power Administration shall include information required of retail providers in this article relating to serving end use California customers and reporting fugitive SF_6 emissions. In particular, WAPA shall include electricity transactions related to sources of electricity located in California that are used to serve WAPA's end-use California customers, power imported to California to serve WAPA's end-use customers including transactions from facilities owned by the Bureau of Reclamation on the Lower Colorado River, and power exported from California.

(2) ***Greenhouse Gas Emissions Data Report: Retail Providers and Marketers.*** Retail providers and marketers shall include the following information in the greenhouse gas emissions data report for each report year. Multi-jurisdictional retail providers shall include the information in sections 95111(b)(2)(A) and 95111(b)(2)(G)-(H) but are exempt from sections 95111(b)(2)(B)-(F).

(A) Fugitive emissions of SF_6 (kg) related to transmission and distribution systems, substations, and circuit breakers located inside California that the retail provider or marketer is responsible to maintain in proper working order. SF_6 emissions shall be calculated using the methodology specified in section 95111(f).

(B) Wholesale power imported (MWh) from specified sources with final point of delivery in California and for which the retail provider or marketer was the deliverer to the first point of delivery in California, designating the region of origin as PNW or SW.

(C) Wholesale power imported (MWh) from unspecified sources with final point of delivery in California and for which the retail provider or marketer was the deliverer to the first point of delivery in California. The retail provider or marketer shall designate the region of origin as PNW, SW, or unknown and shall retain for verification purposes NERC E-tags, settlements data, or other information as confirmation of the region of origin.

(D) Retail providers shall include wholesale power imported from specified and unspecified sources with final point of delivery in California for which the retail provider is not the deliverer to the first point of delivery in California, designating the region of origin. Transactions reported under this section 95111(b)(2)(D) shall not be duplicated under section 95111(b)(3)(F).

(E) Wholesale power exported (MWh) from specified sources located inside California, and designating the region of destination (PNW, SW, or unknown).

(F) Wholesale power exported (MWh) from unspecified sources located inside California, and designating the region of destination (PNW, SW, or unknown).

(G) ***Electricity Transactions Wheeled Through California***. Wholesale power imported (MWh) into California that terminates in a location outside of California, as measured at the first California point of delivery. The retail provider or marketer shall specify these transactions separately by the counterparty supplying power and specify the region of origin (PNW or SW). The retail provider or marketer shall retain for purposes of verification NERC E-tags, settlements data, or other information to confirm the transactions.

(H) Retail providers shall include in their greenhouse gas emissions data report for each report year the additional information listed in section 95111(b)(3).

Developing a Definition for FJD

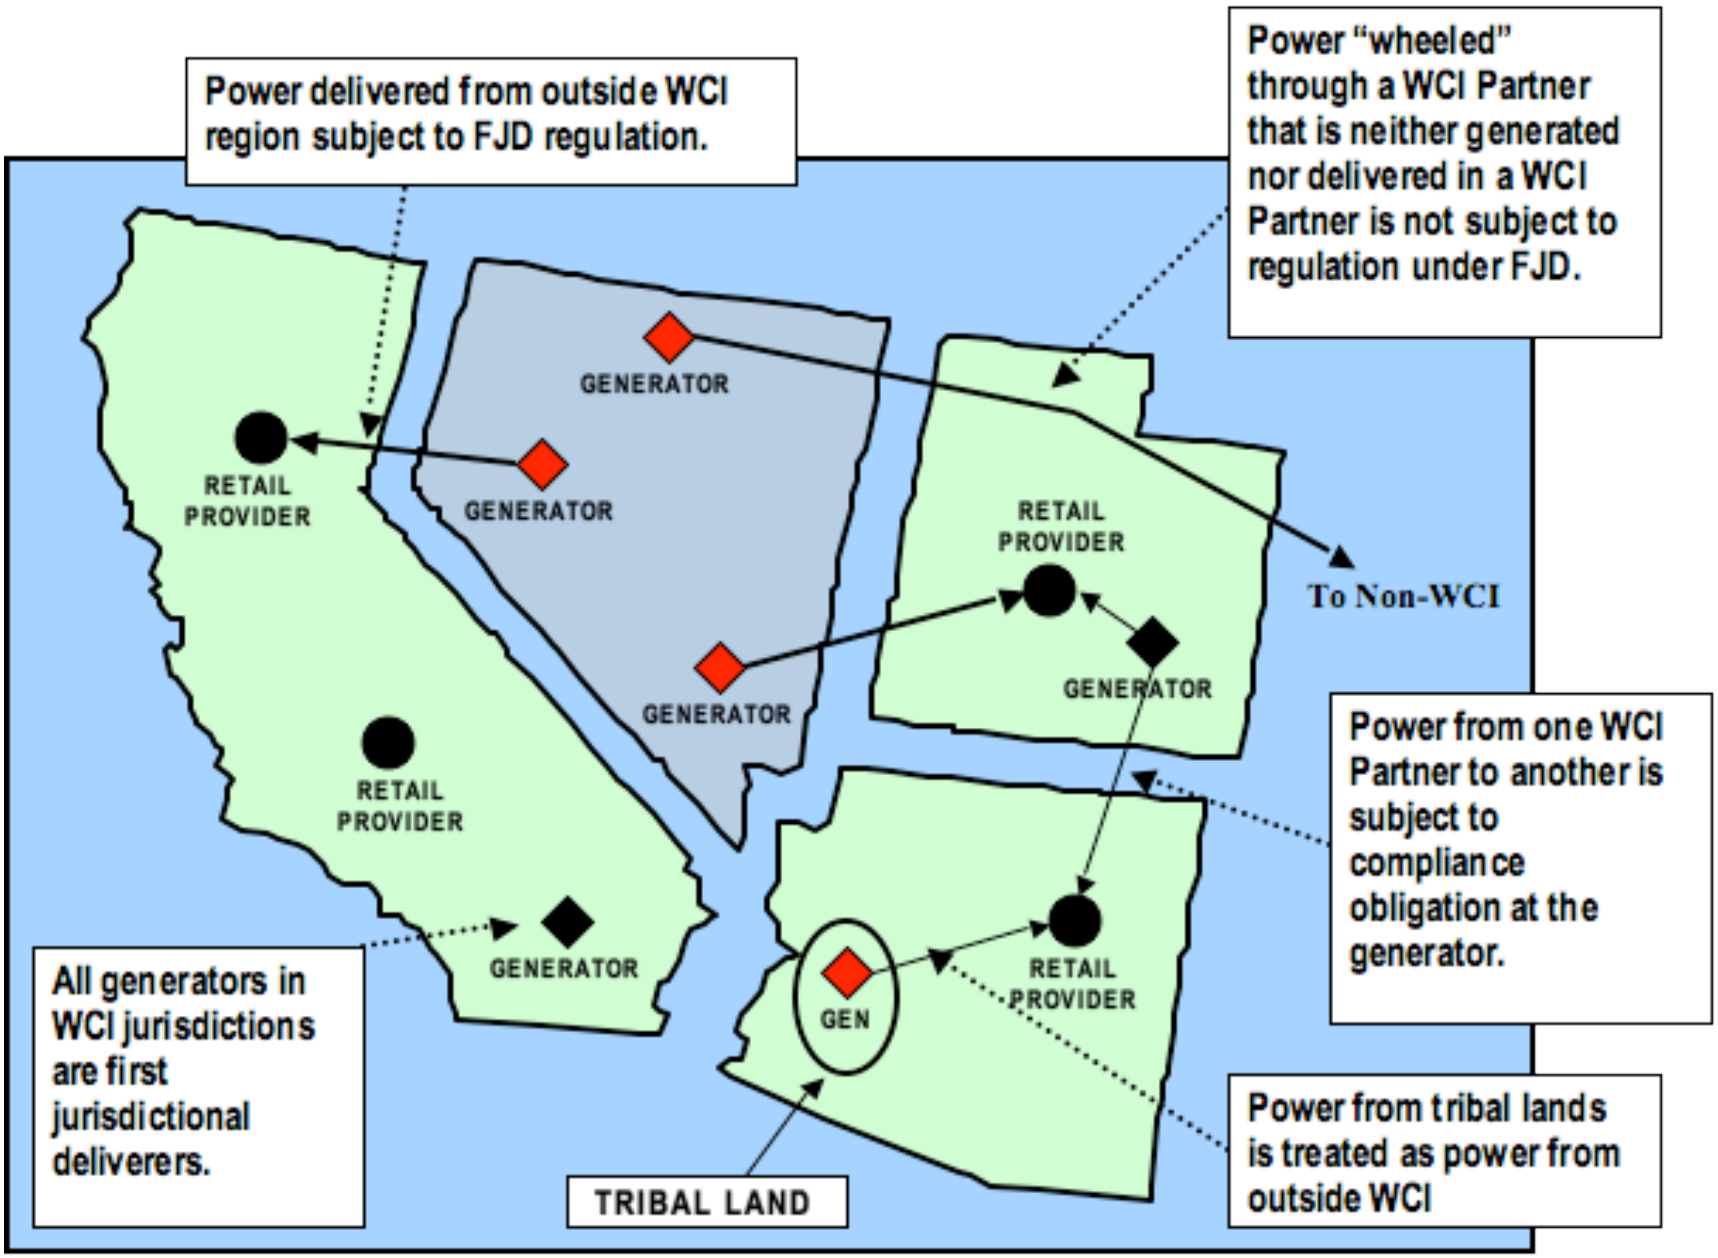
PROVISO

The thinking contained in this presentation and the accompanying 8-page memo represents that of its authors, and not the WCI Partners or the WCI Electricity Subcommittee. The exercise is designed to provoke thought and discussion among the Subcommittee and the expert Technical Advisory Group (TAG).

WORLD RESOURCES INSTITUTE

WCI Design Recommendations

2.2 Electricity: First Jurisdictional Deliverer: For sources within WCI jurisdictions the point of regulation will be at the generator. For power imported into WCI jurisdictions, the point of regulation will be at the first entity that delivers electricity that is generated outside the WCI jurisdictions (or generated by a federal entity or on tribal lands) for consumption within a WCI Partner jurisdiction and over which the WCI partner jurisdiction has regulatory authority.



Power delivered from outside WCI region subject to FJD regulation.
Power "wheeled" through a WCI Partner that is neither generated nor delivered in a WCI Partner is not subject to regulation under FJD.
GENERATOR
RETAIL PROVIDER
GENERATOR
RETAIL PROVIDER
To Non-WCI
GENERATOR
GENERATOR
RETAIL PROVIDER
Power from one WCI Partner to another is subject to compliance obligation at the generator.
GENERATOR
All generators in WCI jurisdictions are first jurisdictional deliverers.
GEN
RETAIL PROVIDER
TRIBAL LAND
Power from tribal lands is treated as power from outside WCI

Purpose of Regulatory Definition

- What entities will subject to a compliance obligation?
- Must “work” across differing factual circumstances
- If the definition (together with other applicability provisions) unintentionally misses a deliverer, then a “loophole” is present
- Ideally the provisions result in one entity as responsible for emissions even where more than one entity may be a “deliverer”

Example: RGGI

- "Owners" and "operators" of each covered electric generating unit must comply
- These terms are defined very broadly to capture all owners and all operators
- It is clear that as to many units, there are many owners and operators
- Yet only one of these entities has to step up to assume responsibility for compliance reports and other obligations
- In practice, many entities becomes one entity for compliance purposes

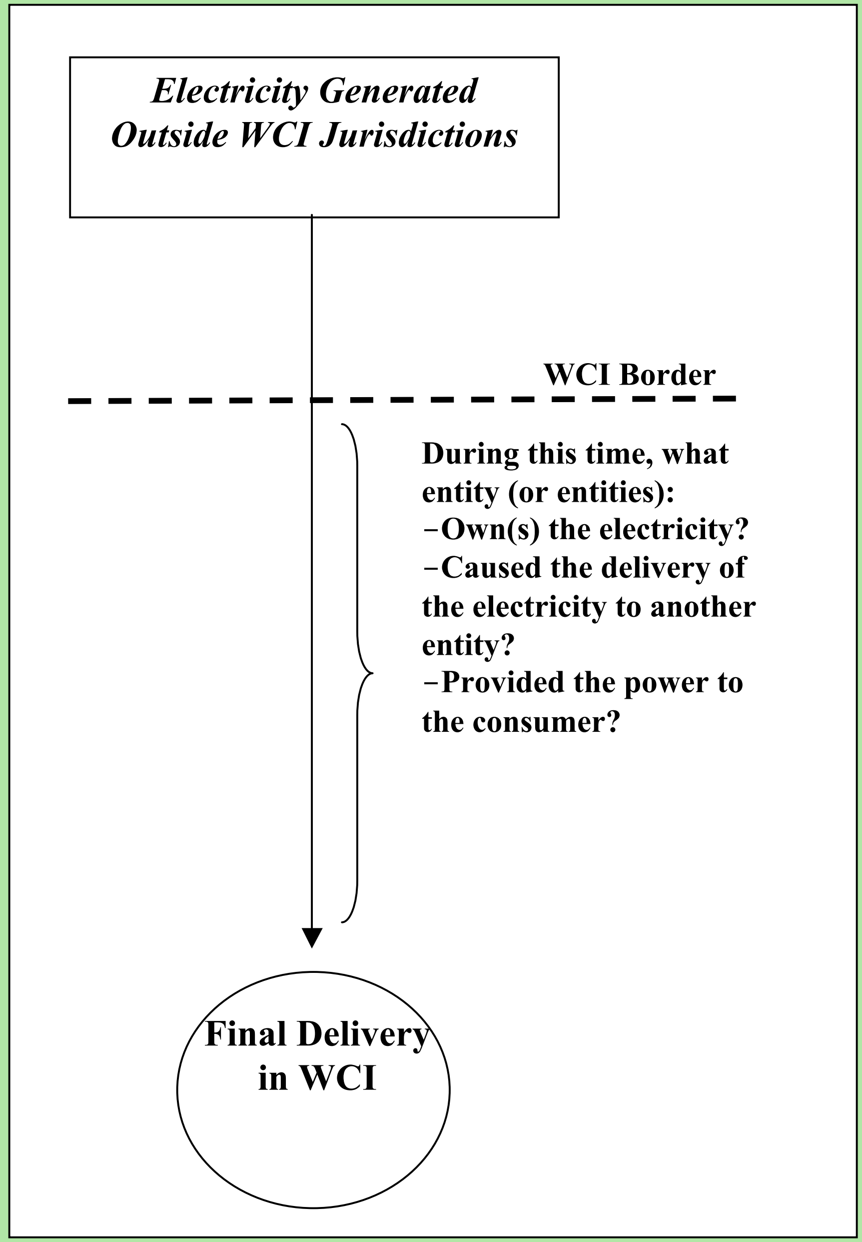
FJD Universe

First Jurisdictional Deliverers

Deliverers from Generating Units Inside WCI Partner Jurisdictions

Deliverers of Power (in the region) Originating Outside the Region

Focusing on those Deliverers that are Not Generators inside WCI

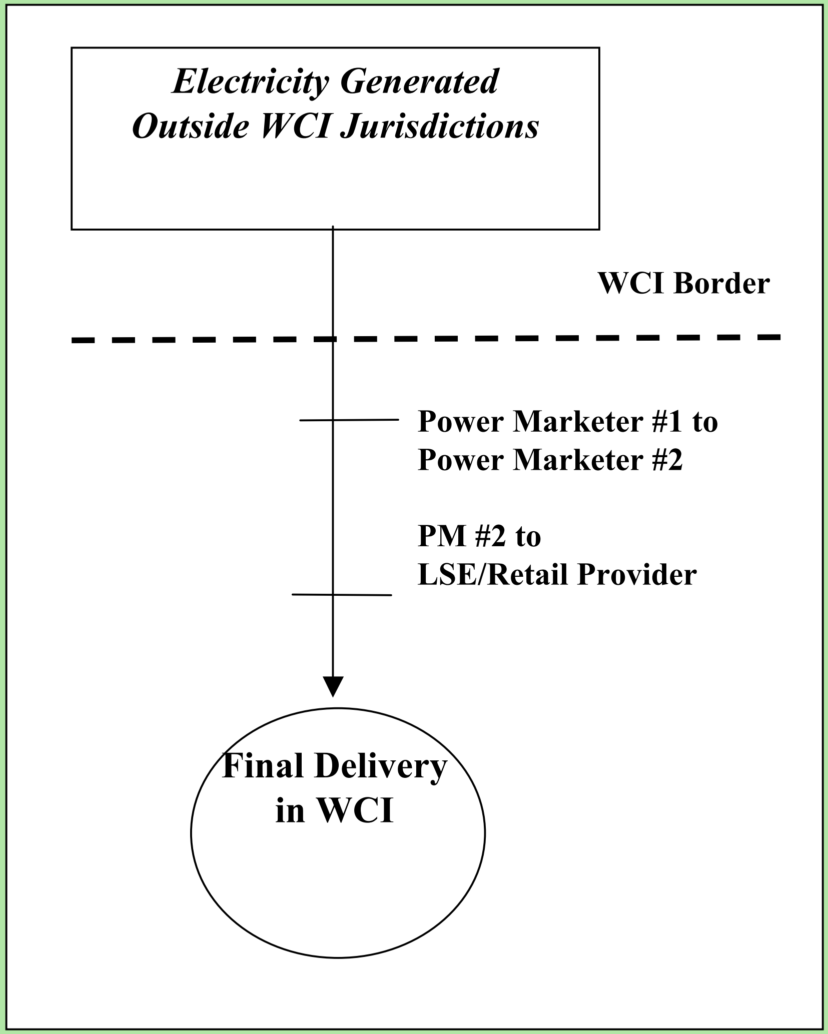


WORLD RESOURCES INSTITUTE

Quick Observations

- FJD seeks to capture emissions attributable to deliveries within the WCI partner jurisdiction
- Need to consider the intangible nature of the power deliveries, as contrasted with the tangible generating units making up the other part of the FJD Universe
  - For example, while an EGU cannot be physically divided to put each part below the applicability threshold (25,000 metric tons), transactions across FJDs could perhaps more easily be divided
- Need to consider that the FJD may in some cases the 2nd entity to deliver the power in the WCI partner jurisdiction, because no jurisdiction over the first entity

Example



Electricity Generated Outside WCI Jurisdictions
WCI Border
Power Marketer #1 to Power Marketer #2
PM #2 to LSE/Retail Provider
Final Delivery in WCI

Possible Definitions?

- *Owner*.

  (2) with respect to electricity generated outside of [the WCI region] and delivered for consumption within WCI <u>any holder of any portion of the legal or equitable title in the electricity</u>; or..

- *Marketer*. Any person who controls, brokers, or arranges for the delivery of electricity that originated outside of [the WCI region] for delivery and consumption in a [WCI partner jurisdiction].

Update on Economic Modeling

Economic Modeling Team

November 7, 2008
Webinar

Outline of Presentation

- Introduction of new co-chairs
- Overview of next steps in modeling and stakeholder input
- Overview of results released in September
- Input on topics for December 3 workshop
- Additional comments and questions

Co-chairs of Economic Modeling Team

- Jessica Youle, Arizona
  - jessicay@azcommerce.com
- Jessica Verhagen, British Columbia
  - Jessica.Verhagen@gov.bc.ca

Next Steps / Stakeholder Input

- WCI is expanding the model to include Manitoba, Ontario, and Quebec.
  - Repeat analyses released in September to include all partners
  - Conduct additional sensitivity analyses

- WCI will hold a workshop on the ENERGY 2020 model and initial results
  - Location: San Francisco. Date/Time: December 3, 10am-4pm **http://www.westernclimateinitiative.org/WCI_Meetings_Events.cfm**
  - Workshop responds to stakeholder requests for in-depth briefing and Q&A
  - We encourage organizations to include technical or modeling staff as attendees
  - **Please register at this link (whether in-person or via webinar):** www.regonline.com/wci-emt12-3-08.

Overview of September Modeling Results

- Reference Case:
  - Economic growth is 3%
  - Growth in GHG emissions is 0.5%/yr
  - Energy consumption is 0.4%/yr
- Treatment of power sector and First Jurisdictional Deliverer (FJD)
- Role of complementary policies
- Cap-and-trade scenarios and impacts:
  - Narrow vs. broad scope
  - Offsets
  - Banking
  - Sensitivity analysis

Note: error in Table B-10 will be corrected.

Treatment of Power Sector and FJD

- Cap-and-trade scenarios place cap on power sector throughout the WECC.
- Attributed 70 Mt to power imports into WCI partner territory in the Reference Case.
- Put a maximum of 45 Mt on GHG reductions that could be attributed to power imports under a cap-and-trade scenario.
- Two scenarios hit this maximum. One scenario reached ~80% of maximum.
- Electricity Subcommittee continues work with stakeholders on FJD definition and methodology, and other topics .

Complementary Policies

- Energy efficiency programs aimed at reducing annual rate of demand growth by 1%
  - Projected GHG reductions: 74 Mt in 2020
- Clean Car Standards (equivalent to California's Pavley I and II)
  - Projected GHG reductions: 30Mt in 2020
- Programs aimed at reducing passenger Vehicle Miles Traveled by 2% from 2020 Reference Case level
  - Projected GHG reductions: additional 4 Mt in 2020
- Together, they are projected to achieve a 108 Mt reduction in 2020
  - About one-half of the projected reductions needed to reach the 15% reduction goal

Cap-and-Trade Scenarios – MMTCO2E

GHG Emissions in 2020 *(MMTCO2E)*	**Reference Case**	**Cap-and-Trade**		
		Broad w/out Offsets	**Broad with Offsets**	**Narrow with Offsets**
WCI Partners	**992.8**	**859.2**	**877.9**	**847.8**
Non-WCI Power Sector	70.0	70.0	70.0	70.0
Non-WCI Power Sector Reductions		-45.0	-37.0	-45.0
Offsets		0.0	-31.8	-18.2
Bank Flow		-31.1	-31.8	-0.2
Compliance Total		**853.1**	**847.2**	**854.3**
Percent of 2006 Emissions		85.2%	84.6%	85.3%
Bank Inventory		72.6	74.4	0.5

Projections from Table B-12 of September report. All cap-and-trade scenarios assume complementary policies. 85% target is calculated off of a base of (WCI Partners + Non-WCI Power Sector) = 992.8+70.0 = 1062.8 MMTCO2E.

Cap-and-Trade and Sensitivity Scenarios

Case	GHG Emission (MMTCO2E)	Offsets Used (MMTCO2E)	Allowance Price (2007 $)	Change in Fuel Expenditures ($M/Yr)	Potential Allowance Value ($M/Yr)	Total Costs (Savings) ($M/Yr)
Reference Case	992.8	--	--	--	--	--
Cap-and-Trade Policy Cases						
Broad Scope, No Offsets	859.2	--	$63	(32,296)	39,516	(23,525)
Broad Scope, With Offsets	877.9	31.8	$24	(31,012)	15,150	(22,080)
Narrow Scope, With Offsets	847.8	18.2	$71	(22,794)	16,092	(11,422)
Sensitivity Cases						
High Price	833.3	12.7	$18	(42,736)	10,521	(30,514)
Low Price	857.0	34.1	$56	(22,598)	35,642	(16,245)
High Natural Gas Price	865.4	26.6	$20	(6,525)	12,434	7,880

Fuel Expenditures and Total Costs (Savings) are changes from Reference Case values.

Potential Allowance Value calculated as emissions times allowance price.

Total Costs (Savings) do not include costs of VMT Reduction programs, Energy Efficiency programs, nor Potential Allowance Value.

December 3 Workshop - Context

- Workshop will go 10am-4pm, and participants can attend in-person or via webinar.
- Format: sessions focused on topics of interest to stakeholders.
- Previous webinars and public comments have indicated ongoing interest in structure of model, input assumptions, outputs, and sensitivity analysis.
- Public comments to date are available at:
  - http://www.westernclimateinitiative.org/Draft_Proposals_Comments.cfm

Input on Topics for December 3 Workshop

Comments and Questions

Straw Proposal on Reporting GHG Emissions Associated with Electricity Imports

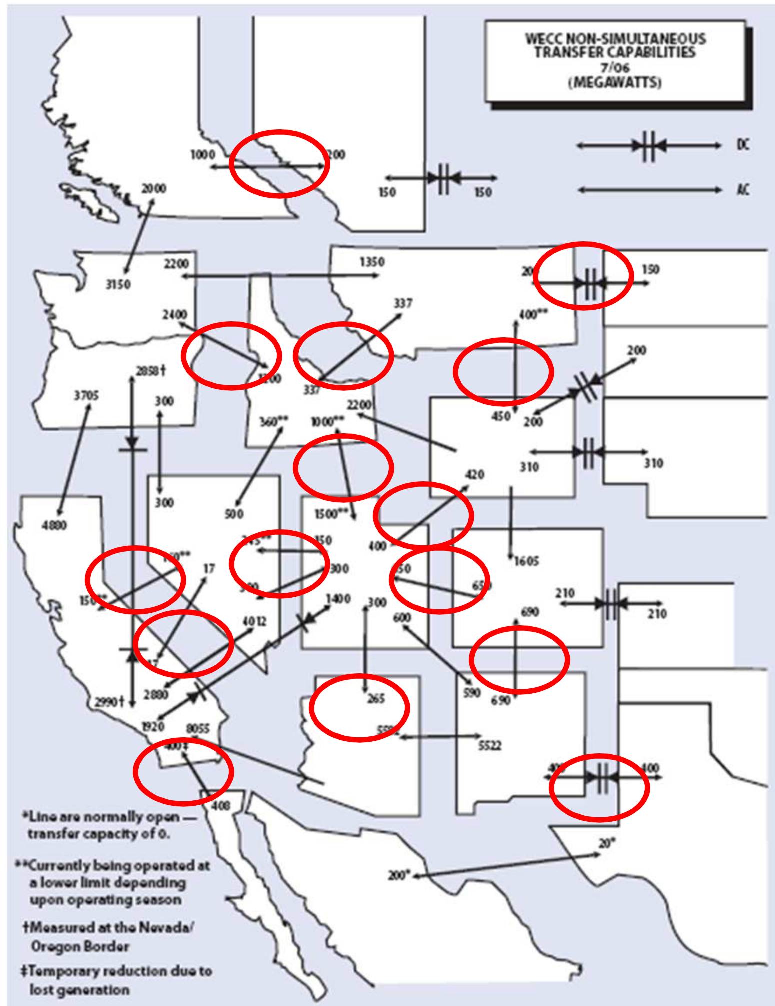
Scott Murtishaw, California PUC

Presented November 13, 2008
WCI Electricity Subcommittee Working Session
Santa Fe, New Mexico

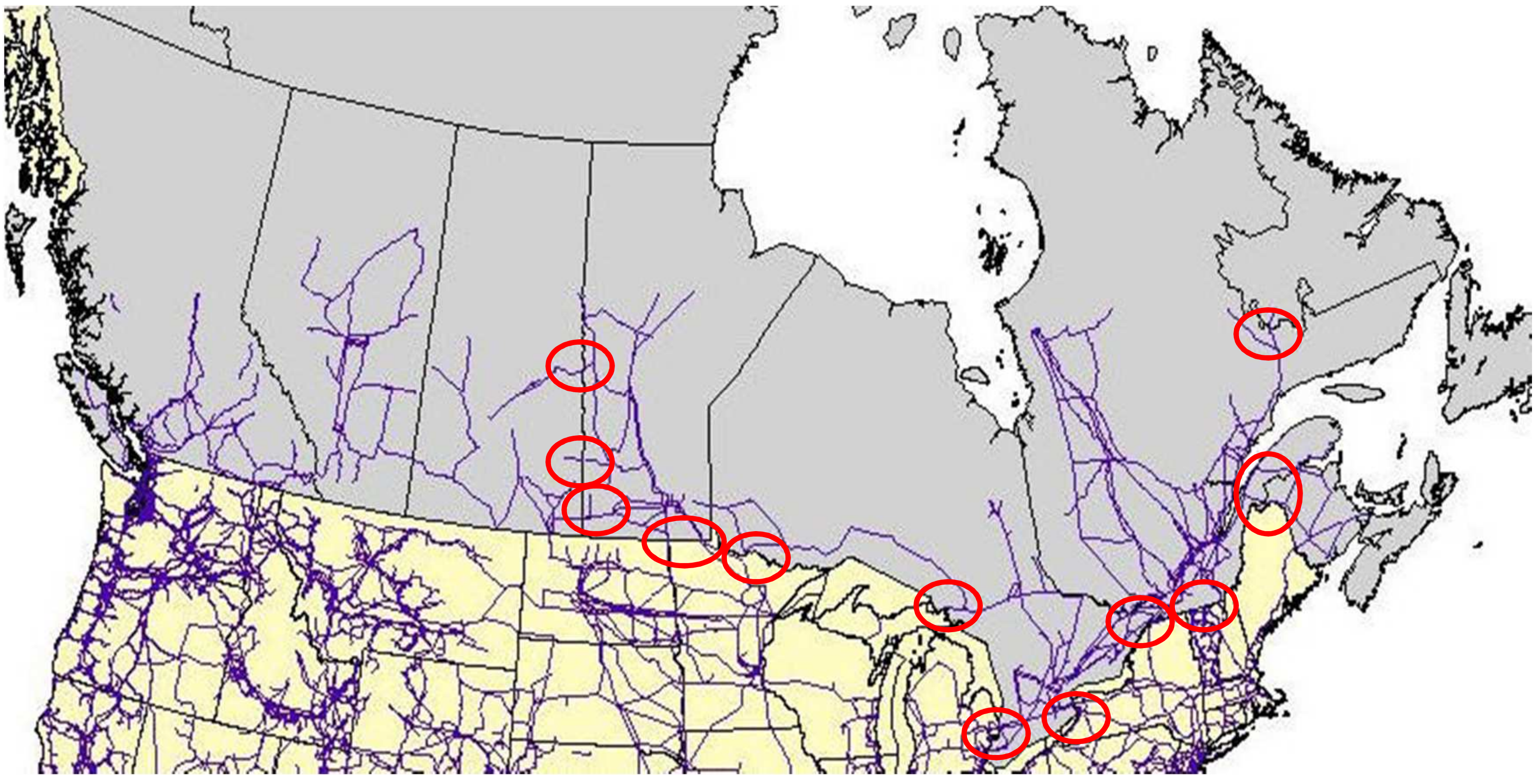
Overview of Presentation

- Identifying the Import Paths
- Reporting the Quantity of Electricity Imported
- Attributing Emissions to Specified Imports
- Unspecified Imports and Default Factors

Identifying the Regulated Western Transmission Paths



Identifying the Regulated Eastern Transmission Paths



Reporting the Quantity of Imported Electricity

- Reporting entity reports the quantities of all electricity imported on the regulated paths
- For paths crossing balancing authority areas (BAAs), e-tags are starting point for establishing reported quantity
- Transactions demonstrated to be wheel-throughs do not trigger a compliance obligation
- For inter-BAA transactions, wheel-throughs identified by last Point of Delivery in the transaction

Electricity Reporting Discussion Questions

- What data and documentation would be used for intra-BAA paths?
- When scheduled transactions are curtailed, what documentation would correct e-tag data?
- How would wheel-throughs be documented when initial import is intra-BAA?
- Should all or some paths that connect to RGGI states be exempt?

Attributing Emissions to Specified Imports

- Reporting entities identify the portion of imports on each path generated by specified facilities
- Emission rate for attribution calculated using verified emission data
- WCI retail providers with ownership shares/PPAs in non-WCI coal plants document the difference between entitlement share and reported imports
- RECs not used for GHG reporting

Conditions on Specified Imports of Low Cost Zero GHG Power

- Conditions placed on zero GHG attribution to imports from specified nuclear or large hydro facilities
  - Ownership Shares
  - PPAs executed prior to January 1, 2008 and still in effect
  - Limited "spill or sell" sales during high hydro season

Specified Import Discussion Questions

- Should a minimum contract duration be required to receive attribution for specified facilities?
- Should RECs have some role in substantiating reported imports of renewable electricity?
- In order to prevent double counting, how should specified claims on non-WCI facilities by non-WCI retail providers be tracked?

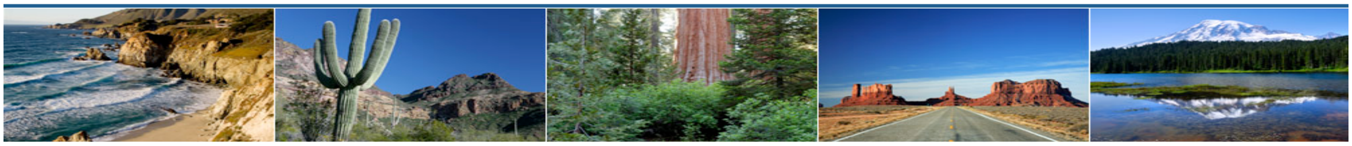
Unspecified Imports and Default Emission Factors

- Default (or "deemed") emission factors used to attribute emissions to remaining imports
- Default factors derived using marginal emission factor method
- Starting proposition
  - Five geographic zones: Alberta, western U.S., Baja, central U.S./Canada, Northeastern U.S.
  - For each zone, only one factor per reporting period (i.e., no TOU or seasonal factors)

Default Factor Discussion Questions

- Are more zones needed? (e.g., Navajo Nation, TX, NB, subsets of the five proposed regions)
- Are seasonal/TOU factors needed to accurately reflect marginal resources from certain zones?
- How far in advance should the WCI Partners publish the default factors?

Western Climate Initiative



ELECTRICITY SUBCOMMITTEE
TECHNICAL WORKING SESSION

SANTE FE, NEW MEXICO
NOVEMBER 13, 2008
9:00 a.m. to 5:00 p.m. Mountain

<u>Location</u>:

8.	**1:30**	**Presentation for Reporting** **Emissions for Unspecified Power and Default Rates** **Scott Murtishaw, CA PUC**
9.	**2:00**	**Comments and Discussion**
10.	**4:30**	**Public Comment Session**
11.	**5:00**	**Adjourn**

<u>An Approach to Implementing FJD in WCI</u>

- Implementing FJD via explicit tracking of all transactions is viewed as unworkable. An approach is proposed that focuses only tracking transactions within the WCI footprint at the generator and imports across a predefined set of transmission paths is proposed.

- The approach is designed to provide a high degree of certainty in reducing leakage and at the same time providing each market participant with certainty at the moment of transaction. The proposal would eliminate the potential for after the point of transaction carbon liability. Moreover there would be no cascading liability under the proposed structure.

- The basic idea is that for any party generating electricity within the WCI footprint the point of regulation is the generator smokestack. The generating party would bear the responsibility to comply with the WCI carbon mitigation requirements. Mitigation would be based upon plant specific emission rates.

- For power imported into the WCI footprint the carbon mitigation compliance obligation would lie with the party holding title to the energy as it is wheeled over a set of well defined and pre-specified transfer paths (as new paths are built they could be added but there would be no reach back if a path had inadvertently been left out of the tablation). Therefore, the energy is "clean" when it reaches the first POD in the WCI footprint. For discussion purposes, we will refer to the in-WCI trading points as "clean hubs" and the key import paths as "hot paths".

    - Specifically, all possible transfer paths from points outside the WCI into the WCI would be identified. These would be tabulated and published. Import liability for carbon mitigation would be triggered by the party electing to wheel energy across one of these paths. Monitoring of these transactions could be made via e-tags which could be supplied by Balancing Areas within the WCI.

    - If energy is wheeled across a hot path and it is delivered from a specified source, the title holder would be required to mitigate the carbon at the plant specific emission rate (e.g. hydro would have no liability). For unspecified sources, a deemed emission rate would be applied. There could be path specific or zone specific deemed emission rates so as to account for the differing generation mix across the WECC.

    - If it is desired to account for losses, a deemed loss factor for each hot path could be specified and published. This approach would be consistent with transmission contracting practices that have long been existence throughout the WECC. The importing party would then be required to comply with carbon content at the WCI POD plus the associated losses (via loss factor) back to the non-WCI POR on the hot path.

- Because the party holding title bears the WCI compliance risk as it wheels across the hot path, subsequent transactions downstream of the importer have no further carbon liability transfer. The compliance relationship shall be defined to be between the importing party and the appropriate WCI regulatory entity (e.g. partner state or province). This requirement will need to be clearly established ahead of WCI implementation. The preferred path for this would be via legislation that would require any party selling electric energy in the jurisdiction to be subject to the provisions of WCI (note – this legal authority may already exist). The terms and conditions would then be easily incorporated into contract terms if desired by market participants.

- The net effect of the above is that the default market product at WCI hubs becomes "seller pays" with respect to carbon dioxide mitigation and effectively all energy sold is "clean". For all market participants, there is certainty when purchasing energy at WCI hubs. Given that the regulatory relationship is between the in-WCI generator and the importing party, the WCI partner entities bear some risk in the event of a default by a party with a compliance obligation (this risk is not expected to be significant). There would be no cascading liability in the event of a default. The WCI partners can manage their credit risk in ways that do not result in the significant disruption that can be expected with cascaded liability.

- While this approach is not perfect, it is judged that it could be quite effective in reducing leakage and it has the benefit of being straightforward and easily implemented.

Straw Proposal on Reporting GHG Emissions Associated with Electricity Imported from non-WCI Jurisdictions

Attachment A. Straw Proposal Regulatory Language 9

1. Background on Reporting Greenhouse Gas Emissions in WCI

On September 23, 2008 the WCI Partners released their design recommendations for a regional cap and trade program. These recommendations stated that the scope of the program would cover emissions from power imported into WCI jurisdictions for consumption in WCI jurisdictions in addition to generator emissions occurring in WCI jurisdictions. The design recommendations further stipulated that the point of regulation for the electricity sector should be the first jurisdictional deliverer (FJD), which for in-jurisdiction sources would be the generator, similar to the point sources covered in the industrial sector. For electricity imports from non-WCI states or provinces, the design recommendations identify the FJD as "the first entity that delivers that electricity over which the consuming WCI partner jurisdiction has regulatory authority." This will generally be a retail provider of electricity or a wholesale marketer (collectively "importer") that owns electricity as it is delivered across the border from a non-WCI jurisdiction into a WCI jurisdiction. If it is determined that the importer for a certain transaction is not subject to the regulatory authority of the WCI states and provinces (for example, a federal power administration may be immune from WCI regulation), the FJD would be the next downstream participant in the transaction.

The Electricity Subcommittee will provide recommended reporting rules for imported electricity to the WCI Reporting Subcommittee, which has been developing reporting requirements for the other sources covered by the scope of the WCI cap. This straw proposal is intended to help focus discussions at the technical working group meeting in Santa Fe on November 13. Participant feedback at the meeting and written comments will help shape the Electricity Subcommittee's recommendations to the Reporting Subcommittee.

2. Overview of Reporting Process

Accounting for emissions from sources located in WCI is a relatively straightforward process of measuring actual emissions or fuel consumption at the source. In contrast, attributing emissions to imports of electricity necessitates identifying electricity imports and matching those quantities of electricity to any of potentially hundreds of underlying generation sources.

For purposes of reporting GHG emissions, the sources of power used for imports can be classified into two types: specified sources that can be clearly tracked back to a specific generating facility or unit and unspecified sources that cannot. Clear links to specific facilities may exist when an importer owns generation facilities, has an equity share in a facility, or has a power purchase agreement with a specific facility. Some U.S. utilities also receive allocations of power from specified federally-managed dams. When these links to specified sources exist, emissions associated with the energy received can be attributed with reasonable certainty. Since the resources used for unspecified power cannot be precisely identified, emissions would have to be attributed using default (or "deemed") emission factors.

Broadly, the process of reporting regulated import transactions would occur in three steps.

1. The FJD reports the amount of electricity delivered into WCI jurisdictions during a reporting period.

2. The FJD reports emissions from deliveries from specified sources using emission data from those sources.

3. Emissions are attributed to deliveries from unspecified sources using default emission factors.

The sections below present more detail and suggested regulatory language for one possible approach to implementing GHG reporting rules for electricity imported into the WCI region.

3. Contract Shuffling

Contract shuffling is the practice of reporting imported electricity as generated by a lower emission facility or group of facilities than is actually the case. The result is to attribute GHG intensive power to states and provinces that do not have a cap while skimming the less GHG intensive power for attribution to imports. Contract shuffling reduces the environmental integrity of WCI implementation because the reported reductions in emissions are not matched by actual changes in total emissions.[1]

There are two different ways that contract shuffling can occur. Specified high GHG sources or system purchases can be shuffled by "cherry picking" specified low GHG sources from the available resources in the uncapped jurisdictions. Imports from specified sources with emission rates higher than the default rate can also be shuffled by delivering the power on an unspecified basis. The E3 presentation at the Salt Lake City workshop showed that roughly 20 million metric tons of CO_2 ($MMTCO_2$) could potentially be shuffled from coal plants using available hydro generation and that another 30 $MMTCO_2$ could be shuffled using a default rate of 1,000 lbs CO_2/MWh. Combined, this represents nearly two-thirds of the total emissions associated with imports in E3's 2020 scenario.[2]

It is important to note that importers or downstream recipients may not necessarily be aware that contract shuffling has taken place. The following example illustrates how this could occur. In Hour 1, a non-WCI utility generates 1,000 MW to serve its own load. In Hour 2, a WCI retail provider has contracted to buy 100 MW of hydro power from the non-WCI utility. The non-WCI utility must now generate 1,100 MW to serve its own load and meet its contractual obligation. The hydro resource is already running at its maximum capacity of 500 MW. The non-WCI utility generates an additional 100 MW from a natural gas plant and sells 100 MW of "hydro" to the WCI utility. The WCI utility believes it is purchasing hydro power, but its purchase actually induces natural gas generation.

4. Reporting Imported Electricity

All entities that own electricity delivered to the first point of delivery inside a WCI state or province from a non-WCI state or province shall report the quantities of electricity imported, whether consumed in a WCI state or province or wheeled through to another non-WCI jurisdiction. For purposes of GHG regulation, an import shall be deemed to have been consumed in a WCI jurisdiction if the final point of delivery for the transaction is located in a

[1] See Bushnell, Peterman and Wolfram 2007 for more information.
[2] See Price 2008.

WCI jurisdiction. Only imports consumed in a WCI state or province will trigger a GHG compliance obligation, but wheel-throughs will be reported in the interest of obtaining complete information.

Based on the current WCI membership the relevant transmission paths include

- British Columbia to Alberta
- Washington to Idaho
- Oregon to Nevada
- California to Nevada and Mexico
- Montana to Alberta, Idaho, Wyoming, and North Dakota
- Utah to Nevada, Idaho, Wyoming and Colorado
- Arizona to Navajo Nation
- New Mexico to Colorado, Texas and Navajo Nation
- Manitoba to Saskatchewan, North Dakota and Minnesota
- Ontario to Michigan and New York
- Quebec to New York, Vermont, New Hampshire, Newfoundland and New Brunswick

For each transmission link connecting these jurisdictions, importers to WCI states and provinces shall report the quantities of imported power separately for each import path. Purchasing/selling entities that are the first to purchase or otherwise receive power from an importer that is non-jurisdictional are the FJDs for purposes of WCI GHG regulation and shall report the information described below.

Because many of the transmission links listed above cross between balancing authority areas, NERC e-tags are required for the power scheduled on these paths. For inter-balancing authority transactions FJDs shall report the quantities of power listed on the e-tags for any power for which they were the purchasing/selling entity on the path that crosses the WCI boundary. The FJD shall document the reason for any discrepancy between the quantities reported on the e-tags and the quantities reported to the state or provincial agency for GHG regulatory purposes. The e-tags will be used to establish the quantity of electricity that must be reported and accounted for. Although specific generating facilities are sometimes listed on e-tags, this information will not be used as the primary source of information for attributing emissions to specified imports.

For the paths that do not cross balancing authority boundaries, regulatory authorities will need work with the transmission operators of those lines to identify the parties that reserve transmission services and ascertain the quantities of electricity imported by each importing entity.

For purchases from specified sources, the FJD shall report the quantities of power purchased as measured at the power plant's busbar. In other words, the reported quantities should include the transmission losses that occurred between the power plant and the first WCI Point of Delivery. For purchases from unspecified sources, the FJD shall report the quantity as measured at the first WCI Point of Delivery or other metered point on the transmission path designated by the WCI Partners. FJDs shall make available all e-tags, meter data, contracts, and settlement data necessary to document the reported transactions.

5. Attribution of Emissions to Imported Electricity

5.1 Specified Imports

For imports of electricity from specified sources, the WCI Partners will attribute emissions to the total quantity of electricity imported in each reporting period using the average emission rate (total CO_2e emissions in metric tons divided by total net generation in MWh) of the power plant during the calendar year when the import occurred based on the most recent greenhouse gas emissions data report that received a positive verification opinion or on CO_2 emissions reported to U.S. EPA under 40 CFR Part 75 or to Environment Canada under Section 71 of the Canadian Environmental Protection Act.[3] The FJD must provide supporting documentation to show that the electricity was generated by the specified generating facility or generating unit, as applicable.

In order to curb the potential for contract shuffling, the attribution of zero GHGs to imports of generation from existing non-WCI large hydro and nuclear facilities will be limited to imports from facilities owned or partially-owned by the FJD or WCI retail provider or to imports made pursuant to a contract negotiated prior to January 1, 2008 that remains in effect or has been renegotiated for the same facility for the same share or quantity of net generation within one year of contract expiration. For coal plants not located in a WCI jurisdiction that are owned or partially owned by WCI retail providers, the retail providers will document the disposition of the power from these plants and account for differences between the share of power the retail provider is entitled to and the quantity reported by the retail provider or other FJDs as consumed in a WCI Partner jurisdiction.

While the WCI Partners may decide to establish an allowance set-aside for the voluntary renewables market, Renewable Energy Certificates used for compliance with Renewable Portfolio Standards, whether in a WCI Partner jurisdiction or not, shall have no bearing on any entity's compliance obligation. Electricity from renewable sources, like electricity from fossil-fired sources, can be imported on a specified basis as long as there is sufficient supporting documentation. The WCI Partners will share reported information on specified imports to ensure that electricity from low-GHG sources is not double-counted.

5.2 Unspecified Imports and Default Emission Factors

For purchases of electricity from unspecified sources, the WCI Partners will attribute emissions using approved default emission factors, published in advance of the reporting period by the WCI Partners. There are several methods the WCI Partners could pursue in developing default emission factors. An average system factor approach (i.e., total emissions divided by total generation) assumes that the non-WCI seller is providing power from a mix of resources that reflects a representative share of baseload and load-following resources in

---

[3] In order to provide the market certainty of an approved ex-ante emission factor it may be desirable to attribute emissions using plant emission rate data from a prior year. A lagged emission rate may even be necessary in order to allow adequate time for collection and verification of a non-WCI plant's emission data.

the region of origin. However, it is unlikely that an average emission factor would be accurate unless the pattern of exports closely matches the load profile of the exporting region, and deep baseload resources had been constructed in part, to provide power for export.

More sophisticated methods seek to identify the underlying plants with more precision. Marginal emission factor methods are based on the dispatch characteristics of the exporting region. These methods employ system modeling tools such as production cost models or simplified load duration curve models to determine which plants provide the incremental additional generation for export. Marginal dispatch analysis may also be used to generate multiple factors that reflect the marginal resources used at different times of they day or year. Whichever approach is adopted, the default factor should exclude all generating facilities, or parts thereof, that are identified as serving loads on a specified basis, whether serving WCI loads or non-WCI loads.[4]

Rather than attempting to discern which resources do in fact generate surplus power for export, some parties have suggested using a high emission rate, in the range of an existing pulverized coal unit, to discourage contract shuffling. The purpose of this approach is to prevent coal plants from shuffling their emissions by using a lower default rate. However, a high default rate would not prevent coal-fired power from being imported into a WCI jurisdiction and reported as having originated from a specified gas-fired power plant. A high default rate would not, on its own, thwart contract shuffling; it would simply affect the tactics used. For this reason, WCI Partners should strive to develop default factors that accurately reflect the mix of resources used to provide power for system sales.

Proposed decision criteria that could guide the Electricity Subcommittee's recommendations on default factors include accuracy, simplicity, and susceptibility to gaming. There are trade-offs among these criteria. Simplicity would argue for maintaining the smallest number of default factors necessary to achieve an acceptable level of accuracy. Attempts to optimize accuracy by developing numerous default factors would complicate the reporting system and could introduce more opportunities for gaming. For example, a low default factor for Idaho could motivate purchasing/selling entities to wheel power from Wyoming to Idaho and then import that power into a WCI state as if it were generated in Idaho. On the other hand, one factor used for an entire reporting period may not reflect significant seasonal or time-of-day differences in the resources used to produce power at the margin in non-WCI states and provinces.

More analysis is needed to determine if the resources used to provide system power differ sufficiently by time and place to warrant the complexity of multiple default factors. For discussion purposes, a starting proposition would be to use factors that are not temporally differentiated but that are disaggregated by the following major geographic zones: Alberta, Western U.S. (NV, ID, WY, and CO), Mexico, central U.S./Canada (MN, ND, SK), and northeastern U.S. If further analysis indicates that gas-fired power is the swing resource that provides most power for export in one or more of these regions and the emission rates do not

[4] See Marnay et al 2002; Sathaye et al 2004; Alvarado 2006; Alvarado and Griffin 2007; Murtishaw and Griffin 2007, and Broekhoff et al 2007 for more information.

differ substantially, the number of regional factors could be reduced. Assuming that natural gas is the swing resource in most of these regions, default factors would probably lie in the 400 kg CO_2e/MWh to 600 kg CO_2e/MWh range. The default factor adopted for California is currently 1,100 lbs CO_2e/MWh (approximately 500 kg CO_2e).

Attachment A. Straw Proposal Regulatory Language

Key Definitions and Reporting Requirements
Related to Electricity Imported into the WCI Region

Definitions

(1) "Balancing authority" means the responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time.

(2) "Balancing authority area" means the collection of generation, transmission, and loads within the metered boundaries of the balancing authority. The balancing authority maintains load-resource balance within this area.

(3) "Busbar" means the power conduit of an electricity generating facility that serves as the starting point for the electricity transmission system.

(4) "Deliverer" means an operator of a generating facility or an importer.

(5) "Electricity transaction" means the purchase, sale, import, export or exchange of electric power.

(6) "Entity" means a person, firm, association, organization, partnership, business trust, corporation, limited liability company, company, or government agency.

(7) "Exchange agreement" means a commitment between electricity market participants to swap energy for energy. Exchange transactions do not involve transfers of payment or receipts of money for the full market value of the energy being exchanged, but may include payment for net differences due to market price differences between the two parts of the transaction or to settle minor imbalances.

(8) "Facility" means any property, plant, building, structure, stationary source, stationary equipment or grouping of stationary equipment or stationary sources located on one or more contiguous or adjacent properties, in actual physical contact or separated solely by a public roadway or other public right-of way, and under common operational control, that emits or may emit any greenhouse gas. Operators of military installations may classify such installations as more than a single facility based on distinct and independent functional groupings within contiguous military properties.

(9) "Final point of delivery" means the last point of delivery for a given electricity transaction.

(10) "First Jurisdictional Deliverer" means an importer that is jurisdictional or the immediate downstream purchaser or recipient of power from a non-jurisdictional importer.

(11) "Generating facility" means a facility that generates electricity and includes one or more generating units at the same location.

(12) "Generating unit" means any combination of physically connected generator(s), reactor(s), boiler(s), combustion turbine(s), or other prime mover(s) operated together to produce electric power.

(13) "Gross generation" means the total electrical output of the generating unit, expressed in megawatt hours (MWh) per year.

(14) "Importer" means a retail provider, or any purchasing/selling entity that is the owner of power as it is delivered to the first point of delivery in the WCI Region for electric power imported into the WCI Region

(15) "Megawatt hour" or "MWh" means the electrical energy unit of measure equal to one million watts of power supplied to, or taken from, an electric circuit steadily for one hour. (A watt is a unit of electrical power equal to one ampere under pressure of one volt, or 1/746 horsepower).

(16) "Nameplate generating capacity" means the maximum rated output of a generator under specific conditions designated by the manufacturer, expressed in megawatts (MW) or kilowatts (kW).

(17) "Net power generated" means the gross generation minus station service or unit service power requirements, expressed in megawatt hours (MWh) per year. In the case of cogeneration, this value is intended to include internal consumption of electricity for the purposes of a production process, as well as power put on the grid.

(18) "NERC E-tag" means North American Electric Reliability Corporation (NERC) energy tag representing transactions on the North American bulk electricity market scheduled to flow between or across balancing authority areas.

(19) "Null power" means any electricity produced by a renewable energy electricity generating facility from which a Western Renewable Energy Generation Information System (WREGIS) or a Nevada Tracks Renewable Energy Credits (NVTREC) certificate or other renewable energy certificate has been unbundled and sold separately.

(20) "NVTREC" means Nevada Tracks Renewable Energy Credits.

(21) "Operational control" for a facility subject to this article means the authority to introduce and implement operating, environmental, health and safety policies. In any circumstance where this authority is shared among multiple entities, the entity holding the permit to operate from the local air pollution control district or air quality management district is considered to have operational control for purposes of this article.

(22) "Operator" means the entity having operational control of a facility, or other entity, from which an emissions data report is required under this article.

(23) "Point of delivery" means a point on an electric system where a power supplier delivers electricity to the receiver of that energy. This point can be an interconnection with another system or a substation where the transmission provider's transmission and distribution systems are connected to another system.

(24) "Point of receipt" means a point on an electric system where an entity receives electricity from a supplier. This point can be an interconnection with another system or a generator busbar.

(25) "Point source" means any separately identifiable stationary point from which greenhouse gases are emitted.

(26) "Power" means electricity, except where the context makes clear that another meaning is intended.

(27) "Power contract" means an arrangement for the purchase of electricity. Power contracts may be, but are not limited to, power purchase agreements and tariff provisions.

(28) "Prime mover" means the type of equipment such as an engine or water wheel that drives an electric generator. "Prime movers" include, but are not limited to, reciprocating engines, combustion or gas turbines, steam turbines, microturbines, and fuel cells.

(29) "Purchasing/selling entity" means an entity that is eligible to purchase or sell energy or capacity and reserve transmission services.

(30) "Qualifying facility" means a cogeneration or small power production facility that meets ownership, operating, and efficiency criteria established by the Federal Energy Regulatory Commission (FERC) pursuant to the Public Utility Regulatory Policies Act.

(31) "Renewable energy" means energy from sources that constantly renew themselves or that are regarded as practically inexhaustible. Renewable energy includes, but is not limited to, energy derived from solar, wind, geothermal, hydroelectric, wood, biomass, tidal power, sea currents, and ocean thermal gradients.

(32) "Retail provider" means an entity that provides electricity to retail end users in the WCI Region

(33) "Source" means greenhouse gas source, as defined in this section.

(34) "Specified source of power" or "specified source" means a particular generating unit or facility for which electrical generation can be confidently tracked due to full or partial ownership or due to its identification in a power contract.

(35) "Unspecified source of power" or "unspecified source" means electricity generation that cannot be matched to a particular generating facility. Unspecified sources of power may include power purchased from entities that own fleets of generating facilities such as independent power producers, retail providers, and federal power agencies and power purchased from electricity marketers, brokers, and markets.

(36) "Western Climate Initiative" or "WCI" means a collaboration of several U.S. states and Canadian provinces working together to reduce greenhouse gases in the region encompassed by their respective jurisdictions.

(37) "WCI Region" means the Canadian provinces of British Columbia, Manitoba, Ontario, and Quebec plus the U.S. states of Arizona, California, Montana, New Mexico, Oregon, Utah, and Washington, excluding any tribal/First Nations' lands that are not subject to state or provincial jurisdiction.

(38) "WREGIS" means Western Renewable Energy Generation Information System.

Greenhouse Gas Emissions Data Report: Electricity Imports.

(1) **General Requirements.** First jurisdictional deliverers shall meet the following general requirements in preparing their greenhouse gas emissions data report for each report year. When reporting electricity transactions, first jurisdictional deliverers shall:

(A) Specify the amount of electricity in MWh;

(B) Aggregate imports by Point of Delivery;

(C) Include electricity transactions associated with both renewable and nonrenewable energy sources of power.

(D) For electricity from specified sources, specify the amount of electricity as measured at the generator busbar;

(E) For electricity from unspecified sources, report the amount of electricity as measured at the first point of delivery in the WCI Region, or nearest metered point designated by the WCI Partners;

(F) For electricity from unspecified sources, disaggregate imports for each Point of Delivery by counterparty from which the power was purchased, if applicable;

(G) For electricity from specified sources, specify the facility name, the WCI designated facility ID, and the generating unit ID for the unit generating the power, if applicable;

(H) Specify the amount of electricity (MWh) that is null power when applicable;

(I) Specify electricity imported under exchange agreements as you would any other import transaction;

(J) When reporting power transactions as imports into the WCI Region, exclude the amount of power imported into the WCI Region that terminates in a location outside of the WCI Region, and report the quantity wheeled as measured at the first point of delivery inside the WCI Region;

(K) Retain for purposes of verification NERC E-tags, settlements data, and all other information needed to confirm the transactions.

(2) **Report Content.** First Jurisdictional Deliverers shall include the following information in the greenhouse gas emissions data report for each report year.

(A) ***Specified Imported Power Transactions.***
Wholesale power imported from specified sources by the First Jurisdictional

Deliverer or that the First Jurisdictional Deliverer purchased or received immediately downstream from a non-jurisdictional importer.

1. Power imported into the WCI Region (MWh) from a specified hydroelectric generating facility with nameplate capacity of > 30 MW[5] or from a specified nuclear facility shall be listed as one of the following:

   a. Power purchased with a contract in effect prior to January 1, 2008 that remains in effect or has been renegotiated for the same facility for the same share or quantity of net generation within one year of contract expiration;

   b. Power purchased not meeting stipulation 1 and that is not associated with an increase in the facility's generating capacity;

   c. Power purchased not meeting stipulation 1 that is associated with an increase in the facility's generating capacity due to increased efficiencies or other capacity increasing actions;

   d. Power purchased from hydroelectric generating facilities during a "spill or sell" situation where power not purchased is lost;

   e. Power purchased that does not meet stipulation 1 due to federal power redistribution polices for federally owned resources and not related to price bidding.

2. If the first jurisdictional deliverer holds a contract that entitles the first jurisdictional deliverer to a specified percentage of the generation in the report year from a facility not located in the WCI Region, the first jurisdictional deliverer shall include power purchased or sold from that facility as being from a partially owned facility.

3. For facilities not located in the WCI Region that are fully or partially owned by the first jurisdictional deliverer, include facility name, WCI designated facility ID, generating unit ID as applicable, percent ownership share at the facility level, ownership share at the generating unit level as applicable, and net power generated in the report year (MWh).

4. For facilities not located in the WCI Region that are fully or partially owned by the first jurisdictional deliverer that have CO_2 emissions greater than 500 kg of CO_2 per MWh based on the most recent greenhouse gas emissions data report that received a positive verification opinion or on CO_2 emissions reported to U.S.EPA under 40 CFR Part 75 or reported to Environment Canada under Section 71 of the Canadian

[5] The 30 MW threshold is based on California's definition of eligible renewable hydro so this may need to be rephrased to make it more broadly applicable.

Environmental Protection Act, the first jurisdictional deliverer may elect to include:

a. Wholesale sales made by the First Jurisdictional Deliverer or on behalf of the First Jurisdictional Deliverer from the facility or unit to counterparties located outside the WCI Region where:

    i. The power could not be delivered to into the WCI Region during the hours in which it was sold due to congestion in the transmission and distribution system or similar issues or;

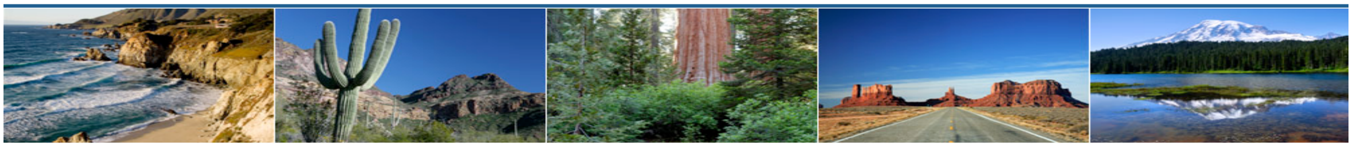
    ii. The First Jurisdictional Deliverer did not need the power during the hours in which it was sold for reasons not related to reducing the first jurisdictional deliverer's greenhouse gas emissions responsibility.

b. Amount of power generation that was reduced from the facility or unit in MWh per year as a result of the reduced demand for power by the First Jurisdictional Deliverer. The First Jurisdictional Deliverer shall retain documentation that associates reduced generation with reduced demand.

(B) ***Unspecified Imported Power Transactions.***
Power imported from unspecified sources by the First Jurisdictional Deliverer or that the First Jurisdictional Deliverer purchased or received immediately downstream from a non-jurisdictional importer with final point of delivery in the WCI Region.

(C) ***Electricity Transactions Wheeled Through the WCI Region***.
Power imported into the WCI Region that terminates in a location outside of the WCI Region, as measured at the first point of delivery in the WCI Region.

Western Climate Initiative



ELECTRICITY SUBCOMMITTEE
TECHNICAL WORKING SESSION

San Francisco, California
December 2, 2008
8:30 a.m. to 3:30 p.m. Pacific

Location:
Westin Hotel
50 Third Street
San Francisco

AGENDA

1.	**8:30 am**	**Welcome and Introductions** **David Van't Hof, Chair, WCI Electricity Subcommittee**
2.	**8:45**	**Review of the Process and Agenda**
3.	**9:00**	**Presentation on Reliability and Liquidity** **Karen Griffin, CA Energy Commission**
4.	**9:30**	**Comments and Suggestions in Response** • **Udi Helman, California ISO** • **Saeed Farrokhpay, FERC** • **Bud Beebe, Sacramento MUD**
5.	**10:00**	**Break**
6.	**10:20**	**Comments and Suggestions from TAG**
7.	**12:00**	**Lunch (On Your Own)**
8.	**1:00**	**Presentation on Potential Impacts on** **Liquidity in Eastern Electricity Markets** **Barry Green, Ontario IESO**
10.	**1:30**	**Comments and Discussion by TAG**
11.	**3:00**	**Public Comment Session**
12.	**3:30**	**Adjourn**

WCI Impacts on Market Liquidity and Reliability Eastern Electricity Markets

Presentation by
Barry Green
WCI San Francisco Meeting
Dec. 2, 2008

Overview

- Eastern context for this discussion
  - Nature of the Ontario market
- Key Issues
- Summary

Ontario Interconnections

Eastern Context

- Representing the Ontario Independent Electricity System Operator (IESO)
  - Power System Operator and Market Operator for the Province of Ontario
  - Also, in NERC terms the IESO is the Balancing Authority and Reliability Coordinator for Ontario

Eastern Context cont'd

- Characteristics of the Ontario market (very round numbers)
  - Total Provincial load ~150 TWh
  - Generation Mix (energy):
    - Nuclear ~51%
    - Hydroelectric ~21%
    - Fossil ~26% (18% coal;8% oil and natural gas)
  - Over the last 5 years, fossil generation has ranged from 35 TWh to 48 TWh representing a range of 23% to 33% of total Ontario generation
- Ontario Market Participants trade actively with all of the neighboring systems, specifically:
  - Hydro Québec—WCI Member/predominately hydro
  - Manitoba Hydro—WCI Member/predominately hydro
  - New York—RGGI Member/predominately fossil and mostly gas
  - Midwest ISO—predominately fossil and mostly coal
- In any given year Ontario might be a net importer or net exporter
  - Over the last 5 years exports have ranged from 6-12 TWh and imports from 6-11 TWh
  - The annual net interchange transactions has ranged from imports of 4 TWh to exports of 5 TWh

RELIABILITY and LIQUIDITY ISSUES

- Currently no identified unsolvable reliability or liquidity issues
- No identified substantial reliability and liquidity differences between East and West
- No identified substantial differences between East and West
- Need to recognize that a cap and trade approach, i.e. a market solution, to emission reductions will raise some potential problems that need to be mitigated
- Also need to recognize that 2012 and 2015 will represent step changes
- Key is to facilitate the emission allowance market
  - Maximize the number of players in the market
  - Transparency
    - In particular allow prices to be seen by all market participants including customers so that they can react to the price signals
  - Recognize transitional issues and not over-react

Identified Reliability Issues

(working from Karen Griffin's paper)

- Transitional issues
  - Existing contracts
- Resource planning issues
  - New supply
    - Back up for intermittent generation
    - New generation
- Allowance management issues
  - LSE conservatism
  - Generators with insufficient allowances
  - Speculators hoarding allowances
  - Annual swings in hydroelectric production
- Overall System Reliability
  - ISO vs. Integrated utility
  - Who orders generation post 2012? Long term vs. short term?
- Currently no other issues identified

Dealing with Reliability Issues

Transitional Issues

- Case specific
- Each partner may need to develop their own approach
- Best solution could depend on:
  - The number of contracts
  - The proportion of the market this represents
  - The solution might be through allocation of allowances

Dealing with Reliability Issues cont'd
Resource Planning Issues

- The issue is dealing with new entrants
  - Need the right mix of generation:
    - Shorter term to back up intermittent generation that is increasing quickly
    - Longer term to account for the allowance reduction trajectory
  - Allowance pricing and allocation mechanisms may help
    - Price transparency should enhance the decision-making process in a market environment or in a central planning environment
    - The allowance market will provide price signals to monetize emissions

Dealing with Reliability Issues cont'd
Allowance Management Issues

- A number of identified issues hypothesize scenarios where allowance pricing distorts the market
  - LSE conservatism
    - LSE holding allowances is not analogous to capacity reserve margins due to:
      - » Obligations are primarily on the generators
      - » Three year compliance period
    - The market for allowances will allow LSEs to "cost" them and make appropriate decisions
  - Price Spikes reducing available generation possibly due to speculation
    - Generators need to be able to pass through the costs of allowances, then should be willing to pay the market price for allowances
    - There will always be a need for market monitors to insure appropriate behavior
  - Annual allowance requirements varying substantially due to water or weather conditions
    - Geographic (east/west) and sectoral (electricity vs. other sectors) diversity will help mitigate this
- Allowances represent one more element of risk in pricing electricity
  - It is not inherently different than fuel price risk
  - Will impact fuels differently and therefore its impacts on various jurisdictions will not be uniform

Dealing with Reliability Issues cont'd
Overall system reliability

- The issue is not substantially different for ISOs vs. Integrated Utilities
  - All operate to the same NERC rules
- The entity responsible for grid reliability, short term or longer term, is not changed by allowance availability
  - We are merely adding another element of risk for market participants to manage
  - We are also adding a tool by which to manage that risk

Summary of Reliability Issues

- The issues identified are real
- Allowance pricing introduces another element of risk
  - Not unlike other risk elements such as fuel although it will impact fuels differently and therefore its impacts on various jurisdictions will not be uniform
  - Now there will be a mechanism for monetizing and dealing with it
  - We must maximize the size of the market in order to attempt to minimize the impact:
    - The use of 3-year compliance periods is a good feature
    - Allowances need to be fungible across as big a market as possible
      - The diversity between the east and west is good
      - As many sectors of the economy as possible should be included with the maximum capability to trade between sectors
  - Price transparency is key
    - All market participants, including customers, need to see prices and adapt behaviors

Identified Liquidity Issues

- Designing a market for good liquidity
- Dealing with the swings in hydroelectric production

Dealing with Liquidity Issues

- Market design for liquidity:
  - Need to anticipate some initial volatility as players learn the market and how it reacts
    - Three year compliance period helps to mitigate volatility
  - Liquidity will be enhanced by a large number of active participants
    - As many sectors of the economy as possible
    - Geographic diversity is helpful
    - A good trading platform would enhance price transparency and liquidity

Dealing with Liquidity Issues cont'd

- The issue here is really swings in fossil requirements and therefore allowance requirements
  - Could be caused by:
    - Hydro-electric availability
    - Nuclear availability
    - Unusually hot or cold weather
- Swings in hydroelectric availability can be mitigated by:
  - Maximizing the diversity amongst the entities included in the program
    - Geographic diversity
    - Sectoral diversity

Comments on the Brainstorming Lists

- Reliability set-aside
  - The need for this should be mitigated by diversifying the players and the 3-year compliance period
  - Both of these would allow for expanding the pool from which allowances can be bought without increasing the total number of allowances
- Reliability exemption for emergency purposes
  - Given the 3-year compliance window this should only be required for an emergency very near the end of the window
  - Criteria could be developed to allow borrowing from a future period under such circumstances
- Pass through of allowance costs
  - Customers do need to see the cost of allowances so they are part of the solution
  - A direct pass through would remove allowance costs from decision-making elsewhere in the resource allocation process
  - Resource planning decisions need to reflect the cost of emissions

Comments on the Brainstorming Lists cont'd

- Balancing Authorities should not be purchasing allowances for reliability contingencies
  - Has the effect of making the Balancing Authorities a market participant
  - The allowances required need to be available to market participants and are part of the price of the energy
- Before adopting any extraordinary measures to improve liquidity, such as restricting purchasers, we should examine the results of other jurisdictions such as the European market

Summary

- With respect to liquidity and reliability issues we have a good starting point
- We have not yet identified any show-stoppers although modelling of the Eastern markets is still to be done
- Key issues are:
  - Transparency
    - All participants right down to the retail customer need to see the cost of their actions
  - Maximize fungibility of the allowances and diversity of the participants
    - Utilize the geographic diversity of the WCI region
    - Utilize the sectoral diversity by maximizing the number of industrial sectors included within the program

Agenda

WCI Economic Modeling Team Workshop

December 3, 2008 10:00 am - 4:00 pm PST
Westin Hotel, 50 Third Street
San Francisco, California

Toll free call in: 1-800-868-1837
Direct dial: 1-404-920-6440
Participant Code: 659537 (followed by #)

Objectives

1. Explain how the economic analysis was performed.
2. Get feedback on how to improve the analysis.
3. Discuss how to structure the next round of analysis.

Workshop Sessions

Introduction: (5 minutes)

Session 1: Understanding Model Outputs (25 minutes)

Session 2: Review of Reference Case (60 minutes)

Session 3: Review of Policy Cases (60 minutes)

Break and Working Lunch w/ box lunch (60 minutes)

Session 4: Review of Electric Sector Results (60 minutes)

Session 5: Review of Sensitivity Analyses (30 minutes)

Session 6: General Discussion and Next Steps (60 minutes)

December 3, 2008 Stakeholder Meeting: Economic Modeling Team Workshop, San Francisco, California

List of Commenters

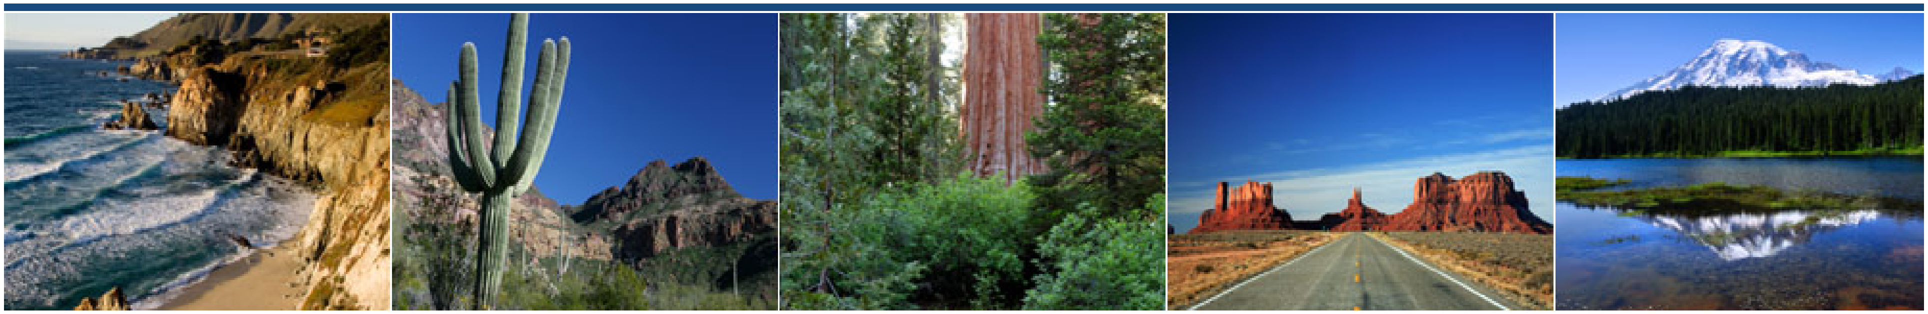
Sempra Energy

Sightline Institute

Van Horn Consulting

WEST Associates

Western Climate Initiative



Economic Modeling Team Workshop

December 3, 2008

San Francisco, California

Workshop Objectives

- Review and discuss WCI economic modeling to date
- Identify issues and concerns
- Plan for the next round of work

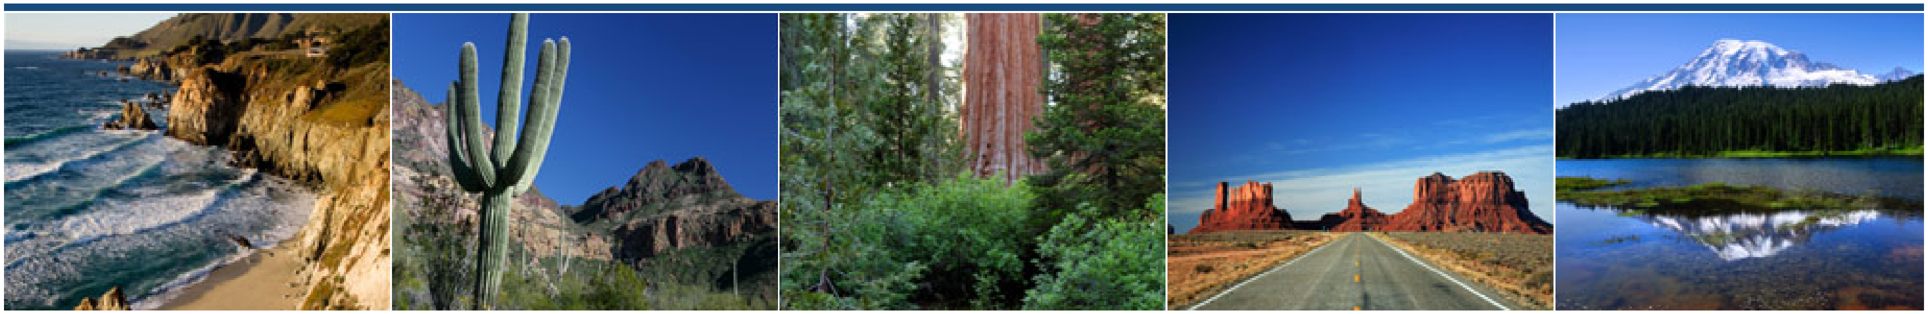
Documents Previously Made Available

- Workshop participants should be familiar with:
  - WCI Design Recommendations (esp. Appendix B)
  - Assumptions Book for ENERGY 2020
  - Documents posted for six conference calls (March to November 2008)
- All are available on the WCI Economic Analysis webpage:
  - http://www.westernclimateinitiative.org/Economic_Analysis.cfm
- In addition, detailed documentation of the ENERGY 2020 model is available at:
  - http://www.arb.ca.gov/cc/scopingplan/economics-sp/models/models.htm

Agenda

- Session 1: Understanding Outputs
- Session 2: Review of Reference Case
- Session 3: Review of Policy Cases
- Break
- Working Lunch (box lunches provided)
- Session 4: Electric Sector Results
- Session 5: Review of Sensitivity Analyses
- Session 6: General Discussion and Next Steps

Western Climate Initiative



Session 1: Understanding Outputs

Economic Modeling Team Workshop

December 3, 2008
San Francisco, California

Outline of Presentation

- Session objective: Review how to read and understand the model outputs.
- Topics:
  - Emissions, Compliance summary, Offsets and Banking
  - Total Energy Use, Electric Sector, Transportation Sector
  - Fuel Prices, Fuel Expenditures, Potential Allowance Value
  - Annualized Costs

Table B-5: Reference Case GHG Emissions

Table B-5: Reference Case Greenhouse Gas Emissions: Eight WCI Partners

GHG Emissions *(MMTCO2E)*	2006	2010	2015	2020	Growth Rate 2006-2020
Residential	49.7	53.7	58.4	63.1	1.7%
Commercial	29.3	30.5	30.7	31.8	0.6%
Energy Intensive Industry	176.8	174.5	181.5	191.0	0.6%
Other Industry	29.8	30.3	30.5	31.0	0.3%
Passenger Transport	290.8	299.4	303.9	294.0	0.1%
Freight Transport	93.0	89.6	89.9	91.7	-0.1%
Power Sector	176.6	166.8	160.0	176.9	0.0%
Waste & Wastewater	25.6	29.1	34.2	38.4	2.9%
Agriculture (non-energy)	59.9	62.1	67.5	74.9	1.6%
Total	**931.6**	**936.1**	**956.6**	**992.8**	**0.5%**

Total in 2006 is key determinant of cap as described on next slide.

Table B-12 GHG Emissions and Compliance Summary, 2020

- Setting the target:

  2020 Target =
  2006 value for WCI Sub-Total (931.6 Mt) +
  non-WCI Power Sector (70 Mt) =
  1001.6 Mt.

- Hitting the target. Case: "Broad, Comp Policies With Offsets." From Compliance Summary:

  Compliance Total =
  WCI Sub-Total (877.9) +
  Non-WCI Power Sector imports (70.0) +
  Non-WCI Power Sector Reductions (-37.0) +
  Offsets (-31.8) +
  Bank Flow (-31.8) =
  847.2 Mt (or 84.6% of 1001.6 Mt)

Table B-12: Cap-and-Trade Cases Greenhouse Gas Emissions and Compliance Summary: Eight WCI Partners

GHG Emissions in 2020 *(MMTCO2E)*	Reference Case	Broad, Comp Policies No Offsets			Broad, Comp Policies With Offsets			Narrow, Comp Policies With Offsets		
		Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff

Allowance Price (2007 $/MT)	**$0**	**$0**	**$6**	**$24**	
Percentage of Offsets Allowed	5%	5%	5%	5%	
Percent Allowable Offsets Used			**0%**	**100%**	
All emissions in million metric tons.					

Offsets and Banking

- Broad scope with offsets, year-by-year projections.
- Offset purchases ramp up as allowance price nears $20/ton.
- Banking *(see Appendix B, Attachment 1, p. 37)*
  - Banking is heavy at outset and declines as allowance price increases.
  - Bank flow turns negative when allowance price goes above $15/ton

Compliance Summary	2012	2013	2014	2015	2016	2017	2018	2019	2020
Offsets	-	-	-	-	-	(0.0)	(26.4)	(29.2)	(31.8)
Bank Flow	-	39.8	46.4	21.2	13.2	1.0	(5.4)	(9.8)	(31.8)
Bank Inventory	0.0	39.8	86.2	107.4	120.5	121.5	116.1	106.2	74.4
Allowance Price (2007 $/Ton)	**$5**	**$5**	**$6**	**$6**	**$7**	**$13**	**$19**	**$20**	**$24**

Total Energy Use (Table B-13)

- Presented by fuel and by sector
- In sectoral table, “Energy Intensive Industry” consists of:
  - Petroleum, Chemicals, Paper, Primary Metals, Non-Metallic Minerals, Mining, and Oil and Gas Extraction
- In sectoral table, “Agriculture” refers to fossil fuel energy use
  - Non-energy emissions are not capped.

Electric Sector, Transportation Sector

- Electric output tables include (Table B-14)
  - MW of capacity by fuel type (no retirements)
  - GWh of generation by fuel type <u>inside</u> WCI
  - Total sales in GWh by customer class (includes imports from outside WCI)
- Session 4 will discuss in more detail
- Proxy of First Jurisdictional Deliverer (FJD)
  - Incorporates all generation in the WECC

- Transportation sector outputs (Table B-15)

Fuel Prices (Table B-16)

- Reference case
  - Start with national price forecast, and add a mark-up for the cost of distribution and delivery of fuel to the partner-specific market.
  - Mark-up is based on historic patterns as estimated inside model.
  - Project a WCI average price by calculating a weighted average of the prices in the 8 partner jurisdictions.
- Cap-and-trade policy cases
  - Add an appropriate component to partner-specific prices reflecting the allowance price and the carbon content of the fuel.
  - Repeat weighted-average calculation for WCI.
- Fuel prices <u>include</u> a component reflecting allowance prices
  - Reasonable assumption regardless of degree to which allowances are auctioned vs. allocated without charge.

Fuel Expenditures, Potential Allowance Value

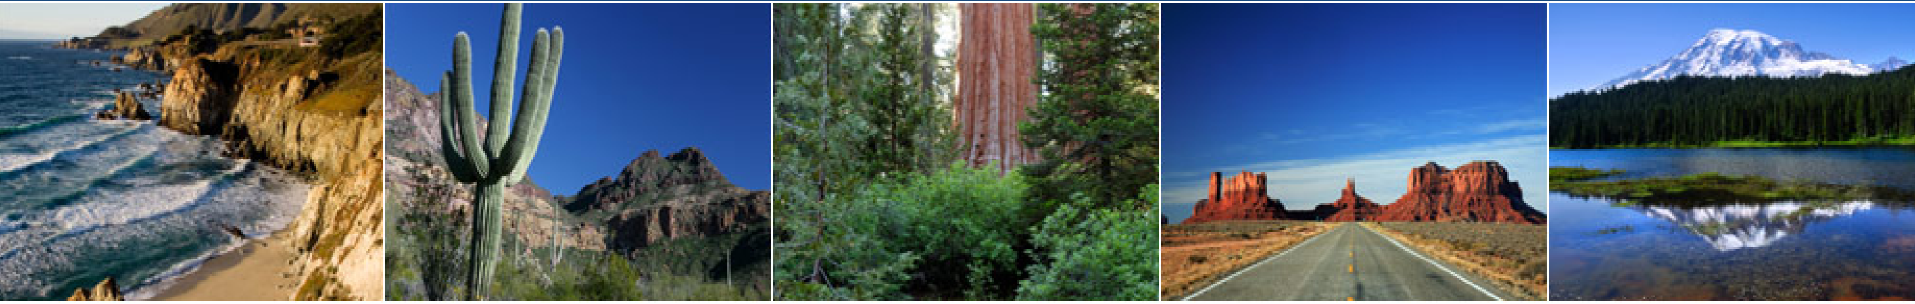
- Fuel expenditures generally do <u>not</u> reflect the price of allowances. (Table B-17)
  - Based on Reference Case fuel prices – no allowance price component
  - Exception: electricity expenditures
- “Potential Allowance Value” reflects the price of allowances and the costs they may impose on a sector. (Table B-18)
  - Projected as allowance price times sector emissions
  - Some or all of the potential value will be incurred by a sector, depending on how allowances are distributed, and the ability to pass on costs
  - When incurred it is an “accounting cost” (i.e., money is transferred), not an “economic cost” in the sense of consuming societal resources.

Annualized Costs (Table B-19)

- These are “compliance cost” estimates for reducing emissions under the cap-and-trade along with complementary policies.
- Annualized costs:
  - Consist of change in fuel expenditures plus annualized change in capital investment (5% real discount rate over life of equipment)
  - Electric sector costs are embedded in electricity prices
  - Do not include programmatic costs of complementary policies
  - Potential Allowance Value reported separately

Discussion

Western Climate Initiative



Review of Reference Case

Economic Modeling Team

December 3, 2008

San Francisco, California

Outline of Presentation:

1. Introduction
2. Key Inputs and Assumptions Used in Reference Case
3. Modeling Efficiency Investment Options
4. Modeling of Policies Included in the Reference Case
5. Review of Reference Case results
6. Discussion

1) Model Process Overview

PURPOSE OF REFERENCE CASE:

- Reference Case presents one possible future based on stated assumptions.
- Policy Cases are compared to the Reference Case to evaluate policy impacts
- Given uncertainties, sensitivity analysis is required:
  - Alternative Reference Cases
  - Implications for policy impacts

2) Key Inputs and Assumptions

Key Inputs and Assumptions Used in Reference Case

- Projected Economic Activity (from a macro-economic forecast)
  - GDP, Gross output by sector, personal Income
  - Several jurisdictions provided jurisdiction-specific demographic and economic forecasts *(See Appendix C of Assumptions Book for demographic & economic data for Arizona, California, New Mexico, and Washington).*
- Historical Data
  - Energy demand, supply, prices, and emissions by state/province
  - Electric generator data
- Projected Fuel Prices
  - For U.S. states: Assumes EIA AEO 2008 High Price Case (see table below)
  - Same forecast for Canadian provinces adjusted for differences in delivered cost.
  - Model calculates adder for delivered price for each jurisdiction based on historic relationship between wholesale and delivered prices.
- Projected Technology Cost and Performance
  - Power generation, vehicles, etc.
  - End-use and energy efficiency, including potential for improvements

2) Key Inputs and Assumptions (cont'd.)

Electric Sector

- Cost & Performance
  - Characteristics of new generation based on values from CPUC GHG modeling updated November 2007 *(Presented in Appendix G of Assumptions Book).*
- New Coal Capacity:
  - Assumed the completion of planned/committed coal capacity in the post-2005 period, based on public data sources and a review by the EMT *(units listed in Appendix F of Assumptions Book)*
  - Assumed no further coal construction within WECC beyond that listed in Appendix F.
- Inter-regional transmission capacity
  - based on FERC sources, supplemented with information supplied by the EMT *(see Appendix D in Assumptions Book)*
- Specific sources of public data used for electric generating capacity and operation data shown in section 4.5 of Assumptions Book *(tables on following slides).*
- ***Electricity sector modeling will be described in greater detail in later session.***

3) Modeling Efficiency Investment Options (cont'd.)

- New investments are assumed to achieve the level of efficiency specified in existing standards (e.g., Residential Device Standards – new gas furnaces must be at least 80% efficient).
- Standards changed over modeled period.
- Higher efficiency can be achieved at a cost.
  (i.e., Device Capital Cost in $/mmBtu/Year).
- Capital costs are presented on annualized basis based on the expected life of the investment.
- Upper limit for available efficiency specified as Maximum Device Efficiency.
  (i.e., Natural gas furnaces cannot exceed 97% efficiency – maximums may increase over time as technologies change).

3) Modeling Efficiency Investment Options (cont'd.)

- Model evaluates efficiency choice based on energy costs, capital and operating costs within range between minimum standard and maximum efficiency available.
- All standards, maximum efficiency levels, costs and equipment life are specified for each sector/fuel/end-use combination.
- Energy choices are modeled based on both price and non-price factors (doesn't assume optimal economic solution)
- Non-price factors include market imperfections as well as non-energy considerations (i.e. equipment features, etc.)

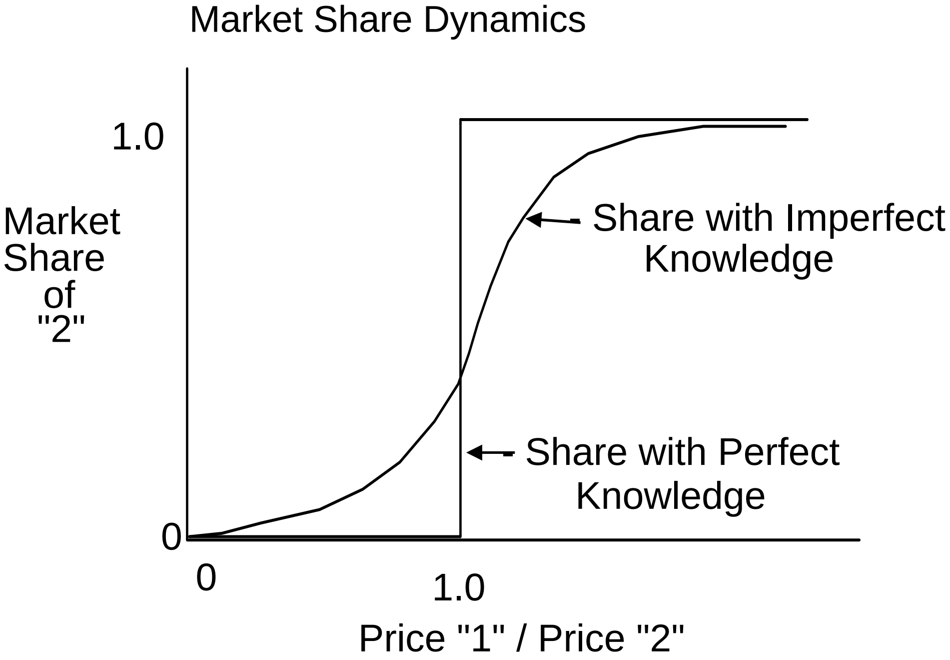
3) Modeling Efficiency Investment Options (cont'd.)

• Investment funds not necessarily allocated to the most economic energy option.

• Uncertainty, regional variations, and limited knowledge make the perceived price a distribution.

• Extent to which 'non-price' considerations affect choice revealed by historic choices: i.e. extent to which past choices varied from optimal economic choice.

• As shown in figure - If all decisions were based on optimal economic solution then choices would shift abruptly when one choice became more economic (perfect knowledge). ENERGY 2020 models imperfect knowledge.



3) Modeling Efficiency Investment Options (cont'd.)

Example 1: Additional water heating requirement

Steps:

- Fuel choice is modeled (fuel use choice actually involves evaluation of subsequent steps):
  - i.e. natural gas, electricity, LPG, oil, solar, etc.
- Portion of market which chooses natural gas for water heating can choose any level of efficiency from 59% (standard) to 86% (maximum).
- Amount of hot water service required (process requirements) may change based on policy and energy costs (e.g., efficient showerheads, front-loading washers, or choice to take shorter showers, etc.)

3) Modeling Efficiency Investment Options (cont'd.)

- Maximum efficiency allowable in model for Natural Gas Water Heater is 86%.

Maximum Device Efficiency							
(Btu/Btu)	Electric	N.Gas	Coal	Oil	Biomass	LPG	Steam
Primary Heat	278%	97%	97%	97%	78%	97%	99%
Water Heating	250%	86%	97%	97%	78%	97%	99%

- Minimum level of efficiency allowable for Natural Gas water heater is 59% (Standard for new NG water heaters).

Device	
Gas hot water from 1990 to the final year	59%
Oil hot water from 1990 to the final year	51%
Electric hot water from 1990 to the final year	92%
LPG hot water from 1990 to the final year	59%

- *from line tables in Appendix J of Assumptions Book.*

3) Modeling Efficiency Investment Options (cont'd.)

Example 1: Additional water heating requirement

Steps:

- The model compares the cost of the water heater efficiency ($36/mmBtu/Year in 2007$) and the additional O&M costs ($0 in this case) vs. the cost of energy saved over the assumed life of the water heater (15 years). Capital cost is equivalent to about $650 for a water heater for an average home.
- For a household using 18 mmBtu/year for water heating, increasing efficiency from 60% to 80% would save about 4.5 mmBtu per year.
- The $162 cost for this efficiency increase *(4.5mmBtu x $36/mmBtu/year)* would be compared to the value of the energy saved as part of the efficiency decision (including applicable carbon permit costs).
- Assuming a cost of $11.50/mmBtu for natural gas, savings over the life of the water heater would equal $776. (4.5mm Btu x 11.50x15 years).

4) Reference Case Programs/Policies

The Reference Case assumes that the provisions of the following policies are implemented in the period modeled:

- Energy Independence & Security Act - 2007
  - New CAFE standards
  - Biofuels mandate (state share assumed constant)
  - Residential boiler and furnace fan standards
  - Walk-in cooler and freezer standards
  - Electric motor efficiency standards
  - External power supply efficiency standards
  - Energy efficient light bulbs
  - Metal halide lamp fixtures
- State Renewable Portfolio Standards currently in place
- Canadian bio-fuels requirements per ecoENERGY for Biofuels/Renewable Fuels Strategy

4) Reference Case Programs/Policies

EISA – Modeling Assumptions

- **Vehicle Efficiency** - Marginal passenger car/light truck efficiency increased by a percentage each year starting in 2011 to reach the mandated fleet efficiency in 2020.
- **Renewable Fuels**:
  - The Act specifies a minimum volume of biofuels to be produced each year.
  - For modeling purposes we have assumed that this volume of biofuels is produced and consumed in each year.
  - Model assumes that each US state will use their pro-rata share of the available fuels.
- **Residential Boilers**: Savings calculated based on ACEEE estimates. Estimates of energy savings associated with furnace fans not included.
- **Walk-In Coolers and Freezers**: Savings calculated based on ACEEE estimates.

4) Reference Case Programs/Policies

EISA – Modeling Assumptions

- Electric Motor Efficiency Standards:
  - Savings calculated based on ACEEE estimates.
- External Power Supply Efficiency Standard:
  - Savings calculated based on ACEEE estimates.
- Energy Efficient Light Bulbs:
  - Implementation of efficiency light bulbs based on assumption that general service lighting accounts for about 90% of residential lighting, 10% of commercial lighting and 5% of industrial lighting.
  - Assumes that CFL’s are used in percentage of existing fixtures.
- Metal Halide Lamp Fixtures:
  - Assumes that 15% of commercial lighting and 60% of industrial lighting now use metal halide fixtures. For new installations the model assumes that 80% of this market would use pulse start ballasts.

4) Reference Case Programs/Policies

Other Policies – Modeling Assumptions

Canadian Biofuels

- 5% renewable content in gasoline required starting in 2010
- 2% average renewable content in diesel fuel and heating oil (distillate) by 2012.

Renewable Portfolio Standards

- All existing RPS for all WECC states and provinces incorporated in model for Reference Case.
- Assumes RPS requirements in any jurisdiction can be met from sources anywhere within WECC
- Provisions of RPS included in model are listed in Appendix I of Assumptions Book.
- Utah RPS not incorporated – will be added in next phase.

5) Reference Case Results

Table B-5: Reference Case Greenhouse Gas Emissions: Eight WCI Partners

GHG Emissions *(MMTCO2e)*	**2006**	**2010**	**2015**	**2020**	**Growth Rate 2006-2020**

5) Reference Case Results

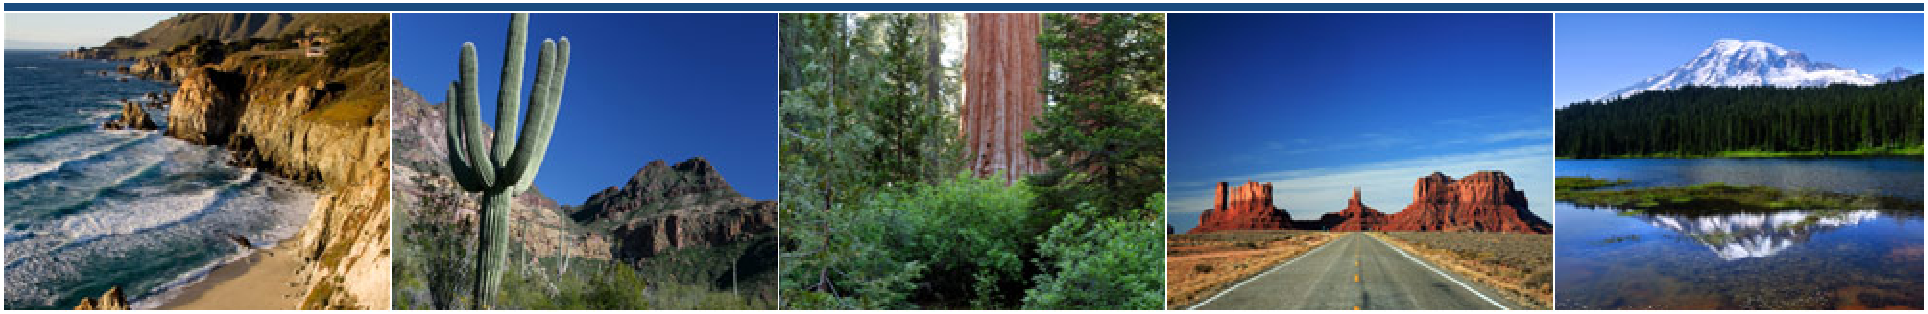
Table B-10: Reference Case Fuel Expenditures: Eight WCI Partners

Summary of Fuel Expenditures (M$/Yr)					
Sector	**2006**	**2010**	**2015**	**2020**	**Growth Rate 2006-2020**
Residential	31,763	37,523	40,670	45,609	2.6%
Commercial	28,452	31,306	31,632	35,373	1.6%
Energy Intensive Industry	28,969	31,248	30,889	32,725	0.9%
Paper	3,709	3,688	3,424	3,514	-0.4%
Chemicals	3,752	4,157	4,215	4,738	1.7%
Petroleum	13,143	14,240	14,295	15,525	1.2%
Nonmetallic Minerals	2,374	2,613	2,614	2,843	1.3%
Primary Metals	2,150	2,262	2,180	2,467	1.0%
Mining Except Oil and Gas	540	524	445	472	-1.0%
Oil and Gas Extraction	3,302	3,764	3,716	3,166	-0.3%
Other Industry	14,567	16,511	16,988	18,496	1.7%
Passenger Transportation	82,031	93,848	103,830	110,035	2.1%
Freight Transportation	28,315	30,055	32,280	35,567	1.6%
Agriculture	3,140	3,142	2,819	2,848	-0.7%
Power Sector	-	-	-	-	n.a.
Waste & Wastewater	-	-	-	-	n.a.
Total	**217,237**	**243,632**	**259,107**	**280,654**	**1.8%**

Note – Table originally presented in September 23 report was subsequently updated on WCI web site on November 10. The incorrect estimates were only used in Table B-10 and did not affect the comparisons of the Reference Case to the policy cases or the sensitivity cases.

Discussion

Western Climate Initiative



Session 3: Review of Policy Cases

Economic Modeling Team Workshop

December 3, 2008

San Francisco, California

Outline of Presentation

- Objective of session: Review Policy Cases
- Topics:
  - Policy Questions
  - Modeling of Cap and Trade
  - Modeling of Complementary Policies
  - Model Results

Policy Questions

- Program Scope: Narrow vs. Broad
- Offsets: Limits
- Banking
- Role of Complementary Policies

Policy Questions

	Two Complementary Policy Cases		Three Cap and Trade Cases		
Scope			Broad	Broad	Narrow
Offsets			No	5%	5%
Banking			Yes	Yes	Yes
Clean Car Standards	Yes	Yes	Yes	Yes	Yes
VMT Reductions	No	Yes	Yes	Yes	Yes
Energy Efficiency	No	No	Yes	Yes	Yes

What We Learned

- Banking
- Offsets
- Complementary Policies:
  - Clean Car Standards
  - VMT
  - Energy Efficiency
- Allowance Prices and Potential Allowance Value
- Compliance Costs

Modeling of Complementary Policies

- Broad-based energy efficiency programs
  - Improved end-use energy efficiencies for electricity and natural gas in iterative fashion until 1% reduction from Reference Case was achieved.
  - Examples provided:
    - **Water heating**
    - **Commercial lighting**
- Clean Car Standards and VMT Reduction
  - Simulated adoption of Clean Car Standards in all partner jurisdictions
  - Improved “process efficiency” in passenger transportation until 2% reduction in 2020 was achieved (WCI-wide)
  - Example provided of both

Example 1 – Natural Gas Water Heat for SF Dwellings

Under the Complementary Policies, by 2020, Natural Gas domestic water heating (DHW):

- Market share for NG decreases 5% - due to increase in solar DHW increases and slight increase in electric DHW
- Process efficiency
  - increases 9% at the margin; 4% on average.
- Process energy requirement for NG decreases by 8%
- Device efficiency
  - Marginal efficiency rises to 70%
  - Average efficiency increases by 8% to 65% on average.
- Energy use for NG water heating decreases by 15% (reduced market share, increased process and device efficiency)
- Device capital cost decreases 6% - reflecting decrease in process requirement offset by increases in device costs.

Example 2: Commercial Lighting

- Lighting requirement may be modified by change in process efficiency (e.g., controls, improved daylighting).
- Device efficiency can increase due to standards or the selection of more efficient lighting at the margin (e.g., CFL lamps, T8’s/electronic ballasts, etc.).

Example 2: Lighting – FIRE* sector

Reference Case

- Average efficiency rises 6% (2005 -2020)

Complementary Policies – by 2020

- Process Efficiency increases 9% on margin, 7% on average
- Device Efficiency increases 19% on margin, 14% on average.
- Energy requirements (mmBtu/year) decrease 18%
- Capital Costs increase by 30% per mmBtu/year
- Device investments increase by 19%.

* FIRE = Finance, Insurance & Real Estate

Example 3: Passenger Transportation

- Transportation requirements (VMT) driven by households and personal income
- May be met by choice of transportation modes or vehicle types.
- CAFE standard in EISA included in Reference Case
- Clean Cars standards included in Complementary Policies.
- Non-price factors tend to dominate vehicle choice

Example 3: Passenger Transportation

Complementary Policies – Change from Reference Case

- No Change to Fuel Prices
- Vehicle efficiency increases 18% at the margin, 15% on average reflecting CA Cars policy.
- VMT decreases by 1.1% reflecting policies aimed at travel demand management.
- Total energy requirements for passenger transportation decreases by 17%.
- Changes in Vehicle Device Investments

Modeling Cap-and-Trade

- Review setting the target:

  2020 Target =
  2006 value for WCI Sub-Total (931.6 Mt) +
  non-WCI Power Sector (70 Mt) =
  1001.6 Mt.

- Hitting the target. Case: "Broad, Comp Policies With Offsets." From Compliance Summary:

  Compliance Total =
  WCI Sub-Total (877.9) +
  Non-WCI Power Sector imports (70.0) +
  Non-WCI Power Sector Reductions (-37.0) +
  Offsets (-31.8) +
  Bank Flow (-31.8) =
  847.2 Mt (or 84.6% of 1001.6 Mt)

Modeling Cap-and-Trade (cont.)

- Model varies the allowance price and iterates to reach a price that results in hitting the target
- Firms and households are simulated as
  - Reducing energy demand
  - Switching to lower-carbon fuel sources
  - And/or taking other mitigation actions

Review of GHG Emissions and Compliance

- See Table B-12 next slide
- Impacts on various sectors of the three cap-and-trade cases are in line with intuition.
- Limit on reduction credit from non-WCI power sector is reached in two of three cases.
- Use of offsets is lower under Narrow vs. Broad Scope.
    - Seems counterintuitive.
    - But both cases use full 5% offsets allowed in 2020, but Narrow Scope is working off a smaller base.
- Banking balance is depleted under Narrow Scope, but healthy in other two cases

Table B-12: GHG Emissions and Compliance Summary

Table B-12: Cap-and-Trade Cases Greenhouse Gas Emissions and Compliance Summary: Eight WCI Partners

GHG Emissions in 2020 *(MMTCO2E)*	**Reference Case**	**Broad, Comp Policies No Offsets**			**Broad, Comp Policies With Offsets**			**Narrow, Comp Policies With Offsets**		
		Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff

All emissions in millions of metric tons.										

Review of Total Energy Use

- See Table B-13 next slide
- Impacts on various fuels are in line with intuition
  - Coal and natural gas
  - Transportation fuels
- Impacts on sectoral energy use are in line with intuition
  - Power sector
  - Industrial sectors
  - Transportation
  - Residential and commercial

Table B-13: Cap-and-Trade Cases Energy Use: Eight WCI Partners

	Reference Case	Broad, Comp Policies No Offsets			Broad, Comp Policies With Offsets			Narrow, Comp Policies With Offsets		
		Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff

Power Sector	3,450	2,626	(824)	-23.9%	2,727	(724)	-21.0%	2,539	(912)	-26.4%
Total	**16,086**	**13,788**	**(2,298)**	**-14.3%**	**13,911**	**(2,176)**	**-13.5%**	**13,718**	**(2,369)**	**-14.7%**

Electric Sector (Table B-14)

- This the focus of Session 4.

Transportation Sector (Table B-15)

- Narrow scope:
  - Excluded from narrow scope cap
  - Clean Car Standards take vehicle efficiency to higher levels
  - VMT reduction policies reduce passenger transportation demand (but not freight)
  - Net reduction in VMT is less than 2% target because higher MPG vehicles encourage people to drive more
- Broad scope
  - Allowance prices increase fuel prices and lead to additional small decreases in VMT, and some decrease in freight demand
  - No measurable effect on vehicle efficiency at projected allowance prices.

Table B-15: Transportation Sector

Table B-15: Cap-and-Trade Cases Transportation Sector Results: Eight WCI Partners

	Reference Case	Broad, Comp Policies No Offsets			Broad, Comp Policies With Offsets			Narrow, Comp Policies With Offsets		
		Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff
Distance Travelled in 2020 *(millions of vehicle miles travelled)*										
Passenger	678,750	672,238	(6,512)	-1.0%	672,665	(6,085)	-0.9%	673,720	(5,031)	-0.7%
Freight	82,189	81,516	(673)	-0.8%	81,715	(474)	-0.6%	82,189	-	0.0%
Passenger: Miles/person	8,844	8,759	(85)	-1.0%	8,765	(79)	-0.9%	8,778	(66)	-0.7%
Vehicle Efficiency in 2020 *(miles/gallon)*										
Light Gas Vehicles	28.5	33	4	15.3%	33	4	15.4%	33	4	15.3%
Medium Gas Vehicles	28.4	33	4	15.3%	33	4	15.3%	33	4	15.3%
Heavy Gas Vehicles	20.4	24	4	17.4%	24	4	17.5%	24	4	17.5%
Heavy Diesel Vehicles	20.3	24	4	17.5%	24	4	17.5%	24	4	17.5%
Vehicle efficiency represents a fleet-wide average, not the average for new vehicles.										

Fuel Prices (Table B-16)

- Generally, percentage changes in non-electric prices are in line with intuition.
- Changes in electricity prices are more complicated and discussed in Session 4.

Table B-16: Cap-and-Trade Cases Fuel Price Results: Eight WCI Partners

Prices in 2020 (2007 $/mmBtu)	Reference Case	Broad, Comp Policies No Offsets	Broad, Comp Policies With Offsets	Narrow, Comp Policies With Offsets
	Price	Percent Diff	Percent Diff	Percent Diff
Residential				
Res Electricity Prices	30.1	-0.3%	1.0%	12.7%
Res Natural Gas Prices	14.5	31.4%	12.2%	1.0%

Res LPG Prices	21.6	14.6%	5.6%	0.0%
Commercial				
Com Electricity Prices	27.3	-2.4%	-0.2%	14.3%
Com Natural Gas Prices	10.1	23.7%	7.9%	-1.0%
Com Oil Prices	24.6	4.9%	2.1%	0.4%
Com LPG Prices	21.4	9.2%	4.4%	1.3%
Industrial				
Ind Electricity Prices	15.4	4.7%	6.6%	35.6%
Ind Natural Gas Prices	6.3	19.2%	7.1%	20.2%
Ind Coal Prices	2.1	167.4%	64.3%	182.4%
Ind Oil Prices	20.7	17.2%	6.5%	19.4%
Ind LPG Prices	23.1	6.2%	2.9%	7.0%
Transportation				
Gasoline Prices	28.0	17.4%	6.6%	0.0%
Diesel Prices	27.7	16.8%	6.4%	0.0%

Fuel Expenditures (Table B-17)

- **Allowance costs are incorporated into electricity expenditures, but not into other fuels.**
- **This causes some some mixed effects, and some are counterintuitive.**
- **Most significant result is very large fuel savings in passenger transportation.**

Table B-17: Fuel Expenditures

Table B-17: Cap-and-Trade Cases Fuel Expenditure Results: Eight WCI Partners

Annual Fuel Expenditures in 2020 (M$/Yr)	Reference Case	Broad, Comp Policies No Offsets			Broad, Comp Policies With Offsets			Narrow, Comp Policies With Offsets		
		Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff	Value	Diff from Reference	Percent Diff
Sector										
Residential	45,609	39,918	(5,691)	-12.5%	40,244	(5,365)	-11.8%	43,138	(2,471)	-5.4%
Commercial	35,373	28,861	(6,512)	-18.4%	29,356	(6,017)	-17.0%	32,098	(3,275)	-9.3%
Energy Intensive Industry	32,725	29,018	(3,707)	-11.3%	29,119	(3,606)	-11.0%	29,831	(2,894)	-8.8%
Other Industry	18,496	17,001	(1,495)	-8.1%	17,062	(1,434)	-7.8%	17,977	(519)	-2.8%
Passenger Transportation	110,035	96,146	(13,889)	-12.6%	96,251	(13,784)	-12.5%	96,577	(13,458)	-12.2%

Agriculture	2,848	2,482	(366)	-12.8%	2,499	(349)	-12.2%	2,669	(178)	-6.3%
Total	**280,654**	**248,358**	**(32,296)**	**-11.5%**	**249,641**	**(31,012)**	**-11.0%**	**257,859**	**(22,794)**	**-8.1%**

Potential Allowance Value

- To review: “Potential Allowance Value” reflects the price of allowances and the costs they may impose on a sector. (Table B-18)
  - Projected as allowance price times emissions, by sector
  - Some or all of this potential value will become a cost incurred by a sector, depending on how allowances are distributed, and the ability of businesses to pass on costs to customers
  - When incurred it is an “accounting cost” (i.e., money is transferred), not an “economic cost” in the sense of consuming societal resources.

Table B-18: Potential Allowance Value

Table B-18: Cap-and-Trade Program Potential Allowance Value: Eight WCI Partners

Allowance Value in 2020 (M$)	Broad, Comp Policies No Offsets	Broad, Comp Policies With Offsets	Narrow, Comp Policies With Offsets
	Diff from Reference	Diff from Reference	Diff from Reference
Sector			
Residential	$3,445	$1,321	$0
Commercial	$1,641	$631	$1,925
Energy Intensive Industry	$10,922	$4,188	$12,293
Other Industry	$1,681	$647	$1,873
Passenger Transportation	$16,197	$6,199	$0
Freight Transportation	$5,630	$2,164	$0
Agriculture	$0	$0	$0
Total	**39,516**	**15,150**	**16,092**
Potential allowance value is calculated as the allowance price times the emissions in the sector. The full allowance value may not be incurred in each sector depending on the manner in which allowances are distributed and the ability to pass allowance costs to customers.			

Annualized Costs (Table B-19)

- These are "compliance cost" estimates for reducing emissions under the cap-and-trade along with complementary policies.
- Review -- Annualized costs:
  - Consist of change in fuel expenditures plus annualized change in capital investment (5% real discount rate over life of equipment)
  - Electric sector costs are embedded in electricity prices
  - Do not include programmatic costs of complementary policies
  - Potential Allowance Value reported separately
- Projected costs:
  - for two industrial sectors are positive
  - for other sectors are negative, and for economy as a whole

Table B-19: Annualized Costs

Table B-19: Cap-and-Trade Cases Cost Results: Eight WCI Partners

Annualized Costs in 2020 (M$/Yr)	Broad, Comp Policies No Offsets	Broad, Comp Policies With Offsets	Narrow, Comp Policies With Offsets
	Diff from Reference	Diff from Reference	Diff from Reference
Sector			
Residential	(6,443)	(6,158)	(3,327)
Commercial	(7,845)	(7,369)	(4,760)
Energy Intensive Industry	10,935	10,908	12,674
Other Industry	1,979	1,996	3,250
Passenger Transportation	(20,988)	(20,511)	(19,005)
Freight Transportation	(722)	(522)	0
Agriculture	(442)	(425)	(254)
Total	**(23,525)**	**(22,080)**	**(11,422)**

These costs do not include costs of VMT Reduction programs, Energy Efficiency programs, nor Potential Allowance Value.

- Electric Prices

Electric Sector Inputs

- Peak Load and Energy from Demand Sector
- Fuel Prices from Supply Sector
- New Plant Data – Capital, O&M and Fuel Costs and Heat Rate
- Outage Rates and Must Run
- Financial Parameters
- Regulatory Environment
- Transmission Network – Capacity, Losses, Prices
- Expansion Plan for “Large” Plants

Electric Sector Outputs

- Generating Capacity
- Generation
- Fuel Use and Emissions
- Electric Prices
- Transmission Flows
- Imports and Exports

Electric Plant Types

- Gas/Oil Peaking
- Gas/Oil Combined Cycle
- Gas/Oil Steam
- Coal
- Advance Coal
- Nuclear
- Base Hydro
- Peak Hydro
- Biomass
- Landfill Gas/Waste
- Wind
- Solar
- Fuel Cells
- Pumped Hydro
- Small Hydro
- Wave
- Geothermal
- Other Storage
- Coal with CCS
- Biogas
- Trash
- Other Generation

Individual Units

- Data for most individual plants and units
- Allows greater variety of technologies – just need to have the technological parameters for each type of plant.

Capacity Expansion

- Specify any Known or Expected Construction
- Economic Decision - Build when Wholesale Prices are higher than Cost of New Plant
- Reserve Margin Decision – Build to meet a Desired Reserve Margin
- Mixed Decision - Build when Price is high and Capacity is needed
- Imperfect Market Information – overbuilding
- Renewable Portfolio Standards

Generation Bids and Costs

- Bid Available Capacity
  - Outage Rates
- Bid Prices
  - Marginal Cost
  - Full Cost
  - Other (must run bid zero)
  - Emission Costs
- Bilateral Contract Costs
  - Capital Costs
  - Fuel and O&M Costs
  - Emission Costs

Electric Generation

- Dispatches peak hydro to maximize value of water
- Dispatches plants to minimize costs of bids subject to:
  - Capacity Limits
  - Transmission Constraints
  - Loads
  - Transmission Losses

Fuels Use and Emissions

- Fuel Use is based on Generation and Heat Rates for each unit
- Emissions are based on Fuel Usage and Emission Factors for each unit.
- Emission Reduction Equipment may be added to each unit.

Electric Prices

- LSE Power Costs
  - Bilateral Contracts (dominates)
  - Purchases from Wholesale Market
- LSE Other Costs
  - Distribution
  - Transmission
  - Other Costs (Regulatory)
- RPS Costs
  - Wholesale Price versus RPS Costs

Generator and LSE

- Electric Prices based on LSE costs.
- LSE purchase only the power they need.
- Generators bear brunt of over-building.
- Generators costs have not yet been reported.

Electric Prices and Permit Costs

- Permits costs are passed from the generator to the LSE through:
  - Wholesale Prices
  - Bilateral Contract – variable costs
- The LSE passes the Permit costs to the ratepayer.
- The costs passed on to the ratepayer will depend on the allocation scheme
- Current assumption is 100% auction.

Proxy of First Jurisdictional Deliverer (FJD)

- All WCI generation is subject to the cap.
- Emissions from non-WCI generation are capped at Reference Case levels to prevent leakage.
- Reduced electricity demand in WCI leads to reduced power imports and thus reduced emissions from non-WCI generation.
  - “Credit” for such reduced emissions is limited to 45 Mt in calculating compliance with WCI target

Electric Sector Results

- See Tables B-7 and B-14 (next slides)

- Note: Complementary Policies case inadvertently caused overbuilding of Gas CC plants.
  - This will be corrected in next round of analysis

Table B-7: Reference Case Electric Sector Results: Eight WCI Partners

Generation Capacity *(MW)*	2006	2010	2015	2020	Growth Rate 2006-2020

Electric Sector Results (cont.)

- Next slides show some key results graphically for four cases: Reference Case and 3 Policy Cases
  - Total Generation decreases slightly (and by about the same amount) in the 3 Policy Cases in response to demand reductions
  - Three types of generation are virtually unaffected by the 3 Policy Cases: Hydro, Nuclear, and "Misc" (Landfill Gas/EFW/Other)
  - The lines representing the four cases for these three generation types appear to be a single line in the graph due to lack of variation. In contrast, natural gas, coal, and wind show far more variation.
- Natural Gas and Coal
  - Cap & Trade displaces coal with gas combined cylce as one would expect when a price is put on GHG emissions.
- Wind
  - Demand reduction from complementary policy reduces total electricity sales.
  - Decline in GWh sales reduces the RPS requirement, hence less wind capacity and wind generation.

Electric Prices

- Complementary Policies (implemented alone) would reduce electric prices
  - Reduction in sales enables a higher percent of generation to come from lower cost resources (hydro, nuclear). This would reduce prices.
- However, Cap & Trade Policies generally would increase electric prices.
  - Net effect would vary significantly by customer class due to different load profiles
  - Largest increases appear in "Narrow, Comp Policies, With Offsets"

- Projections below excerpted from Table B-16.

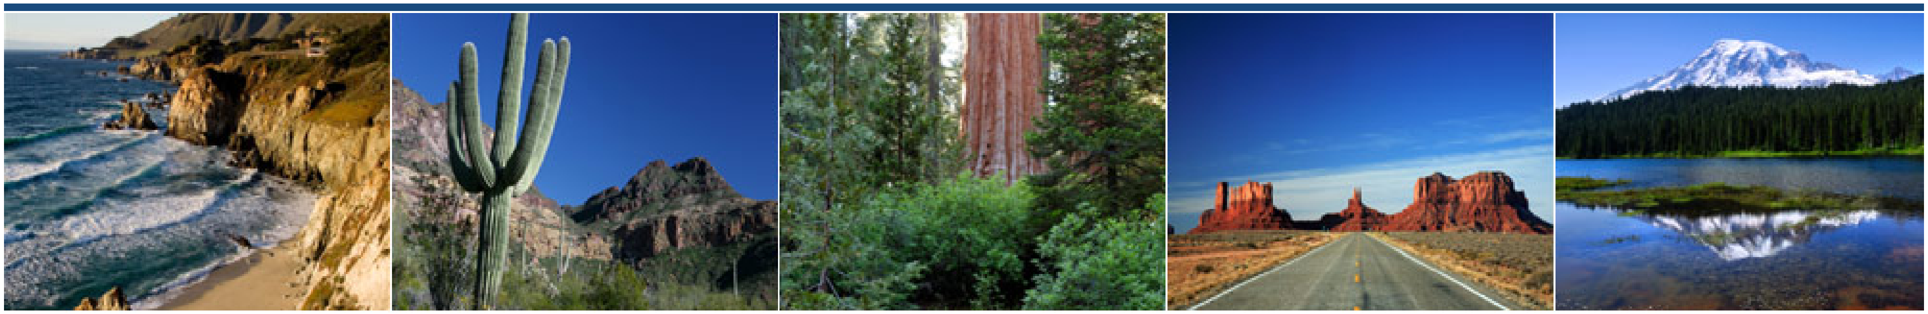
Pct Change in 2020 Electricity Prices by Customer Class	Broad, Comp Polices, No Offsets	Broad, Comp Polices, With Offsets	Narrow, Comp Polices, With Offsets
Residential	-0.3%	1.0%	12.7%
Commercial	-2.4%	-0.2%	14.3%
Industrial	4.7%	6.6%	35.6%

Emissions and Fuel Usage

- How can fuel usage grow faster than emissions?
  - Biomass fuel usage increases
  - There is a shift to newer more efficient natural gas plants with a reduction in oil/gas steam plants and oil/gas combustion turbines.

Discussion

Western Climate Initiative



Session 5: Sensitivity Analysis

Economic Modeling Team Workshop

December 3, 2008

San Francisco, California

Outline of Presentation

- Review assumptions in Sensitivity Analyses
- Review results

Three Sensitivity Cases

- High Energy Prices and High Generation Costs Case
  - Energy prices increase by 50% (real) between now and 2020
  - Capital and O&M costs for generation are 30% higher than Reference Case
- Low Energy Price Case
  - Energy prices are as projected in the mid-price case in EIA Annual Energy Outlook 2008. (Reference Case uses high price case.)
- High Natural Gas Price Gas
  - Assumes that cap-and-trade leads to higher natural gas prices (endogenous)
  - Assumes that natural gas prices increase by 50% real between now and 2020
  - Note: projections for three Policy cases resulted in lower natural gas demand
- All three sensitivity cases were applied to cap-and-trade design of broad scope, complementary policies, with offsets

Fuel Prices: High and Low Cases

Table B-20: Fuel Price Forecast:
High Energy Prices and High Generation Costs Sensitivity Case

	2006	2010	2015	2020
World Oil Price (2007 US$/barrel)	64.21	120.37	143.52	166.67
Natural Gas Wellhead Price (2007 US$/mmBtu)	5.97	11.12	13.26	15.40
Coal Prices (2007 US$/ton)	28.98	41.47	48.52	55.90

Table B-21: Fuel Price Forecast: Low Energy Price Sensitivity Case

	2006	2010	2015	2020
World Oil Price (2007 US$/barrel)	$64.21	$71.60	$57.88	$57.74
Natural Gas Wellhead Price (2007 US$/mmBtu)	$5.97	$7.11	$6.09	$6.25
Coal Prices (2007 US$/ton)	$25.37	$26.66	$23.53	$22.33

Sensitivity Analyses

Excerpt from Table B-22 on three sensitivity analyses

- First and second cases have exogenous price changes that change the Reference Case emissions projection
- Third case has endogenous natural gas price increase, so Reference Case emissions stay the same

- Compare with allowance price of $24/ton with Reference Case fuel prices

GHG Emissions in 2020 *(MMTCO2E)*	Original Reference Case	High Energy Prices & Generation Costs			Low Energy Prices			High Natural Gas Prices		
		Ref Case	Cap-Trade Case	Diff	Ref Case	Cap-Trade Case	Diff	Ref Case	Cap-Trade Case	Diff
WCI Sub-Total	**992.8**	**931.8**	**833.3**	**-98.6**	**1011.4**	**857.0**	**-154.5**	**992.8**	**865.4**	**-127.4**

Percent of 2006 Emissions			*84.7%*			*84.6%*			*85.1%*	
Bank Inventory			30.8			0.1			168.4	
Allowance Price (2007 $/MT)			**$18**			**$56**			**$20**	

Results

- See next slide, table B-30
- As expected, higher energy and generation costs lead to lower allowance price, greater fuel savings, and greater total savings.
  - Vice versa for lower energy prices
- Illustrates importance of looking at full range of outputs, not just allowance price

Table B-30: Summary Results for 2020: Eight WCI Partners

Case	GHG Emission (MMTCO2E)	Offsets Used (MMTCO2E)	Allowance Price (2007 $)	Change in Fuel Expenditures ($M/Yr)	Potential Allowance Value ($M/Yr)	Total Costs (Savings) ($M/Yr)
Reference Case	992.8	--	--	--	--	--
Cap-and-Trade Policy Cases						
Broad Scope, No Offsets	859.2	--	$63	(32,296)	39,516	(23,525)
Broad Scope, With Offsets	877.9	31.8	$24	(31,012)	15,150	(22,080)
Narrow Scope, With Offsets	847.8	18.2	$71	(22,794)	16,092	(11,422)
Sensitivity Cases						
High Price	833.3	12.7	$18	(42,736)	10,521	($30,514)
Low Price	857.0	34.1	$56	(22,598)	35,642	($16,245)
High Natural Gas Price	865.4	26.6	$20	(6,525)	12,434	$7,880

Fuel Expenditures and Total Costs (Savings) are changes from Reference Case values.
Potential Allowance Value calculated as emissions times allowance price.
Total Costs (Savings) do not include costs of VMT Reduction programs, Energy Efficiency programs, nor Potential Allowance Value.

Discussion

Session 6: General Discussion / Next Steps

Economic Modeling Team Workshop

December 3, 2008

San Francisco, California

Future modeling

- Workplan for Economic Modeling Team is under development
  - Input is welcome
- Draft workplan includes:
  - Expand model to include Manitoba, Ontario, and Quebec.
  - Repeat analyses released in September to include all partners.
  - Conduct additional analyses:
    - Policy Cases
    - Sensitivity Cases

Discussion

Questions for the December 10 Stakeholder Discussion on Default Emission Factors for Unspecified Imports[1]

The purpose of this stakeholder call is to help the Electricity Subcommittee develop recommendations to the WCI Partners on the development of default emission factors. There are several issues we hope to cover during call, related to the number of factors needed, calculation methodologies, and other implementation questions. The following questions will be used to help structure the discussion.

1. Geographic disaggregation
   - The straw proposal suggested that default factors be developed for five different import zones: Alberta, western U.S., Baja California, central U.S./Canada, and northeastern U.S. Are more (or fewer) zones needed?
2. Temporal disaggregation
   - Is more than one factor needed for each geographic zone to represent time-of-day or seasonal variation in resources used for export from non-WCI states and provinces or is one factor sufficiently accurate?
3. Methodology for calculating default factors
   - How sophisticated does the methodology need to be? Would a simplified load duration curve approach be acceptable or are more complex production cost models necessary?
   - Alternatively, should a high default emission factor be used?
4. Implementation questions
   - What data are available related to unspecified WCI imports and the resources used to generate the imported power?
   - How far in advance should the default factors be announced?
   - How frequently should the default factors be updated? Every year or every compliance period?

---

Western Climate Initiative

ELECTRICITY SUBCOMMITTEE DISCUSSION PAPER ON RENEWABLE PORTFOLIO STANDARDS, RENEWABLE ENERGY CERTIFICATES, AND GHG ACCOUNTING

December 8, 2008

Scott Murtishaw, California PUC

Introduction

Twenty-six states and the District of Columbia have adopted Renewable Portfolio Standards (RPS) that require retail providers of electricity to meet a minimum share of their loads with renewable energy sources. In order to simplify RPS compliance accounting and minimize locational constraints on renewable development, many RPS programs use Renewable Energy Certificates (RECs) to track compliance. Now that several states and provinces have implemented, or are in the process of implementing, greenhouse gas (GHG) cap and trade systems that cover electricity generation, questions have arisen concerning the appropriate role that RECs should play with respect to GHG accounting in a cap-and-trade system.

Much of the current confusion stems from the fact that some states have defined a REC as including “avoided emissions” of GHGs among the environmental attributes contained in a REC. With the impending need to develop reporting rules for the WCI Partners, it is becoming increasingly important to clarify what value the “avoided emissions” attribute conveys and how RECs may affect a purchasing entity’s GHG compliance obligation.

This discussion paper addresses the relationship between GHG accounting and RECs used for RPS compliance, as well as the “null” power that remains when RECs have been unbundled and sold separately. It does not address two related topics. First, some parties have suggested that RECs be accepted as a form of offset to reduce regulated entities’ GHG compliance obligations. While some REC definitions may allude to “avoided emissions,” recent publications have expressed serious misgivings about the direct use of RECs as offsets (Gillenwater 2007; Point Carbon 2008). Objections are raised on two accounts: 1) estimates of avoided emissions are rarely subject to a rigorous calculation taking into account both short-term (“operating margin”) and longer-term (“build margin") effects and 2) the issuance of RECs is not subject to additionality analysis. A final consideration is that since offsets must come from outside the scope of the capped sectors, the possibility of using RECs as an offset equivalent would be limited to RECs produced by facilities located in uncapped jurisdictions.

The second topic not addressed here is the possible creation of allowance set-asides to support the voluntary renewables market. Such set-asides have been adopted in nine of the ten Regional Greenhouse Gas Initiative (RGGI) states. Set-asides support the voluntary market by allowing sellers of voluntary renewable energy products to continue to make claims that the purchase of their products contributes to GHG reductions. The RGGI states operate their set-asides by reserving a certain quantity of allowances and retiring them at a fixed rate for every megawatt-hour of renewable energy produced within the cap and sold into the voluntary market. In effect, the purchase of voluntary renewable energy reduces GHG emissions by removing allowances from circulation and thereby ratcheting down the cap.[1]

Implications of Cap and Trade on Avoided Emissions

Prior to the implementation of a cap, a wide variety of mandatory programs and voluntary actions contribute to GHG reductions. One of the principal programs for achieving GHG reductions in the electricity sector is the adoption of RPS laws. Because the addition of new renewable resources presumably avoids the need for additional generation from conventional sources, the addition of renewable sources leads to some level of avoided GHG emissions.

After implementation of a GHG cap, individual measures and programs no longer reduce GHG emissions because the allowable level of emissions has been determined by the cap and the corresponding number of allowances issued. To illustrate, imagine that before a cap, a wind farm's generation results in the ramping down of fossil-based generation that would have otherwise been needed to meet load. Every megawatt-hour that wind farm produces avoids the emissions that would have been produced by the marginal generator. Once the cap is in effect, reduced generation by a fossil-based power plant also reduces the compliance obligation of that plant. The need for fewer allowances by these generators frees up allowances that may be used by other generators or any other regulated entity in the economy. However, RPS, energy efficiency programs, tailpipe emission standards and other mandatory programs continue to serve as critical strategies for meeting the cap and ensuring that GHG allowance prices remain at acceptable levels.

Because renewable electricity produced in a capped jurisdiction does not, in a sense, reduce GHG emissions, no avoided emissions occur and consequently, the avoided emission value of a REC generated in a capped region equals zero. In other words, the REC would not have a "negative" value that could be used to

[1] For a general introduction to set-asides, see Petlin 2008.

reduce the GHG compliance obligation of the buyer. To do so would be to treat the REC as an offset despite the fact that the generation that produced the REC was subject to the GHG cap. If RECs from capped jurisdictions were to have an avoided emissions value that could reduce one entity's compliance obligation, then, in order to balance the GHG accounting books, WCI regulators would have to attribute emissions to the null power. Renewable facilities would lose any additional marketable value that RECs might acquire from their offset capacity to the need to also purchase allowances to comply with the GHG cap-and-trade regime.

Continuing to assign an avoided emission value to RPS RECs after a cap would create additional complications because RPS programs and GHG cap-and-trade programs cover two different (but sometimes overlapping) points of regulation. RPS programs, by definition, apply to retail providers of electricity. Since the cap and trade system is applied at the generator level for the electricity sector, retail providers are not, per se, regulated entities in the cap and trade system. Retail providers would only have a compliance obligation for emitting generation plants that they own. Many retail providers have very little, if any, owned fossil-fired generation. This is true of electric service providers, restructured retail providers that are primarily distribution utilities, and utilities served mostly by hydro plants. Any offset value contained in the RECs would be useless to these retail providers. For utilities that do own a substantial amount of fossil-fired generation, the offset value would simply shift the compliance obligation from the utility-owned sources to renewable energy generators, who would have to factor a GHG compliance cost into their prices. While utility-owned sources would potentially benefit from the GHG compliance reduction benefits of the RPS RECs, independent generators would not.

In light of the discussion above, it is recommended that RECs produced in the WCI, or other capped jurisdictions, have no GHG compliance reduction value. These RECs would serve as an RPS compliance accounting tool, but there would be no interaction between these RECs and the reporting of GHG emissions for compliance purposes. If RECs generated within a capped jurisdiction and used for RPS compliance have no avoided emissions value, GHG accounting remains simple and straightforward. This is the approach that has been adopted in the RGGI states.

The treatment of RECs and null power imported from uncapped areas is potentially more complex. Since renewable facilities located in uncapped jurisdictions are not subject to the WCI cap (except to the extent that First Jurisdictional Deliverers (FJDs) import power from these facilities), it could be argued that purchases of RECs from uncapped jurisdictions do avoid emissions. If the RECs from an uncapped region were able to reduce a GHG compliance obligation (e.g., an electricity importer could retire a non-WCI REC for each MWh imported in lieu of surrendering allowances at the default rate) and the null power could be imported as zero-GHG power, the zero-GHG attribute of any given megawatt-hour could be double counted. In order avoid the possibility of double counting the zero-GHG attribute, the WCI Partners should not accept non-WCI

RECs as a compliance reducing mechanism and attribute zero GHG emissions to specified imports of null power.

Preventing double counting of non-WCI renewable power can be accomplished in one of three ways. To receive zero-GHG attribution:

1. renewable power would have to be sold on a bundled basis with both the power imported on a specified basis and the corresponding RECs retired by a WCI entity, or
2. RECs from uncapped jurisdictions could be paired with imported unspecified power in order to “respecify” the power as having originated from the facility designated on the REC and null power from uncapped jurisdictions would be attributed default emissions, or
3. the power from a renewable facility imported on a specified basis would be attributed zero emissions and RECs from uncapped jurisdictions would have no effect on GHG accounting.

A description of each option and the implications of each option for the electricity market, the REC market, and GHG accounting are provided below.

Option 1: Zero GHG Attribution Requires Import of Bundled Renewable Energy and RECs

This option would require imported renewable power to be bundled with RECs in order to receive the attribution of zero GHGs. Consider an example in which a retail provider in WCI enters into a contract for both the power and the RECs from a wind farm in Wyoming. The WCI retail provider retires the RECs from the wind farm in the same year they are generated. The WCI retail provider also arranges the transmission from the wind farm’s balancing authority into its own balancing authority and is therefore the entity shown on the NERC e-tag at the first point of delivery in WCI. In this case, the attribution of zero GHG is clear. The WCI retail provider is the FJD, buys both the power and the RECs, and retires the RECs. However, there are several restrictive assumptions in this scenario that, if violated, would complicate implementation of this option.

First, the retail provider may not necessarily retire RECs in the same year they are purchased. RPS programs generally allow retail providers to bank RECs so that RPS targets do not have to be perfectly matched to generation every year. If the WCI retail provider does not retire the RECs associated with its bundled imports, it could potentially sell the REC back into the market in a subsequent year, and the REC could ultimately be retired by a non-WCI utility. If that were to happen, the WCI retail provider would have received zero GHG attribution for what was essentially null power. A requirement that the RECs from bundled imports be retired during the reporting year to receive zero GHG attribution would prevent this. This would simply incentivize WCI retail providers to retire the RECs associated with bundled imports during the year of the transaction and use only WCI RECs for banking.

An additional complication arises if any entity other than the WCI retail provider retiring the RECs is the FJD selling the bundled product into the WCI. A wholesale power marketer could sell a bundled renewable energy product from a non-WCI jurisdiction to a WCI retail provider, but if the marketer is the FJD, it would depend on the purchasing retail provider to retire the RECs during the reporting year the transaction takes place. Otherwise, the FJD marketer would be hit with a compliance obligation that it did not expect.

Contracts could be structured to deal with these issues in one of two ways. Either the contracts could specify that the WCI utility buying the bundled product would always be the FJD, or the contracts could hold the WCI utility liable for the failure to retire the RECs associated with the bundled product.

Aside from the restrictive rules of this approach, one possible legal concern is that it could trigger objections related to the dormant Commerce Clause. Developers of renewable facilities in non-WCI jurisdictions might argue that the bundling and retirement obligations for imported renewable electricity are more burdensome than the zero GHG attribution given to renewable facilities in WCI, which would face no such requirement.

Option 2: Zero GHG Attribution Stays with RECs

Another option for ensuring that the zero GHG attribute is not double counted is to allow non-WCI RECs to have to the ability to respecify unspecified imported energy such that imported system power bundled with imported RECs would be treated, for GHG accounting purposes, as having originated from the facility identified on the REC.[2] In turn, any renewable energy imported on a specified basis would have emissions attributed to it at the default rate. This would probably result in very little importing of specified renewable power since there would be no compliance benefit.

Similar to Option 1, this option is relatively simple as long as the FJD of the imported power is also the same entity buying and retiring non-WCI RECs. However, FJDs of unspecified power who would have the GHG compliance obligation frequently differ from the retail providers that must purchase and retire RECs for RPS compliance. It would be unfair if marketers were not also enabled to bundle non-WCI RECs with imported system power. Like Option 1, the FJD marketers would depend on the retail providers to which they sell re-bundled power to retire the RECs. Contractual arrangements could also be made similar to Option 1, but this might raise transaction costs between marketers and retail providers. It would also complicate any transactions for FJD marketers wanting to sell the bundled product into a pooled market or at a major hub. The obligation to

[2] Theoretically, non-WCI RECs could also be used to respecify other specified power, but this may induce the use of non-WCI RECs to respecify coal-fired power. The Electricity Subcommittee hesitates to give non-WCI RECs that degree of compliance reduction potential.

retire the RECs during the reporting year would have to flow through to every subsequent buyer until it terminated with a WCI retail provider.

Any unbundled non-WCI RECs purchased by a WCI retail provider would also have foregone value if the WCI retail provider finds itself with more non-WCI RECs than imported system power for which they are the FJDs. This would offer the possibility of deals to be struck between WCI utilities and FJDs facing a compliance obligation for unspecified power. Since a retail provider's non-WCI RECs would have the ability to reduce an FJD's compliance obligation, FJDs could find retail providers who, in exchange for some cost sharing of the non-WCI RECs, would claim that the system power was imported for their loads. The non-WCI RECs would essentially be matched to unspecified imports after the fact.

Because non-WCI RECs would serve the dual function of demonstrating compliance with RPS programs and reducing GHG compliance obligations, non-WCI RECs may fetch a higher price than WCI RECs. However, this would not bias development in favor of non-WCI locations as long as emissions are attributed to the null power. The following tables demonstrate the possible market dynamics that could occur with non-WCI RECs having the ability to respecify imported power as zero-GHG power. Table 1 lists the assumed values used to derive the wholesale power prices, REC values, and compliance costs used for the WCI and non-WCI revenue comparisons in Table 2.

Table 1. Input Values for Comparison of WCI and non-WCI Renewable Energy Generation Revenues

Input Description	Value
GHG Allowance	\$40/metric ton CO_2e
Marginal Operating Emission Rate of in-WCI Generation and Imports	500 kg CO_2/MWh
Default Emission Rate	500 kg CO_2/MWh
Prevailing Wholesale Electricity Price, no GHG Cost	\$60/MWh
Prevailing WCI Wholesale Electricity Price, w/ GHG Cost	\$80/MWh
Levelized Renewable Generation Cost	\$90/MWh
WCI REC Price*	\$10/MWh

* This assumes that REC prices in a mature market will tend to cover the difference between prevailing wholesale prices and the generation cost of renewable resources.

Given these assumptions, it seems possible that non-WCI RECs would sell for a higher price than WCI RECs because the non-WCI RECs would have regulatory value for satisfying RPS requirements as well as reducing GHG compliance obligations. For example non-WCI RECs could sell for around \$30 because they would provide the RPS compliance value that \$10 WCI RECs do and a GHG compliance value of \$20.

Table 2. Comparison of per MWh Revenues for Renewable Energy Facilities in and out of WCI

Revenues and Costs	RE facility in WCI, sells power and RECs to WCI	Non-WCI RE facility sells power and RECs to WCI	Non-WCI RE facility sells RECs to WCI and power to non-WCI
Electricity REC GHG Cost	\$80 \$10 \$0	\$80 \$30 (\$20)	\$60 \$30 \$0
Total	\$90	\$90	\$90

Table 2 shows that whether the renewable facility is located in WCI or outside WCI it will in most cases earn the same per MWh revenues. If a non-WCI facility sells into the WCI markets that reflect an internalized GHG compliance cost, it will earn higher revenues but it will also face a compliance cost. Any additional revenue it could earn would be largely forfeited as an additional compliance cost.

There are some interesting implications of implementing Option 2. One is that by requiring the use of RECs to receive attribution of zero-GHG power, non-WCI renewable energy could not be used both to satisfy the RPS compliance of a non-WCI retail provider and to help the WCI meet its cap. If the REC from a non-WCI renewable facility is used by a non-WCI utility for its RPS, emissions would be attributed to the null power. However, this would not be true for renewable facilities in WCI. Their RECs could potentially be used by a non-WCI utility to meet its RPS requirements, but the null power would have no emissions attributed to it. One would expect that to the extent there are unspecified imports, non-WCI RECs would be used to respecify them as zero-GHG power. Non-WCI retail providers who need RECs would be indifferent to the source. The market would likely match non-WCI RECs closely to the level of unspecified imports, and non-WCI retail providers would purchase WCI RECs to cover any shortfall in non-WCI RECs. Simply put, this approach may induce some REC swapping between capped and uncapped jurisdictions that would not necessarily occur otherwise.

This option would seem to create incentives for unnecessary transactions among WCI retail providers and FJDs of unspecified power and a division of the REC market into two different products with different regulatory values.

Option 3: Renewable Power Imported on a Specified Basis Receives Zero-GHG Attribution and RECs from Uncapped Jurisdictions have no Effect on GHG Accounting

Under Option 3, renewable energy could be imported on a specified basis like electricity from other sources, subject to verification of contractual terms, settlements, and transmission data. Null power and RECs from non-WCI sources would be treated the same as null power and RECs from WCI sources. While this would avoid the complications that stem from explicitly linking RPS programs and RECs to GHG accounting, some parties may object on the grounds that renewable energy generated outside WCI could be used to meet a non-WCI state's RPS targets, while the null power would also receive a zero GHG attribution and thereby contribute to meeting the WCI Partners' cap. However, in this regard, the non-WCI renewable facility would be no different than in-WCI renewable generators because RECs generated in a WCI state could also be used by a non-WCI retail provider to meet its RPS requirements, and the null power would help the WCI Partners meet their cap.

Option 3 would require the WCI Partners to share information on specified imports to ensure that reported imports from any given source do not exceed output during the reporting period. Note that Option 3 does not preclude the use of shaping and firming to efficiently transmit non-WCI renewable energy from its region of origin.

ATTACHMENT 11: ALUMINUM PRODUCTION

Applicability

These methodologies apply to all facilities that convert raw alumina mineral (Al_2O_3) to raw aluminum metal by an electrolytic process. Emissions must be reported for the following processes:

- CO_2 from anode consumption,
- CO_2 from anode and cathode baking,
- PFC from anode effects,
- CO_2 from green coke calcination, and
- SF_6 from cover gas consumption,

Primary aluminum smelting facilities can emit GHG from other activities that are not directly part of the aluminum smelting process. GHG emissions from the following activities are covered under other sections of the reporting Essential Requirements:

- Stationary combustion emissions from boilers, heaters, furnaces (§ WCI.20),
- Nonroad equipment (§ WCI.XX),
- Lime calcination (§ WCI.170), and
- SF_6 use in electrical equipment (§WCI.XX).

HFC use for refrigeration and cooling and not associated with the aluminum processes is not included in this category, nor is bauxite calcination to alumina and raw coke production which are assumed to be performed at other locations.

Emission Calculations

The following emission calculation methods were taken from the *Aluminum Production-Guidance Manual for Estimating Greenhouse Gas Emissions*, Environment Canada, March 2004. Other organizations are recommending very similar methodologies, including the International Aluminum Institute, WRI, IPCC and The Climate Registry.

Emissions will be calculated monthly using the following methods:

Pre-baked Anode Consumption:

To calculate emissions from pre-baked anode consumption, use the following equation:

$$Emissions_{CO_2} = NCC \times MP \times \frac{(100 - \%S_a - \%Ash_a - \%Imp_a)}{100} \times 3.664$$

Where:

Emissions $_{CO2}$ = carbon dioxide emissions (metric tons per year)

NCC = net annode consumption per metric ton of aluminum;(metric ton/ metric ton Al)
MP = annual aluminum production (metric ton);
S_a = sulphur content in baked anodes (wt %);
Ash_a = ash content in baked anodes (wt %);
Imp_a = content of fluorine and other impurities in baked anodes (wt %);
3.664 = conversion factor from carbon to CO_2.

Søderberg Anode Consumption:

To calculate emissions from Søderberg anode consumption, use the following equation:

$$Emissions_{CO_2} = \left[\begin{array}{l} (PC \times MP) - \left(BSM \times \frac{MP}{1000} \right) - \left(\frac{\%BC}{100} \times PC \times MP \times \left(\frac{\%S_p + \%Ash_p + \%H_p}{100} \right) \right) \\ - \left(\frac{100 - \%BC}{100} \times PC \times MP \times \frac{\%S_c + \%Ash_c}{100} \right) \end{array} \right] \times 3.664$$

Where:

$Emissions_{CO2}$ = carbon dioxide emissions (metric tons per year)
PC = paste consumption (metric tons paste/metric ton aluminum);
MP = annual aluminum production (metric tons);
BSM = emissions of benzene-soluble matter (kilograms benzene-soluble matter/metric ton aluminum);
BC = average binder (pitch) content in paste (wt %);
S_p = sulphur content in pitch (wt %);
Ash_p = ash content in pitch (wt %);
H_p = hydrogen content in pitch (wt %);
S_c = sulphur content in calcinated coke (wt %);
Ash_c = ash content in calcinated coke (wt %);
3.664 = conversion factor from carbon to CO_2.

Anode/Cathode Baking:

CO_2 emissions result from the baking of (pre-bake) anodes and cathodes. In cases where baking of anodes and cathodes occurs on-site, emissions should be calculated for both packing coke and pitch coking. The calculations require information on the net rate of raw material used for baked anode/cathode production, plus material composition information. To calculate emissions from packing coke for anodes, use the following equation:

$$Emissions_{CO_2} = \left(PCC \times BAP \times \frac{100 - \%Ash_{pc} - \%S_{pc} - \%Imp}{100} \right) \times 3.664$$

Where:

$Emissions_{CO2}$ = carbon dioxide emissions (metric tons per year)

PCC = packing coke consumption per metric ton of baked anode (metric tons coke/metric ton anodes);
BAP = annual baked anode production (metric tons);
Ash_{pc} = ash content in packing coke (wt %);
S_{pc} = sulphur content in packing coke (wt %);
Imp = content of other impurities (wt %);
3.664 = conversion factor from carbon to CO_2.

To calculate emissions that occur from oxidation of pitch volatile matter in ***pitch coking***, use the following equation:

$$Emissions_{CO_2} = \left(GAW - BAP - \left(\frac{\%H_p}{100} \times \frac{\%PC}{100} \times GAW \right) - RT \right) \times 3.664$$

Where:

$Emissions_{CO2}$ = carbon dioxide emissions (metric tons per year)
GAW = annual green anode tonnage (metric tons);
BAP = annual baked anode production (metric tons).
H_p = hydrogen content in pitch (wt %);
PC = average pitch content (wt %) in green anode;
RT = annual recovered tar (metric tons);
3.664 = conversion factor from carbon to CO_2.

To calculate similar emissions from the baking of cathodes, the methodology follows the above methodology for anodes, where values for baked cathode production, green cathode tonnage and cathode composition data are substituted into the equations for packing coke and pitch coking.

Emissions from Anode Effects:

The two PFCs known to be emitted from the occurrence of anode effects (also termed anode events) during primary aluminum smelting are CF_4 and C_2F_6. The most accurate estimates of these PFC emissions from anode effects are based on either continuous monitoring of emissions or development of smelter-specific relationships for emissions based on measured values and operating conditions. This requires both a comprehensive measurement program to establish the smelter-specific relationship as well as on-going collection of operating parameter data (e.g. frequency and duration of anode effects, anode effect over-voltage) and production data.

If continuous monitoring of PFC emissions is not selected, there are two approaches that may be used to relate monitored emissions, typically obtained from field measurements, to process data in order to develop smelter-specific relationships that can be used to estimate emissions. The two approaches are the Slope method or the Pechiney method, which are described below.

Slope Method - The **Slope** method uses a linear least squares relationship between anode effect frequency and duration and emissions, such that emissions can be calculated using the following equation:

$$Emissions_{CF_4,C_2F_6} = slope_{CF_4,C_2F_6} \times AEF \times AED \times MP$$

Where:

$Emissions_{CF4, C2F6}$	=	Emissions of CF_4 or C_2F_6 (metric tons/yr)
$slope_{CF4, C2F6}$	=	slope of the emissions relationship- measured ([Metric tons of CF_4 or C_2F_6 /metric ton Al]/[anode effect minutes/pot-days]);
AEF	=	anode effect frequency (number of anode effects per pot per day);
AED	=	anode effect duration (minutes per anode effect);
MP	=	total aluminum production (metric tons).

Note that the product of the anode effect frequency and duration can be expressed as "anode effect minutes per pot-day."

Pechiney Method - The **Pechiney** method (or over-voltage method) uses the anode effect over-voltage as the process parameter in combination with the quantity of aluminum produced to calculate PFC emissions. The anode effect over-voltage (AEO) represents the sum of the differences between the total cell voltage and the equilibrium voltage for each second during an anode event divided by the total number of seconds in the chosen period (e.g. one day). This calculation is carried out once the cell voltage exceeds 8 volts and continues until the voltage returns to the equilibrium point. The over-voltage coefficient is determined from the measurement of PFC emissions. The full calculation is:

$$Emission_{CF_4,C_2F_6} = Over-voltage \quad coefficient_{CF_4,C_2F_6} \times \frac{AEO}{CE} \times MP$$

Where:

$Emissions_{CF4, C2F6}$	=	Emissions of CF_4 or C_2F_6 (metric tons/yr)
Over-voltage coefficient $_{CF4, C2F6}$	=	experimentally measured ([Metric tons of CF_4 or C_2F_6/metric ton Al]/ mV)
AEO	=	anode effect over-voltage (millivolts per pot per day);
CE	=	current efficiency of aluminum production process, expressed as a fraction;
MP	=	annual aluminum production (metric tons).

Under either approach, the calculation is to be completed for each of the PFC gases emitted (CF_4 and C_2F_6) and for each operating pot line at the facility.

Note: It has been recommended that facilities be allowed to use a technology based emission factor in place of measuring either the slope coefficient or the over-voltage coefficient required by the above two methods. This approach is equivalent to the IPCC Tier 2 method which has a reported uncertainty of +/-6% to +/-44%, depending on the process. The IPCC Tier 3 method requires the use of site measured values for greater accuracy. The WCI seeks stakeholder *comments regarding the practicalities of requiring the IPCC Tier 3 method as opposed to allowing a Tier 2 method as well.*

CO_2 Emissions from Green Coke Calcination

The process of coke calcination, where coke is heated to high temperatures in order to drive off volatile matter, results in emissions of CO_2. The facility may purchase coke materials in the calcined state, or it may operate a calcining furnace. If coke calcination is conducted on-site at the facility, the following equation can be used to calculate the CO_2 emissions from this process:

$$Emissions_{CO_2} = \left[\left[GC \times \frac{(100 - \%H_2O_{gc} - \%V_{gc} - \%S_{gc})}{100} - (CC + UCC + DE) \times \frac{(100 - \%S_{cc})}{100}\right] \times 3.664\right] + \left[GC \times 0.035 \times \frac{44}{16}\right]$$

Where:

$Emissions_{CO2}$	=	carbon dioxide emissions (metric tons prr year)
GC	=	annual green coke feed (metric tons);
H_2O_{gc}	=	humidity in green coke feed (wt %);
V_{gc}	=	volatiles in green coke feed (wt %);
S_{gc}	=	sulphur content in green coke feed (wt %);
S_{cc}	=	sulphur content in calcinated coke (wt %);
CC	=	annual calcinated coke produced (metric tons);
UCC	=	annual under-calcinated coke produced (metric tons);
DE	=	annual coke dust emissions (metric tons);
3.664	=	conversion factor from carbon to CO_2;
0.035	=	Assumed CH4 and tar content in coke volatiles, contributing to CO_2 emissions
44/16	=	conversion factor from methane to CO_2.

For the composition parameters in the above equation, facility-specific values should be used for the coke input and output streams of the calcining operation to ensure accuracy of the emission estimates.

SF_6 Emissions from Use as a Cover Gas

For some specialized applications, SF_6 may be used as a cover gas at aluminum facilities. SF_6 is essentially non-reactive during this process. If this SF_6 use occurs, emissions are calculated based on the quantity of SF_6 consumed:

$$Emissions_{SF_6} = Consumption_{SF_6}$$

The consumption of SF_6 may be determined by:

- measured weight difference of gas cylinders used at the facility for this purpose;
- accounting of delivered purchases and inventory changes of SF6 used for this purpose; and
- metering of flow rates at the point used.

The first two methods based on weight are generally more accurate. When using measured weights, it is important to account for any gas in the heels of the cylinders returned to the supplier. If accounting or delivery records are used over an annual time period, beginning and end of year inventories must be taken into account.

Reporting Requirements

Annual emissions will be reported by emission source (i.e. emissions from prebaked anode consumption or from anode effect) and by GHG.

Sampling, Analysis, and Measurement Methods

Issue: Sampling, analysis, and measurement methods have not been specified in the available methodologies for the aluminum industry.

Note: The sampling, analysis, and measurement procedures will be standardized for each calculation input to reduce variation between facilities within the aluminum industry. Material sampling frequency and technique is distinct from material analysis conducted in a laboratory. The WCI is seeking stakeholder feedback on this topic and is specifically interested in proposals from stakeholders with expertise in this industry related to sampling, analysis and measurement procedures already in use at these facilities for the material quantities and/or concentrations listed below. Those proposing procedures should include sampling frequency and technique, indicate the uncertainty associated with the procedures, and describe the application of the procedure at a facility.

There are several possible approaches to specifying monitoring methods:

- Specify the accuracy required for each datum and allow the source to select their own methodologies that meet the accuracy requirements, and require the verifiers to certify the accuracy requirements were achieved, [*This approach is especially useful for monitoring that is currently being made with a wide variety of instruments and are likely being made with high accuracy, such as monitoring of raw material flows and product flows; however, much burden is placed on verifiers to ensure the accuracy of the methods used. This approach is used for monitoring fuel flow for combustion sources.*]
- Specify the accuracy required for each datum and require the source to submit a monitoring plan that meets the accuracy requirements, and require the verifiers to certify the source followed the approved plan. [*This approach places significant burden on WCI to approve individual monitoring plans.*]
- Specify the methodologies that should be followed, selecting them from available ASTM, ISO, U.S. EPA, and EC methodologies; however, there are not established methods for all

parameters. Listed below are examples of the available methodologies for monitoring the aluminum industry.

ISO 9055:1988. Carbonaceous materials for the production of aluminum -- Pitch for electrodes -- Determination of sulfur content by the bomb method.

ISO 10238:1999. Carbonaceous materials used in the production of aluminum -- Pitch for electrodes -- Determination of sulfur content by an instrumental method.

ISO 8006:1985. Carbonaceous materials used in the production of aluminum -- Pitch for electrodes -- Determination of ash.

ISO 8005-2005. Carbonaceous materials used in the production of aluminum -- Green and calcined coke -- Determination of ash content

ISO 10237-1997. Carbonaceous materials for use in the production of aluminum -- Calcined coke -- Determination of residual-hydrogen content.

ISO 5931:2000. Carbonaceous materials used in the production of aluminum -- Calcined coke and calcined carbon products -- Determination of total sulfur by the Eschka method.

Slope and Over-voltage Coefficient: *Protocol for Measurement of Tetrafluoromethane and Hexafluoroethane Emissions from Primary Aluminum Production.* U.S. Environmental Protection Agency and International Aluminum Institute. April 2008.

ASTM D3173 Test Method for Moisture in the Analysis Sample of Coal and Coke

The following parameters are not covered by a specific ASTM or ISO methodology. They are candidates for being addressed using one of the first two approaches listed above:

- Mass flow rates or consumption of aluminum, paste, carbon, anodes, coke, recovered tar, and coke dust,
- Emissions of benzene soluble matter,
- Binder content in paste,
- Pitch content in anodes,
- Current efficiency,
- Anode effect frequency,
- Anode effect duration,
- Anode effect over-voltage,
- Current efficiency,
- Volatile content in coke

ATTACHMENT 6: COAL STORAGE

§ WCI.100 COAL STORAGE

§ WCI.101 Source Category Definition

Coal storage piles are located at any facilities that combust coal. Coal storage piles release fugitive CH_4 emissions. Within natural coal deposits, CH_4 is either trapped under pressure within porous void spaces or adsorbed to the coal. Coal mining, post-mining activities, and coal-handling activities release pressurized CH_4 to the atmosphere; adsorbed CH_4 is also released until the CH_4 coal reaches equilibrium with the surrounding atmospheric conditions.

§ WCI.102 Greenhouse Gas Reporting Requirements

The emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

(1) Total CH_4 emissions.

(b) Annual coal purchases in tons.

(c) Source of coal purchases:

(1) Coal basin.
(2) State/province.
(3) Coal mine type (surface or underground).

§ WCI.103 Calculation of CH_4 Emissions

Note that this methodology for calculation of methane emissions uses emission factors for post-mining operations including all processes occurring after mining at the coal deposit and prior to combustion (e.g., preparation, handling, processing, transportation, storage, etc.) even though coal storage piles are only a subset of the overall post-mining operations. This follows the approach in the California Climate Action Registry, attributing all post-mining fugitive methane emissions to the facility combusting the coal, which is ultimately responsible for the coal having been processed and delivered to the facility. The Reporting Subcommittee is considering whether to require reporting of these emissions as indicated below, and whether to include these emissions in the total emissions of the coal-combusting facility. Stakeholder comment is requested.

Canadian-specific default fugitive methane emissions (i.e., a Canadian version of Table 100-1) will be developed.

Calculate fugitive CH_4 emissions from coal storage piles using the following equation:

$$CH_4 = \sum_i (PC \times EF) \times 0.04228 \ / \ 2{,}204.6 \qquad \textbf{Equation 100-1}$$

Where:

CH_4	=	Fugitive emissions from coal storage piles for each coal category *i*, metric tons CH_4 per year.
PC	=	Purchased coal, tons per year.
EF	=	Default CH_4 emission factor specified by location and mine type that coal originated from provided in Table 100-1, scf CH_4 per ton of coal.
0.04228	=	Methane conversion factor to convert scf to lbs.
2,204.6	=	Factor to convert lbs to metric tons.

Table 100-1 provides default CH_4 emission factors for U.S. post-mining operations.

These post-mining operation emission factors were used to estimate emissions from coal storage piles in the CARB rule.

The uncertainty associated with the U.S.-specific emission factors in Table 100-1 emission factors is unknown. Emission factors from U.S. underground mining activities were developed from mine-level emissions measurements; however, the surface mining and post-mining activity emission factors were estimated based upon an average in situ CH_4 content of 32.5%.

Canada-specific coal storage pile or post-mining operation emission factors could not be identified. The Canada National Inventory contains Canada-specific emission factors for coal production from underground and surface mines. Post-mining operations are included within these emission factors, but are not specifically disaggregated.

§ WCI.105 Sampling, Analysis, and Measurement Requirements

(a) Fuel Consumption Monitoring Requirements.

(1) Facilities may determine consumption on the basis of recorded fuel purchase or sales invoices measuring any stock change (short tons) using the following equation:

Fuel Consumption in the Report Year = Total Fuel Purchases – Total Fuel Sales + Amount Stored at Beginning of Year – Amount Stored at Year End

Table 100-1. U.S. Default Fugitive Methane Emission Factors from Post-Mining Coal Storage and Handling (CH_4 ft^3 per Short Ton)			
Coal Origin		**Coal Mine Type**	
Coal Basin	**States**	**Surface Post-Mining Factors**	**Underground Post-Mining Factors**
Northern Appalachia	Maryland, Ohio, Pennsylvania, West Virginia North	19.3	45.0
Central Appalachia (WV)	Tennessee, West Virginia South	8.1	44.5

Source: *Inventory of U.S. Greenhouse Gas Emissions and Sinks:1990 – 2005* April 15, 2007, U.S. Environmental Protection Agency. Annex 3, Methodological Descriptions for Additional Source or Sink Categories, Section 3.3, Table A-115, Coal Surface and Post-Mining CH4 Emission Factors (ft^3 per Short Ton). (Only Post-Mining EFs used from Table). State assignments shown from Table 113 of Annex 3.

ATTACHMENT 14: COAL MINE FUGITIVE EMISSIONS

Applicability

As part of the geological processes of coal formation, CO_2 and CH_4 may also be produced and trapped in the coal seam until the coal is exposed and broken during mining. In general, CH_4 is the predominant greenhouse gas emitted from coal mines. The following five processes are potential source categories for fugitive emissions associated with both underground and surface coal mines:

- Mining (emissions from the breakage of coal and associated strata, including ventilation air and degasification systems for underground mines);
- Post-mining operations (subsequent handling, processing, and transportation of coal);
- Low temperature oxidation (oxidation of coal when exposed to oxygen in air);
- Uncontrolled combustion (active fire caused by trapped heat and increased temperature from low temperature oxidation); and
- Abandoned mines.

The following methodology focuses solely on CH_4 mining emissions. Emissions from post-mining operations (including storage piles) are addressed in Section WCI.100. Coal oxidation occurs in both underground and surface mines; however, emissions are not expected to be significant. Uncontrolled combustion also occurs in underground and surface mines, but it is difficult to quantify and infeasible to include in the methodology. Estimation of emissions from abandoned underground mines requires the emission rate at closure/abandonment (i.e., when all active mine ventilation ceases) and "decline curves" (i.e., hyperbolic models of declining emissions as a function of time). At best, the uncertainty of estimated abandoned mine emissions is ±50 percent.

Emission Calculations

The following emission calculation methods were taken from the 2006 IPCC Guidelines, Volume 2, Section 4.1. The following methods can be used to calculate emissions:

Underground Mining

The Tier 3 method for underground mining is mine-specific measurement data based on ventilation air and degasification system measurements. The Tier 2 method relies on basin-specific emission factors that need to be obtained from sample ventilation air data or from a quantitative relationship that accounts for the gas content of the coal and the surrounding strata affected by the mining process. If Tier 3 or Tier 2 data are not available, then Tier 1 emission factors could be used. If Tier 1 or Tier 2 methods are utilized, then methane recovered and utilized for energy production or flaring should be subtracted from the emission estimates; this subtraction is not needed for the Tier 3 methodology, because the Tier 3 mine-specific measurements should take methane recovery and utilization into account.

The Tier 2 and Tier 1 equations are as follows:

$$E_{Underground-CH4} = E_{Mining-CH4} - R_{CH4}$$

Where:

$E_{Underground\text{-}CH4}$ = Total CH_4 emissions from underground coal mining (metric tons);
$E_{Mining\text{-}CH4}$ = CH_4 emissions from underground coal mining operations (metric tons);
R_{CH4} = CH_4 recovered and utilized for energy production or flared.

$$E_{Mining-CH4} = P_{Underground} \times EF_{Underground-CH4} \times 0.00067$$

Where:

$E_{Mining\text{-}CH4}$ = CH_4 emissions from underground coal mining operations (metric tons);
$P_{Underground}$ = Underground coal production (metric tons);
$EF_{Underground\text{-}CH4}$ = CH_4 emission factor (m^3 CH_4/metric ton coal);
0.00067 = Conversion factor from volume of CH_4 to mass of CH_4 (metric ton/m^3).

The Tier 1 emission factors for underground coal mining are identified as high, average, or low. The high emission factor is 25 m^3/metric ton (i.e., at depths greater than 400 meters). The average emission factor is 18 m^3/metric ton (i.e., at depths between 200 and 400 meters). The low emission factor is 10 m^3/metric ton (i.e., at depths less than 200 meters).

$$E_{Post-CH4} = P_{Underground} \times EF_{Post-CH4} \times 0.00067$$

Where:

$E_{Post\text{-}CH4}$ = CH_4 emissions from underground coal post-mining operations (metric tons);
$P_{Underground}$ = Underground coal production (metric tons);
$EF_{Post\text{-}CH4}$ = CH_4 emission factor (m^3 CH_4/metric ton coal);
0.00067 = Conversion factor from volume of CH_4 to mass of CH_4 (metric ton/m^3).

For underground mines, the uncertainty for the Tier 3 mining emission estimates ranges from ±5 percent for continuous monitoring up to ±30 percent for more infrequent monitoring. The uncertainty of the Tier 2 mining emission factors is ±50-75 percent, while the uncertainty of the Tier 1 mining emission factors is a factor of 2 greater/smaller.

Surface Mining

It is not feasible to collect mine-specific Tier 3 measurement data for mining operations at surface mines, so Tier 2 emission factors are an alternative approach for this category.

$$E_{Mining-CH4} = P_{Surface} \times EF_{Surface-CH4} \times 0.00067$$

Where:

$E_{Mining\text{-}CH4}$ = CH_4 emissions from surface coal mining operations (metric tons);

$P_{Surface}$	=	Surface coal production (metric tons);
$EF_{Surface-CH4}$	=	CH_4 emission factor (m^3 CH_4/metric ton coal);
0.00067	=	Conversion factor from volume of CH_4 to mass of CH_4 (metric ton/m^3).

The Tier 2 emission factors for surface coal mining are identified as high, average, or low. The high emission factor is 2.0 m^3/metric ton (i.e., for overburden depths greater than 50 meters). The average emission factor is 1.2 m^3/metric ton (i.e., for overburden depths between 25 and 50 meters). The low emission factor is 0.3 m^3/metric ton (i.e., for overburden depths less than 25 meters). For surface mines, the uncertainty of the Tier 2 mining emission factors is a factor of 2 greater/smaller.

Because of the high uncertainty associated with estimating emissions from mining operations at surface coal mines, these emissions will not be included in the reporting requirements at this time.

Reporting Requirements

Annual CH_4 emissions will be reported for each specific underground mine using the Tier 3 methodology.

Sampling, Analysis, and Measurement Methods

Note: The sampling, analysis, and measurement procedures will be standardized for each calculation input to reduce variation between facilities within the mining industry. Material sampling frequency and technique is distinct from material analysis conducted in a laboratory. The WCI is seeking stakeholder feedback on this topic and is specifically interested in proposals from stakeholders with expertise in this industry related to sampling, analysis and measurement procedures already in use at these mines for the material quantities and/or concentrations listed below. Those proposing procedures should include sampling frequency and technique, indicate the uncertainty associated with the procedures, and describe the application of the procedure at a mine.

Ventilation air and/or degasification system measurements will need to be taken for development of underground Tier 3 mining emission estimates. More frequent sampling (preferably continuous) will reduce the amount of uncertainty. Appropriate measurement methods are likely specified by the U.S. Mine Safety and Health Administration, although none have been identified to date.

Ventilation measurements are typically conducted on a periodic basis with air flow measurements and handheld methanometers. Drainage gas utilized for energy production is usually continuously measured with a flow meter with gas composition samples taken at a periodic basis. Drainage gas vented to the atmosphere is periodically sampled, along with the associated gas composition.

ATTACHMENT 4: ELECTRICITY GENERATION

§ WCI.40 ELECTRICITY GENERATION

WCI.41 Source Category Definition

An electricity generator is any combustion device that combusts solid, liquid, or gaseous fuel for the purpose of producing electricity either for sale or for use onsite. This source category excludes cogeneration units subject to WCI.50.

WCI.42 Greenhouse Gas Reporting Requirements

For each facility, the emissions data report shall include the following information:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

  (1) Total CO_2 emissions for fossil fuels, reported by fuel type.
  (2) Total CO_2 emissions for all biomass fuels combined.
  (3) Total CH_4 emissions for fuels combined.
  (4) Total N_2O emissions for all fuels combined.

(b) Annual fuel consumption:

  (1) For gases, report in units of million standard cubic feet or cubic meters.
  (2) For liquids, report in units of gallons or liters.
  (3) For non-biomass solids, report in units of short tons or metric tons.
  (4) For biomass-derived solid fuels, report in units of bone dry short tons or bone dry metric tons.

(c) Average carbon content of each fuel, if used to compute CO_2 emissions as specified in WCI.44.

(d) Average high heating value of each fuel, if used to compute CO_2 emissions as specified WCI.44.

(e) The nameplate generating capacity in megawatts and net power generated in the reporting year in megawatt hours.

(f) Process CO_2 emissions from acid gas scrubbers and acid gas reagent.

(g) Fugitive emissions of HFC from cooling units that support power generation.

(h) Fugitive CO_2 emissions from geothermal facilities.

(i) Fugitive CO_2 emissions from coal storage at coal-fired electricity generating facilities shall be reported as specified in section WCI.100.

WCI.43 Calculation of Greenhouse Gas Emissions

(a) Calculation of CO_2 Emissions. Operators shall use CEMS to measure CO_2 emissions if required to operate a CEMS by any other federal, state, provincial, or local regulation. Operators not required to operate a CEMS by another regulation may use either CEMS or the calculation methods specified in paragraphs (a)(1) through (a)(7). Operators using CEMS to determine CO_2 emissions shall comply with the provisions in section WCI.23(d).

(1) Natural Gas. For electric generating units combusting natural gas, use one of the following methods:

(A) If the high heat value is greater than or equal to 975 and less than or equal to 1,100 Btu/scf use either:

i. The measured carbon content of the fuel and calculation methodology 3 in section WCI.23(c); or
ii. The measured heat content of the fuel and the calculation methodology 2 in section WCI.23(b) provided the facility is not subject to the verification requirements of WCI.8.

(B) If the high heat value is less than 975 or greater than 1,100 Btu/scf, use the measured carbon content of the fuel and the calculation methodology 3 in section WCI.23(c).

(2) Coal or Petroleum Coke. For electric generating units combusting coal or petroleum coke, use the measured carbon content of the fuel and calculation methodology 3 in section WCI.23(c).

(3) Middle Distillates, Gasoline, Residual Oil, or Liquid Petroleum Gases. For electric generating units combusting middle distillates (such as diesel, fuel oil, or kerosene), gasoline, residual oil, or LPG (such as ethane, propane, isobutene, n-butane, or unspecified LPG), use one of the following methods:

(A) The measured carbon content of the fuel and calculation methodology 3 in section WCI.23(c); or
(B) The measured heat content of the fuel and calculation methodology 2 in section WCI.23(b) provided the facility is not subject to the verification requirements of WCI.8.

(4) Refinery Fuel Gas, Flexigas, or Associated Gas. For electric generating units combusting refinery fuel gas, flexigas, or associated gas, use the methods specified in section WCI.30.

(5) Landfill Gas, Biogas, or Biomass. For electric generating units combusting landfill gas, biogas, or biomass, use one of the following methods:

(A) The measured carbon content of the fuel and calculation methodology 3 provided in section WCI.23(c); or
(B) The measured heat content of the fuel and calculation methodology 2 in section WCI.23(b) provided the facility is not subject to the verification requirements of WCI.8.

(6) Municipal Solid Waste. Electric generating units combusting municipal solid waste, may use the measured steam generated, the default carbon content emission factor in Table 20-1, and the calculation methodology in section WCI.23(b)(2) provided the facility is not subject to the verification requirements of WCI.8. If the facility is subject to the verification requirements of WCI.8, the operator shall use CEMS to measure CO_2 emissions in accordance with WCI.23(d).

(7) Start-up Fuels. The operators of generating facilities that primarily combust biomass-derived fuels but combust fossil fuels during start-up, shut-down, or malfunction operating

periods only, shall calculate CO_2 emissions from fossil fuel combustion using one of the following methods:

(A) The default emission factors from Tables 20-1 and 20-2 and calculation methodology 1 provided in section WCI.23(a);
(B) The measured heat content of the fuel and calculation methodology 2 provided in section WCI.23(b);
(C) The measured carbon content of the fuel and calculation methodology 3 provided in section WCI.23(c); or
(D) For combustion of refinery fuel gas, the measured heat content and carbon content of the fuel, and the calculation methodology provided in section WCI.30.

(8) Co-fired Electricity Generating Units. For electricity generating units that combust more than one type of fuel, the operator shall calculate CO_2 emissions as follows.

(A) For co-fired electricity generators that burn only fossil fuels, CO_2 emissions shall be determined using one of the following methods:

i. A continuous emission monitoring system in accordance with calculation methodology 4 in section WCI.23(d). Operators using this method need not report emissions separately for each fossil fuel.
ii. For units not equipped with a continuous emission system, calculate the CO2 emissions separately for each fuel type using the methods specified in paragraphs (a)(1) through (a)(4) of this section.

(B) For co-fired electricity generators that burn biomass-derived fuel with a fossil fuel, CO_2 emissions shall be determined using one of the following methods:

i. A continuous emission monitoring system in accordance with calculation methodology 4 in section WCI.23(d). Operators using this method shall determine the portion of the total CO_2 emissions attributable to the biomass-derived fuel and portion of the total CO_2 emissions attributable to the fossil fuel using the methods specified in section WCI.23(d)(4).
ii. For units not equipped with a continuous emission system, calculate the CO_2 emissions separately for each fuel type using the methods specified in paragraphs (a)(1) through (a)(7) of this section.

(b) Calculation of CH_4 and N_2O Emissions. Operators of electricity generating units shall use the methods specified in section WCI.24 to calculate the annual CH_4 and N_2O emissions. For coal combustion, use the default CH_4 emission factor of 1g of CH_4/mmBtu.

(c) Calculation of CO_2 Emissions from Acid Gas Scrubbing. Operators of electricity generating units that use acid gas scrubbers or add an acid gas reagent to the combustion unit shall calculate the annual CO_2 emissions from these processes using Equation 40-1 if these emissions are not already captured in CO_2 emissions determined using a continuous emissions monitoring system.

$$CO_2 = S \times R \times \left(CO_{2\,MW} / Sorbent_{MW} \right) \qquad \textbf{Equation 40-1}$$

Where:

CO_2 = CO_2 emitted from sorbent for the report year, metric tons;

S	=	Limestone or other sorbent used in the report year, metric tons;
R	=	Ratio of moles of CO_2 released upon capture of one mole of acid gas;
$CO_{2\ MW}$	=	Molecular weight of carbon dioxide (44);
$Sorbent_{MW}$	=	Molecular weight of sorbent (if calcium carbonate, 100).

(d) Calculating Fugitive HFC Emissions from Cooling Units. Operators of electricity generating facilities shall calculate fugitive HFC emissions for each HFC compound used in cooling units that support power generation or are used in heat transfers to cool stack gases using either the methodology in paragraph (d)(1) or (d)(2). The Operator is not required to report GHG emissions from air or water cooling systems or condensers that do not contain HFCs.

(1) Use Equation 40-2 to calculate annual HFC emissions:

$$HFC = HFC_{inventory} + HFC_{purchases/acquisitions} - HFC_{sales/disbursements} + HFC_{\Delta capacity}$$ **Equation 40-2**

Where:

HFC	=	Annual fugitive HFC emission, metric tons;
$HFC_{inventory}$	=	The difference between the quantity of HFC in storage at the beginning of the year and the quantity in storage at the end of the year. Stored HFC includes HFC contained in cylinders (such as 115-pound storage cylinders), gas carts, and other storage containers. It does not include HFC gas held in operating equipment. The change in inventory will be negative if the quantity of HFC in storage increases over the course of the year.
$HFC_{purchases/acquisitions}$	=	The sum of all HFC acquired from other entities during the year either in storage containers or in equipment.
$HFC_{sales/disbursements}$	=	The sum of all the HFC sold or otherwise transferred offsite to other entities during the year either in storage containers or in equipment.
$HFC_{\Delta capacity}$	=	The net change in the total nameplate capacity (i.e. the full and proper charge) of the cooling equipment). The net change in capacity will be negative if the total nameplate capacity at the end of the year is less than the total nameplate capacity at the beginning of the year.

(2) Use service logs to document HFC usage and emissions from each cooling unit. Service logs should document all maintenance and service performed on the unit during the report year, including the quantity of HFCs added to or removed from the unit, and include a record at the beginning and end of each report year. The operator may use service log information along with the following simplified material balance equations to quantify fugitive HFCs from unit installation, servicing, and retirement, as applicable. The operator shall include the sum of HFC emissions from the applicable equations in the greenhouse gas emissions data report.

$$HFC_{Install} = R_{new} - C_{new}$$
$$HFC_{Service} = R_{recharge} - R_{Recover}$$
$$HFC_{Retire} = C_{retire} - R_{retire}$$

Where:

$HFC_{Install}$ = HFC emitted during initial charging/installation of the unit, kilograms;
$HFC_{Service}$ = HFC emitted during use and servicing of the unit for the report year, kilograms;
HFC_{Retire} = HFC emitted during the removal from service/retirement of the unit, kilograms;
R_{new} = HFC used to fill new unit (omit if unit was pre-charged by the manufacturer), kilograms;
C_{new} = Nameplate capacity of new unit (omit if unit was pre-charged by the manufacturer), kilograms;
$R_{recharge}$ = HFC used to recharge the unit during maintenance and service, kilograms;
$R_{recover}$ = HFC recovered from the unit during maintenance and service, kilograms;
C_{retire} = Nameplate capacity of the retired unit, kilograms; and
R_{retire} = HFC recovered from the retired unit, kilograms.

(e) Fugitive CO_2 Emissions from Geothermal Facilities. Operators of geothermal electricity generating facilities shall calculate the fugitive CO_2 emissions using one of the following methods:

(1) Calculate the fugitive CO_2 emissions using Equation 40-3:

$$CO_2 = 7.53 \times Heat \times 0.001$$ **Equation 40-3**

Where:

CO_2 = CO_2 emissions, metric tons per year;
7.53 = Default fugitive CO_2 emission factor for geothermal facilities, kg per mmBtu; and
Heat = Heat taken from geothermal steam and/or fluid, mmBtu/yr.

(2) Calculate CO_2 emissions using [*insert jurisdiction*] approved source specific emission factor.

WCI.44 Sampling, Analysis, and Measurement Requirements

(a) CO_2, CH_4 and N_2O Emissions from Fuel Combustion. Operators using CEMS to estimate CO_2 emissions from fuel combustion shall comply with the requirements in section WCI.23(d). Operators using methods other than CEMS shall comply with the applicable fuel sampling, fuel consumption monitoring, heat content monitoring, and carbon content monitoring specified in section WCI.25.

(b) CO_2 Emissions from Acid Gas Scrubbing. Operators of electricity generating units that use acid gas scrubbers or add an acid gas reagent to the combustion unit shall measure the

amount of limestone or other sorbent used during the reporting year using methods that comply with the measurement accuracy provisions in WCI.2(g).

(c) CO_2 Emissions from Geothermal Facilities. Operators of geothermal facilities shall measure the heat recovered from geothermal steam. If using source specific emission factor instead of the default factor, the operator shall conduct an annual test of the CO_2 emission rate using a method approved by [*insert jurisdiction*]. The operator shall submit a test plan to the [*insert jurisdiction*] for approval. Once approved, the annual tests shall be conducted in accordance with the approved test plan under the supervision of the [*insert jurisdiction*].-

ATTACHMENT 2: GENERAL STATIONARY COMBUSTION

§ WCI.20 GENERAL STATIONARY COMBUSTION

§ WCI.21 Source Category Definition

General stationary fuel combustion sources are devices that combust solid, liquid, or gaseous fuel for the purpose of generating steam (or providing useful heat or energy) for industrial, commercial, or institutional use; or reducing the volume of waste by removing combustible matter. General stationary combustion sources are boilers, combustion turbines, engines, incinerators, and process heaters, and any other stationary combustion device that is not specifically addressed under the provisions for another source category in this rule.

Note: The source category definition may need to be revised after the remaining ER sections are completed.

§ WCI.22 Greenhouse Gas Reporting Requirements

The emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

(1) Total CO_2 emissions for fossil fuels, reported by fuel type.
(2) Total CO_2 emissions for all biomass fuels combined.
(3) Total CH_4 emissions for all fuels combined.
(4) Total N_2O emissions for all fuels combined.

(b) Annual fuel consumption:

(1) For gases, report in units of million cubic meters.
(2) For liquids, report in units of liters.
(3) For non-biomass solids, report in units of metric tons.
(4) For biomass-derived solid fuels, report in units of bone dry short tons or bone dry metric tons.

(c) Average carbon content of each fuel, if used to compute CO_2 emissions.

(d) Average high heating value of each fuel, as used to compute CO_2 emissions.

(e) Annual steam generation in pounds or kilograms, for units that burn biomass or municipal solid waste.

Please note that most of the calculation methodologies in this section currently accommodate inputs in English units, only, and not SI units. The section will be revised to allow inputs in SI units, as well as to provide applicable Canadian emission factors from "National Inventory Report 1990-2006: Greenhouse Gas Sources and Sinks in Canada – The Canadian Government's Submission to the UN Framework Convention on Climate Change, April 2008." (http://www.ec.gc.ca/pdb/ghg/inventory_e.cfm)]

§ WCI.23 Calculation of CO_2 Emissions

For each fuel, calculate CO_2 mass emissions using one of the four calculation methodologies specified in this section, subject to the restrictions in §WCI.23 (e).

(a) Calculation Methodology 1. Calculate the annual CO_2 mass emissions by substituting a fuel-specific default CO_2 emission factor, a default high heating value, and the annual fuel consumption into the Equation 20-1:

$$CO_2 = Fuel \times HHV \times EF \times 0.001$$ **Equation 20-1**

Where:

CO_2	=	Annual CO_2 mass emissions for the specific fuel type (metric tons).
Fuel	=	Mass or volume of fuel combusted per year (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).
HHV	=	Default high heat value of the fuel, from column 3 of Table 20-1 (mmBtu per mass or mmBtu per volume, as applicable).
EF	=	Fuel-specific default CO_2 emission factor, from column 5 of Table 20-1 (kg CO_2/mmBtu).
0.001	=	Conversion factor from kilograms to metric tons.

(b) Calculation Methodology 2. Calculate the annual CO_2 mass emissions using a default CO_2 emission factor, and either Equation 20-2 or 20-3, as appropriate:

(1) Equation 20-2 of this section can be used for any type of fuel for which an emission factor is provided in Tables 20-1 or 20-2:

$$CO_2 = \sum_{p=1}^{n} Fuel_P \times HHV_P \times EF \times 0.001$$ **Equation 20-2**

Where:

CO_2	=	Annual CO_2 mass emissions for a specific fuel type (metric tons).
n	=	Number of required heat content measurements for the year as specified in WCI.25.
$Fuel_p$	=	Mass or volume of the fuel combusted during the measurement period "p" (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).
HHV_p	=	High heat value of the fuel for the measurement period (mmBtu per mass or volume).
EF	=	Fuel-specific default CO_2 emission factor, from column 5 of Table 20-1 or from Table 20-2 (kg CO_2/mmBtu).
0.001	=	Conversion factor from kilograms to metric tons.

(2) Equation 20-3 of this section can be used for biomass solid fuels and municipal solid waste only:

$$CO_2 = Steam \times B \times EF \times 0.001$$

Equation 20-3

Where:

CO_2	=	Annual CO_2 mass emissions from MSW combustion (metric tons).
Steam	=	Total mass of steam generated by MSW combustion during the reporting year (lb steam).
B	=	Ratio of the boiler's maximum rated heat input capacity to its design rated steam output capacity (mmBtu/lb steam).
EF	=	Default carbon content for MSW, from column 5 of Table WCI.20-1 (kg CO_2/mmBtu).
0.001	=	Conversion factor from kilograms to metric tons.

(c) Calculation Methodology 3. Calculate the annual CO_2 mass emissions by substituting measurements of fuel carbon content, molecular weight (gaseous fuels, only), and the quantity of fuel combusted into the following equations. For solid fuels, the amount of fuel combusted is obtained from company records kept as provided in this rule. For liquid and gaseous fuels, the volume of fuel combusted is measured directly, using fuel flow meters (including gas billing meters). For fuel oil, tank drop measurements may also be used.

(1) For a solid fuel, use Equation 20-4 of this section:

$$CO_2 = \sum_{i=1}^{n} Fuel_i \times CC_i \times 3.664$$

Equation 20-4

Where:

CO_2	=	Annual CO_2 mass emissions from the combustion of the specific solid fuel (metric tons).
n	=	Number of monthly carbon content determinations for the year.
$Fuel_i$	=	Mass of the solid fuel combusted in month "n" (metric tons).
CC_i	=	Carbon content of the solid fuel, from the fuel analysis results for month "n"(percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).
3.664	=	Ratio of molecular weights, CO_2 to carbon.

(2) For a liquid fuel, use Equation 20-5 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \times 0.001$$

Equation 20-5

Where:

CO_2	=	Annual CO_2 mass emissions from the combustion of the specific liquid fuel (metric tons).
n	=	Number of required carbon content determinations for the year, as specified in WCI.25.
$Fuel_i$	=	Volume of the liquid fuel combusted in month "n" (gallons).
CC_i	=	Carbon content of the liquid fuel, from the fuel analysis results for month "n" (kg C per gallon of fuel).

3.664	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(3) For a gaseous fuel, use Equation 20-6 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \times \frac{MW}{MVC} \times 0.001 \qquad \textbf{Equation 20-6}$$

Where:

CO_2	=	Annual CO_2 mass emissions from combustion of the specific gaseous fuel (metric tons).
n	=	Number of required carbon content and molecular weight determinations for the year, as specified in WCI.25.
$Fuel_i$	=	Volume of the gaseous fuel combusted in a day or month, as applicable (scf).
CC_i	=	Average carbon content of the gaseous fuel, from the fuel analysis results for the day or month, as applicable (kg C per kg of fuel).
MW	=	Molecular weight of the gaseous fuel, from fuel analysis (kg/kg-mole).
MVC	=	Molar volume conversion factor (849.5 scf per kg-mole at standard conditions).
3.664	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(d) Calculation Methodology 4. Calculate the annual CO_2 mass emissions from all fuels combusted in a unit, by using data from continuous emission monitoring systems (CEMS) as specified in (d)(1) through (d)(7).

(1) The operator of a facility that combusts fossil fuels or biomass and operates CEMS in response to federal, state, provincial, or local regulation, may use CO_2 or O_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in 40 CFR Part 75, Appendix F.

(A) The operator shall report CO_2 emissions for the report year in metric tons based on the sum of hourly CO_2 mass emissions over the year, converted to metric tons.

(B) If the operator of a facility that combusts biomass uses O_2 concentrations to calculate CO_2 concentrations, annual source testing must demonstrate that calculated CO_2 concentrations when compared to measured CO_2 concentrations meet the Relative Accuracy Test Audit (RATA) requirements in 40 CFR Part 60, Appendix B, Performance Specification 3.

(2) The operators of a facility that combusts municipal solid waste or other waste-derived fuels and operates a CEMS in response to federal, state, provincial, or local regulations must use CO_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in 40 CFR Part 75, Appendix F.

(A) Annual CO_2 emissions shall be reported in metric tons based on the sum of hourly CO_2 mass emissions over the year.

(B) Emissions calculations shall not be based on O_2 concentrations.

(3) The operator of a facility that combusts MSW or other waste-derived fuels and calculates CO_2 emissions using the methodology provided in WCI.23(d)(2) shall determine the

portion of emissions associated with the combustion of biomass-derived fuels using the method provided in WCI.23(f).

(4) An operator who uses CEMS data to report CO_2 emissions from a facility that co-fires fossil fuels with biomass or waste-derived fuels that are partly biomass shall determine the portion of total CO_2 emissions separately assigned to the fossil fuel and the biomass-derived fuel using the method provided in WCI.23(f), if applicable. The operator who co-fires pure biomass with fossil fuels may elect to calculate CO_2 emissions for the fossil fuels using methods designated in WCI.23(b)(3) by fuel type and then subtract the fossil fuel related emissions from the total CO_2 emissions determined using the CEMS based methodology.

(5) For any units for which CO_2 emissions are reported using CEMS data, the operator is relieved of the requirement to separately report process emissions from combustion emissions or to report emissions separately for different fossil fuels when only fossil fuels are co-fired. In this circumstance, operators shall still report fuel use by fuel type as otherwise required.

(6) If a facility is subject to requirements in 40 CFR Part 60 or 40 CFR Part 75 and the operator chooses to add devices to an existing continuous monitoring system for the purpose of measuring CO_2 concentrations or flue gas flow, the operator shall select and operate the added devices pursuant to the requirements in 40 CFR Part 60 or Part 75 that apply to the facility. If the facility is subject to both 40 CFR Part 60 and 40 CFR Part 75, the operator shall select and operate the added devices pursuant to the requirements in 40 CFR Part 75.

(7) If a facility does not have a continuous emissions monitoring system and the operator chooses to add one in order to measure CO_2 concentrations, the operator shall select and operate the CEMS pursuant to the requirements in 40 CFR Part 75.

(A) The operator shall use CO_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in 40 CFR Part 75, Appendix F.

(B) The operator shall report CO_2 emissions for the report year in metric tons based on the sum of hourly CO_2 mass emissions over the year, converted to metric tons.

(C) Operators who add CEMS under this article are subject to specifications in WCI.23(d)(1)-(5), if applicable.

(e) Use of the Four CO_2 Calculation Methodologies. Use of the four CO_2 emissions calculation methodologies described in paragraphs (a) through (d) of this section is subject to the following requirements and restrictions:

(1) Calculation Methodology 1 may not be used by a facility that is subject to the verification requirements of WCI.8, except for stationary combustion units that combust natural gas with a high heating value between 975 and 1,150 Btu per cubic foot. Otherwise, Calculation Methodology 1 may be used for any type of fuel for which a default CO_2 emission factor and a default high heat value for the fuel is specified in Table 20-1.

(2) Calculation Methodology 2 may not be used by a facility that is subject to the verification requirements of WCI.8, except for stationary combustion units that combust natural gas with a high heating value between 975 and 1,150 Btu per cubic foot. Otherwise, Calculation Methodology 2 may be used for any type of fuel combusted for which a default CO_2 emission factor for the fuel is specified in Table 20-1 or 20-2.

(3) Calculation Methodology 3 may be used for a unit of any size combusting any type of fuel, except when the use of Calculation Methodology 4 is required.
(4) Calculation Methodology 4 may be used for a unit of any size combusting any type of fuel, and must be used for either of the following conditions:

(i) A combustion unit with a CEMS that is required by any federal, state, provincial, or local regulation.

(ii) A municipal solid waste combustion unit that is subject to the verification requirements of WCI.8.

(f) Biogenic CO_2 emissions. The operator that combusts fuels or fuel mixtures that contain biomass shall determine the biomass-derived portion of CO_2 emissions using ASTM D6866-06a, as specified in this paragraph. This procedure is not required for fuels that contain less than 5 percent biomass by weight or for waste-derived fuels that are less than 30 percent biomass by weight on an annual basis.

(1) The operator shall conduct ASTM D6866-06a analysis at least every three months, and shall collect each gas sample for analysis during normal operating conditions over at least 24 consecutive hours.
(2) The operator shall divide total CO_2 emissions between biomass-derived emissions and non-biomass-derived emissions using the average proportionalities of the samples analyzed.
(3) If there is a common fuel source to multiple units at the facility, the operator may elect to conduct ASTM D6866-06a testing for one of the units.

§ WCI.24 Calculation of CH_4 and N_2O Emissions

Calculate the annual CH_4 and N_2O mass emissions from stationary fuel combustion sources using the procedures in paragraph (a), (b), or (c), as appropriate.

(a) If the heat content of the fuel is measured, calculate CH_4 and N_2O emissions the following Equation 20-7:

$$CH_4 \text{ or } N_2O = \sum_{1}^{n} Fuel_P \times HHV_P \times EF \times 0.001 \qquad \textbf{Equation 20-7}$$

Where:

CH_4 or N_2O	=	Combustion emissions from specific fuel type, metric tons CH_4 or N_2O per year.
n	=	Period/frequency of heat content measurements over the year (e.g. monthly n = 12).
$Fuel_P$	=	Mass or volume of fuel combusted for the measurement period specified by fuel type, units of mass or volume per unit time.
HHV_P	=	High heat value measured for the measurement period specified by fuel type, MMBtu per unit mass or volume.
EF	=	Default CH_4 or N_2O emission factor provided in Table 20-3, kg CH_4 or N_2O per MMBtu.
0.001	=	Factor to convert kg to metric tons.

(b) If the heat content of the fuel is not measured, calculate CH_4 and N_2O emissions using the following equation:

$$CH_4 \text{ or } N_2O = \sum_{1}^{n} Fuel \times HHV_D \times EF \times 0.001$$ **Equation 20-8**

Where:

CH_4 or N_2O	=	CH_4 or N_2O emissions from a specific fuel type, metric tons CH_4 or N_2O per year.
Fuel	=	Mass or volume of fuel combusted specified by fuel type, unit of mass or volume per year.
HHV_D	=	Default high heat value specified by fuel type provided in Table 20-3, MMBtu per unit of mass or volume.
EF	=	Default emission factor provided in Table 20-3, kg CH_4 or N_2O per MMBtu.
0.001	=	Factor to convert kg to metric tons.

(c) For municipal solid waste combustion, use Equation 20-9 of this section to estimate CH_4 and N_2O emissions:

$$CH_4 \text{ or } N_2O = Steam \times B \times EF \times 0.001$$ **Equation 20-9**

Where:

CH_4 or N_2O	=	Annual CH_4 or N_2O emissions from the combustion of a municipal solid waste (metric tons).
Steam	=	Total mass of steam generated by MSW combustion during the reporting year (lb steam).
B	=	Ratio of the boiler's maximum rated heat input capacity to its design rated steam output (mmBtu/lb steam).
EF	=	Fuel-specific emission factor for CH_4 or N_2O, from Table WCI.20-3 of this subpart (kg CH_4 or N_2O per mmBtu).
0.001	=	Conversion factor from kilograms to metric tons.

(d) The operator may elect to calculate CH_4 and N_2O emissions using source-specific emission factors derived from source tests conducted at least annually under the supervision of (*jurisdiction*). Upon approval of a source test plan, the source test procedures in that plan shall be repeated in each future year to update the source specific emission factors annually.

§ WCI.25 Sampling, Analysis, and Measurement Requirements

(a) Fuel Sampling Requirements. Fuel sampling must be conducted at the frequency specified in paragraph (a) (1) through (a)(4) of this section.

(1) At receipt of each new fuel shipment or delivery or on a monthly basis for middle distillates (diesel, gasoline, fuel oil, kerosene), residual oil, liquid waste-derived fuels, and LPG (ethane, propane, isobutene, n-Butane, unspecified LPG);

(2) Monthly for natural gas, associated gas, and mixtures of low Btu gas.
(3) Monthly for gases derived from biomass including landfill gas and biogas from wastewater treatment or agricultural processes.
(4) Monthly for solid fuels, as specified below:

(A) The monthly solid fuel sample shall be a composite sample of weekly samples.
(B) The solid fuel shall be sampled at a location after all fuel treatment operations and the samples shall be representative of the fuel chemical and physical characteristics immediately prior to combustion.
(C) Each weekly sub-sample shall be collected at a time (day and hour) of the week when the fuel consumption rate is representative and unbiased.
(D) Four weekly samples (or a sample collected during each week of operation during the month) of equal mass shall be combined to form the monthly composite sample.
(E) The monthly composite sample shall be homogenized and well mixed prior to withdrawal of a sample for analysis.
(F) One in twelve composite samples shall be randomly selected for additional analysis of its discreet constituent samples. This information will be used to monitor the homogeneity of the composite.

(b) Fuel Consumption Monitoring Requirements.

(1) Facilities that are subject to the verification requirements of WCI.8 must determine annual fuel consumption by direct measurement.
(2) Facilities that are not subject the verification requirements of WCI.8 may determine consumption on the basis of recorded fuel purchase or sales invoices measuring any stock change (measured in million Btu, gallons, million standard cubic feet, short tons or bone dry short, tons) using the following equation:

Fuel Consumption in the Report Year = Total Fuel Purchases – Total Fuel Sales + Amount Stored at Beginning of Year – Amount Stored at Year End

(3) Fuel consumption measured in Btu values shall be converted to the required metrics of mass or volume using heat content values that are either provided by the supplier, measured by the facility, or provided in Table 20-1.

(c) Fuel Heat Content Monitoring Requirements. High heat values shall be determined using one of the following methods:

(1) For gases, use ASTM D1826-94 (Reapproved 2003), ASTM D3588-98 (Reapproved 2003), ASTM D4891-89 (Reapproved 2006), GPA Standard 2261-00 "Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography." The operator may alternatively elect to use on-line instrumentation that determines heating value accurate to within ± 5.0 percent. Where existing on-line instrumentation provides only low heating value, the operator shall convert the value to high heating value as specified in section 95125(c)(1)(C).
(2) For middle distillates and oil, or liquid waste-derived fuels, use ASTM D240-02 (Reapproved 2007), ASTM D240-87 (Reapproved 1991), ASTM D4809-00 (Reapproved 2005).
(3) For solid biomass-derived fuels use ASTM D5865-07a.

(4) For waste-derived fuels use ASTM D5865-07a or ASTM D5468-02 (Reapproved 2007). Operators who combust waste-derived fuels that are partly but not pure biomass shall determine the biomass-derived portion of CO_2 emissions using the method specified in section WCI.23(f), if applicable

(d) Fuel Carbon Content Monitoring Requirements. Fuel carbon contents should be monitored in the following manner.

(1) For coal and coke, solid biomass-derived fuels, and waste-derived fuels; use ASTM 5373-02 (Reapproved 2007).

(2) For liquid fuels, use the following ASTM methods: For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291-02 (Reapproved 2007) "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants", ultimate analysis of oil or computations based on ASTM D3238-95 (Reapproved 2005) and either ASTM D2502-04 or ASTM D2503-92 (Reapproved 2002).

(3) For gaseous fuels, use ASTM D1945-03 or ASTM D1946-90 (Reapproved 2006).

Table 20-1. Default Carbon Content, Heat Content, and Carbon Dioxide Emission Factors from Stationary Combustion by Fuel Type				
Fuel Type	**Carbon Content**	**High Heat Value**	**CO_2 Emission Factor**	**CO_2 Emission Factor**
Coal and Coke	**kg C / MMBtu**	**MMBtu / Short Ton**	**kg CO_2 / Short Ton**	**kg CO_2 / MMBtu**
Anthracite	28.26	25.09	2,597.94	103.54
Bituminous	25.49	24.93	2,328.35	93.40
Sub-bituminous	26.48	17.25	1,673.64	97.02
Lignite	26.30	14.21	1,369.32	96.36
Unspecified (Residential/Commercial)	26.00	22.24	2,118.67	95.26
Unspecified (Industrial Coking)	25.56	26.28	2,461.17	93.65
Unspecified (Other Industrial)	25.63	22.18	2,082.89	93.91
Unspecified (Electric Power)	25.76	19.97	1,884.86	94.38
Coke	27.85	24.80	2,530.65	102.04
Natural Gas (By Heat Content)	**kg C / MMBtu**	**Btu / Standard cubic foot**	**kg CO_2 / Standard cubic ft.**	**kg CO_2 / MMBtu**
975 to 1,000 Btu / Standard cubic foot	14.73	n/a	n/a	53.97
1000 to 1,025 Btu / Std cubic foot	14.43	n/a	n/a	52.87
1025 to 1,050 Btu / Std cubic foot	14.47	n/a	n/a	53.02
1050 to 1,075 Btu / Std cubic foot	14.58	n/a	n/a	53.42
1075 to 1,100 Btu / Std cubic foot	14.65	n/a	n/a	53.68
Greater than 1,100 Btu / Std cubic foot	14.92	n/a	n/a	54.67
Unspecified (Weighted U.S. Average)	14.47	1,027	0.0544	53.02

Table 20-1. Default Carbon Content, Heat Content, and Carbon Dioxide Emission Factors from Stationary Combustion by Fuel Type (continued)

Petroleum Products	kg C / MMBtu	MMBtu / Barrel	kg CO_2 / gallon	kg CO_2 / MMBtu
Asphalt & Road Oil	20.62	6.636	11.94	75.55
Aviation Gasoline	18.87	5.048	8.31	69.14
Distillate Fuel Oil (#1, 2 & 4)	19.95	5.825	10.14	73.10
Jet Fuel	19.33	5.670	9.56	70.83
Kerosene	19.72	5.670	9.75	72.25
LPG (energy use)	17.19	3.861	5.79	62.98
Propane	17.20	3.824	5.74	63.02
Ethane	16.25	2.916	4.13	59.54
Isobutane	17.75	4.162	6.44	65.04
n-Butane	17.72	4.328	6.69	64.93
Lubricants	20.24	6.065	10.71	74.16
Motor Gasoline	19.33	5.218	8.80	70.83
Residual Fuel Oil (#5 & 6)	21.49	6.287	11.79	78.74
Crude Oil	20.33	5.800	10.29	74.49
Naphtha (<401 deg. F)	18.14	5.248	8.30	66.46
Natural Gasoline	18.24	4.620	7.35	66.83
Other Oil (>401 deg. F)	19.95	5.825	10.14	73.10
Pentanes Plus	18.24	4.620	7.35	66.83
Petrochemical Feedstocks	19.37	5.428	9.17	70.97
Petroleum Coke	27.85	6.024	14.64	102.04
Still Gas	17.51	6.000	9.17	64.16
Special Naphtha	19.86	5.248	9.09	72.77
Unfinished Oils	20.33	5.825	10.33	74.49
Waxes	19.81	5.537	9.57	72.58
Other Solid Fuels	**kg C / MMBtu**	**MMBtu / Short Ton**	**kg CO_2 / Short Ton**	**kg CO_2 / MMBtu**
Biomass Derived Fuels (Solid). Wood and Wood Waste (12% moisture content) or other solid biomass-derived fuels	25.60	15.38	1,442.62	93.80
Municipal Solid Waste (MSW)	24.74	8.7	788.7	90.65
Biomass-derived Fuels (Gas)	**kg C / MMBtu**	**Btu / Standard cubic foot**	**kg CO_2 / Standard cubic ft.**	**kg CO_2 / MMBtu**
Biogas (includes landfill gas and manure biogas)*	28.4	Varies	Varies	104.06

Note: Heat content factors are based on higher heating values (HHV).

* The emission factors for biogas include both the CO_2 from combustion and the pass-through CO_2, which are assumed to be in equal proportions.

Table 20-2. Default Carbon Dioxide Emission Factors from Stationary Combustion for Waste Derived Fuels

Fuel Type	kg CO_2 / MMBtu
Waste Oil	78
Tires	90
Plastics	79
Solvents	78
Impregnated Saw Dust	79
Other Fossil Based Wastes	84
Dried Sewage Sludge	116
Mixed Industrial Waste	88
Municipal Solid Waste	91

Note: Emission factors are based on higher heating values (HHV). Values were converted from LHV to HHV assuming that LHV are 5 percent lower than HHV for solid and liquid fuels.

Table 20-3. Default CH_4 and N_2O Emission Factors from Stationary Combustion by Fuel Type

Fuel Type	CH_4 Emission Factor (kg CH_4/ MMBtu)	N_2O Emission Factor (kg N_2O / MMBtu)

Note: Heat content factors are based on higher heating values (HHV).

ATTACHMENT 1: GENERAL PROVISIONS

GENERAL PROVISIONS

§ WCI.0 PURPOSE

§ WCI.1 APPLICABILITY

§ WCI.2 GENERAL GREENHOUSE GAS REPORTING REQUIREMENTS AND SCHEDULE

§ WCI.3 CONTENTS OF THE GREENHOUSE GAS EMISSIONS REPORT

§ WCI.4 DOCUMENT RETENTION AND RECORD KEEPING REQUIREMENTS

§ WCI.5 COMPLIANCE AND ENFORCEMENT

§ WCI.6 INCORPORATION BY REFERENCE

§ WCI.7 DESIGNATED REPRESENTATIVE

§ WCI.8 REQUIREMENTS FOR VERIFICATION OF GREENHOUSE GAS EMISSIONS DATA REPORTS AND REQUIREMENTS APPLICABLE TO EMISSIONS DATA VERIFIERS

§ WCI.9 DEFINITIONS

§ WCI.10 GLOBAL WARMING POTENTIALS

EMISSIONS QUANTIFICATION, AND SAMPLING, ANALYSIS AND MEASUREMENT

§ WCI.20 THROUGH § WCI.XX

§ WCI.0 PURPOSE

This rule requires mandatory reporting and verification of greenhouse gas (GHG) emissions data by certain facilities that directly emit GHG, by importers of electricity, and by suppliers of fossil fuels. The GHGs that must be reported under this rule are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFC), perfluorocarbons (PFC), and sulfur hexafluoride (SF_6).

§ WCI.1 APPLICABILITY

(a) The GHG emissions reporting requirements, and related monitoring, recordkeeping, and verification requirements of this rule apply to the owners and operators *[Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices]* of any facility that meets the requirements of paragraph (a)(1) of this section; and any fuel suppliers and electricity importers that meet the requirements of paragraph (a)(2), (a)(3), or (a)(4) of this section:

(1) Any facility that emits 10,000 metric tons CO_2e or more per year in combined emissions from one or more of the source categories listed in this paragraph in any calendar year starting in 2010.

[Please note that the quantification and monitoring methods for many of these source categories are currently being assessed. Only source categories for which adequate quantification methods exist will be included in the final WCI Essential Requirements for mandatory reporting.]

(A) Adipic acid manufacturing [*still being assessed*]
(B) Aluminum manufacturing
(C) Ammonia manufacturing [*still being assessed*]
(D) Carbon dioxide transfer recipients [*still being assessed*]
(E) Cement manufacturing
(F) Coal mine fugitive emissions (active and abandoned)
(G) Coal storage
(H) Cogeneration [*still being assessed*]
(I) Electricity generation
(J) Electronics Manufacturing [*still being assessed*]
(K) Ferroalloy production [*still being assessed*]
(L) General stationary fuel combustion
(M) Glass Production and other uses of carbonates [*still being assessed*]
(N) HCFC-22 production [*still being assessed*]
(O) Hydrogen production
(P) Industrial wastewater *[still being assessed for some industries]*
(Q) Iron and steel manufacturing
(R) Lead production
(S) Lime manufacturing
(T) Magnesium production *[still being assessed]*
(U) Natural gas transmission and distribution systems *[still being assessed]*
(V) Nitric acid manufacturing *[still being assessed]*
(W) Nonroad equipment at facilities *[still being assessed]*

(X) Oil and gas production & gas processing *[still being assessed]*
(Y) Petrochemical production *[still being assessed]*
(Z) Petroleum refineries
(AA) Phosphoric acid production *[still being assessed]*
(BB) Pulp and paper manufacturing
(CC) Refinery fuel gas
(DD) SF_6 from electrical equipment *[still being assessed]*
(EE) Soda ash manufacturing *[still being assessed]*
(FF) Zinc production

(2) All importers of electricity. Importers of electricity include both retail providers and marketers that import electricity into the WCI region. *[This is preliminary language, pending definition of electricity importers by another WCI Committee.]*

(3) Any supplier that within the WCI region distributes transportation fuels in quantities that when combusted would emit 10,000 metric tons CO_2e per year or more in any calendar year starting in 2010. *[This is preliminary language, pending future determination of point of regulation for transportation fuels.]*

(4) Any supplier that distributes within the WCI region residential, commercial, and industrial fuels in quantities that when combusted would emit 10,000 metric tons CO_2e per year or more in any calendar year starting in 2010. *[This is preliminary language, pending future determination of points of regulation for these fuels.]*

(b) To calculate GHG emissions for comparison to the 10,000 metric ton CO_2e per year emission threshold in paragraph (a)(1) of this section, the owner or operator shall calculate annual CO_2e emissions, as described in paragraphs (b)(1) through (b)(4) of this section.

(1) Estimate the annual emissions of CO_2, CH_4, N_2O, HFC, PFC, and SF_6 in metric tons for each unit, process, activity, or operation for which emission calculation methodologies are provided in sections WCI.20 through WCI.XX. The GHG emissions shall be calculated using methodologies specified in each applicable section.

(2) For stationary combustion units, carbon dioxide emissions from the combustion of biomass fuels shall be included in the calculations. *[WCI is considering a limited deduction of biomass fuel combustion emissions from determination of whether the reporting threshold has been met.]*

(3) Sum the total facility emissions for each GHG and calculate the metric tons of CO_2e using equation 1-1 below.

$$CO_2e = \sum_{i=1}^{n} GHG_i \times \mathrm{GWP}_i \qquad \textbf{Equation 1-1}$$

Where:

CO_2e = Carbon dioxide equivalent, metric tons/year.
GHG_i = Mass emissions of each greenhouse gas emitted, metric tons/year.
GWP_i = Global warming potential for each greenhouse gas from Table WCI.10-1 of this regulation.
n = The number of greenhouse gases emitted.

(4) For purpose of determining if an emission threshold has been exceeded, any CO_2 that is captured for on-site use, on-site storage, or transfer off-site must be included in the emissions total.

(c) To calculate GHG emissions for comparison to the 10,000 metric ton CO_2e per year emission threshold for suppliers of transportation fuels in paragraphs (a)(3) of this section, the owner or operator shall follow the procedures of paragraphs (c)(1) through (c)(2) below:

(1) Calculate the total mass in metric tons per year of CO_2, CH_4, and N_2O that would result from the complete combustion or oxidation of all transportation fuels that are distributed within the WCI region. The mass of each GHG shall be calculated using any of the applicable methodologies specified in section WCI.XX [Transportation Fuels Combustion] of this rule.

(2) Sum the emissions of each GHG and calculate total metric tons of CO_2e using Equation 1-1 of this rule.

(d) To calculate GHG emissions for comparison to the 10,000 metric ton CO_2e per year emission threshold for suppliers of residential, commercial, and industrial fuels in paragraph (a)(4) of this section, the owner or operator shall follow the procedures of paragraphs (d)(1) and (d)(2) below:

(1) Calculate the total mass in metric tons per year of CO_2, CH_4, and N_2O that would result from the complete combustion or oxidation of all residential, commercial, and industrial fuels that are distributed within the WCI region. The calculation shall exclude any fuels that are supplied to facilities that are required to report GHG emissions under section WCI.1(a)(1). *[These accounting issues will be dealt with in 2009.]* The mass of each GHG shall be calculated using any of the applicable methodologies specified in section WCI.XX [Residential, Commercial and Industrial Fuels Combustion] of this rule.

(2) Sum the emissions of each GHG and calculate total metric tons of CO_2e using Equation 1-1 of this rule.

(e) If the operations of a facility or fuel supplier that is subject to this rule change such that emissions fall below 10,000 metric tons CO_2e per year, then the following reporting requirements shall apply:

[Please note that the requirements of this subsection do not currently address reporters who emit >25,000 metric tons during 1 or more years, and then drop below 25,000 metric tons and above 10,000 metric tons in subsequent years. A provision for these reporters to cease verification after some period of time is under consideration.]

(1) If, prior to such emission reduction, the emissions report was subject to the verification requirements of this rule; then the owner or operator shall continue to submit verified emission reports until reported emissions are below 10,000 metric tons CO_2e per year for a minimum of 3 consecutive years. If reported emission are less than 10,000 metric tons CO_2 per year during 3 consecutive years, then the owner or operator shall be exempted from further reporting until CO_2e emissions again exceed 10,000 metric tons in any future calendar year.

(2) If, prior to such emission reduction, the emissions report was not subject to the verification requirements of this rule; then the owner or operator shall submit to the *[jurisdiction]* a signed statement certifying that emissions are less than 10,000 metric tons

CO_2e during the prior year. After certifying that emissions are below 10,000 metric tons CO_2e per year for 3 consecutive years, the owner or operator shall be exempted from further reporting until CO_2e emissions again exceed 10,000 metric tons in any future calendar year.

(3) Notwithstanding the requirements of paragraphs (e)(1) and (2) of this section, a facility or fuel supplier that is subject to an emissions limitation under the WCI cap-and-trade program must continue to submit verified annual reports.

(f) Upon request by the [*jurisdiction*], owner or operator of any facility or fuel supply operation must submit a demonstration that emissions have not exceeded one or more of the applicability criteria specified in this section in any year since 2010. Such demonstration shall be provided to the [*jurisdiction*] within 20 working days of receipt of a written request. *[WCI is considering whether this and other deadlines for responses provide sufficient time, and whether such deadlines should be standardized across requirements.]*

§ WCI.2 GENERAL GREENHOUSE GAS REPORTING REQUIREMENTS AND SCHEDULE

[Specific requirements of this section may change based on the future final design of the marketing trading program.]

(a) General. Owners or operators that are subject to this rule must submit an annual GHG emissions report. Owners and operators must collect data; calculate GHG emissions; and follow the procedures for quality assurance, missing data, recordkeeping, and reporting as specified in these General Provisions and in each relevant section WCI.20 through WCI.XX of this rule.

(1) A facility, fuel supplier, or electricity importer that commenced operation before January 1, 2010, must report emissions beginning in 2011 for GHGs emitted in calendar year 2010.

(2) A new facility, fuel supplier, or electricity importer that commences operation on or after January 1, 2010, must report emissions for the first calendar year in which the facility operates, beginning with the first operating month and ending on December 31 of that year. Each subsequent annual report must cover emissions for the calendar year, beginning on January 1 and ending on December 31.

(b) Reporting and Verification Schedule.

(1) Annual GHG emissions reports must be submitted to [*the jurisdiction*] by April 1 of each year for emissions in the previous calendar year.

(2) Reporters subject to the verification requirements of WCI.8, must complete their verification process, including submittal of a verification statement to [*the jurisdiction*], according to the following schedule:

(A) For reporting years 2010 through 2011, September 1 of the year following the reporting year.

(B) For reporting years 2012 and later, *[date to be determined]*.

(c) Submission of GHG Emissions Report. The annual GHG emissions report must be submitted to [*the jurisdiction*] in a format [*to be specified by each jurisdiction*].

(d) Simplified Emission Calculation Methods for De Minimis Sources. The owner or operator may elect to designate as de minimis one or more sources or pollutants that collectively emit no more than 3 percent of the facility's total CO_2e emissions, but not to exceed 20,000 metric tons CO_2e. The owner or operator may estimate emissions for these de minimis sources using alternative methods to those required to be used by this rule. If verification of the emissions report is required by this rule, then the selection of any alternative GHG calculation method is subject to the concurrence of the verification team that the use of such methods provides reasonable assurance that the emissions so designated do not exceed the applicable de minimis limits. The operator shall separately identify and include in the emissions data report the emissions from designated de minimis sources.

(e) GHG Inventory Management Plan. The owner or operator shall prepare and follow a written GHG inventory management plan that ensures that the emissions calculations and other information that is required to be reported under this rule are transparent, accurate, and independently verifiable. The owner or operator shall establish, document, implement, and maintain data acquisition and handling activities for the calculation and reporting of GHG emissions. Such activities shall include measuring, monitoring, analyzing, recording, processing and calculating the parameters specified by this rule. The owner or operator shall implement systems of internal audit, quality assurance, and quality control for the reporting program and the data reported. *[WCI is considering whether a written plan should be mandatory, or advised in guidance materials as a means of assuring a smooth verification process and a positive verification opinion.]*

(f) GHG Emissions Report Revisions.

(1) The owner or operator shall maintain documentation to support any revisions made to a previously submitted annual GHG emissions report. Documentation for all revisions shall be retained by the operator for 7 years.

(2) If, after the verification deadline, a report subject to verification is found to contain an error, or accumulation of errors, greater than 5 percent of the total CO_2e emissions reported, the owner or operator shall revise and resubmit an annual GHG emissions report within 60 days of the finding. To the extent possible, the revised report must correct all identified errors. A revised report will be accepted only if verified according to WCI.8 and approved by [*the jurisdiction*].

(3) If, after the report submittal deadline, a report not subject to verification is found to contain an error, or accumulation of errors, greater than 5 percent of the total CO_2e emissions reported, the owner or operator shall revise and resubmit an annual GHG emissions report within 30 days of the finding. To the extent possible, the revised report must correct all identified errors. A revised report will be accepted only if approved by [*the jurisdiction*].

(4) An owner or operator that voluntarily chooses to correct errors of 5 percent or less in total CO_2e emissions reported may do so according to the following requirements:

(A) For reports subject to verification, a revised report will be accepted only if verified according to WCI.8 and approved by [*the jurisdiction*].

(B) For reports not subject to verification, a revised report will be accepted if approved by [*the jurisdiction*].

(g) Fuel Use Measurement Accuracy. The operator shall use procedures to quantify fuel use (mass or volume flow) that provide data with an accuracy within ±5 percent. All fuel use measurement devices shall be maintained and calibrated in a manner and at a frequency required to maintain this level of accuracy. The operator shall make available to the verification team documentation to support this level of accuracy. The operator who measures solid fuels shall validate fuel consumption estimates with belt or conveyor scale calibrations conducted at least quarterly, and retain record of such calibrations.

(h) Where this rule specifies a choice between use of a fuel-based or mass balance-based calculation or use of a continuous emissions monitoring system (CEMS) to calculate CO_2 emissions, the operator shall make this choice and continue to use the method chosen for all future emissions data reports, unless the use of the alternative calculation method is approved in advance by *[the jurisdiction]*.

§ WCI.3 CONTENTS OF THE GREENHOUSE GAS EMISSIONS REPORT

Each annual GHG emissions report shall contain the following information:

(a) Facility name, identification number, physical address, mailing address, and NAICS code.

(b) Reporting year.

(c) Date of report submittal.

(d) Total facility emissions aggregated from all applicable source categories in subparts WCI.20 through WCI.XX expressed in metric tons of CO_2e calculated using Equation 1-1 of section WCI.1, excluding emissions from CO_2 that is captured and CO_2 emissions from the combustion of biomass and biomass-derived fuels, which are reported separately.

(e) Total facility emissions of CO_2 from the combustion of biomass and biomass-derived fuels.

(f) Total annual mass of CO_2 captured for on-site use, on-site storage, or transfer off site, in metric tons.

(g) For applicable fuel supplier categories in subparts WCI.XX [Transportation Fuels Combustion] and WCI.XX [Residential, Commercial and Industrial Fuels Combustion], total CO_2e emissions aggregated from all specified fuels.

(h) Emissions from each applicable source category or fuel supplier category in subparts WCI.20 through WCI.XX, expressed in metric tons per year of CO_2, CH_4, N_2O, HFC, PFC, and SF_6. CO_2 emissions from the combustion of biomass and biomass-derived fuels shall be reported separately.

(i) For electricity importers, the information required by WCI.XX [Electricity Imports].

(j) Emissions and other data for individual units, processes, activities, and operations as specified for each source category in sections WCI.20 through WCI.XX of this rule.

(k) Mass emissions from each designated de minimis source or pollutant, reported in metric tons per year of each GHG for which an alternative emission calculation method is used.

(l) Name and contact information including e-mail address and telephone number of the person primarily responsible for preparing and submitting the emissions report.

(m) A signed and dated statement provided by the owner or operator, or their designated representative, certifying that the report has been prepared in accordance with this rule and that, subject to verification, the statements and information contained in the emissions data report are true, accurate, and complete to the best of their knowledge.

§ WCI.4 DOCUMENT RETENTION AND RECORD KEEPING REQUIREMENTS

(a) The operator shall establish and maintain procedures for document retention and record keeping. The operator shall retain all documents regarding the design, development and maintenance of the GHG inventory in paper, electronic or other usable format for a period of not less than 7 years following submission of each emissions data report. The retained documents, including GHG emissions data, shall be sufficient to allow for the verification of each emissions data report.

(b) Upon request by *[jurisdiction]*, the operator shall provide within 10 working days all documents and data used to develop an emissions data report.

(c) In addition to information submitted as part of the emissions data report, each operator shall retain, at a minimum, the following information for at least 7 years after the submission of the report:

(1) A list of all GHG sources (i.e., units, operations, processes, and activities) included in the emission estimates.
(2) All data used to calculate emissions for each source, categorized by process and fuel or material type.
(3) Documentation of the process for collecting emissions data.
(4) Any GHG emissions calculations and methods used;
(5) All emission factors used for emission estimates, including documentation for any factors not provided in the rule.
(6) All input data used for emission estimates.
(7) Documentation of biomass fractions for specific fuels.
(8) All other data submitted to the [*jurisdiction*] under this rule, including the GHG emissions report.
(9) All computations made to gap-fill missing data.
(10) Names and documentation of key facility personnel involved in emissions calculating and reporting;
(11) Any other information that is required for the verification of the GHG emissions report.
(12) A log to be prepared for each reporting year, beginning January 1, documenting all procedural changes made in GHG accounting methods and changes to instrumentation for GHG emissions estimation.
(13) A copy of the GHG Inventory Management Plan.

(d) For measurement based methodologies, the following information also must be retained for at least 7 years after the submission of the emissions data report:

(1) List of all emission points monitored.
(2) Collected monitoring data.
(3) Quality assurance and quality control information collected under the GHG Inventory Management Plan required by section WCI.2 of this rule.

(4) A detailed technical description of the continuous measurement system, including documentation of any findings and approvals by federal, State or local agencies.
(5) Raw and aggregated data from the continuous measurement system.
(6) A log book of all system down-times, calibrations, servicing, and maintenance of the continuous measurement system.
(7) Documentation of any changes in the continuous measurement system over time.

§ WCI.5 COMPLIANCE AND ENFORCEMENT

(a) Knowing submission of false information to the *[jurisdiction*] or a verification body, shall constitute a single, separate violation of the requirements of this article for each day after the information has been received by the [*jurisdiction*].

(b) Each violation of this rule shall constitute a single, separate violation for each day beyond the specified reporting date. A violation includes failure to submit any report, failure to collect data needed to calculate GHG emissions, failure to monitor and test as required, failure to calculate GHG emissions following the methodologies specified in this rule, failure to retain required records, failure to provide all information required in the report, and failure to submit a report on time. For the purposes of this rule, "report" means any GHG emissions data report, verification statement, or other document required to be submitted by this rule.

§ WCI.6 INCORPORATION BY REFERENCE

The following documents are incorporated by reference into this rule. These materials are incorporated as they exist on the date this article is adopted.

[This list will be revised as additional calculation methods are selected. Canadian Standards Association methods equivalent to the specified ASTM methods will be identified as substitutes for these in rulemaking by Canadian jurisdictions.]

(a) American Society for Testing and Materials (ASTM) D1826-94 (Reapproved 2003), ASTM D3588-98 (Reapproved 2003), ASTM D4891-89 (Reapproved 2006), ASTM D240-02 (Reapproved 2007), ASTM D4809-00 (Reapproved 2005), ASTM 5373-02 (Reapproved 2007), ASTM D5291-02 (Reapproved 2007), ASTM D3238-95 (Reapproved 2005), ASTM D2502-04, ASTM D2503-92 (Reapproved 2002), ASTM D1945-03, ASTM D1946-90 (Reapproved 2006), ASTM D6866-06a, ASTM D388-05, ASTM D5468-02 (Reapproved 2007), ASTM D240-87 (Reapproved 1991), ASTM D5865-07a, ASTM Specification D396-07, ASTM Specification D975-07b.

(b) California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities, California Air Pollution Control Officers Association (CAPCOA) and California Air Resources Board (ARB), February 1999.

(c) Control of Emissions from Refinery Flares, Rule 118, South Coast Air Quality Management District, Amended November 4, 2005.

(d) U.S. EPA TANKS Version 4.09D, US Environmental Protection Agency, October 2005.

(e) Gas Processors Association (GPA) Standard 2261-00, Revised 2000.

§ WCI.7 DESIGNATED REPRESENTATIVE

(a) General. Each fuel supplier, electricity importer, and owner or operator of a facility that is subject to this rule, shall select a designated representative that is responsible for certifying and submitting GHG emissions reports under this reporting rule.

(b) Authorization of a Designated Representative. The designated representative of the facility shall be selected by a certificate of representation agreement that is signed by the designated representative and owners or operators of the facility. The designated representative must be an individual having responsibility for the overall operation of the facility or activity such as the position of the plant manager, operator of a well or a well field, superintendent, position of equivalent responsibility, or an individual or position having overall responsibility for environmental matters for the company.

(c) Responsibility of the Designated Representative.

(1) The designated representative of the facility shall represent and by any representations, actions, inactions, or submissions, legally bind each owner and operator in all matters pertaining to this rule.

(2) Each GHG emission report submitted under this rule must be signed by the designated representative and must contain the following certification statement: “I have been authorized to make this submission on behalf of the owners and operators of the facility (or supply operation, as appropriate). I certify under penalty of law that I have personally examined the information submitted in this document. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment."

(d) Changing a Designated Representative. The designated representative may be changed at any time upon submission of a superseding certificate of representation. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous designated representative before time of the superseding certificate of representation shall be binding on the new designated representative and the owners and operators.

(e) Changes in Owners and Operators. In the event of any change in ownership of the facility, any new owner or operator shall be deemed to be bound by the representations, actions, inactions, and submissions of the designated representative of the facility until such time as the designated representative is changed.

(f) Certificate of Representation. A certificate of representation must be submitted to *[the jurisdiction]* and kept on location by the facility, fuel supplier, or electricity importer. The certificate shall include the following information:

(1) Identification of the facility, fuel supplier, or electricity importer for which the certificate of representation is submitted.

(2) The name, address, e-mail address (if any), telephone number, and facsimile transmission number (if any) of the designated representative.

(3) A list of the owners and operators.

(4) Certification statements that the actions of the designated representative with respect to this rule are binding on the owners and operators, and that the designated representative has the necessary authority to carry out duties and responsibilities on behalf of the owners and operators.

(5) The signature of the designated representative and owner(s) and operator(s), and the dates signed.

§WCI.8 REQUIREMENTS FOR VERIFICATION OF GREENHOUSE GAS EMISSIONS DATA REPORTS AND REQUIREMENTS APPLICABLE TO EMISSIONS DATA VERIFIERS

(a) Applicability. Owners or operators [Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices] are required to obtain annual verification when the reported annual emissions of the operation subject to this rule:

(1) Are equal to 25,000 metric tons of CO_2e or more; or

(2) Are subject to an emissions limit under the WCI cap-and-trade program as required under WCI.1(e)(3); or

(3) Were verified and then fall below 10,000 metric tons of CO_2e in a subsequent year as stipulated under WCI.1(e)(1).

[WCI is considering a limited deduction of biomass fuel combustion emissions from determination of whether the verification threshold has been met.]

(b) Requirements for Annual Verification of Emissions Data Reports.

(1) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification shall be subject to full verification requirements in the first year that verification is required. Upon completion of a positive verification statement under full verification requirements, the facility owner or operator, fuel supplier, or electricity importer may choose to obtain two years of less intensive verification services. This cycle may be repeated in subsequent three-year cycles, but full verification requirements shall apply at least once every three years.

(2) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification will be required to obtain full verification services if any of the following apply:

(A) Change in the verification body from the previous year; or

(B) A verification body was not able to provide a positive verification statement for the reporters emissions report for the previous year.

(3) Facility owners or operators, fuel suppliers, or electricity importers subject to annual verification shall not use the same verification body for a period of more than six consecutive years. If a facility owner or operator, fuel supplier, or electricity importer is required or elects to contract with another verification body, they may contract verification services from the previous verification body only after not using the previous verification body for at least three years.

(c) Requirements for Verification Services. Verification services shall be subject to the following requirements.

(1) Notice of Verification Services. After the [*WCI Regional Body, jurisdiction, or other organization to be determined (TBD)*] has provided a determination that the potential for a conflict of interest is acceptable as specified in section WCI.8(e) and that verification services may proceed, the verification body shall submit a notice of verification services to [*TBD*]. The verification body may begin verification services for the operator 15 working days after the notice is received by the [*TBD*], or earlier if approved by the [*TBD*] in writing. The notice shall include the following information:

(A) A list of the staff who will be designated to provide verification services as a verification team, including the names of each designated staff member, the lead verifier, and all subcontractors, and a description of the roles and responsibilities each member will have during verification;

(B) Documentation that the verification team has the skills required to provide verification services for the reporting facility, fuel supply or electricity import operation. This shall include a demonstration that a verification team includes at least one member with source category specific skills to provide source-category specific verification services when required below:

i. For providing verification of emissions reported under WCI.60 [Electricity Importers] at least one verification team member must have demonstrated knowledge as an electricity transactions specialist.

ii. For providing verification of emissions reported under WCI.200 [Petroleum refineries] or WCI.140 [Hydrogen production], at least one verification team member must have demonstrated knowledge as a refinery specialist;

iii. For providing verification of emissions reported under WCI.90 [Cement], at least one verification team member must have demonstrated knowledge as a cement specialist.

[Note that other source-category specialist skills may be required. These requirements are being discussed by the WCI, as are any additional accreditation requirements for individual lead verifiers, general verifiers, or sector specialists.]

(C) General information on the lead verifier and the operator, including:

i. The name, office address, telephone number, and e-mail address of the lead verifier;

ii. The name of the owner or operator, and the facilities and other locations that will be subject to verification services, owner or operator contact, address, telephone number, and e-mail address;

iii. The industry sector, and the Standard Industrial Classification and North American Industry Classification System (NAICS) codes of the facility, fuel supplier, or electricity importer;

iv. The expected date(s) of on-site visits, with facility or fuel supply location address and contact information;

v. A brief description of expected verification services to be performed, including expected completion date.

(2) Verification services shall include, but are not limited to, the following:

(A) Verification Plan. The verification team shall obtain information from the owner or operator necessary to develop a verification plan. Such information shall include but is not limited to:

i. Information to allow the verification team to develop a general understanding of facility or entity boundaries, operations, emissions sources, and electricity transactions as applicable;
ii. Information regarding the training or qualifications of personnel involved in developing the GHG emissions data report;
iii. Description of the specific methodologies used to quantify and report GHG emissions, electricity transactions, and other required data as applicable;
iv. Information about the data management system used to track GHG emissions, electricity transactions, and other required data as applicable.

(B) The verification team shall develop a verification plan that includes, at a minimum:

i. Dates of proposed meetings and interviews with reporting facility, fuel supply, or electricity import personnel;
ii. Dates of proposed site visits;
iii. Types of proposed document and data reviews;
iv. Expected date for completing verification services.

(C) The verification team shall discuss with the owner or operator the scope of the verification services and request any information and documents needed for initial verification services. The verification team shall review the documents submitted and plan and conduct a review of original documents and supporting data for the emissions data report.

(D) Site visits. At least one member of the verification team shall at a minimum make one site visit, in the first year of each three-year reporting cycle or if full verification requirements are required under WCI.8(b)(3), to each facility or fuel supply location [Note that exact location of fuel supplier site visits remains TBD] for which an emissions data report is submitted. The verification team member(s) shall visit the headquarters or other location of central data management when the owner or operator is an electricity importer. During the site visit, the verification team member(s) shall conduct the following:

i. The verification team member(s) shall check that all sources specified in sections WCI.20 to WCI.XX as applicable to the owner or operator, are identified appropriately.
ii. The verification team member(s) shall review and understand the data management systems used by the owner or operator to track, quantify, and report greenhouse gas emissions and, when applicable, electricity transactions. The verification team member(s) shall evaluate the uncertainty and effectiveness of these systems.
iii. The verification team shall collect and review other information that, in the professional judgment of the team, is needed in the verification process.

(E) The verification team shall review facility, fuel supplier, or electricity importer operations to identify applicable GHG emissions sources. This shall include a review of the emissions inventory and each type of emission source to assure that all sources listed in sections WCI.20 through WCI.XX are properly included in the inventory.

(F) Owners or operators shall make available to the verification team all information and documentation used to calculate and report emissions, electricity transactions, and other information required under this rule, as applicable.

(G) As applicable for electricity importers, the verification team shall review electricity transaction records, including receipts of power attributed to the Northwest or Southwest region as verifiable via North American Electric Reliability Corporation (NERC) E-Tags, settlements data, or other information as confirmation of the region of origin. [Note that this procedure is subject to change pending WCI Electricity Committee review.]

(H) Sampling Plan. As part of confirming emissions data or electricity transactions the verification team shall develop a sampling plan that meets the following requirements:

i. The verification team shall develop a sampling plan based on a strategic analysis developed from document reviews and interviews to assess the likely nature, scale and complexity of the verification services for an owner or operator. The analysis shall review the inputs for the development of the submitted emissions data report, the rigor and appropriateness of the GHG or electricity transaction data management system, and the coordination within a facility, fuel supplier's, or electricity importer's organization to manage the operation and maintenance of equipment and systems used to develop emissions data reports.

ii. The verification team shall include in the sampling plan a ranking of emissions sources by amount of contribution to total CO_2e emissions for the owner or operator and a ranking of emissions sources with the largest calculation uncertainty. As applicable and deemed appropriate by the verification team, electricity transactions shall also be ranked or evaluated relative to the amount of power exchanged and uncertainties that may apply to data provided by the electricity importer.

iii. The verification team shall include in the sampling plan a qualitative narrative of uncertainty risk assessment in the following areas as applicable under sections WCI.20 through WCI.XX:

- Data acquisition equipment;
- Data sampling and frequency;
- Data processing and tracking;
- Emissions calculations;
- Data reporting;
- Management policies or practices in developing emissions data reports.

iv. The verification team may change the sampling plan as relevant information becomes available and potential issues emerge of material misstatement or nonconformance with the requirements of this rule.

v. The verification body shall retain the sampling plan in paper, electronic, or other format for a period of not less than five years following the submission of each verification statement. The sampling plan shall be made available to *[TBD]* upon request.

(I) Data Checks. To determine the reliability of the submitted emissions data report, the verification team shall use data checks. Such data checks shall focus first on the largest and most uncertain estimates of emissions and electricity transactions, and shall include the following:

i. The verification team shall use data checks to ensure that the appropriate methodologies and emission factors have been applied for the emissions sources and electricity transactions covered under sections WCI.20 through WCI.XX;
ii. The verification team shall choose emissions sources, and electricity transactions data as applicable, for data checks based on their relative sizes and risks of material misstatement as indicated in the sampling plan;
iii. The verification team shall use professional judgment in the number of data checks required for the team to conclude with reasonable assurance whether the reported emissions and transactions are free of material misstatement and the emissions data report otherwise conforms to the requirements of this rule.

(J) Emissions Data Report Modifications. If as a result of review by the verification team and prior to completion of a verification statement the operator chooses to make improvements or corrections to the submitted emissions data report, a revised emissions data report may be submitted to [the jurisdiction] as specified by section WCI.2(f). The operator shall maintain documentation to support any revisions made to the initial emissions data report. Documentation for all emissions data report submittals shall be retained by the operator for seven years pursuant to section WCI.4.
(K) Findings. To verify that the emissions data report is free of material misstatement, the verification team shall make its own determination of emissions for sources checked according to WCI.8(c)(1), and shall determine whether there is reasonable assurance that the reported facility, fuel supply, or electricity import emissions are within 95 percent of actual total emissions for the facility, on a CO_2e basis. To assess conformance with this rule the verification team shall review the methods and factors used to develop the emissions data report for adherence to the requirement of this rule. The verification team shall keep a log of any issues identified in the course of verification activities that may affect determinations of material misstatement and nonconformance, and how those issues were resolved.

(3) Completion of verification services shall include:

(A) Verification Statement. Upon completion of the verification services specified in section WCI.8(c)(2), the verification body shall complete a verification statement, and provide that statement to the owner or operator and [the jurisdiction] according to the schedule specified in section WCI.2(b). Before that statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed within the verification body by a lead verifier not involved in services for that operator during that year.

(B) When the verification team completes its findings:

i. The verification body shall provide to the owner or operator a detailed verification report. The verification report shall at minimum include the verification plan, the detailed comparison of the data checks with the submitted emissions data report, the log of issues identified in the course of verification activities and their resolution, and any qualifying comments on findings during verification services. The detailed verification report shall be made available to [*the jurisdiction*] upon request.

ii. The verification body shall provide the verification statement to the owner or operator and [*the jurisdiction*], attesting that the verification body has found the submitted emissions data report free of material misstatement and in conformance with the requirements of this rule or, alternatively, that the emissions data report contains material misstatement or otherwise does not conform with the requirements of this rule.

iii. The lead verifier in the verification team shall attest that the verification team has carried out all verification services as required by this rule, and the lead verifier who has conducted the independent review of verification services and findings specified in section WCI.8(c)(3)(A) shall attest to his or her independent review on behalf of the verification body and his or her concurrence with the verification findings.

(C) Prior to the verification body providing an adverse verification statement to [*the* jurisdiction], the owner or operator shall be provided at least 10 working days to modify the emissions data report to correct any material misstatement or nonconformance found by the verification team. The modified report and verification statement must be submitted to [*the jurisdiction*] before the applicable verification deadline, unless the operator makes a request to [*the jurisidiction]* as follows

i. If the owner or operator and the verification body cannot reach agreement on modifications to the emissions data report that result in a positive verification statement, the operator may petition *[TBD]* to make a final decision as to the verifiability of the submitted emissions data report.

ii. If *[TBD]* determines that the emissions data report does not meet the standards and requirements specified in this rule, the owner or operator shall have the opportunity to submit within 60 calendar days of the date of this decision [Note that this time frame may need to be changed pending details of cap-and-trade system design and needs.] any emissions data report revisions that address *[TBD's]* determination, for re-verification of the emissions data report. In re-verifying a revised emissions data report, the verification body and verification team shall be subject to the requirements in section WCI.8(c)(3).

(4) Upon provision of the verification statement to *[the jurisdiction]*, the emissions data report shall be considered final and no changes shall be made except as provided in

section WCI.2(f). All verification requirements of this rule shall be considered complete upon provision of the verification statement.

(5) If the *[TBD]* finds a high level of conflict of interest existed between a verification body and an owner or operator or an emissions data report that received a positive verification statement fails an audit by *[TBD]*, the *[TBD]* may set aside the positive verification statement submitted by the verification body.

(6) Upon request by *[TBD]*, the owner or operator shall provide the data used to generate an emissions data report, including all data available to a verifier in the conduct of verification services. *[TBD]* may also review the full verification report given by the verification body to the owner or operator. The full verification report shall be provided to the *[TBD]* upon request.

(7) Upon written notification by the *[TBD]*, the verification body shall make itself available for a verification services audit.

(d) Accreditation Requirements for Verification Bodies, Lead Verifiers, and Verifiers.

(1) The accreditation requirements specified in this subsection shall apply to all verification bodies, lead verifiers, and verifiers that wish to provide verification services under this rule.

(2) Verification bodies accredited according to the requirements of the California Air Resources Board [provide regulatory citation] or to ISO 14065 through a program developed under ISO 17011 with demonstrated knowledge of WCI reporting requirements to conduct verification activities for WCI emissions data, are qualified to conduct verification activities for the WCI.

[Note the details of WCI's specific accreditation process for verification bodies (which has yet to be developed) will be consistent with ISO 14065 through an accreditation program that will developed under ISO 17011 and will include demonstrated knowledge of the WCI reporting requirements. WCI will explore additional accreditation requirements for individual lead verifiers, general verifiers, or sector specialists.]

(3) Subcontracting. The following requirements shall apply to any verification body that elects to subcontract verification services.

(A) The verification body must assume full responsibility for verification services performed by subcontractor verifiers or verification bodies.

(B) A verification body or verifier acting as a subcontractor to another verification body shall not further subcontract or outsource verification services for an operator.

(C) A verification body that engages a subcontractor shall be responsible for demonstrating an acceptable level of conflict of interest, as provided in section WCI.8(e) between its subcontractor and the operator for which it will provide verification services.

(4) If any WCI accredited verification body is suspended in any other mandatory or voluntary GHG reporting or trading program, that verification body will not be allowed to provide any verification services under WCI until that suspension ends. If any WCI accredited verification body has their verification body accreditation revoked under any other mandatory or voluntary GHG reporting or trading program, that verification body will no longer be allowed to provide verification services under WCI.

(e) Conflict of Interest Requirements for Verification Bodies.

(1) The conflict of interest provisions of this section shall apply to the verification body, entities related to the verification body, and the verification team accredited according to the requirements of WCI.8(d) to perform verification services for the WCI cap-and-trade program. Member for purposes of this section means any employee or subcontractor of the verification body or entities related to the verification body. Member also includes any individual with a majority equity share in the verification body or entities related to the verification body.

(2) The potential for a conflict of interest shall be deemed to be high where:

(A) The verification body and owner or operator share any management staff or board of directors membership, or any of the management staff of the owner or operator have been employed by the verification body, or vice versa, within the previous three years; or

(B) Within the previous three years, any member of the verification body, any entity related to the verification body, and the verification team has provided to the owner or operator any of the following non-verification services:

i. Designing, developing, implementing, or maintaining an inventory or information or data management system for facility greenhouse gases, or, where applicable, electricity transactions;
ii. Developing greenhouse gas emission factors or other greenhouse gas-related engineering analysis;
iii. Designing energy efficiency, renewable power, or other projects which explicitly identify greenhouse gas reductions as a benefit;
iv. Preparing or producing greenhouse gas-related manuals, handbooks, or procedures specifically for the reporting facility;
v. Appraisal services of carbon or greenhouse gas liabilities or assets;
vi. Brokering in, advising on, or assisting in any way in carbon or greenhouse gas-related markets;
vii. Managing any health, environment or safety functions;
viii. Bookkeeping or other services related to the accounting records or financial statements;
ix. Any service related to information systems, unless those systems will not be part of the verification process;
x. Appraisal and valuation services, both tangible and intangible;
xi. Fairness opinions and contribution-in-kind reports in which the verification body has provided its opinion on the adequacy of consideration in a transaction, unless the resulting services shall not be part of the verification process;
xii. Any actuarially oriented advisory service involving the determination of amounts recorded in financial statements and related accounts;
xiii. Any internal audit service that has been outsourced by the operator that relates to the owner's or operator's internal accounting controls, financial systems or financial statements, unless the result of those services shall not be part of the verification process;
xiv. Acting as a broker-dealer (registered or unregistered), promoter or underwriter on behalf of the owner or operator;

xv. Any legal services;

xvi. Expert services to the owner or operator or his or her legal representative for the purpose of advocating his or her's interests in litigation or in a regulatory or administrative proceeding or investigation, unless providing factual testimony.

(C) The potential for a conflict of interest shall also be deemed to be high where any staff member of the verification body, entity related to the verification body, or the verification team has provided verification services for the owner or operator within the last three years, except within the time periods in which the owner or operator is allowed to use the same verification body as specified in sections WCI.8(b).

(D) The potential for a conflict of interest shall be deemed high where the lead verifier doing the independent review for the verification team has provided verification or non-verification services for the operator in the last year as specified in section WCI.8(b).

(3) The potential for a conflict of interest shall be deemed to be low where:

(A) No potential for a conflict of interest is found under section WCI.8(e)(2) and any non-verification services provided by all members of the verification body and the verification team to the owner or operator within the last three years are valued at less than [Percent of the fee TBD] for the proposed verification.

(B) Any non-verification services provided at any time by a member of the verification body or the verification team did not include development of a GHG inventory system still in use by the owner or operator.

(4) The potential for a conflict of interest shall be deemed to be medium where the potential for a conflict of interest is not deemed to be either high or low as specified in sections WCI.8(e)(2)-(3).

(A) If a verification body identifies a medium potential for conflict of interest and wishes to provide verification services for the owner or operator, then the verification body shall submit, in addition to the submittal requirements specified in section WCI.8(e)(5), below, a plan to avoid, neutralize, or mitigate the potential conflict of interest situation. At a minimum, the conflict of interest mitigation plan shall include:

i. A demonstration that any individuals in the verification body or team with potential conflicts have been removed and insulated from the project.

ii. An explanation of any changes to the verification body or verification team to remove the potential conflict of interest, including changes to organization structure to demonstrate that a unit with potential conflicts has been divested or moved into an insulated related entity.

iii. A description of any other circumstance that specifically addresses other sources for potential conflict of interest.

(B) As provided in section WCI.8(e)(6), below, the [TBD] shall evaluate the conflict of interest mitigation plan and determine whether verification services may proceed.

(5) Conflict of Interest Submittal Requirements for Accredited Verification Bodies.

(A) Before the start of any work related to providing verification services to an owner or operator, a verification body must first be authorized in writing by *[TBD]* to provide verification services. To obtain authorization the verification body shall submit to *[TBD]* a self-evaluation of the potential for any conflict of interest that the verification body, entities related to the verification body, and members of the verification team including, subcontractors may have with the owner or operator or their related entities for which it will perform verification services. The submittal shall include the following:

i. Identification of whether the potential for conflict of interest is high, low, or medium based on factors specified in sections WCI.8(e)(2)-(4);

ii. An organizational chart of the business structure of the verification body, including its related entities and brief description of the primary work done by the verification body and related entities;

iii. Identification of whether any member of the verification body, entities related to the verification body, or the verification team including subcontractors has previously provided verification services for the owner or operator or its related entities and, if so, the years in which such verification services were provided;

iv. Identification of whether any member of the verification body, entities related to the verification body, or the verification team or including subcontractors has engaged in any non-verification services of any nature with the owner or operator or related entities either within or outside the WCI region during the previous three years. If non-verification services have previously been provided, the following information shall also be submitted:

- Identification of the nature and location of the work performed for the owner or operator and whether the work is similar to the type of work to be performed during verification, such as emissions inventory, auditing, energy efficiency, renewable energy, or other work with implications for the operator's greenhouse gas emissions or the accounting of greenhouse gas emissions or electricity transactions;
- The nature of past, present or future relationships the verification body, entities related to the verification body, and members of the verification team including subcontractors have with the owner or operator or related entity including:
  - Instances when any member has performed or intends to perform work for the owner or operator;
  - Identification of whether work is currently being performed for the owner or operator and, if so, the nature of the work;
  - Whether any member has any contracts or other arrangements to perform work for the owner or operator or a related entity;
  - Identify how much work was performed in the last three years, as a percentage of the verification body's total gross income for the last three years;
  - Identify how much work related to greenhouse gases or electricity transactions was has performed for the owner or operator or related

entities in the last three years, as a percentage of the verification body's income for the last three years;

– Identify how much work was performed by each subcontractor for the operator in the last three years, as a percentage of each subcontractor's total gross income for the last three years.

- Explanation of how the amount and nature of work previously performed is such that any member of the verification team's credibility and lack of bias should not be under question.

v. A list of names of the staff that will perform verification services for the owner or operator and a description of any instances of personal or family relationships with management or employees of the owner or operator that potentially represent a conflict of interest; and,

vi. Identification of any other circumstances or relevant information known to the verification body or owner or operator that could result in a conflict of interest, or any situation where the appearance of impartiality could undermine confidence in the verification body's ability to asses the reported emissions.

(6) Conflict of Interest Determinations. The *[TBD]* shall review the self-evaluation submitted by the verification body and determine whether the verification body is authorized to perform verification services for the owner or operator

(A) The *[TBD]* shall notify the verification body in writing when the conflict of interest evaluation information submitted under section WCI.8(e)(5) is deemed complete. Within *[Number of days TBD]* of deeming the evaluation information complete, *[TBD]* shall determine whether the verification body is authorized to proceed with verification and shall so notify the verification body.

(B) If *[TBD]* determines the verification body or any member of the verification team meets the criteria specified in section WCI.8(e)(2), *[TBD]* shall find a high potential conflict of interest and verification services may not proceed.

(C) If *[TBD]* determines that there is a low potential conflict of interest, verification services may proceed.

(D) If *[TBD]* determines that the verification body and verification team have a medium potential for a conflict of interest, *[TBD]* shall evaluate the conflict of interest mitigation plan submitted pursuant to sections WCI.8(e)(4), and may request additional information from the applicant to complete the determination. In determining whether verification services may proceed, *[TBD]* may consider factors including, but not limited to, the nature of previous work performed, the current and past relationships between the verification body and its subcontractors with the owner or operator, and the cost of the verification services to be performed. If *[TBD]* determines that these factors when considered in combination demonstrate an acceptable level of potential conflict of interest, then *[TBD]* will authorize the verification body to provide verification services.

(f) Monitoring Conflict of Interest Situations.

(1) After commencement of verification services, the verification body shall monitor and immediately make full disclosure in writing to *[TBD]* regarding any potential for a conflict of interest situation that arises. This disclosure shall include a description of actions that the verification body has taken or proposes to take to avoid, neutralize, or mitigate the potential for a conflict of interest.
(2) The verification body shall monitor arrangements or relationships that may be present for a period of one year after the completion of verification services. During that period, within 30 calendar days of any change in arrangements or relationships with the owner or operator for which the body has provided verification services, the verification body shall notify *[TBD]* of the change and provide a description of the nature of the change.
(3) The verification body shall report to *[TBD]* any changes in its organizational structure, including mergers, acquisitions, or divestitures, for one year after completion of verification services.
(4) *[TBD]* may invalidate a verification finding if a potential conflict of interest has arisen for any member of the verification team. In such a case, the owner or operator shall be provided 180 calendar days to complete re-verification.
(5) If the verification body or its subcontractor(s) are found to have violated the conflict of interest requirements of this section, *[TBD]* may rescind accreditation of the body, its verifier staff, or its subcontractor(s) for any appropriate period of time as provided in section WCI.8(d) *[TBD – accreditation requirements]*.

§ WCI.9 DEFINITIONS

[This is a partial list of definitions. Additional definitions are under development based on the Canadian regulations come from "Section 71 of the Canadian Environmental Protection Act (CEPA) 1999"and the CARB definitions come from "Title 17, Subchapter 10, Article 2, Section 95102 of the California Code of Regulations.]

"Adverse verification statement" means a verification statement rendered by a verification body stating that the verification body cannot say with reasonable assurance that the submitted emissions data report is free of material misstatement, or that it cannot provide a qualifying statement that the emissions data report conforms to the requirements of this article.

"Biomass fuels" or "biomass-derived fuels" means fuels derived entirely from biomass.

"Carbon dioxide equivalent" or "CO_2 equivalent" or "CO_2e" means a measure for comparing carbon dioxide with other GHGs, based on the quantity of those gases multiplied by the appropriate global warming potential (GWP) factor and commonly expressed as metric tons of carbon dioxide equivalent.

"Conflict of interest" means a situation in which, because of financial or other activities or relationships with other persons or organizations, a person or body is unable or potentially unable to render an impartial verification opinion of a potential client's greenhouse gas emissions, or the person or body's objectivity in performing verification services is or might be otherwise compromised.

“Continuous emissions monitoring system” or “CEMS” means the total equipment required to obtain a continuous measurement of a gas concentration or emission rate from combustion or industrial processes.

“Electricity generating unit” or “EGU” means any combination of physically connected generator(s), reactor(s), boiler(s), combustion turbine(s), or other prime mover(s) operated together to produce electric power.

“Exporter” means…*[To be defined later for transportation and RCI fuels accounting]*

“Facility” means any property, plant, building, structure, stationary source, stationary equipment or grouping of stationary equipment or stationary sources located on one or more contiguous or adjacent properties, in actual physical contact or separated solely by a public roadway or other public right-of-way, under common operational control, and having the same first two digits of the Standard Industrial Classification (SIC) or same first three digits of the North American Industry Classification System (NAICS) code. *[Some special facilities, such as oil and gas production fields will have separate definitions.]*

“Full verification” means all verification services as provided in section WCI.8(c).

“Global warming potential” or “GWP factor” means the radiative forcing impact of one mass-based unit of a given greenhouse gas relative to an equivalent unit of carbon dioxide over a given period of time.

“Greenhouse gas”, “greenhouse gases” or “GHG” means carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), hydrofluorocarbons (HFCs), and perfluorocarbons (PFCs).

“Hydrofluorocarbons” or “HFCs” means a class of GHGs primarily used as refrigerants, consisting of hydrogen, fluorine, and carbon.

“Importer” means…*[To be defined later with input from the Electricity Subcommittee.]*

“Lead verifier” means a person that has met all of the requirements in section WCI.8 *[TBD]*, and who may act as the lead verifier of a verification team providing verification services or as a lead verifier providing an independent review of verification services rendered.

“Material misstatement” means one or more inaccuracies identified in the course of verification that result in the total reported emissions being outside the 95 percent accuracy required to receive a positive verification statement.

“Owner or operator” means any person who owns, leases, operates, controls, or supervises a facility or fuel supply operation; or who imports electricity into the WCI region.

“Perfluorocarbons” or “PFCs” means a class of greenhouse gases consisting on the molecular level of carbon and fluorine.

"Positive verification statement" means a verification statement rendered by a verification body stating that the verification body can say with reasonable assurance that the submitted emissions data report is free of material misstatement and includes a qualifying statement that the emissions data report conforms to the requirements of this article.

"Pure" means consisting of at least 97 percent by mass of a specified substance. For facilities burning biomass fuels, this means the fraction of biomass carbon accounts for at least 97 percent of the total amount of carbon in the fuel burned at the facility.

"Reasonable assurance" means a high degree of confidence that submitted data and statements are valid.

"Stationary combustion unit" means any boiler, heater, furnace, kiln, turbine, internal combustion engine, incinerator or other non-mobile source device that combusts any solid, liquid, or gaseous fuel for purposes of producing useful heat or energy for industrial, commercial, or institutional use; or for purposes of reducing the volume of waste by removing combustible material.

"Supplier" means . . . *[To be defined later for transportation and RCI fuels accounting.]*.

"Verification" means the process used to ensure that an operator's emissions data report is free of material misstatement and complies with WCI's reporting procedures and methods for calculating and reporting GHG emissions.

"Verification body" means a firm accredited by the jurisdiction or its designee, that is able to render a verification statement and provide verification services for operators subject to reporting under this article.

"Verification cycle" means one year of full verification and the next consecutive two years of less intensive verification for operators subject to annual verification. For operators subject to triennial verification, a verification cycle means one year of full verification, and if elected, the next consecutive two years of less intensive verification. A verification cycle cannot exceed three calendar years.

"Verification statement" means the final opinion rendered by a verification body attesting whether an operator's emissions data report is free of material misstatement and a qualifying statement whether the emissions data report conforms to the requirements of this article.

"Verification services" means services provided during verification as specified in section WCI.8, including but not limited to reviewing an owner's or operator's emissions data report, verifying its accuracy according to the standards specified in this section, assessing the owner's or operator's compliance with this section, and submitting a verification statement to the *[jurisdiction or its agent]*.

"Verification team" means all of those working for a verification body, including all subcontractors, to provide verification services for an operator. The lead verifier for the verification team shall be a lead verifier in the verification body.

"Verifier" means an individual accredited by the jurisdiction or its designee to carry out verification services as specified in section WCI.8.

"Waste-derived fuel" means a fuel typically derived from waste and generally used as a substitute for conventional fossil fuels. Waste-derived fuels can include fossil fuels such as waste oil, plastics, or solvents; biomass such as dried sewage or impregnated saw dust; or fractions of both fossil fuels and biomass such as municipal solid waste or tires.

§ WCI.10 Global Warming Potentials

Owners and operators must use the global warming potential (GWP) values given in Table WCI.10-1 when converting emissions of greenhouse gases to metric tons of carbon dioxide equivalent (CO_2e), using Equation 1-1.

Table WCI.10-1. Global Warming Potential Factors for Greenhouse Gases			
Common Name	**Formula**	**Chemical Name**	**GWP**
Carbon dioxide	CO_2		1
Methane	CH_4		21
Nitrous oxide	N_2O		310
Sulfur hexafluoride	SF_6		23,900
Hydrofluorocarbons (HFCs)			
HFC-23	CHF_3	trifluoromethane	11,700
HFC-32	CH_2F_2	difluoromethane	650
HFC-41	CH_3F	fluoromethane	150
HFC-43-10mee	$C_5H_2F_{10}$	1,1,1,2,3,4,4,5,5,5- decafluoropentane	1,300
HFC-125	C_2HF_5	pentafluoroethane	2,800
HFC-134	$C_2H_2F_4$	1,1,2,2-tetrafluoroethane	1,000
HFC-134a	$C_2H_2F_4$	1,1,1,2-tetrafluoroethane	1,300
HFC-143	$C_2H_3F_3$	1,1,2-trifluoroethane	300
HFC-143a	$C_2H_3F_3$	1,1,1-trifluoroethane	3,800
HFC-152	$C_2H_4F_2$	1,2-difluoroethane	43
HFC-152a	$C_2H_4F_2$	1,1-difluoroethane	140
HFC-161	C_2H_5F	fluoroethane	12
HFC-227ea	C_3HF_7	1,1,1,2,3,3,3- heptafluoropropane	2,900
HFC-236cb	$C_3H_2F_6$	1,1,1,2,2,3-hexafluoropropane	1,300
HFC-236ea	$C_3H_2F_6$	1,1,1,2,3,3-hexafluoropropane	1,200
HFC-236fa	$C_3H_2F_6$	1,1,1,3,3,3-hexafluoropropane	6,300
HFC-245ca	$C_3H_3F_5$	1,1,2,2,3-pentafluoropropane	560
HFC-245fa	$C_3H_3F_5$	1,1,1,3,3-pentafluoropropane	950
HFC-365mfc	$C_4H_5F_5$	1,1,1,3,3-pentafluorobutane	890
Perfluorocarbons (PFCs)			
Perfluoromethane	CF_4	tetrafluoromethane	6,500
Perfluoroethane	C_2F_6	hexafluoroethane	9,200
Perfluoropropane	C_3F_8	octafluoropropane	7,000
Perfluorobutane	C_4F_{10}	decafluorobutane	7,000
Perfluorocyclobutane	$c\text{-}C_4F_8$	octafluorocyclobutane	8,700
Perfluoropentane	C_5F_{12}	dodecafluoropentane	7,500
Perfluorohexane	C_6F_{14}	tetradecafluorohexane	7,400

ATTACHMENT 8: IRON AND STEEL MANUFACTURING

§ WCI.150 IRON AND STEEL MANUFACTURING

§ WCI.151 Source Category Definition

Iron and steel manufacturing comprises four categories: primary facilities that produce both iron and steel, secondary steelmaking facilities, iron production facilities, and offsite production of metallurgical coke. These processes may occur together in an "integrated" facility or they may occur in separate offsite facilities.

§ WCI.152 Greenhouse Gas Reporting Requirements

In addition to the information required by WCI.3, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2 and CH_4 in metric tons at the facility level.

(b) CO_2 and CH_4 emissions from coke production (metric tons) and the following information:

(1) Quantity of coking coal consumed in coke production (metric tons)
(2) Quantity of other process materials (e.g., natural gas, fuel oil, etc.) consumed in coke production (metric tons)
(3) Quantity of blast furnace gas consumed in coke production (metric tons)
(4) Quantity of coke produced (metric tons)
(5) Quantity of coke oven gas transferred offsite (metric tons)
(6) Quantity of other coke oven by-products (e.g., coal tar, light oil, coke breeze, etc.) transferred offsite (metric tons)
(7) Carbon content of material inputs and outputs listed in (b)(1) through (b)(6) (metric tons of C per unit of material)

(c) CO_2 and CH_4 emissions from iron and steel production (metric tons) and the following information:

(1) Quantity of coke consumed in iron and steel production (excluding sinter production) (metric tons)
(2) Quantity of on-site coke oven by-products (e.g., coal tar, light oil, coke breeze, etc.) consumed in blast furnace (metric tons)
(3) Quantity of coal directly injected into blast furnace (metric tons)
(4) Quantity of limestone directly injected into blast furnace (metric tons)
(5) Quantity of dolomite directly injected into blast furnace (metric tons)
(6) Quantity of carbon electrodes consumed in EAFs (metric tons)
(7) Quantity of other carbonaceous or process material (e.g., sinter, waste plastic, etc.) consumed in iron and steel production (metric tons)
(8) Quantity of coke oven gas consume in blast furnace (metric tons)
(9) Quantity of steel produced (metric tons)
(10) Quantity of iron production not converted to steel (metric tons)
(11) Quantity of blast furnace gas transferred offsite (metric tons)
(12) Carbon content of material inputs and outputs listed in (c)(1) through (c)(11) (metric tons of C per unit of material)

(d) Process CO_2 and CH_4 emissions from sinter production (metric tons) and the following information:

(1) Quantity of coke breeze (purchased and produced on-site) used for sinter production (metric tons)
(2) Quantity of coke oven gas consumed in blast furnace in sinter production (metric tons)
(3) Quantity of blast furnace gas consumed in sinter production (metric tons)
(4) Quantity of other process materials (e.g., natural gas, fuel oil, etc.) consumed in sinter production (metric tons)
(5) Quantity of sinter off gas transferred offsite (metric tons)
(6) Carbon content of material inputs and outputs listed in (d)(1) through (d)(5) (metric tons of C per unit of material)

(e) Process CO_2 and CH_4 emissions from direct reduced iron production (metric tons) and the following information:

(1) Energy from natural gas used in direct reduced iron production (gigajoules [GJ])
(2) Energy from coke breeze used in direct reduced iron production (GJ)
(3) Energy from metallurgical coke used in direct reduced iron production (GJ)
(4) Carbon of material inputs listed in (e)(1) through (e)(3) (metric tons of C per GJ)

§ WCI.153 Calculation of CO_2 Emissions

(a) Process CO_2 emissions. Determine process CO_2 emissions as specified under either paragraph (1) or (2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).
(2) Calculation methodologies specified in paragraph (b) of this section.

(b) Process CO_2 Emissions Calculation Methodology. Calculate total CO_2 process emissions using the following mass balance approach:

(1) Calculate the coke production CO_2 (either within integrated facilities or at offsite facilities) emissions using Equation 150-1 (if applicable):

$$E_{coke} = \left[(CC \times C_{CC}) + \sum_a (PM_a \times C_a) + (BG \times C_{BG}) - (CO \times C_{CO}) - (COG \times C_{COG}) - \sum_b (COB_b \times C_b) \right] \times 3.664$$

Equation 150-1

Where:

E_{coke}	=	Emissions of CO_2 from coke production (metric tons);
CC	=	Quantity of coking coal (metric tons);
PM_a	=	Quantity of other process material *a* (not included as separate terms), such as natural gas or fuel oil (metric tons);
BG	=	Quantity of blast furnace gas consumed in coke ovens (metric tons);
CO	=	Quantity of coke produced (metric tons)
COG	=	Quantity of coke oven gas transferred offsite (metric tons);
COB_b	=	Quantity of coke oven by-product *b* transferred offsite (metric tons);

C_x = Carbon content of material input or output *x* (metric tons C/metric tons of *x*);
3.664 = Conversion factor from metric tons of C to metric tons of CO_2.

(2) Calculate the iron and steel production CO_2 emissions using Equation 150-2:

$$E_{iron,steel} = \Big[(CO \times C_{CO}) + \sum_a (COB_a \times C_a) + (CI \times C_{CI}) + (L \times C_L) + (D \times C_D) + (CE \times C_{CE}) + \sum_b (O_b \times C_b) + (COG \times C_{COG}) - (S \times C_S) - (IP \times C_{IP}) - (BG \times C_{BG}) \Big] \times 3.664$$

Equation 150-2

Where:

$E_{iron,steel}$ = Emissions of CO_2 from iron and steel production (metric tons);
CO = Quantity of coke consumed (excluding sinter production) (metric tons);
COB_a = Quantity of coke oven by-product *a* consumed in blast furnace (metric tons);
CI = Quantity of coal directly injected into blast furnace (metric tons);
L = Quantity of limestone consumed (metric tons);
D = Quantity of dolomite consumed (metric tons);
CE = Quantity of carbon electrodes consumed in EAFs (metric tons);
O_b = Quantity of other carbonaceous and process material *b*, such as sinter or waste plastic (metric tons);
COG = Quantity of coke oven gas consumed in blast furnace (metric tons);
S = Quantity of steel produced (metric tons);
IP = Quantity of iron production not converted to steel (metric tons);
BG = Quantity of blast furnace gas transferred offsite (metric tons);
C_x = Carbon content of material input or output *x* (metric tons C/metric tons of *x*);
3.664 = Conversion factor from metric tons of C to metric tons of CO_2.

(3) Calculate the sinter production CO_2 emissions using Equation 150-3 (if applicable):

$$E_{sinter} = \Big[(CBR \times C_{CBR}) + (COG \times C_{COG}) + (BG \times C_{BG}) + \sum_a (PM_a \times C_a) - (SOG \times C_{SOG}) \Big] \times 3.664$$

Equation 150-3

Where:

E_{sinter} = Emissions of CO_2 from sinter production (metric tons);
CBR = Quantity of purchased and onsite produced coke breeze used for sinter production (metric tons);
COG = Quantity of coke oven gas consumed in blast furnace for sinter production (metric tons);
BG = Quantity of blast furnace gas consumed for sinter production (metric tons);
PM_a = Quantity of other process material *a* consumed for sinter production (not included as separate terms), such as natural gas or fuel oil (metric tons);
SOG = Quantity of sinter off gas transferred offsite (metric tons);
C_x = Carbon content of material input or output *x* (metric tons C/metric tons of *x*);
3.664 = Conversion factor from metric tons of C to metric tons of CO_2.

(4) Calculate the direct reduced iron production CO_2 emissions using Equation 150-4 (if applicable):

$$E_{DRI} = [(DRI_{NG} \times C_{NG}) + (DRI_{BZ} \times C_{BZ}) + (DRI_{CK} \times C_{CK})] \times 3.664$$

Equation 150-4

Where:

E_{DRI} = Emissions of CO_2 from direct reduced iron production (metric tons);
DRI_{NG} = Energy from natural gas used in direct reduced iron production (GJ);
DRI_{BZ} = Energy from coke breeze used in direct reduced iron production (GJ);
DRI_{CK} = Energy from metallurgical coke used in direct reduced iron production (GJ);
C_{NG} = Carbon content of natural gas (metric ton C/GJ);
C_{BZ} = Carbon content of coke breeze (metric ton C/GJ);
C_{CK} = Carbon content of metallurgical coke (metric ton C/GJ);
3.664 = Conversion factor from metric tons of C to metric tons of CO_2.

(5) Calculate the total CO_2 emissions using Equation 150-5:

$$E_{CO2} = E_{coke} + E_{iron,steel} + E_{sinter} + E_{DRI}$$

Equation 150-5

Where:

E_{CO2} = Total CO_2 emissions (metric tons);
E_{coke} = Emissions from coke production (metric tons);
$E_{iron,steel}$ = Emissions from iron and steel production (metric tons);
E_{sinter} = Emissions from sinter production (metric tons);
E_{DRI} = Emissions from direct reduced iron production (metric tons).

§ WCI.154 Calculation of CH_4 Emissions

(a) Process CH_4 emissions. Determine process CH_4 emissions as specified under paragraph (1) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

§ WCI.155 Sampling, Analysis, and Measurement Requirements

Measurements of carbon contents of the material balance input, output, and by-product materials shall be conducted as described below.

Note: The sampling, analysis, and measurement procedures will be standardized for each calculation input to reduce variation between facilities within the iron and steel industry. Material sampling frequency and technique is distinct from material analysis conducted in a laboratory. The WCI is seeking stakeholder feedback on this topic and is specifically interested in proposals from stakeholders with expertise in this industry related to sampling, analysis and measurement procedures already in use at these facilities for the material quantities and/or concentrations listed below. Those proposing procedures should include sampling frequency and technique, indicate the uncertainty associated with the procedures, and describe the application of the procedure at a facility.

(b) Fuel Carbon Content Requirements. Fuel carbon contents should be monitored in the following manner (from § WCI.25):

(1) For coal and coke, solid biomass-derived fuels, and waste-derived fuels; use ASTM 5373-02 (Reapproved 2007).
(2) For liquid fuels, use the following ASTM methods: For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291-02 (Reapproved 2007) "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants", ultimate analysis of oil or computations based on ASTM D3238-95 (Reapproved 2005) and either ASTM D2502-04 or ASTM D2503-92 (Reapproved 2002).
(3) For gaseous fuels, use ASTM D1945-03 or ASTM D1946-90 (Reapproved 2006).

(c) By-Product Carbon Content Requirements. Carbon contents of by-products (e.g., blast furnace gas, coke oven gas, coal tar, light oil, coke breeze, sinter off gas, etc.) from all iron and steel production processes should be monitored in the following manner:

(1) [Methodology to be determined.]

(d) Flux Carbon Content Requirements. Carbon contents of fluxes (i.e., limestone and dolomite) from all iron and steel production processes should be monitored in the following manner:

(1) For limestone and dolomite, use ASTM C25-06.

(e) Electrode Carbon Content Requirements. Carbon contents of carbon electrodes used in electric arc furnaces (EAFs) should be monitored in the following manner:

(1) [Methodology to be determined.]

(f) Finished Product Carbon Content Requirements. Carbon contents of finished products (i.e., steel, iron not converted to steel, and direct reduced iron) from all iron and steel production processes should be monitored in the following manner:

(1) For iron and steel, use ASTM E1019-08 or ASTM E351-93.

(g) Quantity Measurement Requirements. The quantities of process inputs, outputs, and by-products must be determined using the following methods:

(1) For solid process inputs, outputs, and by-products, quantities must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.
(2) For liquid process inputs, outputs, and by-products, quantities must be determined by direct volume measurement using the same plant instruments used for accounting purposes.
(3) For gaseous process inputs, outputs, and by-products, quantities must be determined by direct volume measurement using the same plant instruments used for accounting purposes.

ATTACHMENT 12: LEAD PRODUCTION

Applicability

There are two primary production processes used to produce lead from lead concentrates: the sintering/smelting process and the direct smelting process. In the sintering/smelting process, the lead concentrates are initially combined with recycled sinter, lime rock and silica, oxygen, and high lead content sludge to produce a sinter roast. The sinter roast is then put into a blast furnace (i.e., traditional blast or Imperial Smelting) with other metal-containing ores, air, smelter by-products, and metallurgical coke. This reduction of lead oxide in the furnace results in the production of CO_2 emissions. In the direct smelting process, the sintering step is skipped and the lead concentrates are entered directly into the furnace (i.e., Isasmelt-Ausmelt, Queneau-Schumann-Lurgi, and Kaldo for bath smelting and Kivcet for flash smelting) with reducing agents.

In addition to the sintering/smelting and direct smelting primary production processes, secondary production or recycling of lead is also conducted. Most of the recycled lead comes from scrapped lead acid batteries. The lead acid batteries are either crushed with a hammer mill or smelted whole. All of the furnaces used for primary production, as well as electric arc and electric resistance furnaces, can be used to smelt recycled scrap lead.

Emission Calculations

The following emission calculation methods are from the 2006 IPCC Guidelines, Volume 3, Section 4.6.

The Tier 3 methodology recommends using actual directly measured CO_2 emissions data, if available. Alternatively, facility-specific data regarding reducing agents and carbon contents can be used to calculate emissions for the Tier 3 methodology. The Tier 2 methodology is similar to the Tier 3 method, except that default carbon contents for the reducing agents are used instead of facility-specific carbon contents. Default carbon contents are available for the following reducing agents: blast furnace gas, charcoal, coal, coal tar, coke, coke oven gas, coking coal, electric arc furnace (EAF) carbon electrodes, EAF charge carbon, fuel oil, gas coke, natural gas, and petroleum coke.

The emission calculation equation is:

$$E_{Pb} = \sum_x (RA_x \times C_x) \times 3.664$$

Where:

E_{Pb}	=	CO_2 emissions from lead production (metric tons);
RA_x	=	Quantity of reducing agent *x* used (metric tons);
C_x	=	Carbon content of reducing agent *x* (metric tons C/metric tons of *x*);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

The Tier 3 method (using either actual directly measured CO_2 emissions data or facility-specific reducing agent quantities and carbon contents) is recommended to estimate emissions from lead production facilities.

The uncertainty for Tier 3 facility-specific measured CO_2 data has been estimated to be ±5 percent. The uncertainty associated with the Tier 3 facility-specific reducing agent quantities and carbon contents is also estimated to be ±5 percent. The uncertainty of the Tier 2 reducing agent carbon contents is estimated to be ±15 percent.

Reporting Requirements

Annual CO_2 emissions (measured or calculated) based on the IPCC Tier 3 method will be reported for each facility. Facility-specific quantities and carbon contents of each reducing agent used will also be reported.

Sampling, Analysis, and Measurement Methods

The Tier 3 method from the 2006 IPCC Guidelines specifies facility-specific emission measurements or facility-specific data regarding reducing agents and carbon contents. The following measurement methods should be used.

Note: The sampling, analysis, and measurement procedures will be standardized for each calculation input to reduce variation between facilities within the lead industry. Material sampling frequency and technique is distinct from material analysis conducted in a laboratory. The WCI is seeking stakeholder feedback on this topic and is specifically interested in proposals from stakeholders with expertise in this industry related to sampling, analysis and measurement procedures already in use at these facilities for the material quantities and/or concentrations listed below. Those proposing procedures should include sampling frequency and technique, indicate the uncertainty associated with the procedures, and describe the application of the procedure at a facility.

(a) Facility CO_2 emissions. Determine facility CO_2 emissions using continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

Wherever possible, measurements of carbon contents of the material balance input materials should be conducted as described below.

(b) Fuel Carbon Content Requirements. Fuel carbon contents should be measured in the following manner (from WCI.25):

(1) For coal and coke, solid biomass-derived fuels, and waste-derived fuels; use ASTM 5373-02 (Reapproved 2007).
(2) For liquid fuels, use the following ASTM methods: For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291-02 (Reapproved 2007) “Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants”, ultimate analysis of oil or computations based on ASTM D3238-95 (Reapproved 2005) and either ASTM D2502-04 or ASTM D2503-92 (Reapproved 2002).
(3) For gaseous fuels, use ASTM D1945-03 or ASTM D1946-90 (Reapproved 2006).

(c) By-Product Carbon Content Monitoring Requirements. Carbon contents of by-products (e.g., blast furnace gas, coke oven gas, coal tar, light oil, coke breeze, sinter off gas, etc.) used in lead production processes should be monitored in the following manner:
[Method to be determined.]

(d) Electrode Carbon Content Requirements. Carbon contents of carbon electrodes used in lead production processes should be monitored in the following manner:
[Method to be determined.]

(e) Quantity Measurement Requirements. The quantities of process inputs, outputs, and by-products must be determined using the following methods:

- For solid process inputs, outputs, and by-products, quantities must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.
- For liquid process inputs, outputs, and by-products, quantities must be determined by direct volume measurement using the same plant instruments used for accounting purposes, such as *[Method to be determined]*.
- For gaseous process inputs, outputs, and by-products, quantities must be determined by direct volume measurement using the same plant instruments used for accounting purposes, such as *[Method to be determined]*.

ATTACHMENT 9: LIME MANUFACTURING

§ WCI.170 LIME MANUFACTURING

§ WCI.171 Source Category Definition

Lime manufacturing is comprised of all processes that are used to manufacture quick lime (i.e. calcium oxide or calcium-magnesium oxide). Lime is produced via the calcination of limestone or other highly calcareous materials such as dolomite, aragonite, chalk, coral, marble, and shell.

§ WCI.172 Greenhouse Gas Reporting Requirements

In addition to the information required by WCI.3, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2, CH_4, and N_2O in metric tons.

(b) CO_2 process emissions from quick lime production (metric tons) and the following information:

(1) Quick lime emission factor (kg CO_2/metric ton quick lime).
(A) Quantity of quick lime produced (metric tons).
(B) Total Calcium Oxide (CaO) content of quick lime (weight fraction).
(C) Total Magnesium Oxide (MgO) content of quick lime (weight fraction).
(D) Uncalcined CaO (weight fraction).
(E) Uncalcined MgO (weight fraction).

(2) Lime kiln dust (LKD) emission factor (kg CO_2/metric ton LKD).
(A) Quantity of LKD discarded (metric tons).
(B) Total Calcium Oxide (CaO) content of LKD (weight fraction).
(C) Total Magnesium Oxide (MgO) content of LKD (weight fraction).
(D) Uncalcined CaO content of LKD (weight fraction).
(E) Uncalcined MgO content of LKD (weight fraction).

(c) CO_2, CH_4, and N_2O emissions from fuel combustion in all kilns combined, following the calculation methods and reporting requirements specified in WCI.173(c) (metric tons).

(d) CO_2, CH_4, and N_2O emissions from all other fuel combustion units combined (kilns excluded), following the calculation methods and reporting requirements specified in WCI.20 (metric tons).

(e) If a continuous emissions monitor is used to measure CO_2 emissions from kilns, then the requirements of paragraphs (b) and (c) of this section do not apply for CO_2. Lime plants that measure CO_2 emissions using CEMS shall report fuel usage by fuel type for kilns.

(f) Operators of lime plants shall also comply with the reporting requirements for any other applicable source category listed at WCI.1(a), including but not limited to the following:

(1) Coal fuel storage as specified in WCI.100.

(2) Electricity generating as specified in WCI.40.

(3) Cogeneration systems as specified in WCI.XX.

§ WCI.173 Calculation of greenhouse Gas Emissions from Kilns

(a) Determine process CO_2 emissions as specified under either paragraph (a)(1) or (a)(2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Calculate the sum of CO_2 process emissions from kilns and CO_2 fuel combustion emissions from kilns using the calculation methodologies specified in paragraph (b) and (c) of this section**.**

(b) Process CO_2 Emissions Calculation Methodology. Calculate total CO_2 process emissions as the sum of emissions from quick lime production, using the method specified in paragraph (b)(1) of this section.

(1) CO_2 Process Emissions. Calculate CO_2 emissions from quick lime production from each kiln using Equation 170-1 and a plant-specific quick lime emission factor and a plant-specific lime kiln dust (LKD) emission factor as specified in this section.

$$CO_2 = \sum_{I=1}^{12} [(QL) \times (EF_{QL})] + [(LKD) \times (EF_{LKD})]$$

Equation 170-1

Where:

CO_2	=	CO_2 emissions in metric tones/yr.
QL	=	Monthly Quantity of quick lime produced, metric tons.
EF_{QL}	=	Monthly Quick lime emission factor, metric tons CO_2/metric ton quick lime computed as specified in paragraph (b)(1)(A) of this section.
LKD	=	Monthly Quantity LKD discarded (i.e., not recycled to the kiln), metric tons.
EF_{LKD}	=	Monthly LKD emission factor, computed as specified in paragraph (b)(1)(B) of this section.

(A) Monthly Quick Lime Emission Factor. Calculate a plant-specific quick lime emission factor _(EF_{QL}) for each kiln and month based on the percent of measured CaO and MgO content in quick lime and using Equation 170-2.

$$EF_{QL} = [(CaO\ content - uncalcined\ CaO) \times Molecular\ ratio\ of\ CO_2 / CaO] + [(MgO\ Content - uncalcined\ MgO) \times Molecular\ ratio\ of\ CO_2 / MgO]$$

Equation 170-2

Where:

CaO Content (by weight)	=	Total CaO content of Quick Lime, including calcined and uncalcined (weight fraction).
Uncalcined CaO (by weight)	=	Uncalcined CaO content of Quick Lime (weight fraction).
Molecular ratio of CO_2/CaO	=	0.785.
MgO Content (by weight)	=	Total MgO content of Quick Lime, including calcined and uncalcined (weight fraction).
Uncalcined MgO	=	Uncalcined MgO content of Quick Lime (weight fraction).
Molecular ratio of CO_2/MgO	=	1.092.

(B) Monthly LKD Emission Factor. If LKD is generated and not recycled back to the kiln, then calculate a plant-specific LKD emission factor for each kiln and month. The LKD emission factor shall be calculated using Equation 170-3.

$$EF_{LKD} = [(CaO\ \ content - uncalcined\ \ CaO) \times Molecular\ \ ratio\ \ of\ \ CO_2 / CaO] + [(MgO\ \ Content - uncalcined\ \ MgO) \times Molecular\ \ ratio\ \ of\ \ CO_2 / MgO]$$

Equation 170-3

Where:

EF_{LKD}	=	LKD emission factor.
CaO Content (by weight)	=	Total CaO content of LKD, including calcined and uncalcined (weight fraction).
Uncalcined CaO (by weight)	=	Uncalcined CaO content of LKD (weight fraction).
Molecular ratio of CO_2/CaO	=	0.785.
MgO Content (by weight)	=	Total MgO content of LKD, including calcined and uncalcined (weight fraction).
Uncalcined MgO	=	Uncalcined MgO content of LKD (weight fraction).
Molecular ratio of CO_2/MgO	=	1.092.

(c) Fuel Combustion Emissions in Kilns. Calculate CO_2, CH_4, and N_2O emissions from stationary fuel combustion emissions following the calculation methods specified in WCI.20. Operators of lime manufacturing plants that primarily combust biomass-derived fuels and combust fossil fuels only during periods of start-up, shut-down, or malfunction may report CO_2 emissions from fossil fuels using the emission factor methodology in WCI.23(a). "Pure" means that the biomass-derived fuels account for 97 percent of the total amount of carbon in the fuels burned.

§ WCI.174 Sampling, Analysis, and Measurement Requirements

Note: The sampling, analysis, and measurement procedures will be standardized for each calculation input to reduce variation between facilities within the lime industry. Material sampling frequency and technique is distinct from material analysis conducted in a laboratory. The WCI is seeking stakeholder feedback on this topic and is specifically interested in proposals from stakeholders with expertise in this industry related to sampling, analysis and measurement *procedures already in use at these facilities for the material quantities and/or concentrations listed below. Those proposing procedures should include sampling frequency and technique, indicate the uncertainty associated with the procedures, and describe the application of the procedure at a facility.*

(a) Determine the plant-specific weight fractions of CaO, MgO, uncalcined CaO, and uncalcined MgO in quick lime from each kiln using (method to be determined). Determine the plant-specific fraction of CaO, MgO, uncalcined CaO, and uncalcined MgO in LKD not recycled to the kiln using (method to be determined). The monitoring must be conducted monthly for each kiln from samples drawn from bulk storage.

(b) The quantity of quick lime produced must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

(c) The quantity of LKD discarded must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

(d) The quantity of raw materials consumed (i.e. limestone, dolomite, aragonite, chalk, coral, marble, and shell.) must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

ATTACHMENT 10: PETROLEUM REFINERIES

§ WCI.200 PETROLEUM REFINERIES

§ WCI.201 Source Category Definition

A petroleum refinery consists of all processes used to produce gasoline, aromatics, kerosene, distillate fuel oils, residual fuel oils, lubricants, asphalt, or other products through distillation of petroleum or through redistillation, cracking, rearrangement or reforming of unfinished petroleum derivatives.

WCI.202 Greenhouse Gas Reporting Requirements

The annual emissions report must contain the following information reported at the facility level:

(a) Catalyst Regeneration. Report CO_2 emissions.

(b) Process Vents. Report CO_2, N_2O, and CH_4 emissions.

(c) Asphalt Production. Report CO_2 and CH_4 emissions.

(d) Sulfur Recovery. Report CO_2 emissions.

(e) Stationary Combustion Units Other than Flares and Control Devices. Report CO_2, N_2O, and CH_4 emissions as specified in WCI.23.

(f) Flares and Other Control Devices. Report CO_2, N_2O, and CH_4 emissions.

(g) Above-Ground Storage Tanks. Report CH_4 emissions.

(h) Wastewater Treatment. Report CH_4 and N_2O emissions.

(i) Oil-Water Separators. Report CH_4 emissions.

(j) Equipment Leaks. Report CH_4 emissions.

(k) Feedstock Consumption: Report feedstock consumption by type for all feedstocks which result in GHG emissions in the reporting year (including petroleum coke) in units of million standard cubic feet for gases, gallons for liquids, short tons for non-biomass solids, and bone dry short tons for biomass-derived solid fuels.

(l) Fuel Consumption: Report fuel consumption by fuel type consumed in the reporting year in units of million standard cubic feet for gases, gallons for liquids, short tons for non-biomass solids, and bone dry short tons for biomass-derived solid fuels.

WCI.203 Calculation of Greenhouse Gas Emissions

The operator shall calculate GHG emissions using the methods in paragraphs (a) through (i) of this section.

(a) Catalyst Regeneration. For units equipped with CEMS, operators shall calculate CO_2 process emissions resulting from catalyst regeneration using CEMS in accordance with WCI.20. In the absence of CEMS data, the operator shall use the methods in paragraphs (a)(1) through (a)(3).

(1) The operator shall calculate process CO_2 emissions from the continuous regeneration of catalyst material in fluid catalytic cracking units (FCCU) and fluid cokers using Equations 200-1, 200-2, and 200-3.

$$CO_2 = \sum_{d=1}^{n} CR_d \times CF \times 3.664 \times 0.001 \qquad \textbf{Equation 200-1}$$

Where:

CO_2	=	CO_2 emissions (metric tons/yr)
n	=	number of days of operation in the report year
CR_d	=	daily average coke burn rate (kg/day)
CF	=	carbon fraction in coke burned
3.664	=	ratio of molecular weights, CO_2 to carbon
0.001	=	conversion factor – kg to metric tons

$$CR_d = \left[\sum_{i=1}^{n} [K_1 Q_r \times (\%CO_2 + \%CO) + K_2 Q_a - K_3 Q_r \times [\%CO/2 + \%CO_2 + \%O_2] + K_3 Q_{oxy} \times (\%O_{oxy})]_i \right] / n$$

Equation 200-2

Where:

CR_d	=	daily average coke burn rate (kg/day or lb/day)
K_1, K_2, K_3	=	material balance and conversion factors (K_1, K_2, and K_3 from Table 200-1
n	=	number of hours per day
Q_r	=	volumetric flow rate of exhaust gas before entering the emission control system (dscm/min or dscf/min)
Q_a	=	volumetric flow rate of air to regenerator as determined from control room instrumentation (dscm/min or dscf/min)
$\%CO_2$	=	CO_2 concentration in regenerator exhaust, percent by volume – dry basis
%CO	=	CO concentration in regenerator exhaust, percent by volume – dry basis
$\%O_2$	=	O_2 concentration in regenerator exhaust, percent by volume – dry basis
Q_{oxy}	=	volumetric flow rate of O_2 enriched air to regenerator as determined from control room instrumentation (dscm/min or dscf/min)
$\%O_{xy}$	=	O_2 concentration in O_2 enriched air stream inlet to regenerator, percent by volume – dry basis

$$Q_r = (79 \times Q_a + (100 - \%Q_{xy}) \times Q_{oxy}) / (100 - \%CO_2 - \%CO - \%O_2) \qquad \textbf{Equation 200-3}$$

Where:

Q_r = volumetric flow rate of exhaust gas from regenerator before entering the emission control system (dscm/min or dscf/min)
Q_a = volumetric flow rate of air to regenerator, as determined from control room instrumentation (dscm/min or dscf/min)
$\%Q_{xy}$ = oxygen concentration in oxygen enriched air stream, percent by volume – dry basis
Q_{oxy} = volumetric flow rate of O_2 enriched air to regenerator as determined from catalytic cracking unit control room instrumentation (dscm/min or dscf/min)
$\%CO_2$ = carbon dioxide concentration in regenerator exhaust, percent by volume – dry basis
$\%CO$ = CO concentration in regenerator exhaust, percent by volume – dry basis. When no auxiliary fuel is burned and a continuous CO monitor is not required, assume %CO to be zero
$\%O_2$ = O_2 concentration in regenerator exhaust, percent by volume – dry basis

(2) The operator shall calculate process CO_2 emissions resulting from periodic catalyst regeneration using Equation 200-4.

$$CO_2 = \sum_{i=1}^{n} CRR \times \left(CF_{spent} - CF_{regen}\right)_i \times 3.664 \times 0.001 \qquad \textbf{Equation 200-4}$$

Where:

CO_2 = CO_2 emissions (metric tons/yr)
CRR = mass of catalyst regenerated (mass/regeneration cycle)
CF_{spent} = weight fraction carbon on spent catalyst
CF_{regen} = weight fraction carbon on regenerated catalyst (default = 0)
n = number of regeneration cycles
3.664 = ratio of molecular weights, CO_2 to carbon
0.001 = conversion factor – kg to metric tons

(3) The operator shall calculate process CO_2 emissions resulting from continuous catalyst regeneration in operations other than FCCUs and fluid cokers (e.g. catalytic reforming) using Equation 200-5.

$$CO_2 = CC_{irc} \times (CF_{spent} - CF_{regen}) \times H \times 3.664 \qquad \textbf{Equation 200-5}$$

Where:

CO_2 = CO_2 emissions (metric tons/yr)
CC_{irc} = average catalyst regeneration rate (metric tons/hr)
CF_{spent} = weight carbon fraction on spent catalyst
CF_{regen} = weight carbon fraction on regenerated catalyst (default = 0)
H = hours regenerator was operational (hr/yr)
3.664 = ratio of molecular weights, CO_2 to carbon

(b) Process Vents. Except for process emissions reported under other requirements of this regulation, the operator shall calculate process emissions of CO_2, CH_4, and N_2O from process vents using Equation 200-6.

Equation 200-6

$$E_x = \sum_{i=1}^{n} VR_i \times F_{xi} \times (MW_x / MVC) \times VT_i \times 0.001$$

Where:

E_x	=	emissions of x (metric tons/yr), where x = CO_2, N_2O, or CH_4
VR_i	=	vent rate for venting event i (scf/unit time)
F_{xi}	=	molar fraction of x in vent gas stream during event i
MW_x	=	molecular weight of x (kg/kg-mole)
MVC	=	molar volume conversion (849.5 scf/kg-mole for STP of 20°C and 1 atmosphere or 836 scf/kg-mole for STP of 60°F, and 1 atmosphere)
VT_i	=	time duration of venting event i
n	=	number of venting events
0.001	=	conversion factor – kg to metric tons

(c) Asphalt Production. The operator shall calculate CO_2 and CH_4 process emissions from asphalt blowing activities using Equations 200-7 and 200-8.

Equation 200-7

$$CH_4 = (M_A \times EF \times MW_{CH4} / MVC) \times (1 - DE) \times 0.001$$

Where:

CH_4	=	CH_4 emissions (metric tons/yr)
M_A	=	mass of asphalt blown (10^3 bbl/yr)
EF	=	emission factor (EF = 2,555 scf $CH_4/10^3$ bbl)
MW_{CH4}	=	CH_4 molecular weight (16.04 kg/kg-mole)
MVC	=	molar volume conversion factor (849.5 scf/kg- mole, for STP of 20°C and 1 atmosphere)
DE	=	control measure destruction efficiency (DE = 98% expressed as 0.98)
0.001	=	conversion factor – kg to metric tons

Equation 200-8

$$CO_2 = (M_A \times EF \times MW_{CH4} / MVC) \times DE \times 2.743 \times 0.001$$

Where:

CO_2	=	CO_2 emissions (metric tons/yr)
M_A	=	mass of asphalt blown (10^3 bbl/yr)
EF	=	emission factor (EF = 2,555 scf $CH_4/10^3$ bbl)
MW_{CH4}	=	CH_4 molecular weight (16.04 kg/kg-mole)
MVC	=	molar volume conversion factor (849.5 scf/kg mole, for STP of 20°C and 1 atmosphere)
DE	=	control measure destruction efficiency (DE = 98% expressed as 0.98)

2.743	=	CH_4 to CO_2 conversion factor
0.001	=	conversion factor – kg to metric tons

(d) Sulfur Recovery. The operator shall calculate CO_2 process emissions from sulfur recovery units (SRUs) using Equation 200-9. For the molecular fraction (MF) of CO_2 in the sour gas, use either a default factor of 0.20 or a source specific molecular fraction value approved by [*insert jurisdiction*] and derived from source tests conducted at least once per calendar year under the supervision of [*insert jurisdiction*].

$$CO_2 = FR \times MW_{CO2} / MVC \times MF \times 0.001$$ **Equation 200-9**

Where:

CO_2	=	emissions of CO_2 (metric tons/yr)
FR	=	volumetric flow rate of acid gas to SRU (scf/year)
MW_{CO2}	=	molecular weight of CO_2 (44 kg/kg-mole)
MVC	=	molar volume conversion (849.5 scf/ kg-mole, for STP of 20°C and 1 atmosphere or 836 scf/kg-mole, for STP of 60°F, and 1 atmosphere)
MF	=	molecular fraction (%) of CO_2 in sour gas (default MF = 20% expressed as 0.20)
0.001	=	conversion factor – kg to metric tons

(e) Flares and Other Control Devices.

(1) The operator shall calculate and report CO_2, CH_4 and N_2O emissions resulting from the combustion of flare pilot and purge gas using the appropriate method(s) specified in sections WCI.20.

(2) The operator shall calculate and report CO_2 emissions resulting from the combustion of hydrocarbons routed to flares for destruction using Equation 200-10.

$$CO_2 = RFI \times EF_{NMHC} \times CF_{NMHC} \times 3.664 \times 0.001$$ **Equation 200-10**

Where:

CO_2	=	CO_2 emissions (metric tons/year)
RFT	=	refinery feed input (m^3/yr)
EF_{NMHC}	=	non-methane hydrocarbon emission factor (EF_{NMHC} = 0.002 kg/m^3 throughput)
CF_{NMHC}	=	conversion factor – NMHC to carbon (CF_{NMHC}= 0.6)
3.664	=	ratio of molecular weights, CO_2 to carbon 0.001 = conversion factor – kg to metric tons

(3) The operator who uses methods other than flares (e.g. incineration, combustion as a supplemental fuel in heaters or boilers) to destroy low Btu gases (e.g. coker flue gas, gases from vapor recovery systems, casing vents and product storage tanks) shall calculate CO_2 emissions using Equation 200-11. The operator shall determine CC_A and MW_A quarterly using methods specified in section WCI.20 and use the annual average values of CC_A and MW_A to calculate CO_2 emissions.

$$CO_2 = GV_A \times CC_A \times MW_A / MVC \times 3.664 \times 0.001 \quad \textbf{Equation 200-11}$$

Where:

CO_2	=	CO_2 emissions (metric tons/year)
GV_A	=	volume of gas A destroyed annually (scf/year)
CC_A	=	carbon content of gas A (kg C/kg fuel)
MW_A	=	molecular weight of gas A
MVC	=	molar volume conversion factor (849.5 scf/kg- mole for STP of 20°C and 1 atmosphere or 836 scf/kg-mole, for STP of 60°F, and 1 atmosphere)
3.664	=	ratio of molecular weights, CO_2 to carbon
0.001	=	conversion factor – kg to metric tons

(f) Storage Tanks. For above-ground storage tanks containing crude oil, asphalt, naphtha, and distillate oils that are not equipped with vapor recovery technology, the operator shall calculate CH_4 emissions using the U.S. EPA TANKS Model (Version 4.09D). For crude oil, naphtha, and distillate oils, use the default chemical databases for crude oil (RVP 5), distillate fuel oil No. 2, and jet naphtha (JP4), respectively. For asphalt, use the data in Table 200-4 to create an asphalt chemical database. The annual throughput for each storage tank must be distributed equally across the twelve months of the year and the single-component liquid option selected. The total VOC emission values generated by the model shall be converted to methane emissions using:

(1) A default conversion factor of 0.6 (CH_4 = 0.6 * VOC); or

(2) Species specific conversion factors determined by storage tank headspace vapor analysis using a sampling and analysis methodology approved by [*insert jurisdiction*].

(g) Wastewater Treatment.

(1) The operator shall calculate CH_4 emissions from wastewater treatment using Equation 200-12.

$$CH_4 = [(Q \times COD_{qave}) - S] \times B \times MCF \times 0.001 \quad \textbf{Equation 200-12}$$

Where:

CH_4	=	emission of methane (tons/yr)
Q	=	volume of wastewater treated (m^3/yr)
COD_{qave}	=	average of quarterly determinations of chemical oxygen demand of the wastewater (kg/m^3)
S	=	organic component removed as sludge (kg COD/yr)
B	=	methane generation capacity (B = 0.25 kg CH_4/kg COD)
MCF	=	methane conversion factor for anaerobic decay (0-1.0) from Table 200-2
0.001	=	conversion factor – kg to metric tons

(2) The operator shall calculate N_2O emissions from wastewater treatment using Equation 200-13.

$$N_2O = Q \times N_{qave} \times EF_{N2O} \times 1.571 \times 0.001 \quad \textbf{Equation 200-13}$$

Where:

N_2O = emissions of N_2O (metric tons/yr)
Q = volume of wastewater treated (m^3/yr)
N_{qave} = average of quarterly determinations of N in effluent (kg N/m^3)
EF_{N2O} = emission factor for N_2O from discharged wastewater (0.005 kg N_2O-N/kg N)
1.571 = conversion factor – kg N_2O-N to kg N_2O
0.001 = conversion factor – kg to metric tons

(h) Oil-Water Separators. The operator shall calculate CH_4 emissions from oil-water separators using Equation 200-14.

$$CH_4 = EF_{sep} \times V_{water} \times CF_{NMHC} \times 0.001$$ **Equation 200-14**

Where:

CH_4 = emission of methane (tons/yr)
EF_{sep} = NMHC (non methane hydrocarbon) emission factor (kg/m^3) from Table 200-3.
V_{water} = volume of waste water treated by the separator (m^3/yr)
CF_{NMHC} = NMHC to CH_4 conversion factor (CF_{NMHC} = 0.6)
0.001 = conversion factor – kg to metric tons

(i) Equipment leaks. The operator shall calculate CH_4 emissions for all components in natural gas, refinery fuel gas, and PSA off-gas systems as follows:

(1) Components shall be identified as one of the following classification types: valve, pump seal, connector, flange, open-ended line. Operators shall use the Component Identification and Counting Methodology and screening methods found in Method 3 in CAPCOA (1999), which is incorporated by reference in WCI.6. Operators shall measure and record emissions using instrumentation capable of detecting methane.

(2) The VOC emissions shall be calculated using the following methods:

(A) For components where the measured screening value (SV) is indistinguishable from zero when corrected for background, operators shall calculate VOC emissions using Equation 200-15:

$$E_{VOC-0} = \sum_{i=1}^{6} CC_i \times ZF_{i0} \times t$$ **Equation 200-15**

Where:

E_{VOC-0} = zero component VOC emission (kg/screening period)
i = component type (1 = valve, 2 = pump seal, 3 = other, 4 = connector, 5 = flange, 6 = open-ended line)
CC_i = number of i components where SV = 0
ZF_{i0} = zero VOC emission factor (kg/hr) for component i from Table 200-5
t = time (hours) since last screening

(B) For leaking components, operators shall calculate VOC emissions using the following methods:

(i) For screening values between background and 9,999 ppmv, the operator shall calculate the VOC emissions using Equation 200-16.

$$E_{VOCL-C} = \sum_{i=1}^{6} \sum_{n=1}^{n} \left(\sigma_i \times SV_n^{\beta i}\right) \times t \qquad \textbf{Equation 200-16}$$

Where:

E_{VOCL-C}	=	leaking components VOC emissions (kg/screening period)
i	=	component type (1=valve, 2=pump seal, 3=others, 4=connector, 5=flange, 6=open ended-line)
n	=	number of i components
σ_i	=	correlation equation coefficient for component type i from Table 200-5
SV_n	=	screening value for component n
βi	=	correlation equation exponent for component type i from Table 200-5
t	=	time (hours) component has been leaking – default value is time from last screening

(ii) For screening values greater than 9,999 ppmv, the operator shall calculate the VOC emissions using Equation 200-17.

$$E_{VOCP} = \sum_{i=1}^{6} CC_i \times PF_{iP} \times t \qquad \textbf{Equation 200-17}$$

Where:

E_{VOCP}	=	VOC emissions for components pegged over SV 9,999 ppmv (kg/screening period)
i	=	component type (1=valve, 2=pump seal, 3=others, 4=connector, 5=flange, 6=open-ended line)
CC_i	=	number of i components pegged over 9,999 ppmv
PF_{iP}	=	VOC emission factor (kg/hr) for component type i pegged over 9,999 ppmv from Table 200-5
t	=	time component has been leaking (hours) – default value is time since last screening

(C) The operator shall calculate CH_4 emissions using Equation 200-18. Operators shall use system specific determinations of gas composition and methane content (refinery fuel gas, natural gas, associated gas, flexigas, low Btu gas), where available, to determine a CF_{VOC} value. When representative data is not available, operators shall use the default value of 0.6 for CF_{VOC}.

$$CH_4 = \sum_{1}^{n} \left(E_{VOC-0} + E_{VOC-LC} + E_{VOCP}\right)_n \times CF_{VOC} \times 0.001 \qquad \textbf{Equation 200-18}$$

Where:

CH_4	=	methane emissions (metric tons/year)
n	=	number of screenings/year
E_{VOC-0}	=	zero component VOC emissions (kg/screening period)
E_{VOC-LC}	=	leaking component VOC emissions (kg/screening period)
E_{VOCP}	=	VOC emissions for components pegged over 9,999 ppmv (kg/screening period)
CF_{VOC}	=	VOC to CH_4 conversion factor (default CF_{VOC}=0.6)
0.001	=	conversion factor – kg to metric tons

WCI.204 Sampling, Analysis, and Measurement Requirements

(a) Catalyst Regeneration.

(1) For FCCUs and fluid coking units, the operators shall measure the following parameters using methods that comply with the measurement accuracy provisions in WCI.2(g).

(A) The daily oxygen concentration in the oxygen enriched air stream inlet to the regenerator.
(B) Continuous measurements of the volumetric flow rate of air and oxygen enriched air entering the regenerator.
(C) Continuous measurement of the volumetric flow rate of exhaust gas leaving the regenerator.
(D) Continuous measurements of the CO_2, CO and O_2 concentrations in the regenerator exhaust gas.
(E) Daily measurements of the carbon content of the coke burned.
(F) The number of days of operation.

(2) For periodic catalyst regeneration, the operators shall measure the following parameters using methods that comply with the measurement accuracy provisions in WCI.2(g).

(A) The mass of catalyst regenerated in each regeneration cycle.
(B) The weight fraction of carbon on the catalyst prior to and after catalyst regeneration.

(3) For continuous catalyst regeneration in operations other than FCCUs and fluid cokers, the operators shall measure the following parameters using methods that comply with the measurement accuracy provisions in WCI.2(g).

(A) The hourly catalyst regeneration rate.
(B) The weight fraction of carbon on the catalyst prior to and after catalyst regeneration.
(C) The number of hours of operation.

(b) Process vents. Operators shall measure the following parameters for each process vent using methods that comply with the measurement accuracy provisions in WCI.2(g).

(1) The vent flow rate for each venting event.
(2) The molar fraction of CO_2, N_2O, and CH_4 in the vent gas stream during each venting event.
(3) The duration of each venting event.

(c) Asphalt Production. Operators shall measure the mass of asphalt blown using methods that comply with the measurement accuracy provisions in WCI.2(g).

(d) Sulfur Recovery. The operator shall measure the volumetric flow rate of acid gas to the SRU using methods that comply with the measurement accuracy provisions in WCI.2(g). If using source specific molecular faction value instead of the default factor, the operator shall conduct an annual test of the CO_2 content using methods approved by [insert jurisdiction]. The operator shall submit a test plan to the [insert jurisdiction] for approval. Once approved, the annual tests shall be conducted in accordance with the approved test plan under the supervision of the [*insert jurisdiction*].

(e) Flares and Other Control Devices. The operator shall measure:

(1) The volume of gas destroyed annually determined to accuracy of ± 7.5%.
(2) The carbon content using methods that comply with the measurement accuracy provisions in WCI.2(g).

(f) Storage Tanks. The operator shall measure the annual throughput of crude oil, naphtha, distillate oil, asphalt, and gas oil for each storage tank using flow meters that comply with the measurement accuracy provisions in WCI.2(g).

(g) Wastewater Treatment. Operators shall measure the following parameters using methods that comply with the measurement accuracy provisions in WCI.2(g).

(1) The daily volume of waste water treated.
(2) The quarterly chemical oxygen demand of the wastewater.
(3) The amount of sludge removed and the organic content of the sludge.
(4) The quarterly nitrogen content of the wastewater.

(h) Oil-Water Separators. Operators shall measure the daily volume of waste water treated by the oil-water separators using methods that comply with the measurement accuracy provisions in WCI.2(g).

(i) Equipment Leaks. Operators shall measure screening values for each valve, pump seal, connector, flange, and open-ended line used in natural gas, refinery fuel gas, and PSA off-gas systems using the methods specified in CAPCOA (1999) Method 3: Correlation Equation Method and an instrument capable of detecting methane. Operators shall conduct screenings at the frequency interval required by [*insert jurisdiction*].

Note: Comparability of the Canadian regulations to the leak detection and repair r regulations under 40 CFR 63, Subpart CC and 40 CFR 60, Subpart VV is under determination. These U.S EPA regulations require initially monthly monitoring for valves and pumps, which may be reduced to quarterly, semi-annual, or annual based on the percentage of leaking components.

Table 200-1. Coke burn rate material balance and conversion factors

	(kg min)/(hr dscm %)	(lb min)/(hr dscf %)
K_1	0.2982	0.0186
K_2	2.0880	0.1303
K_3	0.0994	0.0062

Table 200-2. Default MCF Values for Industrial Wastewater			
Type of Treatment and Discharge Pathway or System	**Comments**	**MCF**	**Range**
Untreated			
Sea, river and lake discharge	Rivers with high organic loading may turn anaerobic, however this is not considered here	0.1	0 - 0.2
Treated			
Aerobic treatment plant	Well maintained, some CH_4 may be emitted from settling basins	0	0 – 0.1
Aerobic treatment plant	Not well maintained, overloaded	0.3	0.2 – 0.4
Anaerobic digester for sludge	CH_4 recovery not considered here	0.8	0.8 – 1.0
Anaerobic reactor	CH_4 recovery not considered here	0.8	0.8 – 1.0
Anaerobic shallow lagoon	Depth less than 2 meters	0.2	0 – 0.3
Anaerobic deep lagoon	Depth more than 2 meters	0.8	0.8 – 1.0

For CH_4 generation capacity (B) in kg CH_4/kg COD, use default factor of 0.25 kg CH_4/kg COD.

The emission factor for N_2O from discharged wastewater (EF_{N2O}) is 0.005 kg N_2O-N/kg-N.

MCF = methane correction factor – the fraction of waste treated anaerobically.
COD = chemical oxygen demand (kg COD/m^3).

Table 200-3. Emission Factors for Oil/Water Separators	
Separator Type	**Emission factor (EF_{sep})[a] kg NMHC/m^3 wastewater treated**
Gravity type - uncovered	1.11e-01

Open-ended lines (6)	2.0×10^{-6}	$1.90 \times 10^{-6}(SV)^{0.724}$	0.033

ATTACHMENT 3: REFINERY FUEL GAS COMBUSTION

§ WCI.30 REFINERY FUEL GAS COMBUSTION

WCI.31 Source Category Definition

This source category consists of any combustion device that is located at a petroleum refinery and that combusts refinery fuel gas, still gas, flexigas, or associated gas.

WCI.32 Greenhouse Gas Reporting Requirements

In addition to the information required by WCI.3, the emissions data report shall include the following information at the facility level:

(a) Annual CO_2, CH_4, and N_2O emissions from refinery fuel gas combustion in metric tons.

(b) Annual fuel consumption in units of million standard cubic feet or cubic meters.

(c) Average carbon content of each fuel, if used to compute CO_2 emissions.

(d) Average high heating value of each fuel, if used to compute CO_2 emissions.

WCI.33 Calculation of Greenhouse Gas Emissions

(a) Calculation of CO_2 Emissions. Owners and operators shall calculate daily CO_2 emissions for each fuel gas system using any of the methods specified in paragraphs (a)(1) through (a)(5) of this section. Calculate the total annual CO_2 emissions from combustion of all fuel gas by summing the CO_2 emissions from each fuel gas system.

(1) Use a CEMS that complies with the provisions in section WCI.23(d).
(2) Calculate CO_2 emissions from each refinery fuel gas system and flexigas system using measured carbon content and molecular weight of the gas and Equation 30-1.

$$CO_2 = \sum_{i=1}^{n} Fuel_i \times CC_i \times \frac{MW}{MVC} \times 3.664 \times 0.001 \qquad \textbf{Equation 30-1}$$

Where:

CO_2	=	Carbon dioxide emissions, metric tons/year.
$Fuel_i$	=	Daily refinery fuel or flexigas combusted (scf).
CC_i	=	Daily sample of carbon content of the fuel (kg C/kg fuel).
MW	=	Daily sample of molecular weight of fuel.
MVC	=	Molar volume conversion factor (849.5 scf/kg-mole for STP of 20°C and 1 atmosphere, or 836 scf/kg-mole for STP of 60°F and 1 atmosphere).
3.664	=	Conversion factor for carbon to carbon dioxide.
0.001	=	Conversion factor for kg to metric tons.
n	=	Number of days in a year.

(A) For refinery fuel gas, the daily carbon content shall be determined a minimum of 3 times a day (once every 8 hours) using on-line instrumentation or discrete laboratory analysis using the methods specified in WCI.34.
(B) For flexigas, the daily carbon content shall be determined once per day using the methods specified in WCI.34.

(3) Calculate CO_2 emissions from each fuel gas system and flexigas system using Equation 30-2 and a daily average high heating value that is monitored using a continuous on-line instrument.

$$CO_2 = \sum_{i=1}^{n} HHV_i \times Fuel_i \times EF_{CO2,i} \times 0.000001 \qquad \textbf{Equation 30-2}$$

Where:

CO_2	=	CO_2 emissions resulting from the combustion of fuel gas from an individual fuel gas system (metric tons/yr).
HHV_i	=	Daily average high heating value of fuel gas, derived from a continuous analyzer and integrated over a 24-hour period (Btu/scf).
$Fuel_i$	=	Daily fuel consumption from all fuel combustion units burning gas from the system (scf/d).
$EF_{CO2,i}$	=	Daily CO_2 emission factor for an individual fuel gas system, developed using Equation 30-3 (metric tons CO_2/MM Btu).
0.000001	=	Conversion factor for Btu to MMBtu.
n	=	Number of days per year.

$$EF_{CO2,i} = CC/HHV \times MW/MVC \times 3.664 \times 1000 \qquad \textbf{Equation 30-3}$$

Where:

$EF_{CO2,i}$	=	Daily CO_2 emission factor for an individual fuel gas system (metric tons CO_2/MMBtu).
CC	=	Daily sample of gas carbon content for a fuel gas system, collected according to paragraph (a)(3)(A) of this section (kg carbon/kg fuel).
HHV	=	Daily sample of gas high heating value for a fuel gas system, collected according to paragraph (a)(3)(A) of this section (Btu/scf).
MW	=	Refinery fuel A molecular weight (kg/kg-mole).
MVC	=	Molar volume conversion (849.5 scf/ kg-mole, for STP of 20°C and 1 atmosphere, or 836 scf/kg-mole for STP of 60°F and 1 atmosphere).
3.664	=	Conversion factor for carbon to carbon dioxide.
1000	=	Conversion factor for kg/Btu to metric tons/MMBtu.

(A) For Equation 30-3, the carbon content shall be determined once per day by on-line instrumentation or by laboratory analysis of a representative sample using the methods specified in WCI.34. The HHV shall be determined from either the same sample used to conduct the carbon analysis or from on-line instrumentation using the hourly average value that coincides with the same hour in which the carbon content was determined.

(B) For facilities that meet the definition of a small refiner in WCI.10, the emissions measurements and calculations for Equation 30-2 and 30-3 may be conducted weekly.

(4) For associated gas, low Btu gas, or other fossil fuels; follow the requirements for general stationary source combustion sources in WCI .23(b) or (c), as appropriate for each fuel.

(5) Where individual fuels are mixed prior to combustion, the operator may choose to calculate CO_2 emissions for each fuel prior to mixing instead of using the methods in paragraphs (a)(1), (a)(2), or (a)(3) of this section. In this case, the operator must determine the fuel flow rate and appropriate fuel specific parameters (e.g. carbon content, HHV) of each fuel stream prior to mixing, calculate CO_2 emissions for each fuel stream, and sum the emissions of the individual fuel streams to determine total CO_2 emissions from the mixture. CO_2 emissions for each fuel stream must be estimated using the following methods:

(A) For natural gas and associated gas, use the appropriate methodology specified in section WCI.23(b) or (c).

(B) For refinery fuel gas and flexigas, use the methodology in either paragraph (a)(2) or (a)(3) of this section.

(C) For low Btu gas, use the methodology in paragraph (a)(2) of this section.

(b) Calculation of CH_4 and N_2O Emissions. Owners and operators shall use the methods specified in section WCI.24 to calculate the annual CH_4 and N_2O emissions.

WCI.34 Sampling, Analysis, and Measurement Requirements

(a) Measure the fuel consumption rate daily using methods specified in WCI.25(b).

(b) Measure the carbon content for fuel gas and flexigas using either ASTM D1945-03 or ASTM D1946-90 (Reapproved 2006).

(c) Measure high heating value using the monitoring requirements specified in WCI.25(c) for gaseous fuels.

ATTACHMENT 13: ZINC PRODUCTION

Applicability

There are three primary production processes used to produce zinc: electro-thermic distillation, pyrometallurgical, and electrolytic. In electro-thermic distillation, roasted concentrate and secondary zinc products are combined into a sinter feed that is then burned resulting in a zinc oxide-rich sinter. This sinter is then fed into an electric retort furnace with metallurgical coke which reduces the zinc oxide; the resultant vaporized zinc is then captured in a vacuum condenser. The pyrometallurgical process utilizes an Imperial Smelting Furnace, which allows for the simultaneous treatment of both lead and zinc concentrates (estimated emissions must be allocated to both lead and zinc production to avoid double-counting). In the electrolytic process, zinc sulfide is calcined, which results in the production of zinc oxide. The zinc oxide is leached in sulfuric acid and then drawn out of solution using electrolysis. The electrolytic process does not result in non-energy CO_2 emissions.

In addition to primary production, zinc can be recovered from various materials using more than 40 hydrometallurgical and pyrometallurgical technologies. The preferred technologies are dependent upon the zinc source and the desired end use for the recovered zinc. In general, the processes consist of zinc concentration, sintering, smelting, and refining. Many of the sintering, smelting, and refining steps are identical to the primary production process steps. Two concentration processes are the Waelz Kiln and slag reduction or fuming processes.

Emission Calculations

The following emission calculation methods are taken from the 2006 IPCC Guidelines, Volume 3, Section 4.7.

The Tier 3 methodology recommends using actual directly measured CO_2 emissions data, if available. Alternatively, facility-specific emission factors and material quantities can be used to calculate emissions for the Tier 3 methodology. The Tier 2 methodology uses country-specific emission factors developed from facility statistics regarding reducing agent use, furnace types, and other process materials. Unlike lead, default carbon contents are not provided for reducing agents used in zinc production.

The Tier 1 methodology for zinc production uses default emission factors for different zinc product types. The emission calculation equation for Tier 1 is:

$$E_{Zn} = (Zn_{ET} \times EF_{ET}) + (Zn_{PM} \times EF_{PM}) + (Zn_{Sec} \times EF_{Sec})$$

Where:

E_{Zn} = CO_2 emissions from zinc production (metric tons);
Zn_{ET} = Quantity of zinc produced by electro-thermic distillation (metric tons);
EF_{ET} = Emission factor for electro-thermic distillation (metric tons CO_2/metric tons of zinc produced);
Zn_{PM} = Quantity of zinc produced by pyrometallurgical process (Imperial Smelting Furnace Process (metric tons);
EF_{PM} = Emission factor for pyrometallurgical process (metric tons CO_2/metric tons of zinc produced);
Zn_{Sec} = Quantity of zinc produced by secondary production process (e.g., Waelz Kiln, etc.) (metric tons);
EF_{Sec} = Emission factor for secondary production process (metric tons CO_2/metric tons of zinc produced).

A default emission factor is not available for the electro-thermic distillation process because of a lack of data; emissions will be underestimated if a facility-specific emission factor for the electro-thermic distillation process is not identified and used. The default emission factor for the pyrometallurgical process (i.e., Imperial Smelting Furnace) is 0.43 metric tons CO_2/metric tons of zinc produced. The default emission factor for the secondary production process (i.e., Waelz Kiln) is 3.66 metric tons CO_2/metric tons of zinc produced.

The uncertainty for Tier 3 facility-specific measured CO_2 data has been estimated to be ±5 percent. The uncertainty associated with the Tier 3 facility-specific reducing agent quantities and carbon contents is also estimated to be ±5 percent. The uncertainty of the Tier 2 country-specific emission factors is estimated to be ±15 percent. The uncertainty of the Tier 1 default emission factors is estimated to be ±50 percent.

The Tier 3 method (using either actual directly measured CO_2 emissions data or facility-specific emission factors and material quantities) is recommended to estimate emissions from zinc production facilities.

Reporting Requirements

Annual CO_2 emissions (measured or calculated) based on the IPCC Tier 3 or Tier 2 method will be reported for each facility.

Sampling, Analysis, and Measurement Methods

(a) Facility CO_2 emissions. The Tier 3 method from the 2006 IPCC Guidelines specifies facility-specific emission measurements. Determine facility CO_2 emissions using continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).
(b) Quantity Measurement Requirements. Alternatively, Tier 3 facility-specific emission factors can be used if facility-specific emission measurements are not available. For solid process outputs, quantities must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

ATTACHMENT 7: HYDROGEN PRODUCTION

§ WCI.130 HYDROGEN PRODUCTION

§ WCI.131 Source Category Definition

A hydrogen production process produces hydrogen gas by steam hydrocarbon reforming, partial oxidation of hydrocarbons, or other transformation of hydrocarbon feedstock. The hydrogen produced may be either transferred offsite or used onsite at petrochemical, ammonia production, refineries, and other plants.

§ WCI.132 Greenhouse Gas Reporting Requirements

For each facility, the annual emissions report must contain the following information:

(a) Process CO_2 Emissions. The CO_2 process emissions from the hydrogen produced process.

(b) Feedstock Consumption. Annual feedstock consumption by feedstock type (including petroleum coke) reported in units of million standard cubic feet for gases, gallons for liquids, short tons for non-biomass solids, and bone dry short tons for biomass-derived solid fuels.

(c) Production. Annual hydrogen produced.

(d) Stationary Combustion Units. Report CO_2, N_2O, and CH_4 emissions as specified in WCI.20.

§ WCI.133 Calculation of Greenhouse Gas Emissions

The owner or operator shall calculate and report CO_2 process emissions using the methods in paragraphs (a) or (b) of this section.

(a) Continuous Emission Monitoring Systems. The owner or operator may calculate CO_2 process emissions using CEMS. The owner or operator must comply with the requirements in section WCI.20.

(b) Feedstock Material Balance. The owner or operator may calculate CO_2 process emissions using the following method. The factor S shall be used only for CO_2 and/or CH_4 emissions that are calculated and reported using applicable methods specified in this regulation. For example, carbon species in uncoverted feedstock contained in PSA off-gas and hydrogen plant product that is diverted to fuel gas systems, fed to downstream units, or diverted to flare may be included in the factor S provided the CO_2 and/or CH_4 emissions are reported using other methods in this regulation.

$$CO_2(Feedstock) = \sum_{i=1}^{n} \sum_{j=1}^{y} \left[\left(FS_j * CF_j \right) - S_j \right] * 3.664 * 0.001 \qquad \textbf{Equation 130-1}$$

Where:

CO_2 (Feedstock) = CO_2 emitted from feedstock (metric tons/year).

n	=	Days of operation per year.
FS_j	=	Feedstock b consumption rate (scf/day).
CF_j	=	Carbon content of feedstock j (kg C/scf feedstock).
y	=	Total number of feedstocks.
S_j	=	Carbon accounted for elsewhere (kg C/day).
3.664	=	ratio of molecular weights, CO_2 to carbon
0.001	=	conversion factor – kg to metric tons

WCI.134 Sampling, Analysis, and Measurement Requirements

(a) Owners or operators using CEMS to estimate CO_2 emissions shall comply with the monitoring requirements in section WCI.20.

(b) Owners or operators using the method in section WCI.103 (b) shall perform the following monitoring:

(1) The owner or operator shall measure the feedstock consumption rate daily using methods that comply with the measurement accuracy provisions in WCI.2(g).
(2) The owner or operator shall collect samples of each feedstock consumed and analyze each sample for carbon content using the methods specified in WCI.25(d). For natural gas feedstock not mixed with another feedstock prior to consumption, samples shall be collected and analyzed once per month. For all other feedstocks, samples shall be collected and analyzed daily. The samples shall be collected from a location in the feedstock handling system that provides samples representative of the feedstock consumed in the hydrogen production process.
(3) Owners or operators shall measure the hydrogen produced daily using methods that comply with the measurement accuracy provisions in WCI.2(g).
(4) Owners or operators shall measure the CO_2 and CO collected daily using methods that comply with the measurement accuracy provisions in WCI.2(g).

ATTACHMENT 15: PULP AND PAPER MANUFACTURING

Several documents were identified as having the most comprehensive estimation methods for the pulp and paper industry. In these documents, the primary authority for estimating GHG emissions from pulp and paper manufacturing is: *Calculation Tools for Estimating Greenhouse Gas Emissions from Pulp and Paper Mills, Version 1.1, July 8, 2005, a project of The Climate Change Working Group of The International Council of Forest and Paper Associations (ICFPA).* This reference is the basis of the GHG estimation methodology used by WRI and by Climate Leaders.

Applicability

The ICFPA methodology lists the following sources of GHG at pulp and paper manufacturing facilities:

1. Stationary combustion units such as fossil and biomass fired boilers and dryers (§ WCI.20)
2. Lime kilns and calciners (§ WCI.170)
3. Electric generation units (§ WCI.40)
4. Nonroad equipment (§ WCI.XX)
5. Anaerobic waste and wastewater treatment
6. Black liquor boilers

Methods for estimating emissions from sources 1 through 4 in the above list are or will be addressed under other sections of the Essential Requirements for mandatory reporting, as noted. However, most of the process CO_2 emissions from the lime kilns at pulp and paper mills is derived from organic carbon, which must be tracked separately from the fossil CO_2.

Emission Calculations – Anaerobic Treatment and Black Liquor Boilers

For purposes of reporting, WCI will likely require a method similar to that required for reporting wastewater CH_4 and N_2O emissions from refineries in WCI.203(g). WCI will examine the uncertainty of the biogenic decay models, such as those used to estimate emissions for municipal landfills and municipal wastewater treatment plants, to determine their appropriateness for estimating anaerobic treatment processes for purposes of including these emissions in the cap-and-trade program.

Black liquor boilers are a source of CO_2, CH_4 and N_2O emissions. The ICFPA reports that all CO_2 emissions from black liquor boilers are of biogenic origin and not reportable. Thus, they do not present a methodology for determining CO_2 emissions from this source. The Climate Registry (TCR) and the IPCC offer only emission factors for determining CO_2 emissions from black liquor boilers. The IPCC reports that the 95% confidence interval for their CO_2 factor ranges from 80,700 to 110,000 (± 15%) kg/TJ. Similarly, the reported IPCC factors for CH_4 and N_2O emissions from black liquor boilers range by a factor of 10 at the 95% confidence level.

Recommended Reporting Requirements (Under Development)

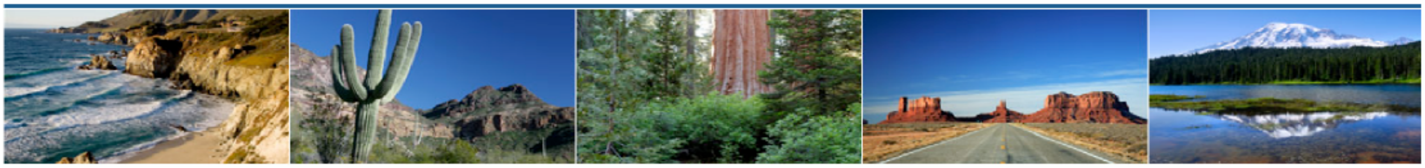
Methods for estimating emissions from sources 1 through 4 in the above list are or will be covered under other sections of the Essential Requirements. In January 2009, special instructions will be developed for lime kilns (source 2) to instruct reporters on how to account for biogenic and fossil process CO_2 emissions, and a specific methodology based on the refinery method (WCI.203(g)) will be prescribed for estimating wastewater emissions (source 5).

Later in 2009, a new methodology will be developed for black liquor boilers (source 6) Note that both fossil and biogenic carbon leave the black liquor boiler as both a gas (CO_2) and a solid (Na_2CO_3), thus a unique material balance methodology will be needed. As with any new methodology, it should be peer reviewed before being finalized for use in the WCI program.

Sampling, Analysis, and Measurement Methods

All further methods development will stipulate that fossil and biogenic process emissions will be reported separately, and will contain requirements pertaining to sampling, analysis, and measurements, as applicable to the specific emission quantification method input(s).

Western Climate Initiative



January 6, 2009

To All Interested Parties:

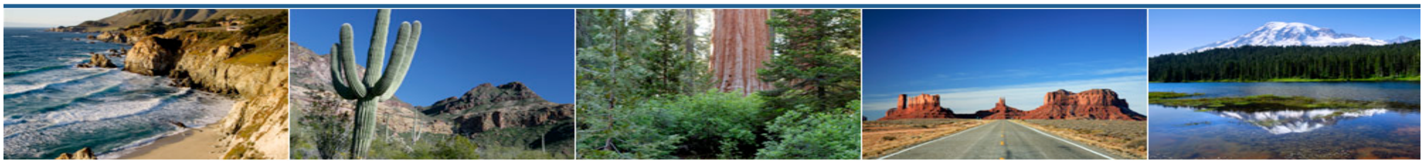
Today, the WCI is releasing their document "Background Document and Progress Report for Essential Requirements of Mandatory Reporting for the Western Climate Initiative, Third Draft." Attached to this document are the Essential Requirements of Mandatory Reporting (i.e., reporting requirements in rule language or narrative format)

You are invited to participate in a stakeholder conference call to discuss the present draft on January 12, 2009, at 12:30 PM to 2:30 PM Pacific Time. The call-in number is 800-868-1837 (direct dial 404-920-6440), access code 659-537#. We ask that written comments be submitted through the WCI Website (www.westernclimateinitiative.org) by January 20, 2009

Sincerely,

Jim Norton, Chair
WCI Reporting Committee
State of New Mexico

Western Climate Initiative



Background Document and Progress Report for Essential Requirements of Mandatory Reporting for the Western Climate Initiative, Third Draft

January 6, 2009

Purpose

The Background Document and Progress Report shows how the scope and design of the cap-and-trade program informs mandatory reporting requirements, discusses stakeholder comments received to date, and explains the basis for the WCI's specific recommendations on mandatory reporting. Attached to this document are the Essential Requirements of Mandatory Reporting (i.e., reporting requirements in rule language or narrative format). This document will be made available to WCI partner states and provinces for their consideration as they propose and adopt mandatory reporting rules in their jurisdictions.

This document revises and expands upon the document issued on September 30, 2008 that addressed continuing work conducted by the WCI Partners and its Reporting Subcommittee (now designated the Reporting Committee). It provides a progress report on the development of the Essential Requirements for reporting and strives to address comments made by stakeholders on previous drafts. Its purposes are similar to previous documents, namely to: 1) document the current status of WCI's consideration of Essential Requirements for reporting; 2) identify ongoing work and decisions that remain to be made; and 3) seek public comment on these reporting Essential Requirements.

Comments on this document should be submitted in writing by January 20, 2009, through the WCI Website (www.westernclimateinitiative.org).

Introduction

The "Design Recommendations for the WCI Regional Cap-and-Trade Program" (September 23, 2008) state that "prior to the start of the mandatory reporting program, the WCI Partner jurisdictions will establish the essential requirements for reporting by all entities and facilities required to report in each of the WCI Partner jurisdictions." To complete the Essential Requirements for reporting, the WCI must make numerous decisions about how it wishes to define, and structure the elements that have been identified as necessary to an effective WCI cap-and-trade program. This document and its companion document, the "Essential Requirements of Mandatory Reporting," reflect the draft recommendations made to date and offered for stakeholder comment.

This document is organized somewhat differently and has a more narrative style than previous versions. Each section contains some introductory comments that explain the content of the section and provides some background information, a recitation of the relevant WCI design recommendations made earlier a brief summary of stakeholder comments and recommendations received to date, a plain language description of WCI's recommendations on Essential Requirements for reporting with a discussion of intent and purpose, and a brief summary of any work and decisions that remain to be made.

This document has 10 sections that address the following Essential Requirements for reporting, which are also referred to as "General Provisions". These sections address: applicability, general requirements and schedule, contents of the report, document retention and record keeping, confidentiality, compliance and enforcement, designated representative, verification, definitions, and pollutants and global warming potentials. An additional section provides the background and progress toward identification of GHG emissions quantification, and sampling, analysis, and measurement methods by source category. For some source categories, the Essential Requirements provide draft language that the WCI Partner jurisdictions can use for implementing the WCI program within their jurisdiction; for other source categories, the Essential Requirements provide a narrative discussion of the adequacy of available GHG quantification and monitoring methods with recommendations for WCI reporting.

It is noted that some of the WCI recommendations on reporting requirements differ from the existing provisions of state or provincial reporting rules. The intent is for those WCI Partner jurisdictions to amend their reporting rules in 2009 to align them with WCI Essential Requirements. It is also noted that, pending final decisions on which emissions will correspond with a requirement to hold allowances, the current recommendations may require reporting and verification for some emissions that are later determined not to result in an allowance requirement. For example, in some circumstances, verification may be required for some sources to validate that their emissions are indeed below the level that would trigger allowance obligations.

Stakeholders should note that the identification of adequate quantification methods is an ongoing process. At this point the methods discussed in this document apply only for purposes of reporting. A recommended quantification method for a given combustion or non-combustion source category may need to be revised and/or updated prior to the beginning of the first compliance period. The fact that a source has a recommended quantification method does not necessarily indicate whether or not that source category will be subject to the cap.

Finally, while the WCI has tried to be as comprehensive as possible in defining reporting requirements, it is not feasible to anticipate every detail at this stage of cap-and-trade program development. Reporting requirements will be developed later in 2009 for several important source categories, including electricity importers, distributors of fuels for transportation, residential, commercial and industrial use, natural gas transmission and distribution non-combustion emissions, oil and gas production and gas processing, and others noted elsewhere in this document. Furthermore, WCI Partner jurisdictions expect to revisit and if necessary revise reporting requirements several years down the road as the WCI cap-and-trade program enters the mandatory compliance phase, if they find that changes are needed to reconcile reporting requirements with the schedule and architecture of the final compliance and trading program.

Applicability (§ WCI.1)

This section describes the facilities, electricity importers, and fuel suppliers that must report their emissions in order to support the cap-and-trade program. It contains reporting thresholds stated as metric tons of carbon dioxide equivalents (CO_2e) per year. This section also addresses the point of regulation (POR) as it pertains to reporting by each included source category. Note that current language within this section describing electricity importers and fuel suppliers should be viewed as preliminary and is subject to revision when the reporting requirements for these source categories are developed by WCI later in 2009.

Relevant Scope and Design Recommendations

The scope of the cap-and-trade program addresses sources that produce 80 to 90 percent of estimated 2005 GHG emissions in WCI Partner jurisdictions. The program design includes combustion and non-combustion emissions. These sources are included in the cap-and-trade program (i.e., will have a requirement to hold emissions allowances) in two phases. Combustion and non-combustion emissions from electrical generation, large industrial and commercial facilities, and oil and gas production and gas processing, are covered in the first compliance period, while combustion emissions from residential, smaller commercial and industrial, and transportation fuels are included in the second compliance period. Adequate quantification methods are a prerequisite to including any source of emissions in the requirements to hold emissions allowances. While source categories will be brought into the cap-and-trade program in phases, emissions reporting is required for all included source categories beginning with 2010 emissions.

The POR, and therefore the reporting requirements, vary by source category. Many sources, including electrical generation within WCI Partner jurisdictions and most industrial source categories are regulated at, and will report at, the facility level. Electrical power imported into WCI Partner jurisdictions is regulated at the first entity that receives the imported power and delivers electricity for consumption within a WCI Partner jurisdiction, over which the WCI partner jurisdiction has regulatory authority. Fuel combustion emissions from residential sources, from commercial and industrial sources with emissions below the reporting threshold, and from transportation sources are regulated upstream of the point of combustion, where the fuels enter commerce in the WCI Partner jurisdictions. This will generally be at a distributor, though the precise point may vary by jurisdiction.

Carbon dioxide emissions from the combustion of biomass and pure biofuels, including those used in blends, are subject to reporting requirements. Carbon dioxide emissions from combustion of biomass determined to be carbon neutral will not be included in the cap-and-trade program. WCI jurisdictions will address the issues of carbon neutrality and lifecycle emissions of biomass and biofuel combustion later in development of the cap-and-trade program.

The emissions threshold for inclusion in cap-and-trade is 25,000 metric tons of CO_2e on an annual basis. The facilities, electricity importers, and fuel suppliers subject to reporting are those with annual emissions equal to or greater than 10,000 metric tons of CO_2e. Nothing in the WCI program design limits any WCI Partner jurisdiction's discretion to require reporting earlier, at lower thresholds, or for entities and facilities not covered by the cap-and-trade program.

Stakeholder Input

Thresholds – Some stakeholders supported the reporting threshold of 10,000 metric tons CO_2e, a few believed it was too low, while others thought it was too high, lacked justification or would unduly burden small companies. Other comments were that the thresholds should be industry-specific, should be identical throughout the WCI region, that electrical generating facilities should report at the lower threshold level required in California, and that the burden on small sources could be reduced by phasing them in and/or by providing assistance.

Source Categories – Some stakeholders urged the WCI to minimize exclusions while others advocated including specific source categories such as oil and gas production, transportation fuels, natural gas distribution and biomass emissions. Others suggested excluding specific source categories or sources within facilities, citing various reasons. For example stakeholders suggested excluding landfills and vented and fugitive methane emissions from oil and gas sources because of inaccurate quantification methods. Other suggested exclusions for emergency engines and emergency generators, and for "accidental" emissions.

Other comments urged reporting requirements that would encourage combined heat and power installations, distinguish between biogenic and anthropogenic CO_2 emissions, and that would consider lifecycle emissions of biomass fuels.

Point of Regulation/Reporting – Stakeholders offered various views on the POR and reporting. Several industrial commenters strongly supported reporting at the corporate or facility level. A major oil and gas trade association supported facility level reporting and noted that reporting at the process unit level would add significantly to data management requirements and could expose closely held trade or business secrets. Other commenters supported developing a unique definition of reporting entity for oil and gas production fields that will aggregate small facilities, such as by production field. Stakeholders recommended uniform point of regulation for residential, commercial and industrial fuel use and transportation at all WCI jurisdictions.

Reporting Recommendations and Discussion

Thresholds – The WCI reporting threshold is 10,000 metric tons CO_2e per year, well below the 25,000 metric tons CO_2e per year threshold for inclusion in the cap-and-trade program. The reporting threshold is set lower than the cap-and-trade threshold to ensure that accurate emissions data are available to document the exclusion of those facilities and other reporting entities whose emissions are below the 25,000 metric tons threshold. Second, reporting down to a threshold of 10,000 metric tons of CO_2e will provide the information needed to determine whether the threshold for inclusion in the cap-and-trade program is set at the appropriate level. Third, the lower reporting threshold will allow the WCI to monitor potential leakage to facilities below the threshold of the cap-and-trade program. Finally, a threshold of 10,000 metric tons of CO_2e is consistent with the level being considered in potential legislation for a U.S. federal cap-and-trade program.

Stationary Combustion – Reporting requirements apply to facilities with stationary combustion units[1] that individually or in combination emit 10,000 metric tons of CO_2e on an annual basis, **even if they are not associated with one of the source categories listed below**.

Carbon dioxide emissions from the combustion of biomass fuels are to be included in the calculations for purposes of determining whether this threshold has been met or exceeded. However, the WCI is aware that this requirement may be burdensome for many small businesses (especially in northern WCI Partner jurisdictions), which are being encouraged to use wood waste as a substitute for fossil fuel. The WCI is considering whether some limited deduction of biomass combustion emissions might be appropriate for purposes of determining whether the reporting threshold has been met.

Source Categories – Reporting requirements also apply to any facility[2] that emits 10,000 metric tons CO_2e or more per calendar year in combined emissions, which includes emissions from one or more of the source categories listed in Table 1 in addition to combustion emissions. Affected facilities must report both combustion emissions and, to the extent adequate

[1] General stationary combustion units are boilers, combustion turbines, engines, incinerators, and process heaters, and any other stationary combustion device that burns any liquid, gaseous or solid fuel.

[2] "Facility" means any property, plant, building, structure, stationary source, stationary equipment or grouping of stationary equipment or stationary sources located on one or more contiguous or adjacent properties, in actual physical contact or separated solely by a public roadway or other public right-of way, and under common operational control. Some special "facilities" such as oil or gas production fields, will have separate definitions.

quantification methods are currently available and have been specified in the Essential Requirements, non-combustion emissions. If, as expected, adequate quantification methods are not currently available for some sources and activities at these facilities, these source category emissions are not included in the reporting requirements at this time.

The WCI developed the list of source categories in Table 1 in order to capture both combustion and non-combustion GHG emissions in the cap-and-trade program. Note that facilities which do not have emissions from the source categories listed in Table 1 are not thereby categorically excluded from the reporting requirements, but are required to report their combustion emissions if those emissions exceed the threshold. As part of its scope and design evaluation, the WCI developed a list of source categories by reviewing national emissions guidelines, determining whether facilities in these source categories existed in WCI Partner jurisdictions, assessing whether they are addressed in The Climate Registry (TCR) or other reporting protocols, and making a preliminary determination of whether quantification methods for these non-combustion sources might be adequate. The assessment of whether quantification methods are adequate is continuing on a source category-by-source category basis.

Table 1. Source Categories Subject to Category-Specific Reporting Requirements in Addition to General Stationary Combustion Reporting Requirements

• Adipic acid manufacturing[TBD] • Aluminum production • Ammonia manufacturing[TBD] • Carbon dioxide transfer recipients[TBD] • Cement production • Coal mines (active and abandoned) • Coal storage • Cogeneration[TBD] • Electricity generation • Electronics manufacturing[TBD] • Ferroalloy production[TBD]	• Glass production and other uses of carbonates[TBD] • HCFC-22 production[TBD] • Hydrogen production • Industrial Wastewater • Iron and steel production • Lead production • Lime manufacturing • Magnesium production[TBD] • Natural gas distribution systems[TBD] • Nitric acid manufacturing[TBD] • Nonroad equipment at facilities[TBD]	• Oil and gas production and gas processing[TBD] • Petrochemical production[TBD] • Petroleum refineries • Phosphoric acid production[TBD] • Pulp and paper manufacturing • Refinery gas combustion • SF_6 from electrical equipment[TBD] • Soda ash manufacturing[TBD] • Zinc production

TBD = To be determined. The assessment of adequate quantification and monitoring methods for this source category is on going.

In addition to the facility-based sources listed above, requirements will be developed for several other source categories to report emissions at the entity level:

- To account for the emissions of electrical generation that is located outside of, but used within WCI Partner jurisdictions, reporting requirements will be developed to apply to entities that import electricity into the WCI region.
- The largest emissions source category in the WCI-wide inventory is the combustion of transportation fuels by millions of individual motor vehicles and other mobile sources. To account for these emissions efficiently, the POR and reporting is moved upstream to fuel suppliers that distribute transportation fuels within the WCI region. Suppliers must report the expected downstream emissions from combustion of the transportation fuels they distribute within the WCI region, if when combusted the distributed fuels would emit 10,000 metric tons CO_2e per year or more. The specific point of regulation in the fuel supply system is yet to be determined, and may differ between jurisdictions.
- Cumulatively, the combustion of natural gas and fuel oil at residential units, commercial buildings, and at small industrial operations, produces considerable emissions, but it is infeasible or impractical to place the point of regulation/reporting on individual residents or owners. As a result, the POR and reporting requirements are moved somewhat upstream to fuel suppliers. Suppliers must report the expected downstream emissions from combustion of the residential, commercial, and industrial fuels they distribute, within the WCI region, if when combusted the distributed fuels would emit 10,000 metric tons CO_2e per year or more. The specific point of regulation in the fuel supply system is yet to be determined, and may differ between jurisdictions and by fuel type.

Source Categories Not Included – A number of source categories are not included in reporting at this time. Agriculture emissions are excluded because they cannot currently be calculated or measured precisely and cost-effectively at the producer or farm level. Similarly, forestry emissions cannot currently be calculated or measured precisely and cost- effectively. Also, agriculture, forestry, and land use emissions would be administratively difficult to report due to the huge number of entities that would have to report. Non-combustion emissions from municipal wastewater treatment and municipal landfills are not included at this time because of concern for the adequacy of currently available quantification methods.[3]

Discontinuing Reporting – Facilities and fuel suppliers that have an emissions limitation under the cap-and-trade program must continue to report verified emissions as long as they have such an obligation. However there are some circumstances in which a facility or fuel supplier

[3] Note that noncombustion emissions from wastewater at certain types of facilities (e.g., refineries) are required to be reported.

that does not have a compliance obligation can discontinue mandatory reporting when they reduce emissions below 10,000 metric tons CO_2e per year. Those reporting entities that are subject to verification must continue to report verified emissions data until reported emissions are below 10,000 metric tons CO_2e per year for a minimum of 3 consecutive years. The owner or operator would then be exempted from further reporting until CO_2e emissions again exceed 10,000 metric tons in any future calendar year.

If the facility or fuel supplier is ***not*** subject to verification requirements, the reporter can submit a signed statement, in lieu of the emissions report, certifying that emissions were less than 10,000 metric tons CO_2e the previous year. After certifying that emissions are below 10,000 metric tons CO_2e per year for 3 consecutive years, the owner or operator shall be exempted from further reporting unless and until CO_2e emissions again exceed 10,000 metric tons.

Sources That Do Not Report - WCI Partner jurisdictions will have the option of requesting any facility or fuel supply operation in its jurisdiction to submit, within 20 days of being requested to do so, a demonstration that the facility or supply operation has not exceeded the reporting threshold/criteria since 2010. WCI is considering whether this and other deadlines for responses provide sufficient time, and whether such deadlines should be standardized across requirements.

Carbon Dioxide Capture and Transfer – Carbon dioxide that is captured for on-site use, on-site storage, or transfer off-site is included in the emissions total for purposes of determining if an emissions threshold has been exceeded, but is to be reported separately. A source category for recipients of CO_2 captured and transferred off-site will be included to account for possible downstream emissions of such captured and transferred CO_2.

Ongoing Work

The WCI has completed some decisions on which non-combustion emissions sources within the covered source categories will be subject to mandatory reporting, and will continue to evaluate additional source categories. The decisions will be based primarily on the availability of adequate quantification methods. The WCI will also refine decisions on the point of regulation and reporting for complex source categories like oil and gas production and gas processing and distribution, and determine whether alternatives to the 10,000 metric tons CO_2e

per year threshold are appropriate for some source categories. The WCI is considering whether verification may be discontinued for sources that drop below 25,000 metric tons annual emissions, but remain above 10,000 metric tons, for a period of years.

Finally, additional work is needed to develop an accounting process to avoid double-counting and potential gaps in reporting combustion emissions from residential, commercial, industrial, and transportation fuels. This may be addressed through the reporting rule or through incorporation in a market implementation rule that WCI will develop. Finally, the WCI will determine whether some limited deduction of biomass combustion emissions might be appropriate for purposes of determining whether the reporting threshold has been met.

General Greenhouse Gas Reporting Requirements and Schedule (§ WCI.2)

This section describes the responsibilities and requirements that are common to all reporting facilities, electricity importers and fuel suppliers. The section lays out general data collection and management responsibilities, the schedule for submitting reports, where reports are to be submitted, a provision allowing the use of simplified quantification methods for de minimis sources and gases, requirements to maintain program plans, the process for making report revisions, and criteria for the accuracy of fuel use measurements.

Relevant Scope and Design Recommendations

Relevant scope and design recommendations address the schedule. The cap-and-trade program will launch January 1, 2012; that is the date on which the first 3-year compliance period begins for facilities and other entities with emissions exceeding the threshold of 25,000 metric tons of CO_2e per year. Mandatory measurement and monitoring for the six included GHG gas emissions will commence January 1, 2010 for all entities and facilities subject to reporting. Reporting of 2010 emissions will begin in 2011. During 2009, WCI Partner jurisdictions will need to incorporate these Essential Requirements into their rules, which in some cases will require modifications to their existing GHG reporting rules.

Each covered entity or facility will demonstrate compliance with the cap-and-trade program by surrendering sufficient allowances by July 1 of the year following the end of each compliance period. To ensure transparency and maintain public confidence, certain data from the emissions reports, allowances, and offsets that are used for compliance will be made public in a timely manner.

The WCI has recommended using a WCI central repository implemented by TCR for data storage.

Stakeholder Input

Schedule – Given the decision to launch the cap-and-trade program in 2012, stakeholders supported beginning data collection in 2010 with reporting in 2011. A major trade association noted however, that it would be very difficult to get complex reporting requirements in place in each state and province in that timeframe, particularly for complex source categories like oil and gas production. This stakeholder recommended allowing reporting for 2010 based on best available data.

One commenter was concerned that there would initially be problems dealing with new reporting requirements and therefore supported giving reporters later deadlines for report submission during the first years of the program. A number of stakeholders suggested that reports be submitted 6-8 months after the end of the reporting year. Several commenters supported a single reporting deadline rather than a staggered deadline. Finally, there was support for consistent reporting deadlines across the WCI region and a schedule that would be consistent with the reporting requirements of the TCR and/or other programs.

Other General Requirements – Most commenters favored reporting annually, while one thought that monthly or quarterly reporting would be appropriate to make the trading program more efficient.

Several commenters recommended setting de minimis emissions levels at 3 percent and using the same list of de minimis activities as used in the Title V program. Another commenter recommended 5 percent. One suggested that WCI rely solely on the 3 percent threshold and eliminate the additional maximum threshold of 20,000 metric tons CO_2e that is contained in the CARB rule.

Commenters held a full range of views about where reports should be submitted. One thought the option of reporting to either the TCR or the state/province was appropriate. Another supported direct reporting to the TCR's Climate Registry Information System (CRIS) with no requirement to file separate reports to individual jurisdictions. One commenter suggested that any TCR fees should be borne by the jurisdiction so, ultimately, the use of TCR would be cost neutral to regulated reporters. Finally one commenter felt that compliance would be enhanced if reports were submitted to the appropriate jurisdictions, which would then transfer the information into a regional database.

Reporting Recommendations and Discussion

Schedule for Starting Reporting – Beginning in 2011, facilities, electricity importers and fuel suppliers that commenced operation before January 1, 2010 must report annual emissions, using prescribed quantification methods, for calendar year 2010 and each subsequent calendar year. This start date is widely supported by stakeholders and needed by sources and WCI Partner jurisdictions to prepare for the start of the cap-and-trade program in 2012. These reported data will also help verify emission totals and trends as the program enters its first compliance period and may be used as one of several factors, time permitting, in setting Partner and regional allowance budgets. The WCI Partners recognize the burdens that would be created by multiple, divergent reporting programs, and will encourage national reporting programs in the U.S. and Canada to accommodate the needs of regional cap-and-trade programs that are ahead in the development process.

Reporting and Verification Deadlines - The WCI structured reporting and verification deadlines to provide reporters and verifiers with sufficient time to adjust to new requirements during the initial reporting years before phasing in the more demanding deadlines that will be necessary to provide timely and coordinated information to the public and allowance market participants, and to determine the compliance obligation of reporters subject to the cap-and-trade program.

The deadline for the submission of annual reports is April 1. The reporting date is early in the year so that verification can occur in a timely fashion and, in the case of 2011, at least one year of complete data will be available to prepare sources and WCI Partner jurisdictions for the cap–and-trade program and to verify emission totals and trends as they enter the first compliance period. In addition, verified 2010 data could be used to ensure that allowance allocations during the first compliance period do not exceed the anticipated emissions. Incorporation of this schedule into jurisdictional reporting rules will likely require modification of existing GHG reporting schedules where they already exist.

For reporting years 2010 through 2011, reporters that are subject to verification requirements must complete their verification process, including submittal of a verification statement, by September 1. This deadline provides five months after reports are submitted to allow reporters and verifiers to become accustomed to the process during the early years of mandatory reporting. However, no later than reporting year 2014, verification will need to be completed earlier than September 1. The WCI program design calls for facilities, electricity importers and fuel suppliers that are subject to the cap-and-trade program to surrender allowances by July 1, beginning in 2015, the year after the first 3-year compliance period ends. Deadlines for the 2012 and subsequent reporting years will be determined later as decisions on market functioning are made by WCI.

Early verification deadlines require a different approach in which the reporter and verifier work together throughout the year rather than after reports are developed. This approach can greatly reduce the time lapse between the end of the reporting year and the completion of verification. As an example, the European Union emissions trading program requires completion of the verification process by the end of March, just 3 months after the end of the reporting year.

New facilities that are subject to reporting requirements will begin collecting data during the first month of operation and will report emissions generated from their first month of operation through the end of the first calendar year. For subsequent years they will report on the same basis and schedule as existing facilities.

Regulated facilities and other entities subject to reporting will submit emissions reports to the WCI Partner jurisdiction in which they are located. All WCI Partner jurisdictions must submit the emissions data from their regulated facilities/sources to WCI's regional database for purposes of aggregation and analysis. The Climate Registry will manage WCI's regional database using a modified version of TCR's Climate Registry Information System (CRIS) to support mandatory reporting (CRIS Common Framework). Some WCI Partner jurisdictions may also choose to use the CRIS Common Framework to meet their individual jurisdictional database needs for emission collection, verification, and compliance. Other states and provinces will collect data through their independent reporting systems and databases and then transfer the data to WCI's regional database. Each WCI Partner jurisdiction will specify the format of the emissions report, but these formats will be compatible with eventual consolidation in TCR's CRIS Common Framework.

Reporting facilities may elect to designate as "de minimis" one or more sources or pollutants that collectively account for no more than 3 percent the facility's total CO_2e emissions, but not to exceed 20,000 metric tons CO_2e. Emissions for those sources must be reported, but the facility may use simplified, alternative quantification methods to those otherwise required. If verification of the emissions report is required, the selection of any alternative GHG calculation method is also subject to verification and must provide reasonable assurance that the emissions so designated do not exceed the applicable de minimis limits. Emissions that are calculated by alternative methods must be separately identified in the report.

In order to ensure as accurate and reliable data as possible and protect the integrity of the cap-and-trade program, all facilities and other reporting entities have a number of general administrative obligations in addition to those that are specific to their source category. In preparing their annual emissions report, they must collect emissions and other required data; calculate GHG emissions; and follow the procedures for quality assurance, missing data, and recordkeeping that are specified in the essential requirements for reporting. The facility or other reporting entity is required to prepare and follow a written GHG inventory management plan that ensures that emissions calculations and other information that is required to be reported are transparent, accurate, and independently verifiable. (WCI is considering whether a written plan should be mandatory, or advised in guidance materials as a means of assuring a smooth verification process and a positive verification statement.)

The facility or other reporting entity must also establish, document, implement, and maintain data acquisition and handling activities needed for the calculation and reporting of GHG emissions. Such activities shall include measuring, monitoring, analyzing, recording, processing and calculating the parameters specified in the reporting rule. They must implement systems of internal audit, quality assurance, and quality control for the reporting program and the data reported.

Facilities, electricity importers and fuel suppliers must revise and resubmit an annual GHG emissions report if the initial report is found to contain an error, or accumulation of errors, greater than 5 percent of reported CO_2e emissions. To the extent possible, the revised report must correct all identified errors, identified omissions and misstatements. If the original report was subject to verification, the revision must be completed within 60 days of the finding and the corrected data must also be verified.

For annual reports not subject to verification, the owner or operator shall revise and resubmit an annual GHG emissions report within 30 days of the finding. To the extent possible, the revised report must correct all identified errors. A revised report will be accepted only if approved by the state or province with jurisdiction over the reporter.

Voluntary revisions are also allowed for reporting errors of less than 5 percent, however verification is required if the original report was subject to verification, and the appropriate jurisdiction must approve the change.

The provisions described above apply during the first several years of reporting but will be revisited during the first compliance period. Since verified data is integral to the operation of a cap-and-trade program, any changes to previously verified emissions data will have consequences that must be carefully considered. The most appropriate time to do so is when the architecture and planned operation of the WCI cap-and-trade program is more advanced.

All facilities, electricity importers and fuel suppliers that are subject to mandatory reporting shall maintain documentation needed to support any revisions made to a previously submitted emissions data report for 7 years.

The measurement of fuel use is so central to the consistent and accurate reporting of all combustion emissions that it is important to have a WCI-wide standard for measurement accuracy for any situation in which a continuous emissions monitoring system (CEMS) is not in use. In these situations, facilities and other reporting entities shall use procedures to quantify fuel use (mass or volume flow) that provide data accuracy within ±5 percent. All fuel use measurement devices shall be maintained and calibrated in a manner and at a frequency required to maintain this level of accuracy. Facilities shall conduct belt or conveyor scale calibrations at least quarterly to validate fuel consumption estimates of solid fuels. The facility will maintain for seven years the documentation that allows the above level of accuracy to be independently verified.

Ongoing Work

When the architecture and planned operation of the WCI cap-and-trade program is more advanced the WCI will revisit the schedule and process for report revisions. In addition, a provision will be considered that would allow reporters that are not subject to emissions limitations, and that reduce their emissions below 25,000 metric tons of CO_2e, to cease verification after some period of time.

The WCI and TCR will work closely in 2009 to identify the system requirements necessary to design and implement the regional database for reporting so the reporting mechanism is important for WCI to continue to move forward ready for the first year of reporting in 2010.

Also, the WCI Reporting Committee will coordinate closely with the WCI Market Operations and Oversight Committee to ensure a smooth flow between the emissions reporting database and the development and implementation of the allowance tracking and offsets tracking systems.

Contents of the Greenhouse Gas Emissions Report (§ WCI.3)

This section describes the general information that must be included in every emissions report, regardless of source category.

Relevant Scope and Design Recommendations

The WCI agreed to establish the essential requirements for reporting by all facilities and other entities required to report in each of the WCI Partner jurisdictions.

Stakeholder Input

In general, stakeholders want a reporting system that is fair, easy to manage, and not costly to implement for either reporters or jurisdictions. Commenters generally support a single WCI reporting rule, citing the advantages of administrative simplicity and cost effectiveness. Stakeholders also expressed concern that a lack of consistency would undermine confidence in the use of reported data in a market system. There were a number of comments supporting the concept that WCI reporting requirements should be identical or equivalent to the forthcoming U.S. EPA and Environment Canada mandatory GHG reporting regulations.

Reporting Recommendations and Discussion

To improve reporting consistency and facilitate data management throughout the WCI region, the following information is required for each report submitted by a facility, electricity importer and fuel supplier. This includes basic information that is in addition to data and information identified in the source category-specific requirements contained in the reporting rule.

- Name of facility or other reporting entity, including identification number, physical address, mailing address and NAICS code,
- Reporting year,
- Date of report submittal,
- Total emissions aggregated from all applicable sources expressed in metric tons of CO_2e, excluding CO_2 that is captured and CO_2 emissions from the combustion of biomass fuels, which are reported separately,
- Total emissions of CO_2e from the combustion of biomass and biomass-derived fuels,
- Total annual mass of CO_2 captured for on-site use, on-site storage, or transfer off site, in metric tons,
- For applicable fuel supplier categories identified as Essential Requirements for transportation fuels combustion and residential, commercial and industrial fuels combustion, total estimated end-user CO_2e emissions aggregated from all specified fuel,
- Emissions from each applicable source category or fuel supplier category in subparts WCI.20 through WCI.XX, expressed in metric tons per year of CO_2, CH_4, N_2O, HFC, PFC, and SF_6. CO_2 emissions from the combustion of biomass and biomass-derived fuels shall be reported separately,
- For electricity importers, information required in the Essential Requirements section for this source category,
- Emissions and other data for individual units, processes, activities, and operations as specified for each source category covered in the Essential Requirements,
- Emissions from each designated de minimis source or pollutant for which an alternative emission calculation method is used,
- Name and contact information including email address and telephone number of the person primarily responsible for preparing and submitting the emissions report, and

- A signed and dated statement provided by the owner or operator, or their designated representative, certifying that the report has been prepared in accordance with this rule, and that, subject to verification, the statements and information contained in the emissions data report are to the best of their knowledge, true, accurate, and complete.

Any state or province may request additional information beyond that specified above.

Ongoing Work

As noted above, WCI is considering a provision for discontinuation of the verification requirement for sources that are not subject to an emissions limitation and that reduce emissions below the 25,000 metric tons for a sufficient number of years.

WCI will review and address any further stakeholder comments.

Document Retention and Record Keeping Requirements (§ WCI.4)

This section describes which records must be kept by each reporting entity and for how long. The purpose of recordkeeping is to ensure that reporting entities retain enough information on hand to support their emissions calculations. For those facilities subject to verification requirements, retention and record keeping requirements provide the information needed to allow verifiers to confirm their emissions reports. In addition, retained data allow internal or independent reviewers or auditors to evaluate, and if necessary, reconstruct or correct, past emissions reports. Existing reporting systems call for such records to be retained for 3-10 years depending on the jurisdiction.

Relevant Design Recommendations

WCI Partner jurisdictions will establish the essential requirements for reporting by all entities and facilities required to report in each of the WCI Partner jurisdictions.

Stakeholder Input

There were few comments directly addressing retention time and recordkeeping, but there is a general level of support for consistency across the WCI region and with other reporting systems. One commenter advocated maintaining all records indefinitely until the reporting system is running effectively.

Reporting Recommendations and Discussion

Facilities and other reporting entities must establish and maintain procedures for document retention and recordkeeping. They must retain all documents regarding the design, development and maintenance of the emissions inventory in paper, electronic or other usable format for a period of not less than seven years following submission of each emissions data report. This is longer than some other programs require because of the three-year length of compliance periods for the WCI cap-and-trade program. They must be able to produce all documents and data they are required to retain upon request within 10 working days. In general the retained documents and data shall be sufficient to allow for the verification of each emissions data report.

The following information must be retained in addition to information submitted as part of the emissions data report, for at least seven years.

- A list of all GHG sources (i.e., units, operations, processes, and activities) included in the emission estimates,
- All data used to calculate emissions for each source and gas, categorized by process and fuel or material type,
- Documentation of the process for collecting emissions data,
- Any GHG emissions calculations and methods used,
- All emission factors used for emission estimates, including documentation for any factors not provided in the rule,
- All input data used for emission estimates,
- Documentation of biomass fractions for specific fuels,
- All other data submitted under this rule, including the GHG emissions report,
- All computations made to gap-fill missing data,
- Names and documentation of key facility personnel involved in emissions calculating and reporting,
- Any other information that is required for the verification of the GHG emissions report,
- A log to be prepared for each reporting year, beginning January 1, documenting all procedural changes made in GHG accounting methods and changes to instrumentation for GHG emissions estimation, and
- A copy of the GHG Inventory Management Plan.

For quantification methodologies based on direct measurement of emissions, the following information must be retained for at least seven years after the submission of the emissions data report.

- List of all emission points monitored,
- Collected monitoring data,
- Quality assurance and quality control information collected under the GHG Inventory Management Plan required by the Essential Requirements,
- A detailed technical description of the continuous measurement system, including documentation of any findings and approvals by federal, state or local agencies,
- Raw and aggregated data from the continuous measurement system,
- A log book showing all system down-times, calibrations, servicing, and maintenance of the continuous measurement system, and
- Documentation of any changes in the continuous measurement system over time.

The Essential Requirements for quantification methods may also include some source category-specific record retention requirements.

Ongoing Work

WCI will review and address any further stakeholder comments.

Confidentiality

The challenge in dealing with public access to reported data is to strike an appropriate balance between revealing information that is important to the public interest while protecting information that if disclosed would harm the reporting entity. In general, air emissions data that are collected by public agencies are not considered confidential – in fact, transparent emissions data are essential to the successful operation of a cap-and-trade program. Nevertheless, in some cases the operational and technical information that is used to calculate emissions is sensitive and could reveal trade secrets or other facts that are damaging to the reporting entity's competitive position.

WCI Partner jurisdictions have existing laws and procedures to address the issues associated with balancing public and private interests. They generally provide for public disclosure of information that is submitted to government agencies, but allow for reporting entities to assert a claim of confidentiality on a case-by-case basis and seek to prevent disclosure of trade secrets or other confidential business information. Laws usually provide guidance or criteria that the appropriate agency must consider in evaluating confidentiality claims.

Relevant Design Recommendations

While WCI design recommendations do not directly address the balance between disclosure and confidentiality, they do prescribe the disclosure of emissions information to ensure transparency, maintain public confidence and allow the market to function properly. The WCI calls for making public in a timely manner certain data from the emissions reports, allowances, and offsets that are used for compliance. Moreover the design recommendations call for each jurisdiction to make its data available for other jurisdiction's review and consideration for possible expansion of the cap-and-trade program.

Stakeholder Input

Stakeholders have offered a range of comments with some favoring a narrow construction of confidentiality to protect the public's right to know, and others favoring a broader construction that would better protect sensitive operational information from competitors. Some have offered specific recommendations as to what types of data and information should be considered confidential, suggesting that production rates, breakouts of fuels used, process level emissions and similar information be considered confidential. There are conflicting views on who should make decisions on confidentiality, with some favoring the individual WCI Partner jurisdictions while others felt that the prospect of having to follow separate rules in each WCI Partner jurisdiction was a concern. One commenter noted that third party verification gives assurance to the public that reported emissions information is accurate without the need to reveal sensitive business information or trade secrets.

Reporting Recommendations and Discussion

In general, emissions data submitted to any WCI Partner jurisdiction under the reporting rule are public information and shall not be designated as confidential. Each state or province shall address claims of confidentiality, for information that is not emissions data, from reporting entities in their jurisdictions under that jurisdiction's laws and procedures. Therefore, confidentiality is not addressed further in the Essential Requirements.

Embargoing of emissions data until a specified public release date may be needed for proper functioning of the allowance market. This issue will be addressed later, as decisions are made on the details of market operation.

Ongoing Work

WCI will review and address any further stakeholder comments.

Compliance and Enforcement (§ WCI.5)

Mandatory reporting programs are weakened if a facility, electricity importer or fuel supplier fails to submit a report by the required deadline, submits incomplete information, fails to address missing or incorrect data, doesn't retain records as required by the rule, or intentionally submits false or misleading information. Compliance, for purposes of this discussion means the degree to which facilities and other reporting entities submit timely, complete and accurate reports. Enforcement refers to the action taken in response to a violation or non-compliance situation.

A clear definition of what actions or inactions are considered a violation not only serves notice to those subject to a regulatory requirement but it is typically considered a prerequisite to taking any enforcement action. If violations are defined consistently by WCI Partner jurisdictions, there is a better basis for members to exercise their enforcement prerogatives in an even-handed manner. Reporting violations will be defined within the Essential Requirements for reporting.

Relevant Design Recommendations

The WCI Partners' consideration of compliance and enforcement issues focused on facilities subject to cap-and-trade obligations and did not specifically address reporting compliance and enforcement.

Stakeholder Input

Few stakeholders commented on compliance or enforcement issues. One favored third-party verification and argued that verification is an important means of bolstering compliance by ensuring the accuracy of reported data. Several commenters also saw appropriate models in the

California approach, which combines verification with strong penalties, and the U.S. Acid Rain program in which traditional enforcement is minimized because of a reporting regime that includes incentives, stringent missing data provisions and automatic penalties and that serve as an incentive to complete and accurate reporting. One commenter noted that while jurisdictions must ultimately enforce the reporting rule in keeping with their own legislation, the rules of reporting should be consistently enforced across all jurisdictions. They recommended two triggers for a violation of the reporting rule, the failure to file completed emissions information as required and the failure to file by the reporting deadline.

Reporting Recommendations and Discussion

While the WCI does not see a need to achieve complete uniformity in how each WCP Partner jurisdiction reacts to reporting violations in terms of levying fines or imposing other penalties, it is important that the Essential Requirements for reporting contain a consistent definition of which acts constitute violations of the reporting rule.

It is a violation to knowingly submit false information to a state or province, or to a verification body. It is also a violation to fail to:

- Submit any report (GHG emissions data report, verification opinion, or other document) required to be submitted,
- Collect data needed to calculate GHG emissions,
- Monitor and test as required,
- Calculate GHG emissions following the methodologies specified in this rule,
- Retain required records, provide all information required in the report, and
- Submit a report on time.

Each violation of this rule shall be considered a single, separate violation for each day beyond the specified reporting date.

There are also a number of other mechanisms to encourage compliance and consistent enforcement practices that are addressed in various sections of the Essential Requirements. For example, third party verification, which serves as a key compliance assurance tool for both the overall cap-and-trade program and mandatory reporting, is addressed in some detail. The Essential Requirements for reporting also contain provisions for records retention and making report revisions.

Ongoing Work

The WCI will continue to consider whether to develop additional guidelines to promote consistent administrative practices and responses to non-compliance issues among its jurisdictions.

Designated Representative (§ WCI.7)

To ensure accountability and facilitate communication, a designated individual must be responsible for certifying and submitting GHG emissions reports. Because of the legal implications, the WCI considers detailed and consistent requirements across WCI Partner jurisdictions to be Essential Requirements.

Relevant Design Recommendations

There are no design recommendations specific to the responsibility for submitting reports.

Stakeholder Input

This is a new section in this version of the Essential Requirements, thus no comments have yet been received from stakeholders.

Reporting Recommendations and Discussion

The designated representative of the facility, electricity importer or fuel supplier shall be selected and identified in writing by an agreement that is signed by the designated representative and owners or operators of the facility or other reporting entity. The designated representative must be an individual that has responsibility for the overall operation of the facility or activity being reported, a position of equivalent responsibility, or an individual having overall responsibility for environmental matters for the company. The responsibilities of a designated representative are:

- To represent, and by any representations, actions, inactions, or submissions, legally bind each owner and operator in all matters pertaining to these Essential Requirements, and
- Sign each emission report submitted under these Essential Requirements. The signature statement must include the following certification statement or its

> equivalent: "I have been authorized to make this submission on behalf of the owners and operators of the facility (importer or supply operation, as appropriate). I certify under penalty of law that I have personally examined the information submitted in this document. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment."

The designated representative may be changed at any time but all prior representations, actions, inactions, and submissions by the previous designated representative are binding on the new designated representative and the facility owners and operators. In the event of any change in ownership of the facility, electricity importer or fuel supplier, the new owner or operator remains bound by the representations, actions, inactions, and submissions of the designated representative until the designated representative is changed.

A complete certificate of representation containing the following information must be kept on site at the facility:

- Identification of the facility (importer or supply operation) for which the certificate of representation is submitted,
- The name, address, e-mail address (if any), telephone number, and facsimile transmission number (if any) of the designated representative,
- A list of the owners and operators of the facility (importer or supply operation),
- Certification statements that the actions of the designated representative with respect to this rule are binding on the owners and operators, and that the designated representative has the necessary authority to carry out duties and responsibilities on behalf of the owners and operators, and
- The signature of the designated representative and owner(s) and the dates signed.

Ongoing Work

WCI will review and address any further stakeholder comments.

Requirements for Verification of Emissions Data Reports (§ WCI.8)

This essential requirement addresses how reported information will be verified against international standards for GHG emissions data. ISO 14064-3[4] and ISO 14065[5] are international standards for greenhouse gas verification and accreditation, respectively. In an effort to promote international consistency of greenhouse gas reporting and verification, many reporting and market programs, including TCR, have based their verification programs on these standards. The key subject areas are accreditation of verifiers, core verification services, and conflict of interest requirements. The WCI verification requirements will also ensure an enforceable verification program with direct oversight. Although the development of the WCI verification program is not complete, a number of recommendations pertain to the foundation of the program and its implementation; these are described below.

Relevant Design Recommendations

WCI Partner jurisdictions will require third party verification of reported emissions from entities and facilities that will be included under the cap.

Stakeholder Input

Third party verification remains a significant issue to stakeholders. Most commenters on this topic were from industry, and most opposed it, arguing that the use of defined protocols, self-certification, and opportunity for agency audit should be sufficient to encourage accurate reporting. One commenter with experience with third-party verification argued that the actual inaccuracies identified were too small to be material. Some commenters objected to the cost, which one industry trade group estimated at $10,000 per facility per year.

A number of commenters suggested ways to reduce the cost of verification. Several supported a multiple year verification cycle as outlined in CARB regulations, with the first year of "full verification", and less intensive verification activities in the remaining years. Some

[4] ISO (2006) ISO 14064-3: Greenhouse Gases-Part 3: Specification with guidance for the validation and verification of greenhouse gas assertions, March, 2006, International Organization for Standardization, Switzerland.

[5] ISO (2007) ISO 14065: Greenhouse Gases-Requirements for greenhouse gas validation and verification bodies for use in accreditation or other forms of recognition, April, 2007. International Organization for Standardization, Switzerland.

recommended exemptions, such as combustion units with certified continuous emissions monitors (CEMs), facilities with existing Title V permits, or sources not selling credits.

A few commenters indicated support for verification and advocated a standardized approach to verification across the WCI region to protect the integrity of the market.

Reporting Recommendations and Discussion

Comprehensive mandatory and accurate reporting is especially important to a cap-and-trade program because of its focus on actual emissions performance and emission allowance trading. The WCI Partner jurisdictions have considered the advantages and disadvantages of third-party verification and jurisdictional audit and quality assurance. The WCI Partner jurisdictions note that in a cap-and-trade program, every metric ton of emissions translates into a financial obligation or benefit, whereas in existing air pollutant reporting and compliance, errors in emissions data can be inconsequential if they do not affect whether a compliance limit has been exceeded. For those facilities and entities with cap-and-trade compliance obligations (i.e., required to hold allowances), there are no inconsequential emissions totals. A high degree of accuracy and reliability for this emissions data is needed for market transparency and credibility, as well as for potential linkage to other emissions trading programs.

The goals of the WCI verification program are to root the program in international standards and best practices, to ensure high quality data, and to promote consistency across similar mandatory greenhouse gas reporting and cap-and-trade programs. The recommendations are drawn from international standards (ISO 14064-3 and ISO 14065) and other verification programs.

The recommendations listed below are divided into those intended to support the immediate needs of a credible WCI mandatory reporting program, and those that support the development of the overall verification program. Once the rules of a market have been developed, some parts of the verification requirements will need to be revised.

<u>Recommendations Directly Related to Reporting</u>

Applicability of Verification Requirements - Third party verification of reported emissions is required from all facilities and other entities with emissions of 25,000 metric tons per year or more, and any others that are covered under the cap. If, as discussed earlier, WCI establishes a limited deduction of biomass combustion emissions for purposes of determining the reporting threshold, WCI will also consider whether the deduction should affect the verification threshold.

Materiality threshold – The threshold is five percent, applied at the facility or other designated level of reporting.

Data adjustment – All misstatements in an emissions data report must be corrected if uncovered during the course of verification, even if they do not affect materiality.

Level of assurance – The WCI will require that verification bodies provide a reasonable level of assurance of reported emissions; i.e., based on the verification activities conducted (ISO 14064-3, Section A.2.3.2), the emissions data report is materially correct and was prepared according to the appropriate standard.

Verification document retention – Records and documents must be retained for seven years.

Recommendations Related to Verification Program Development

In 2009, WCI will develop the implementation structure to support third party verification. Pending these decisions, the following discussion simply refers to the implementing body as the WCI Partner jurisdiction "or their designee," which may be a regional organization. Note that the WCI is considering the formation of a Regional Body for purposes of implementation and ongoing operation of the reporting and cap-and-trade programs. A WCI Regional Body may have responsibility for implementing several reporting verification items, such as providing Conflict of Interest determinations, reporter-verifier dispute resolution, etc.

Verification cycle – During the first year (Year 1) of the verification cycle, a verification body must conduct a comprehensive verification that includes visits to the reporter's facilities at which direct emissions occur. Verification Years 2 and 3 permit a less intensive verification with data checks based on the last sampling plan that resulted in a positive verification opinion.

Enforcement and Compliance – Each WCI partner will have the responsibility for ensuring compliance with verification requirements in their jurisdiction.

Accreditation of verifiers – WCI will implement an accreditation process consistent with ISO 14065 developed under ISO 17011, and will also require verifiers to demonstrate knowledge of WCI reporting requirements. WCI will require "specialist" accreditations in order to verify emission reports for electricity importers, petroleum refineries, hydrogen production, cement, and possibly other sources categories to be determined.

Common standard – Verifications will be conducted according to ISO 14064-3.

Verification statement – WCI Partner jurisdictions will require a standard verification statement throughout the WCI region that allows verification bodies to provide comments and supplemental information.

Verification report – Verification bodies must develop and provide a detailed report that includes a verification plan, data checks, and a log of problems encountered during the verification process and how they were resolved. The report will be made available to a WCI Partner jurisdiction or its designee.

Sampling plan – To assess the likely nature, scale and complexity of verification services the verification body shall develop a sampling plan for each reporter. The plan will be based on a strategic analysis developed from document reviews and interviews. The analysis shall review the inputs for submitted emissions data, the rigor and appropriateness of the data management systems, and the coordination that is employed to manage the operation and maintenance of the equipment and systems used to develop emissions data reports. The plan must identify which areas of the emissions data report should undergo data checks. The sampling plan will be retained by the verification body and made available to the WCI Partner jurisdiction or its designee upon request.

Notice of verification services – WCI Partner jurisdictions may elect to attend selected verification meetings and site visits. To facilitate their attendance, verifiers must notify the jurisdiction or their designee at least 15 working days prior to commencement of any proposed verification services for facilities within the jurisdiction, and receive notification from the WCI jurisdiction of approval for commencement of verification services.

Conflict of interest – Before verification may proceed, a verification body must perform a conflict of interest self-assessment and provide it for the approval of the jurisdiction or its designee. This self-assessment must take place for each verification body-reporter relationship for every year that the verification body provides services.

Report of dismissal - All facilities, electricity importers, fuel suppliers and verifiers will report to the jurisdiction or their designee when a verifier has been dismissed by a facility, and the reasons for the dismissal. This information will be kept confidential to protect the interests of both parties.

Ongoing Work

The WCI will consider whether it is appropriate to structure verification requirements in a cycle during which more intensive “full verification” will occur the first year of reporting and less intensive verification is allowed in subsequent years.

Although not part of the Essential Requirements for reporting, the following additional work by the WCI is necessary for implementation of the verification system.

In 2009, the WCI will complete the design of the process for accreditation of verifiers. The WCI will specify an accreditation cycle, including frequency of surveillance audits and re-accreditation. The WCI will develop a process for revoking accreditation of any verification body found to be incompetent. Beyond the requirements of ISO 14065, the WCI will determine any additional competencies or requirements for subcontractors, verification bodies, or individual verifiers for use in the WCI program. The WCI will specify if there is any required training for individual verifiers.

The WCI will complete and make available a standardized verification statement that allows verification bodies to provide comments and supplemental information. The WCI will coordinate with other GHG programs to explore the potential for developing a universal verification statement.

The WCI will decide whether to establish a Reporting and Verification Panel, perhaps as a component of the Regional Body, to foster standardization in key elements of implementing the WCI verification program. The panel would be comprised of representatives from each of the WCI Partner jurisdictions. An alternative to creating a WCI Panel could be for WCI to contract elements of verification program administration to a third party, such as TCR. If a WCI Reporting and Verification Panel is formed one of its assignments would be adoption of a unified plan to conduct surveillance audits to ensure that all WCI Partner jurisdictions have a similar level of oversight and that the audits are carried out on a standardized basis. A central panel or designee could administer consistent audits across the WCI Partner jurisdictions, or the partners could agree to an audit plan developed and approved by all of the partners. The partners would have to adhere to the level of oversight laid out in the plan, acknowledging that the plan may go beyond auditing plans for existing air programs since it would need to support a market program. The Reporting and Verification Panel may also play a role in reviewing complaints submitted to the verification body, a jurisdiction or the WCI, in ensuring consistency in evaluating individual cases of conflict of interest, and in processing notices that verification services are about to begin. Many of these activities would reduce the administrative burden on WCI Partner jurisdictions.

The WCI will develop and make available a standardized appeals process to handle a situation in which the verification body and reporter have a dispute over an emissions report. Standardization of the appeals process is paramount for ensuring consistency across the WCI Partner jurisdictions.

A policy will be developed to address facts discovered after the verification statement has been issued that could materially affect the verification outcome. Any revisions are subject to third-party verification.

Definitions (§ WCI.9)

This essential requirement contains clear and appropriately detailed definitions of key terms used in the monitoring and reporting rule. The WCI has borrowed definitions from other jurisdictions' mandatory GHG reporting rules and relevant GHG protocols whenever appropriate. In addition to their direct regulatory application, definitions facilitate communications among WCI Partner jurisdictions and stakeholders by defining common terminology used throughout the reporting program.

This section contains a partial list of the definitions that will be used in the Essential Requirements, with a focus on terms that are important to understanding general reporting requirements. In addition, definitions of terms that are specific to individual source categories are provided in the rule sections that contain those reporting requirements.

Relevant Design Recommendations

There were no recommendations specific to Definitions.

Stakeholder Input

There were limited stakeholder comments on definitions. Several commenters supported the approach of using definitions from existing reporting programs as a starting point in order to ensure as much consistency as possible among various reporting rules. One commenter specifically advocated using definitions from the U.S. EPA mandatory reporting rule that is under development. Several stakeholders proposed the addition of specific definitions, including "process emissions", "fugitive emissions", and a number of terms associated with natural gas production and distribution. One commenter noted that natural gas pipeline facilities would not fit well under the general definition of a facility and urged the use of definitions contained in the Canadian Environmental Protection Act.

Reporting Recommendations and Discussion

The Essential Requirements for reporting provide definitions that are necessary to understanding specific reporting requirements and generally avoid definitions that are not essential. For example, terms that are used in their common English context (e.g., fence line, unit) or that explain acronyms or chemical formulae are not specifically defined. Definitions are listed in the Essential Requirements and are not repeated here. Additional definitions are under development based on the Canadian regulations from "Section 71 of the Canadian Environmental Protection Act (CEPA) 1999"and the CARB definitions from "Title 17, Subchapter 10, Article 2, Section 95102 of the California Code of Regulations.

Ongoing Work

Definitions are continuing to be developed.

Pollutants and Global Warming Potentials (§ WCI.10)

This section addresses the greenhouse gas pollutants that must be reported and their 100-year global warming potential (GWP) factors. The GWP is used to convert emissions of a greenhouse gas to metric tons of carbon dioxide equivalent (CO_2e). The technical definition of the GWP of a greenhouse gas is the ratio of the time-integrated radiative forcing from the instantaneous release of 1 kilogram (kg) of a trace substance relative to that of 1 kg of a reference gas, which is CO_2.

Relevant Design Recommendations

The greenhouse gases covered by the cap-and-trade program are carbon dioxide, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride. Both the annual emissions threshold for a compliance obligation and the threshold for reporting are stated in terms of metric tons of carbon dioxide equivalents (CO_2e) annually.

Stakeholder Input

Nearly all comments addressing GWP values recommended using the values used by the Intergovernmental Panel on Climate Change (IPCC), and some specified use of the 1995 IPCC Second Assessment Report values. None recommended use of other values.

Reporting Recommendations and Discussion

Reporting entities must use the GWP factors provided in Table WCI.10-1 of the Essential Requirements when converting emissions of greenhouse gases to metric tons of carbon dioxide equivalent values (CO_2e) for purposes of estimating emissions under the rule. These factors are the same as those used regionally and internationally and are based on the IPCC Second Assessment Report, 1995, updated to add new greenhouse gases identified in the IPCC Third Assessment Report, 2001. The table is the same as contained in the TCR General Reporting Protocol, Version 1.1, May 2008. Hydrofluorocarbons and perfluorocarbons are families of pollutants, and individual compounds within the families have different GWP factors.

Ongoing Work

In the future, the WCI will establish a mechanism for periodically updating GWP factors as the international community adopts more recent GWP values as standard practice (e.g., when reporting under the United Nations Framework Convention on Climate Change [UNFCCC]).

Emissions Quantification, and Sampling, Analysis, and Measurement (§ WCI.20 through § WCI.XX)

These sections contain source-category specific GHG emissions quantification methods, and sampling, analysis and measurement requirements.

Relevant Design Recommendations

The WCI design recommendations specify that only emission sources with adequate quantification methods will be included in the cap-and-trade program.

Stakeholder Input

Stakeholders held a variety of concerns about quantification methods and their use for reporting.

Some commenters pointed out problems or uncertainties associated with specific sources of emissions. For example one natural gas producer felt that existing methods of quantifying fugitive methane emissions from the gas industry had significant uncertainties that, unless addressed, could undermine the integrity of the cap- and-trade program. A solid waste manager noted a number of problems with current methods of quantifying landfill emissions, including a poor understanding of the variability among individual landfills and an incomplete understanding of lifecycle emissions including emission sinks. Another commenter stressed the importance of improving systems and protocols for tracking energy and carbon flows within the Western region electrical grid.

A number of stakeholders advocated the use of specific quantification protocols for their industries. For example a forestry association suggested the use of parametric estimation tools specifically developed for pulp and paper mills and sawmills and the Canadian Cement Association advocated the use of the CSI Cement CO_2 Protocol, as is proposed under the Climate Registry. One commenter specifically advocated the use of ASTM D6866 'Standard Test Methods for Determining the Biobased Content of Natural Range Materials Using Radiocarbon and Isotope Ratio Mass Spectrometry Analysis' for the measurement and verification of biogenic/biomass CO_2. The National Lime Association raised concern that the protocol that had been developed for its members by TCR would underestimate emissions and advocated the use of one they had developed instead.

Several commenters suggested additional process solutions to address problems and uncertainties. Several advocated the formation of special working groups or task forces that included industry experts, and/or the use of extended comment periods, to help the WCI develop and refine more accurate and appropriate quantification protocols. One commenter thought that the WCI reporting framework represented a significant opportunity to improve the existing capabilities to track and measure the quantities and life-cycle impacts of unconventional fuels. Some held the view that methods development could be regional effort within the WCI region while others suggested it ought to be done nationally or internationally to ensure maximum consistency. It was noted that some of the methods gathered by such reporting entities as TCR and the California Climate Action Registry (CCAR) were mainly efforts to compile existing methodologies rather than improve their accuracy to the level needed for a cap-and-trade program. In some cases a large, multi-year effort would be needed involving field tests, sampling and statistical analysis to improve methods appropriately.

Some commenters urged flexibility arguing that the WCI should not mandate the use of CEMs if alternative calculation methodologies were available to facilities and if the accuracy of alternate methods could be controlled by a materiality threshold.

One commenter suggested leaving sources of non-combustion emissions with uncertain quantification methods out of the mandatory reporting and cap-and-trade program initially, while allowing them to be used as offsets provided the proponents develop sufficiently robust methods of quantifying emissions. With the offset incentive in place, better quantification methods would be developed without expending significant state or federal funds while the integrity of cap-and-trade would be protected.

Reporting Recommendations and Discussion

To ensure that the design recommendation of including only source categories with "adequate" emission quantification methods is comprehensively implemented, the WCI assessed the adequacy of available methods for nearly all of the source categories initially identified by the WCI as having potential for inclusion in the cap-and-trade program. (Some source category quantification methods were assessed and documented in rule-like language, while others were researched and documented in a plain-English recommendation format; see below.) Without extensive analysis, however, it is not possible to determine absolute levels of accuracy (e.g., ± %) for every method, as these data are not universally available.

Therefore, for some source categories we identified the relative accuracy of available methods and recommended the methods with the greatest accuracy, with some allowances for less accurate methods. For example, methods that rely on emission factors are recommended for estimating CH_4 and N_2O emissions from stationary combustion sources, although these emission factors are relatively inaccurate as compared to the CO_2 emission factors for the same sources. The WCI considers these CH_4 and N_2O emissions factors to be adequate for purposes of reporting because CH_4 and N_2O emissions are relatively insignificant as compared to CO_2 emissions from these sources, and we are striving to be comprehensive in our requirements to address all GHGs as required by the design recommendations. However, for some categories of non-combustion emission sources (e.g., CH_4 from landfills), we determined that the existing methods are simply too inaccurate and biased at the facility level to justify including them in the reporting program at this time, when these emissions comprise a large fraction of the facility's total emissions. For these and other categories, we will conduct research and continue to request input from and work with stakeholders and industries to identify, and possibly develop, accurate methods for source categories that may be excluded from reporting and/or the cap-and-trade program in the first few years.

Table 2 lists the source categories initially identified by the WCI for reporting and potential inclusion in the cap-and-trade program and some additional source categories identified by the WCI along with our current assessment of the adequacy of available quantification and monitoring methods. Where adequate methods have been identified, specific GHG emission estimation and monitoring method recommendations are provided in attachments to this background document.

Some of the recommended estimation methods, including descriptions of the source category applicability, reporting requirements, and monitoring (e.g., fuel sampling, fuel consumption, fuel heat content, and fuel carbon content) requirements, are provided in "rule like" language. Most of these source category requirements were based on the CARB mandatory reporting rule and modified to fit the WCI requirements. Estimation methods for other source

Table 2. WCI Source Categories and Status of GHG Emission Quantification and Monitoring Methods

Source Category	*Status of Quantification Method Assessment*			*Comments*
	Recommended in Reporting ERs	***Inadequate at this Time***	***Analysis On-Going***	
Stationary Combustion Sources				
Electricity Generation	●			
Cogeneration				*Draft method pending review by WCI*
Electricity Importers (retail providers, marketers)			●	*Being developed by WCI Electricity Subcommittee*
General Stationary Combustion: Fossil and biomass fuel combustion in equipment	●			
Fuel Suppliers: Transportation fuels			●	*To be addressed in 2009*
Fuel Suppliers: Residential, commercial, industrial (RCI) fuels			●	
Petroleum refineries	●			
Refinery fuel gas combustion	●			
Noncombustion Emissions (Combustion Emissions for these and other Sources are Included in Stationary Combustion Sources, Above)				
Oil and gas production & gas processing			●	*Being developed by WRAP/TCR*
Natural gas distribution systems			●	*Being developed by CCAR/TCR*
Carbon dioxide transfers			●	*To be addressed in 2009*
Cement manufacturing	●			
Hydrogen production	●			
Lime manufacturing	●			
Glass production and other uses of carbonates			●	*Method drafted, pending review by WCI*
Soda ash manufacturing			●	
Aluminum manufacturing	●			
Ferroalloy production			●	*Method drafted, pending review by WCI*
Zinc production	●			
Lead production	●			
Pulp and paper manufacturing	●			
Iron and steel manufacturing	●			
Electronics manufacturing			●	*Method drafted, pending review by WCI*
Petrochemical production			●	
HCFC-22 production			●	*Method dratted, pending review by WCI*
Adipic acid manufacturing			●	
Ammonia manufacturing			●	
Magnesium production				*To be addressed in 2009*
Nitric acid manufacturing				
Phosphoric acid production				
SF_6 from electrical equipment			●	*Method drafted, pending review by WCI*
Coal storage	●			
Coal mines (fugitives, active and abandoned)	●			
Nonroad equipment			●	*Method drafted, pending review by WCI*
Landfills		●		
Industrial wastewater			●	
Municipal wastewater		●		

categories not contained in the CARB rule are provided in a narrative format; based on final input from the stakeholders, these will be adopted by the WCI Partner jurisdictions using their appropriate rulemaking requirements. These methods are based on a current review of emission estimation protocols used by voluntary and mandatory programs (e.g., TCR, CCAR, IPCC, EU ETS), as well as methods used by industry groups such as National Lime Association.

It is important to note that although a quantification method is recommended for a given combustion or non-combustion source category, this applies strictly to reporting and does not indicate whether or not a given source category will be under the cap. These quantification recommendations apply strictly to reporting at this time.

In addition to bracketed comments and notes within the individual sections, the following provides clarification and requests stakeholder input related to specific technical details of the GHG emissions quantification and monitoring methods:

- Electric generating units (EGUs): The Canadian Partners acknowledge the potential need to address reporting requirements related to some Canadian off-grid EGUs located in remote areas.
- Metric and English units: For many source categories, the recommended quantification methods currently use English units only, because the sources of equations and/or emission factors using these methods were available in English units and/or take English unit inputs. In the future, these will be provided in both English and metric units. The WCI requests stakeholder input on the specific metric unit inputs and/or emission factors to use (e.g., liters or cubic meters). Table 3 lists, by source category, the emission equation input parameter and current unit(s) of measure in English units. Stakeholder can use this table to provide preferred metric units.
- Sampling, Analysis and Measurement: Where methods for quantifying emissions from industrial processes rely on measurement and/or characterization of input materials, the Essential Requirements will specify the sampling, analytical, and measurement procedures for obtaining these values. The sampling, analysis and measurement procedures must be standardized for each calculation input to reduce variation between facilities within a given industry. Note that material sampling frequency and technique is distinct from the method of material analysis conducted in a laboratory.

  The WCI seeks stakeholder feedback on this topic and is specifically interested in proposals for sampling, analysis and measurement procedures already in use at facilities for the material quantities and concentrations listed in Table 4, below. Those proposed procedures should include sampling frequency and technique, indicate the uncertainty associated with the procedures, and describe the application of the procedure at the specified industry.

Table 3. Emission Estimation Input Parameters and Units of Measure

Source Category	Input Parameter	Current Units of Measure	Stakeholder Preferred Metric Units
General combustion	carbon content of liquid fuel	kg/gallon	
	carbon content of MSW	kg/MMBtu	
	CO_2, CH_4, and N_2O emission factor	kg/MMBtu	
	higher heating value of coal	MMBtu/ ton	
	higher heating value of gas	Btu/standard cubic foot (scf)	
	higher heating value of liquid fuel	MMBtu/barrel	
	mass of steam	lb	
	ratio of boiler max rated heat input capacity to design rated steam output capacity	MMBtu/lb	
	volume of gaseous fuel combusted	scf	
	volume of liquid fuel combusted	gallons	
Electric generation	default fugitive CO_2 emission factor for geothermal facilities	kg/MMBtu	
	heat taken from geothermal steam and/or fluid	MMBtu/year	
Refineries	molar volume conversion factor	scf/kg-mol	
	gas concentration	ppm	
	daily average coke burn rate	lb/day	
	emission factor	scf/10^3 bbl	
	mass of asphalt blown	10^3 bbl/year	
	mass of catalyst regenerated	mass/regeneration cycle	
	coke burn rate material balance and conversion factors (Table 200-1)	(kg-min)/(hr-dscm-%) <u>or</u> (lb-min/hr-dscf-%)	
	vent rate for venting event	scf/ unit time	
	volumetric flow rate of gas	dscm/min or dscf/min	
Refinery fuel gas	CO_2 emission factor for individual fuel system	metric tons/MMBtu	
	refinery fuel or flexigas combusted / daily fuel consumption	scf/day	
	standard temperature for gases	20ºC <u>or</u> 60ºF	
Hydrogen, Ammonia	carbon content of feedstock	kg/scf	
	feedstock consumption rate	scf/day	
Coal storage	CH_4 emission factor for coal storage	scf/ton	
	purchased coal	tons/year	

Table 4. Input Parameters for Which Stakeholder Comments on Sampling, Analysis, and Measurement Procedures are Requested

Industry	Input Parameter
Cement Manufacturing	Weight fractions: • Plant-specific weight fractions in clinker from each kiln of: CaO, MgO, uncalcined CaO, uncalcined MgO • Weight fraction of carbonate CO_2 in the CKD • Weight fraction of carbonate CO_2 in the raw material
	Total organic carbon contents of raw materials.
	Quantity of clinker produced
	Quantity of CKD discarded
	Quantity of raw materials consumed (i.e. limestone, sand, shale, iron oxide, and alumina)
Lime Manufacturing	Weight fractions: • Plant-specific weight fractions in quick lime from each kiln of: CaO, MgO, uncalcined CaO, uncalcined MgO • Plant-specific weight fractions in lime kiln dust (LKD) from each kiln of: CaO, MgO, uncalcined CaO, uncalcined MgO
	Quantity of quick lime produced
	Quantity of LKD discarded
	Quantity of raw materials consumed (i.e., limestone, dolomite, aragonite, chalk, coral, marble, and shell)
Iron and Steel Manufacturing	Carbon contents: • By-products: blast furnace gas, coke oven gas, coal tar, light oil, coke breeze, sinter off gas • Carbon electrodes Direct reduced iron inputs: natural gas, coke breeze, metallurgical coke
	Energy used in direct reduced iron production (i.e., from natural gas, coke breeze, metallurgical coke)
	Quantity of coke production inputs (i.e., coking coal, blast furnace gas, other process materials)
	Quantity of coke produced
	Quantity of other coke production outputs (i.e., coke oven gas, other by-products)
	Quantity of iron and steel production inputs (i.e., coke, coke oven by-products, directly injected coal, limestone, dolomite, carbon electrodes, other carbonaceous and process material, coke oven gas)
	Quantity of steel produced
	Quantity of iron produced (not converted to steel)
	Quantity of blast furnace gas produced
	Quantity of sinter production inputs (i.e., coke breeze, coke oven gas, blast furnace gas, other process materials) and outputs (i.e., sinter off gas)
Electronics (Semiconductor) Manufacturing[a]	Fraction of gas remaining in shipping contained (i.e., heel)
	Mass of individual gas species fed into individual processes
	Use rate (i.e., fraction destroyed or transformed) of each gas species/process
	Fraction of each gas species/process fed into process with emission control technology
	Fraction of gas destroyed by emission control technology
	By-product emission factor for amount of CF_4/C_2F_6/CHF_3/ C_3F_8 created for each gas species/process

Table 4. Continued

Industry	Input Parameter
Lead Production	Carbon contents of reducing agents: blast furnace gas, charcoal, coal, coal tar, coke, coke oven gas, coking coal, electric arc furnace (EAF) carbon electrodes, EAF charge carbon, fuel oil, gas coke, natural gas petroleum coke
	Quantity of reducing agents (i.e., blast furnace gas, charcoal, coal, coal tar, coke, coke oven gas, coking coal, electric arc furnace [EAF] carbon electrodes, EAF charge carbon, fuel oil, gas coke, natural gas petroleum coke)
Soda Ash Manufacturing[a]	Carbon contents: • Ore • Sodium carbonate-rich brine • Soda ash Waste material (i.e., collected kiln dust)
	Quantity of soda ash produced
	Quantity of waste material
	Quantity of raw materials consumed (i.e., trona ore, nacholite ore, sodium carbonate-rich brine)
Adipic Acid Manufacturing[a]	Destruction factor
	Chemical composition of feedstock (i.e., cyclohexanone, cyclohexanol)
Aluminum Manufacturing	Quantity of materials consumed (i.e., paste, carbon, anodes, coke, recovered tar, coke dust)
	Quantity of aluminum produced
	Binder content in paste
	Pitch content in anodes
	Volatile content in coke
	Smelter-specific operating parameters (i.e., current efficiency, anode effect frequency, anode effect duration, anode effect over-voltage)
Ferroalloy Production[a]	Carbon contents: • Ore • Finished product • Non-product outgoing stream Volatiles in individual reducing agents
	Quantity of inputs (i.e., ore, individual reducing agents, individual slag-forming materials)
	Mass fractions in individual reducing agents: • Fixed carbon • Volatiles • Ash
HCFC-22 Production[a]	Concentration of HFC-23 in vented gas stream
	Gas stream mass flow rate
	Current process operating rate used as proxy
	Duration of atmospheric venting (not to a destruction system)
	Quantity of HFC-23 recovered for use as a chemical feedstock
	Concentration of HFC-23 in product reactor
	Mass of HCFC-22 produced at specific concentrations of HFC-23
Coal Mines	Mine-specific methane measurements from ventilation air and/or degasification systems

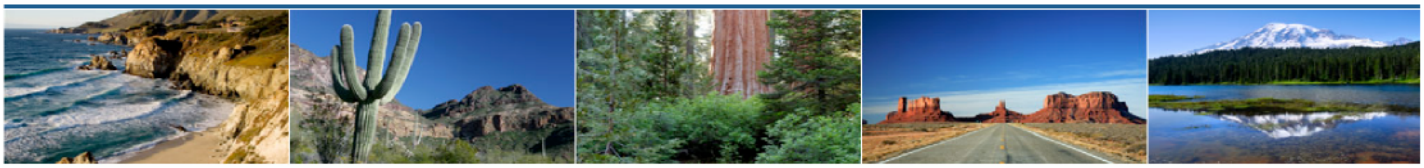
[a] Process emissions quantification method for this source category is still under development.

Ongoing Work

In the future, work will continue in these main areas related to emissions quantification and monitoring methods for mandatory reporting:

- Address any remaining stakeholder comments on quantification methods for source categories that were not prepared for public review prior to the January 12, 2009, stakeholder conference call.
- Oil and Gas Exploration and Gas Processing: Write emissions quantification and monitoring and related Essential Requirement sections (definitions, report requirements, etc.) based on interim TCR/WRAP O&G Protocol Project Task 2 output (i.e., available methods). Work will include developing "facility" or "reporting entity" definitions that will aggregate small, dispersed emissions sources, and consideration of appropriate reporting thresholds for such aggregated reporting entities.
- Natural Gas Transmission and Distribution: Write emissions quantification and monitoring and related Essential Requirement sections (definitions, report requirements, etc.) based on CCAR protocol (for eventual adoption by TCR) for process (i.e., fugitive CH_4) emissions.
- Transportation and RCI fuels GHG emission estimation methods, differences across jurisdictions, and accounting. Develop the reporting Essential Requirements for transportation fuels. Work may include identifying differences across WCI Partner jurisdictions with regard to regulating and dispensing RCI and transportation fuels, writing draft requirements, workshops with industry representatives and modification of such requirements. Update the portions of the Essential Requirements pertaining to transportation and RCI fuels to adapt decisions made by WCI with regard to transaction “accounting” to avoid double-counting of emissions and/or gaps in reported emissions by fuel suppliers, industrial sources, and jurisdictions. Current recommendations for GHG emissions quantification and monitoring methods to be included in the Essential Requirements completed in January 2009 will need to be revised.
- Pursue research to develop accurate emissions factors and/or quantification methods for the source categories for which adequate GHG emissions factors and/or quantification/monitoring methods are not currently available. This analysis would include establishing priorities, and would likely involve source testing and measurements. Some source data may be relatively inexpensive to obtain, while others will be more extensive and expensive to develop.
- The WCI Partner jurisdictions recommended the inclusion of certain emission categories in the Essential Reporting Requirements for which it was acknowledged that for specific emissions sources either quantification method uncertainties may be high or for which quantification methods are being developed. The WCI will evaluate the acceptable level of accuracy of quantification methods for inclusion in compliance reporting. Various forms of accuracy such as the level of uncertainty, bias, measurement error, sampling error and other pertinent factors (possibly

including factors other than methodological uncertainty) will be reviewed for the source categories under consideration. This will help the Partners consistently and transparently determine which emissions sources should be included and which emissions sources have justification for delayed inclusion or exclusion.



ATTACHMENT 1: GENERAL PROVISIONS

GENERAL PROVISIONS

§ WCI.0 PURPOSE

§ WCI.1 APPLICABILITY

§ WCI.2 GENERAL GREENHOUSE GAS REPORTING REQUIREMENTS AND SCHEDULE

§ WCI.3 CONTENTS OF THE GREENHOUSE GAS EMISSIONS REPORT

§ WCI.4 DOCUMENT RETENTION AND RECORD KEEPING REQUIREMENTS

§ WCI.5 COMPLIANCE AND ENFORCEMENT

§ WCI.6 INCORPORATION BY REFERENCE

§ WCI.7 DESIGNATED REPRESENTATIVE

§ WCI.8 REQUIREMENTS FOR VERIFICATION OF GREENHOUSE GAS EMISSIONS DATA REPORTS AND REQUIREMENTS APPLICABLE TO EMISSIONS DATA VERIFIERS

§ WCI.9 DEFINITIONS

§ WCI.10 GLOBAL WARMING POTENTIALS

EMISSIONS QUANTIFICATION, AND SAMPLING, ANALYSIS AND MEASUREMENT

§ WCI.20 THROUGH § WCI.XX

§ WCI.0 PURPOSE

This rule requires mandatory reporting and verification of greenhouse gas (GHG) emissions data by certain facilities that directly emit GHG, by importers of electricity, and by suppliers of fossil fuels. The GHGs that must be reported under this rule are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFC), perfluorocarbons (PFC), and sulfur hexafluoride (SF_6).

§ WCI.1 APPLICABILITY

(a) The GHG emissions reporting requirements, and related monitoring, recordkeeping, and verification requirements of this rule apply to the owners and operators *[Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices]* of any facility that meets the requirements of paragraph (a)(1) of this section; and any fuel suppliers and electricity importers that meet the requirements of paragraph (a)(2), (a)(3), or (a)(4) of this section:

(1) Any facility that emits 10,000 metric tons CO_2e or more per year in combined emissions from one or more of the source categories listed in this paragraph in any calendar year starting in 2010.

[Please note that the quantification and monitoring methods for many of these source categories are currently being assessed. Only source categories for which adequate quantification methods exist will be included in the final WCI Essential Requirements for mandatory reporting.]

(A) Adipic acid manufacturing [*still being assessed*]
(B) Aluminum manufacturing
(C) Ammonia manufacturing [*still being assessed*]
(D) Carbon dioxide transfer recipients [*still being assessed*]
(E) Cement manufacturing
(F) Coal mine fugitive emissions (active and abandoned)
(G) Coal storage
(H) Cogeneration [*still being assessed*]
(I) Electricity generation
(J) Electronics Manufacturing [*still being assessed*]
(K) Ferroalloy production [*still being assessed*]
(L) General stationary fuel combustion
(M) Glass Production and other uses of carbonates [*still being assessed*]
(N) HCFC-22 production [*still being assessed*]
(O) Hydrogen production
(P) Industrial wastewater *[still being assessed for some industries]*
(Q) Iron and steel manufacturing
(R) Lead production
(S) Lime manufacturing
(T) Magnesium production *[still being assessed]*
(U) Natural gas transmission and distribution systems *[still being assessed]*
(V) Nitric acid manufacturing *[still being assessed]*
(W) Nonroad equipment at facilities *[still being assessed]*

(X) Oil and gas production & gas processing *[still being assessed]*
(Y) Petrochemical production *[still being assessed]*
(Z) Petroleum refineries
(AA) Phosphoric acid production *[still being assessed]*
(BB) Pulp and paper manufacturing
(CC) Refinery fuel gas
(DD) SF_6 from electrical equipment *[still being assessed]*
(EE) Soda ash manufacturing *[still being assessed]*
(FF) Zinc production

(2) All importers of electricity. Importers of electricity include both retail providers and marketers that import electricity into the WCI region. *[This is preliminary language, pending definition of electricity importers by another WCI Committee.]*

(3) Any supplier that within the WCI region distributes transportation fuels in quantities that when combusted would emit 10,000 metric tons CO_2e per year or more in any calendar year starting in 2010. *[This is preliminary language, pending future determination of point of regulation for transportation fuels.]*

(4) Any supplier that distributes within the WCI region residential, commercial, and industrial fuels in quantities that when combusted would emit 10,000 metric tons CO_2e per year or more in any calendar year starting in 2010. *[This is preliminary language, pending future determination of points of regulation for these fuels.]*

(b) To calculate GHG emissions for comparison to the 10,000 metric ton CO_2e per year emission threshold in paragraph (a)(1) of this section, the owner or operator shall calculate annual CO_2e emissions, as described in paragraphs (b)(1) through (b)(4) of this section.

(1) Estimate the annual emissions of CO_2, CH_4, N_2O, HFC, PFC, and SF_6 in metric tons for each unit, process, activity, or operation for which emission calculation methodologies are provided in sections WCI.20 through WCI.XX. The GHG emissions shall be calculated using methodologies specified in each applicable section.

(2) For stationary combustion units, carbon dioxide emissions from the combustion of biomass fuels shall be included in the calculations. *[WCI is considering a limited deduction of biomass fuel combustion emissions from determination of whether the reporting threshold has been met.]*

(3) Sum the total facility emissions for each GHG and calculate the metric tons of CO_2e using equation 1-1 below.

$$CO_2e = \sum_{i=1}^{n} GHG_i \times GWP_i \qquad \textbf{Equation 1-1}$$

Where:

CO_2e = Carbon dioxide equivalent, metric tons/year.
GHG_i = Mass emissions of each greenhouse gas emitted, metric tons/year.
GWP_i = Global warming potential for each greenhouse gas from Table WCI.10-1 of this regulation.
n = The number of greenhouse gases emitted.

(4) For purpose of determining if an emission threshold has been exceeded, any CO_2 that is captured for on-site use, on-site storage, or transfer off-site must be included in the emissions total.

(c) To calculate GHG emissions for comparison to the 10,000 metric ton CO_2e per year emission threshold for suppliers of transportation fuels in paragraphs (a)(3) of this section, the owner or operator shall follow the procedures of paragraphs (c)(1) through (c)(2) below:

(1) Calculate the total mass in metric tons per year of CO_2, CH_4, and N_2O that would result from the complete combustion or oxidation of all transportation fuels that are distributed within the WCI region. The mass of each GHG shall be calculated using any of the applicable methodologies specified in section WCI.XX [Transportation Fuels Combustion] of this rule.

(2) Sum the emissions of each GHG and calculate total metric tons of CO_2e using Equation 1-1 of this rule.

(d) To calculate GHG emissions for comparison to the 10,000 metric ton CO_2e per year emission threshold for suppliers of residential, commercial, and industrial fuels in paragraph (a)(4) of this section, the owner or operator shall follow the procedures of paragraphs (d)(1) and (d)(2) below:

(1) Calculate the total mass in metric tons per year of CO_2, CH_4, and N_2O that would result from the complete combustion or oxidation of all residential, commercial, and industrial fuels that are distributed within the WCI region. The calculation shall exclude any fuels that are supplied to facilities that are required to report GHG emissions under section WCI.1(a)(1). *[These accounting issues will be dealt with in 2009.]* The mass of each GHG shall be calculated using any of the applicable methodologies specified in section WCI.XX [Residential, Commercial and Industrial Fuels Combustion] of this rule.

(2) Sum the emissions of each GHG and calculate total metric tons of CO_2e using Equation 1-1 of this rule.

(e) If the operations of a facility or fuel supplier that is subject to this rule change such that emissions fall below 10,000 metric tons CO_2e per year, then the following reporting requirements shall apply:

[Please note that the requirements of this subsection do not currently address reporters who emit >25,000 metric tons during 1 or more years, and then drop below 25,000 metric tons and above 10,000 metric tons in subsequent years. A provision for these reporters to cease verification after some period of time is under consideration.]

(1) If, prior to such emission reduction, the emissions report was subject to the verification requirements of this rule; then the owner or operator shall continue to submit verified emission reports until reported emissions are below 10,000 metric tons CO_2e per year for a minimum of 3 consecutive years. If reported emission are less than 10,000 metric tons CO_2 per year during 3 consecutive years, then the owner or operator shall be exempted from further reporting until CO_2e emissions again exceed 10,000 metric tons in any future calendar year.

(2) If, prior to such emission reduction, the emissions report was not subject to the verification requirements of this rule; then the owner or operator shall submit to the *[jurisdiction]* a signed statement certifying that emissions are less than 10,000 metric tons

CO_2e during the prior year. After certifying that emissions are below 10,000 metric tons CO_2e per year for 3 consecutive years, the owner or operator shall be exempted from further reporting until CO_2e emissions again exceed 10,000 metric tons in any future calendar year.

(3) Notwithstanding the requirements of paragraphs (e)(1) and (2) of this section, a facility or fuel supplier that is subject to an emissions limitation under the WCI cap-and-trade program must continue to submit verified annual reports.

(f) Upon request by the [*jurisdiction*], owner or operator of any facility or fuel supply operation must submit a demonstration that emissions have not exceeded one or more of the applicability criteria specified in this section in any year since 2010. Such demonstration shall be provided to the [*jurisdiction*] within 20 working days of receipt of a written request. *[WCI is considering whether this and other deadlines for responses provide sufficient time, and whether such deadlines should be standardized across requirements.]*

§ WCI.2 GENERAL GREENHOUSE GAS REPORTING REQUIREMENTS AND SCHEDULE

[Specific requirements of this section may change based on the future final design of the marketing trading program.]

(a) General. Owners or operators that are subject to this rule must submit an annual GHG emissions report. Owners and operators must collect data; calculate GHG emissions; and follow the procedures for quality assurance, missing data, recordkeeping, and reporting as specified in these General Provisions and in each relevant section WCI.20 through WCI.XX of this rule.

(1) A facility, fuel supplier, or electricity importer that commenced operation before January 1, 2010, must report emissions beginning in 2011 for GHGs emitted in calendar year 2010.

(2) A new facility, fuel supplier, or electricity importer that commences operation on or after January 1, 2010, must report emissions for the first calendar year in which the facility operates, beginning with the first operating month and ending on December 31 of that year. Each subsequent annual report must cover emissions for the calendar year, beginning on January 1 and ending on December 31.

(b) Reporting and Verification Schedule.

(1) Annual GHG emissions reports must be submitted to [*the jurisdiction*] by April 1 of each year for emissions in the previous calendar year.

(2) Reporters subject to the verification requirements of WCI.8, must complete their verification process, including submittal of a verification statement to [*the jurisdiction*], according to the following schedule:

(A) For reporting years 2010 through 2011, September 1 of the year following the reporting year.

(B) For reporting years 2012 and later, *[date to be determined]*.

(c) Submission of GHG Emissions Report. The annual GHG emissions report must be submitted to [*the jurisdiction*] in a format [*to be specified by each jurisdiction*].

(d) Simplified Emission Calculation Methods for De Minimis Sources. The owner or operator may elect to designate as de minimis one or more sources or pollutants that collectively emit no more than 3 percent of the facility's total CO_2e emissions, but not to exceed 20,000 metric tons CO_2e. The owner or operator may estimate emissions for these de minimis sources using alternative methods to those required to be used by this rule. If verification of the emissions report is required by this rule, then the selection of any alternative GHG calculation method is subject to the concurrence of the verification team that the use of such methods provides reasonable assurance that the emissions so designated do not exceed the applicable de minimis limits. The operator shall separately identify and include in the emissions data report the emissions from designated de minimis sources.

(e) GHG Inventory Management Plan. The owner or operator shall prepare and follow a written GHG inventory management plan that ensures that the emissions calculations and other information that is required to be reported under this rule are transparent, accurate, and independently verifiable. The owner or operator shall establish, document, implement, and maintain data acquisition and handling activities for the calculation and reporting of GHG emissions. Such activities shall include measuring, monitoring, analyzing, recording, processing and calculating the parameters specified by this rule. The owner or operator shall implement systems of internal audit, quality assurance, and quality control for the reporting program and the data reported. *[WCI is considering whether a written plan should be mandatory, or advised in guidance materials as a means of assuring a smooth verification process and a positive verification opinion.]*

(f) GHG Emissions Report Revisions.

(1) The owner or operator shall maintain documentation to support any revisions made to a previously submitted annual GHG emissions report. Documentation for all revisions shall be retained by the operator for 7 years.

(2) If, after the verification deadline, a report subject to verification is found to contain an error, or accumulation of errors, greater than 5 percent of the total CO_2e emissions reported, the owner or operator shall revise and resubmit an annual GHG emissions report within 60 days of the finding. To the extent possible, the revised report must correct all identified errors. A revised report will be accepted only if verified according to WCI.8 and approved by [*the jurisdiction*].

(3) If, after the report submittal deadline, a report not subject to verification is found to contain an error, or accumulation of errors, greater than 5 percent of the total CO_2e emissions reported, the owner or operator shall revise and resubmit an annual GHG emissions report within 30 days of the finding. To the extent possible, the revised report must correct all identified errors. A revised report will be accepted only if approved by [*the jurisdiction*].

(4) An owner or operator that voluntarily chooses to correct errors of 5 percent or less in total CO_2e emissions reported may do so according to the following requirements:

(A) For reports subject to verification, a revised report will be accepted only if verified according to WCI.8 and approved by [*the jurisdiction*].

(B) For reports not subject to verification, a revised report will be accepted if approved by [*the jurisdiction*].

(g) Fuel Use Measurement Accuracy. The operator shall use procedures to quantify fuel use (mass or volume flow) that provide data with an accuracy within ±5 percent. All fuel use measurement devices shall be maintained and calibrated in a manner and at a frequency required to maintain this level of accuracy. The operator shall make available to the verification team documentation to support this level of accuracy. The operator who measures solid fuels shall validate fuel consumption estimates with belt or conveyor scale calibrations conducted at least quarterly, and retain record of such calibrations.

(h) Where this rule specifies a choice between use of a fuel-based or mass balance-based calculation or use of a continuous emissions monitoring system (CEMS) to calculate CO_2 emissions, the operator shall make this choice and continue to use the method chosen for all future emissions data reports, unless the use of the alternative calculation method is approved in advance by *[the jurisdiction]*.

§ WCI.3 CONTENTS OF THE GREENHOUSE GAS EMISSIONS REPORT

Each annual GHG emissions report shall contain the following information:

(a) Facility name, identification number, physical address, mailing address, and NAICS code.

(b) Reporting year.

(c) Date of report submittal.

(d) Total facility emissions aggregated from all applicable source categories in subparts WCI.20 through WCI.XX expressed in metric tons of CO_2e calculated using Equation 1-1 of section WCI.1, excluding emissions from CO_2 that is captured and CO_2 emissions from the combustion of biomass and biomass-derived fuels, which are reported separately.

(e) Total facility emissions of CO_2 from the combustion of biomass and biomass-derived fuels.

(f) Total annual mass of CO_2 captured for on-site use, on-site storage, or transfer off site, in metric tons.

(g) For applicable fuel supplier categories in subparts WCI.XX [Transportation Fuels Combustion] and WCI.XX [Residential, Commercial and Industrial Fuels Combustion], total CO_2e emissions aggregated from all specified fuels.

(h) Emissions from each applicable source category or fuel supplier category in subparts WCI.20 through WCI.XX, expressed in metric tons per year of CO_2, CH_4, N_2O, HFC, PFC, and SF_6. CO_2 emissions from the combustion of biomass and biomass-derived fuels shall be reported separately.

(i) For electricity importers, the information required by WCI.XX [Electricity Imports].

(j) Emissions and other data for individual units, processes, activities, and operations as specified for each source category in sections WCI.20 through WCI.XX of this rule.

(k) Mass emissions from each designated de minimis source or pollutant, reported in metric tons per year of each GHG for which an alternative emission calculation method is used.

(l) Name and contact information including e-mail address and telephone number of the person primarily responsible for preparing and submitting the emissions report.

(m) A signed and dated statement provided by the owner or operator, or their designated representative, certifying that the report has been prepared in accordance with this rule and that, subject to verification, the statements and information contained in the emissions data report are true, accurate, and complete to the best of their knowledge.

§ WCI.4 DOCUMENT RETENTION AND RECORD KEEPING REQUIREMENTS

(a) The operator shall establish and maintain procedures for document retention and record keeping. The operator shall retain all documents regarding the design, development and maintenance of the GHG inventory in paper, electronic or other usable format for a period of not less than 7 years following submission of each emissions data report. The retained documents, including GHG emissions data, shall be sufficient to allow for the verification of each emissions data report.

(b) Upon request by *[jurisdiction],* the operator shall provide within 10 working days all documents and data used to develop an emissions data report.

(c) In addition to information submitted as part of the emissions data report, each operator shall retain, at a minimum, the following information for at least 7 years after the submission of the report:

(1) A list of all GHG sources (i.e., units, operations, processes, and activities) included in the emission estimates.
(2) All data used to calculate emissions for each source, categorized by process and fuel or material type.
(3) Documentation of the process for collecting emissions data.
(4) Any GHG emissions calculations and methods used;
(5) All emission factors used for emission estimates, including documentation for any factors not provided in the rule.
(6) All input data used for emission estimates.
(7) Documentation of biomass fractions for specific fuels.
(8) All other data submitted to the [*jurisdiction*] under this rule, including the GHG emissions report.
(9) All computations made to gap-fill missing data.
(10) Names and documentation of key facility personnel involved in emissions calculating and reporting;
(11) Any other information that is required for the verification of the GHG emissions report.
(12) A log to be prepared for each reporting year, beginning January 1, documenting all procedural changes made in GHG accounting methods and changes to instrumentation for GHG emissions estimation.
(13) A copy of the GHG Inventory Management Plan.

(d) For measurement based methodologies, the following information also must be retained for at least 7 years after the submission of the emissions data report:

(1) List of all emission points monitored.
(2) Collected monitoring data.
(3) Quality assurance and quality control information collected under the GHG Inventory Management Plan required by section WCI.2 of this rule.

(4) A detailed technical description of the continuous measurement system, including documentation of any findings and approvals by federal, State or local agencies.
(5) Raw and aggregated data from the continuous measurement system.
(6) A log book of all system down-times, calibrations, servicing, and maintenance of the continuous measurement system.
(7) Documentation of any changes in the continuous measurement system over time.

§ WCI.5 COMPLIANCE AND ENFORCEMENT

(a) Knowing submission of false information to the *[jurisdiction*] or a verification body, shall constitute a single, separate violation of the requirements of this article for each day after the information has been received by the [*jurisdiction*].

(b) Each violation of this rule shall constitute a single, separate violation for each day beyond the specified reporting date. A violation includes failure to submit any report, failure to collect data needed to calculate GHG emissions, failure to monitor and test as required, failure to calculate GHG emissions following the methodologies specified in this rule, failure to retain required records, failure to provide all information required in the report, and failure to submit a report on time. For the purposes of this rule, "report" means any GHG emissions data report, verification statement, or other document required to be submitted by this rule.

§ WCI.6 INCORPORATION BY REFERENCE

The following documents are incorporated by reference into this rule. These materials are incorporated as they exist on the date this article is adopted.

[This list will be revised as additional calculation methods are selected. Canadian Standards Association methods equivalent to the specified ASTM methods will be identified as substitutes for these in rulemaking by Canadian jurisdictions.]

(a) American Society for Testing and Materials (ASTM) D1826-94 (Reapproved 2003), ASTM D3588-98 (Reapproved 2003), ASTM D4891-89 (Reapproved 2006), ASTM D240-02 (Reapproved 2007), ASTM D4809-00 (Reapproved 2005), ASTM 5373-02 (Reapproved 2007), ASTM D5291-02 (Reapproved 2007), ASTM D3238-95 (Reapproved 2005), ASTM D2502-04, ASTM D2503-92 (Reapproved 2002), ASTM D1945-03, ASTM D1946-90 (Reapproved 2006), ASTM D6866-06a, ASTM D388-05, ASTM D5468-02 (Reapproved 2007), ASTM D240-87 (Reapproved 1991), ASTM D5865-07a, ASTM Specification D396-07, ASTM Specification D975-07b.

(b) California Implementation Guidelines for Estimating Mass Emissions of Fugitive Hydrocarbon Leaks at Petroleum Facilities, California Air Pollution Control Officers Association (CAPCOA) and California Air Resources Board (ARB), February 1999.

(c) Control of Emissions from Refinery Flares, Rule 118, South Coast Air Quality Management District, Amended November 4, 2005.

(d) U.S. EPA TANKS Version 4.09D, US Environmental Protection Agency, October 2005.

(e) Gas Processors Association (GPA) Standard 2261-00, Revised 2000.

§ WCI.7 DESIGNATED REPRESENTATIVE

(a) General. Each fuel supplier, electricity importer, and owner or operator of a facility that is subject to this rule, shall select a designated representative that is responsible for certifying and submitting GHG emissions reports under this reporting rule.

(b) Authorization of a Designated Representative. The designated representative of the facility shall be selected by a certificate of representation agreement that is signed by the designated representative and owners or operators of the facility. The designated representative must be an individual having responsibility for the overall operation of the facility or activity such as the position of the plant manager, operator of a well or a well field, superintendent, position of equivalent responsibility, or an individual or position having overall responsibility for environmental matters for the company.

(c) Responsibility of the Designated Representative.

(1) The designated representative of the facility shall represent and by any representations, actions, inactions, or submissions, legally bind each owner and operator in all matters pertaining to this rule.

(2) Each GHG emission report submitted under this rule must be signed by the designated representative and must contain the following certification statement: "I have been authorized to make this submission on behalf of the owners and operators of the facility (or supply operation, as appropriate). I certify under penalty of law that I have personally examined the information submitted in this document. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment."

(d) Changing a Designated Representative. The designated representative may be changed at any time upon submission of a superseding certificate of representation. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous designated representative before time of the superseding certificate of representation shall be binding on the new designated representative and the owners and operators.

(e) Changes in Owners and Operators. In the event of any change in ownership of the facility, any new owner or operator shall be deemed to be bound by the representations, actions, inactions, and submissions of the designated representative of the facility until such time as the designated representative is changed.

(f) Certificate of Representation. A certificate of representation must be submitted to *[the jurisdiction]* and kept on location by the facility, fuel supplier, or electricity importer. The certificate shall include the following information:

(1) Identification of the facility, fuel supplier, or electricity importer for which the certificate of representation is submitted.

(2) The name, address, e-mail address (if any), telephone number, and facsimile transmission number (if any) of the designated representative.

(3) A list of the owners and operators.

(4) Certification statements that the actions of the designated representative with respect to this rule are binding on the owners and operators, and that the designated representative has the necessary authority to carry out duties and responsibilities on behalf of the owners and operators.
(5) The signature of the designated representative and owner(s) and operator(s), and the dates signed.

§WCI.8 REQUIREMENTS FOR VERIFICATION OF GREENHOUSE GAS EMISSIONS DATA REPORTS AND REQUIREMENTS APPLICABLE TO EMISSIONS DATA VERIFIERS

(a) Applicability. Owners or operators [Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices] are required to obtain annual verification when the reported annual emissions of the operation subject to this rule:

(1) Are equal to 25,000 metric tons of CO_2e or more; or
(2) Are subject to an emissions limit under the WCI cap-and-trade program as required under WCI.1(e)(3); or
(3) Were verified and then fall below 10,000 metric tons of CO_2e in a subsequent year as stipulated under WCI.1(e)(1).

[WCI is considering a limited deduction of biomass fuel combustion emissions from determination of whether the verification threshold has been met.]

(b) Requirements for Annual Verification of Emissions Data Reports.

(1) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification shall be subject to full verification requirements in the first year that verification is required. Upon completion of a positive verification statement under full verification requirements, the facility owner or operator, fuel supplier, or electricity importer may choose to obtain two years of less intensive verification services. This cycle may be repeated in subsequent three-year cycles, but full verification requirements shall apply at least once every three years.
(2) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification will be required to obtain full verification services if any of the following apply:

(A) Change in the verification body from the previous year; or
(B) A verification body was not able to provide a positive verification statement for the reporters emissions report for the previous year.

(3) Facility owners or operators, fuel suppliers, or electricity importers subject to annual verification shall not use the same verification body for a period of more than six consecutive years. If a facility owner or operator, fuel supplier, or electricity importer is required or elects to contract with another verification body, they may contract verification services from the previous verification body only after not using the previous verification body for at least three years.

(c) Requirements for Verification Services. Verification services shall be subject to the following requirements.

(1) Notice of Verification Services. After the [*WCI Regional Body, jurisdiction, or other organization to be determined (TBD)*] has provided a determination that the potential for a conflict of interest is acceptable as specified in section WCI.8(e) and that verification services may proceed, the verification body shall submit a notice of verification services to [*TBD*]. The verification body may begin verification services for the operator 15 working days after the notice is received by the [*TBD*], or earlier if approved by the [*TBD*] in writing. The notice shall include the following information:

(A) A list of the staff who will be designated to provide verification services as a verification team, including the names of each designated staff member, the lead verifier, and all subcontractors, and a description of the roles and responsibilities each member will have during verification;

(B) Documentation that the verification team has the skills required to provide verification services for the reporting facility, fuel supply or electricity import operation. This shall include a demonstration that a verification team includes at least one member with source category specific skills to provide source-category specific verification services when required below:

i. For providing verification of emissions reported under WCI.60 [Electricity Importers] at least one verification team member must have demonstrated knowledge as an electricity transactions specialist.

ii. For providing verification of emissions reported under WCI.200 [Petroleum refineries] or WCI.140 [Hydrogen production], at least one verification team member must have demonstrated knowledge as a refinery specialist;

iii. For providing verification of emissions reported under WCI.90 [Cement], at least one verification team member must have demonstrated knowledge as a cement specialist.

[Note that other source-category specialist skills may be required. These requirements are being discussed by the WCI, as are any additional accreditation requirements for individual lead verifiers, general verifiers, or sector specialists.]

(C) General information on the lead verifier and the operator, including:

i. The name, office address, telephone number, and e-mail address of the lead verifier;

ii. The name of the owner or operator, and the facilities and other locations that will be subject to verification services, owner or operator contact, address, telephone number, and e-mail address;

iii. The industry sector, and the Standard Industrial Classification and North American Industry Classification System (NAICS) codes of the facility, fuel supplier, or electricity importer;

iv. The expected date(s) of on-site visits, with facility or fuel supply location address and contact information;

v. A brief description of expected verification services to be performed, including expected completion date.

(2) Verification services shall include, but are not limited to, the following:

(A) Verification Plan. The verification team shall obtain information from the owner or operator necessary to develop a verification plan. Such information shall include but is not limited to:

i. Information to allow the verification team to develop a general understanding of facility or entity boundaries, operations, emissions sources, and electricity transactions as applicable;
ii. Information regarding the training or qualifications of personnel involved in developing the GHG emissions data report;
iii. Description of the specific methodologies used to quantify and report GHG emissions, electricity transactions, and other required data as applicable;
iv. Information about the data management system used to track GHG emissions, electricity transactions, and other required data as applicable.

(B) The verification team shall develop a verification plan that includes, at a minimum:

i. Dates of proposed meetings and interviews with reporting facility, fuel supply, or electricity import personnel;
ii. Dates of proposed site visits;
iii. Types of proposed document and data reviews;
iv. Expected date for completing verification services.

(C) The verification team shall discuss with the owner or operator the scope of the verification services and request any information and documents needed for initial verification services. The verification team shall review the documents submitted and plan and conduct a review of original documents and supporting data for the emissions data report.

(D) Site visits. At least one member of the verification team shall at a minimum make one site visit, in the first year of each three-year reporting cycle or if full verification requirements are required under WCI.8(b)(3), to each facility or fuel supply location [Note that exact location of fuel supplier site visits remains TBD] for which an emissions data report is submitted. The verification team member(s) shall visit the headquarters or other location of central data management when the owner or operator is an electricity importer. During the site visit, the verification team member(s) shall conduct the following:

i. The verification team member(s) shall check that all sources specified in sections WCI.20 to WCI.XX as applicable to the owner or operator, are identified appropriately.
ii. The verification team member(s) shall review and understand the data management systems used by the owner or operator to track, quantify, and report greenhouse gas emissions and, when applicable, electricity transactions. The verification team member(s) shall evaluate the uncertainty and effectiveness of these systems.
iii. The verification team shall collect and review other information that, in the professional judgment of the team, is needed in the verification process.

(E) The verification team shall review facility, fuel supplier, or electricity importer operations to identify applicable GHG emissions sources. This shall include a review of the emissions inventory and each type of emission source to assure that all sources listed in sections WCI.20 through WCI.XX are properly included in the inventory.

(F) Owners or operators shall make available to the verification team all information and documentation used to calculate and report emissions, electricity transactions, and other information required under this rule, as applicable.

(G) As applicable for electricity importers, the verification team shall review electricity transaction records, including receipts of power attributed to the Northwest or Southwest region as verifiable via North American Electric Reliability Corporation (NERC) E-Tags, settlements data, or other information as confirmation of the region of origin. [Note that this procedure is subject to change pending WCI Electricity Committee review.]

(H) Sampling Plan. As part of confirming emissions data or electricity transactions the verification team shall develop a sampling plan that meets the following requirements:

i. The verification team shall develop a sampling plan based on a strategic analysis developed from document reviews and interviews to assess the likely nature, scale and complexity of the verification services for an owner or operator. The analysis shall review the inputs for the development of the submitted emissions data report, the rigor and appropriateness of the GHG or electricity transaction data management system, and the coordination within a facility, fuel supplier's, or electricity importer's organization to manage the operation and maintenance of equipment and systems used to develop emissions data reports.

ii. The verification team shall include in the sampling plan a ranking of emissions sources by amount of contribution to total CO_2e emissions for the owner or operator and a ranking of emissions sources with the largest calculation uncertainty. As applicable and deemed appropriate by the verification team, electricity transactions shall also be ranked or evaluated relative to the amount of power exchanged and uncertainties that may apply to data provided by the electricity importer.

iii. The verification team shall include in the sampling plan a qualitative narrative of uncertainty risk assessment in the following areas as applicable under sections WCI.20 through WCI.XX:

- Data acquisition equipment;
- Data sampling and frequency;
- Data processing and tracking;
- Emissions calculations;
- Data reporting;
- Management policies or practices in developing emissions data reports.

iv. The verification team may change the sampling plan as relevant information becomes available and potential issues emerge of material misstatement or nonconformance with the requirements of this rule.

v. The verification body shall retain the sampling plan in paper, electronic, or other format for a period of not less than five years following the submission of each verification statement. The sampling plan shall be made available to *[TBD]* upon request.

(I) Data Checks. To determine the reliability of the submitted emissions data report, the verification team shall use data checks. Such data checks shall focus first on the largest and most uncertain estimates of emissions and electricity transactions, and shall include the following:

i. The verification team shall use data checks to ensure that the appropriate methodologies and emission factors have been applied for the emissions sources and electricity transactions covered under sections WCI.20 through WCI.XX;
ii. The verification team shall choose emissions sources, and electricity transactions data as applicable, for data checks based on their relative sizes and risks of material misstatement as indicated in the sampling plan;
iii. The verification team shall use professional judgment in the number of data checks required for the team to conclude with reasonable assurance whether the reported emissions and transactions are free of material misstatement and the emissions data report otherwise conforms to the requirements of this rule.

(J) Emissions Data Report Modifications. If as a result of review by the verification team and prior to completion of a verification statement the operator chooses to make improvements or corrections to the submitted emissions data report, a revised emissions data report may be submitted to [the jurisdiction] as specified by section WCI.2(f). The operator shall maintain documentation to support any revisions made to the initial emissions data report. Documentation for all emissions data report submittals shall be retained by the operator for seven years pursuant to section WCI.4.
(K) Findings. To verify that the emissions data report is free of material misstatement, the verification team shall make its own determination of emissions for sources checked according to WCI.8(c)(1), and shall determine whether there is reasonable assurance that the reported facility, fuel supply, or electricity import emissions are within 95 percent of actual total emissions for the facility, on a CO_2e basis. To assess conformance with this rule the verification team shall review the methods and factors used to develop the emissions data report for adherence to the requirement of this rule. The verification team shall keep a log of any issues identified in the course of verification activities that may affect determinations of material misstatement and nonconformance, and how those issues were resolved.

(3) Completion of verification services shall include:

(A) Verification Statement. Upon completion of the verification services specified in section WCI.8(c)(2), the verification body shall complete a verification statement, and provide that statement to the owner or operator and [the jurisdiction] according to the schedule specified in section WCI.2(b). Before that statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed within the verification body by a lead verifier not involved in services for that operator during that year.

(B) When the verification team completes its findings:

i. The verification body shall provide to the owner or operator a detailed verification report. The verification report shall at minimum include the verification plan, the detailed comparison of the data checks with the submitted emissions data report, the log of issues identified in the course of verification activities and their resolution, and any qualifying comments on findings during verification services. The detailed verification report shall be made available to [*the jurisdiction*] upon request.

ii. The verification body shall provide the verification statement to the owner or operator and [*the jurisdiction*], attesting that the verification body has found the submitted emissions data report free of material misstatement and in conformance with the requirements of this rule or, alternatively, that the emissions data report contains material misstatement or otherwise does not conform with the requirements of this rule.

iii. The lead verifier in the verification team shall attest that the verification team has carried out all verification services as required by this rule, and the lead verifier who has conducted the independent review of verification services and findings specified in section WCI.8(c)(3)(A) shall attest to his or her independent review on behalf of the verification body and his or her concurrence with the verification findings.

(C) Prior to the verification body providing an adverse verification statement to [*the* jurisdiction], the owner or operator shall be provided at least 10 working days to modify the emissions data report to correct any material misstatement or nonconformance found by the verification team. The modified report and verification statement must be submitted to [*the jurisdiction*] before the applicable verification deadline, unless the operator makes a request to [*the jurisidiction]* as follows

i. If the owner or operator and the verification body cannot reach agreement on modifications to the emissions data report that result in a positive verification statement, the operator may petition *[TBD]* to make a final decision as to the verifiability of the submitted emissions data report.

ii. If *[TBD]* determines that the emissions data report does not meet the standards and requirements specified in this rule, the owner or operator shall have the opportunity to submit within 60 calendar days of the date of this decision [Note that this time frame may need to be changed pending details of cap-and-trade system design and needs.] any emissions data report revisions that address *[TBD's]* determination, for re-verification of the emissions data report. In re-verifying a revised emissions data report, the verification body and verification team shall be subject to the requirements in section WCI.8(c)(3).

(4) Upon provision of the verification statement to *[the jurisdiction]*, the emissions data report shall be considered final and no changes shall be made except as provided in

section WCI.2(f). All verification requirements of this rule shall be considered complete upon provision of the verification statement.

(5) If the *[TBD]* finds a high level of conflict of interest existed between a verification body and an owner or operator or an emissions data report that received a positive verification statement fails an audit by *[TBD]*, the *[TBD]* may set aside the positive verification statement submitted by the verification body.

(6) Upon request by *[TBD]*, the owner or operator shall provide the data used to generate an emissions data report, including all data available to a verifier in the conduct of verification services. *[TBD]* may also review the full verification report given by the verification body to the owner or operator. The full verification report shall be provided to the *[TBD]* upon request.

(7) Upon written notification by the *[TBD]*, the verification body shall make itself available for a verification services audit.

(d) Accreditation Requirements for Verification Bodies, Lead Verifiers, and Verifiers.

(1) The accreditation requirements specified in this subsection shall apply to all verification bodies, lead verifiers, and verifiers that wish to provide verification services under this rule.

(2) Verification bodies accredited according to the requirements of the California Air Resources Board [provide regulatory citation] or to ISO 14065 through a program developed under ISO 17011 with demonstrated knowledge of WCI reporting requirements to conduct verification activities for WCI emissions data, are qualified to conduct verification activities for the WCI.

[Note the details of WCI's specific accreditation process for verification bodies (which has yet to be developed) will be consistent with ISO 14065 through an accreditation program that will developed under ISO 17011 and will include demonstrated knowledge of the WCI reporting requirements. WCI will explore additional accreditation requirements for individual lead verifiers, general verifiers, or sector specialists.]

(3) Subcontracting. The following requirements shall apply to any verification body that elects to subcontract verification services.

(A) The verification body must assume full responsibility for verification services performed by subcontractor verifiers or verification bodies.

(B) A verification body or verifier acting as a subcontractor to another verification body shall not further subcontract or outsource verification services for an operator.

(C) A verification body that engages a subcontractor shall be responsible for demonstrating an acceptable level of conflict of interest, as provided in section WCI.8(e) between its subcontractor and the operator for which it will provide verification services.

(4) If any WCI accredited verification body is suspended in any other mandatory or voluntary GHG reporting or trading program, that verification body will not be allowed to provide any verification services under WCI until that suspension ends. If any WCI accredited verification body has their verification body accreditation revoked under any other mandatory or voluntary GHG reporting or trading program, that verification body will no longer be allowed to provide verification services under WCI.

(e) Conflict of Interest Requirements for Verification Bodies.

(1) The conflict of interest provisions of this section shall apply to the verification body, entities related to the verification body, and the verification team accredited according to the requirements of WCI.8(d) to perform verification services for the WCI cap-and-trade program. Member for purposes of this section means any employee or subcontractor of the verification body or entities related to the verification body. Member also includes any individual with a majority equity share in the verification body or entities related to the verification body.

(2) The potential for a conflict of interest shall be deemed to be high where:

(A) The verification body and owner or operator share any management staff or board of directors membership, or any of the management staff of the owner or operator have been employed by the verification body, or vice versa, within the previous three years; or

(B) Within the previous three years, any member of the verification body, any entity related to the verification body, and the verification team has provided to the owner or operator any of the following non-verification services:

i. Designing, developing, implementing, or maintaining an inventory or information or data management system for facility greenhouse gases, or, where applicable, electricity transactions;
ii. Developing greenhouse gas emission factors or other greenhouse gas-related engineering analysis;
iii. Designing energy efficiency, renewable power, or other projects which explicitly identify greenhouse gas reductions as a benefit;
iv. Preparing or producing greenhouse gas-related manuals, handbooks, or procedures specifically for the reporting facility;
v. Appraisal services of carbon or greenhouse gas liabilities or assets;
vi. Brokering in, advising on, or assisting in any way in carbon or greenhouse gas-related markets;
vii. Managing any health, environment or safety functions;
viii. Bookkeeping or other services related to the accounting records or financial statements;
ix. Any service related to information systems, unless those systems will not be part of the verification process;
x. Appraisal and valuation services, both tangible and intangible;
xi. Fairness opinions and contribution-in-kind reports in which the verification body has provided its opinion on the adequacy of consideration in a transaction, unless the resulting services shall not be part of the verification process;
xii. Any actuarially oriented advisory service involving the determination of amounts recorded in financial statements and related accounts;
xiii. Any internal audit service that has been outsourced by the operator that relates to the owner's or operator's internal accounting controls, financial systems or financial statements, unless the result of those services shall not be part of the verification process;
xiv. Acting as a broker-dealer (registered or unregistered), promoter or underwriter on behalf of the owner or operator;

xv. Any legal services;
xvi. Expert services to the owner or operator or his or her legal representative for the purpose of advocating his or her's interests in litigation or in a regulatory or administrative proceeding or investigation, unless providing factual testimony.

(C) The potential for a conflict of interest shall also be deemed to be high where any staff member of the verification body, entity related to the verification body, or the verification team has provided verification services for the owner or operator within the last three years, except within the time periods in which the owner or operator is allowed to use the same verification body as specified in sections WCI.8(b).
(D) The potential for a conflict of interest shall be deemed high where the lead verifier doing the independent review for the verification team has provided verification or non-verification services for the operator in the last year as specified in section WCI.8(b).

(3) The potential for a conflict of interest shall be deemed to be low where:

(A) No potential for a conflict of interest is found under section WCI.8(e)(2) and any non-verification services provided by all members of the verification body and the verification team to the owner or operator within the last three years are valued at less than [Percent of the fee TBD] for the proposed verification.
(B) Any non-verification services provided at any time by a member of the verification body or the verification team did not include development of a GHG inventory system still in use by the owner or operator.

(4) The potential for a conflict of interest shall be deemed to be medium where the potential for a conflict of interest is not deemed to be either high or low as specified in sections WCI.8(e)(2)-(3).

(A) If a verification body identifies a medium potential for conflict of interest and wishes to provide verification services for the owner or operator, then the verification body shall submit, in addition to the submittal requirements specified in section WCI.8(e)(5), below, a plan to avoid, neutralize, or mitigate the potential conflict of interest situation. At a minimum, the conflict of interest mitigation plan shall include:

i. A demonstration that any individuals in the verification body or team with potential conflicts have been removed and insulated from the project.
ii. An explanation of any changes to the verification body or verification team to remove the potential conflict of interest, including changes to organization structure to demonstrate that a unit with potential conflicts has been divested or moved into an insulated related entity.
iii. A description of any other circumstance that specifically addresses other sources for potential conflict of interest.

(B) As provided in section WCI.8(e)(6), below, the [TBD] shall evaluate the conflict of interest mitigation plan and determine whether verification services may proceed.

(5) Conflict of Interest Submittal Requirements for Accredited Verification Bodies.

(A) Before the start of any work related to providing verification services to an owner or operator, a verification body must first be authorized in writing by *[TBD]* to provide verification services. To obtain authorization the verification body shall submit to *[TBD]* a self-evaluation of the potential for any conflict of interest that the verification body, entities related to the verification body, and members of the verification team including, subcontractors may have with the owner or operator or their related entities for which it will perform verification services. The submittal shall include the following:

i. Identification of whether the potential for conflict of interest is high, low, or medium based on factors specified in sections WCI.8(e)(2)-(4);
ii. An organizational chart of the business structure of the verification body, including its related entities and brief description of the primary work done by the verification body and related entities;
iii. Identification of whether any member of the verification body, entities related to the verification body, or the verification team including subcontractors has previously provided verification services for the owner or operator or its related entities and, if so, the years in which such verification services were provided;
iv. Identification of whether any member of the verification body, entities related to the verification body, or the verification team or including subcontractors has engaged in any non-verification services of any nature with the owner or operator or related entities either within or outside the WCI region during the previous three years. If non-verification services have previously been provided, the following information shall also be submitted:

- Identification of the nature and location of the work performed for the owner or operator and whether the work is similar to the type of work to be performed during verification, such as emissions inventory, auditing, energy efficiency, renewable energy, or other work with implications for the operator's greenhouse gas emissions or the accounting of greenhouse gas emissions or electricity transactions;
- The nature of past, present or future relationships the verification body, entities related to the verification body, and members of the verification team including subcontractors have with the owner or operator or related entity including:
  - Instances when any member has performed or intends to perform work for the owner or operator;
  - Identification of whether work is currently being performed for the owner or operator and, if so, the nature of the work;
  - Whether any member has any contracts or other arrangements to perform work for the owner or operator or a related entity;
  - Identify how much work was performed in the last three years, as a percentage of the verification body's total gross income for the last three years;
  - Identify how much work related to greenhouse gases or electricity transactions was has performed for the owner or operator or related

entities in the last three years, as a percentage of the verification body's income for the last three years;
  - Identify how much work was performed by each subcontractor for the operator in the last three years, as a percentage of each subcontractor's total gross income for the last three years.

- Explanation of how the amount and nature of work previously performed is such that any member of the verification team's credibility and lack of bias should not be under question.

v. A list of names of the staff that will perform verification services for the owner or operator and a description of any instances of personal or family relationships with management or employees of the owner or operator that potentially represent a conflict of interest; and,

vi. Identification of any other circumstances or relevant information known to the verification body or owner or operator that could result in a conflict of interest, or any situation where the appearance of impartiality could undermine confidence in the verification body's ability to asses the reported emissions.

(6) Conflict of Interest Determinations. The *[TBD]* shall review the self-evaluation submitted by the verification body and determine whether the verification body is authorized to perform verification services for the owner or operator

(A) The *[TBD]* shall notify the verification body in writing when the conflict of interest evaluation information submitted under section WCI.8(e)(5) is deemed complete. Within *[Number of days TBD]* of deeming the evaluation information complete, *[TBD]* shall determine whether the verification body is authorized to proceed with verification and shall so notify the verification body.

(B) If *[TBD]* determines the verification body or any member of the verification team meets the criteria specified in section WCI.8(e)(2), *[TBD]* shall find a high potential conflict of interest and verification services may not proceed.

(C) If *[TBD]* determines that there is a low potential conflict of interest, verification services may proceed.

(D) If *[TBD]* determines that the verification body and verification team have a medium potential for a conflict of interest, *[TBD]* shall evaluate the conflict of interest mitigation plan submitted pursuant to sections WCI.8(e)(4), and may request additional information from the applicant to complete the determination. In determining whether verification services may proceed, *[TBD]* may consider factors including, but not limited to, the nature of previous work performed, the current and past relationships between the verification body and its subcontractors with the owner or operator, and the cost of the verification services to be performed. If *[TBD]* determines that these factors when considered in combination demonstrate an acceptable level of potential conflict of interest, then *[TBD]* will authorize the verification body to provide verification services.

(f) Monitoring Conflict of Interest Situations.

(1) After commencement of verification services, the verification body shall monitor and immediately make full disclosure in writing to *[TBD]* regarding any potential for a conflict of interest situation that arises. This disclosure shall include a description of actions that the verification body has taken or proposes to take to avoid, neutralize, or mitigate the potential for a conflict of interest.
(2) The verification body shall monitor arrangements or relationships that may be present for a period of one year after the completion of verification services. During that period, within 30 calendar days of any change in arrangements or relationships with the owner or operator for which the body has provided verification services, the verification body shall notify *[TBD]* of the change and provide a description of the nature of the change.
(3) The verification body shall report to *[TBD]* any changes in its organizational structure, including mergers, acquisitions, or divestitures, for one year after completion of verification services.
(4) *[TBD]* may invalidate a verification finding if a potential conflict of interest has arisen for any member of the verification team. In such a case, the owner or operator shall be provided 180 calendar days to complete re-verification.
(5) If the verification body or its subcontractor(s) are found to have violated the conflict of interest requirements of this section, *[TBD]* may rescind accreditation of the body, its verifier staff, or its subcontractor(s) for any appropriate period of time as provided in section WCI.8(d) *[TBD – accreditation requirements]*.

§ WCI.9 DEFINITIONS

[This is a partial list of definitions. Additional definitions are under development based on the Canadian regulations come from "Section 71 of the Canadian Environmental Protection Act (CEPA) 1999"and the CARB definitions come from "Title 17, Subchapter 10, Article 2, Section 95102 of the California Code of Regulations.]

"Adverse verification statement" means a verification statement rendered by a verification body stating that the verification body cannot say with reasonable assurance that the submitted emissions data report is free of material misstatement, or that it cannot provide a qualifying statement that the emissions data report conforms to the requirements of this article.

"Biomass fuels" or "biomass-derived fuels" means fuels derived entirely from biomass.

"Carbon dioxide equivalent" or "CO_2 equivalent" or "CO_2e" means a measure for comparing carbon dioxide with other GHGs, based on the quantity of those gases multiplied by the appropriate global warming potential (GWP) factor and commonly expressed as metric tons of carbon dioxide equivalent.

"Conflict of interest" means a situation in which, because of financial or other activities or relationships with other persons or organizations, a person or body is unable or potentially unable to render an impartial verification opinion of a potential client's greenhouse gas emissions, or the person or body's objectivity in performing verification services is or might be otherwise compromised.

"Continuous emissions monitoring system" or "CEMS" means the total equipment required to obtain a continuous measurement of a gas concentration or emission rate from combustion or industrial processes.

"Electricity generating unit" or "EGU" means any combination of physically connected generator(s), reactor(s), boiler(s), combustion turbine(s), or other prime mover(s) operated together to produce electric power.

"Exporter" means…*[To be defined later for transportation and RCI fuels accounting]*

"Facility" means any property, plant, building, structure, stationary source, stationary equipment or grouping of stationary equipment or stationary sources located on one or more contiguous or adjacent properties, in actual physical contact or separated solely by a public roadway or other public right-of-way, under common operational control, and having the same first two digits of the Standard Industrial Classification (SIC) or same first three digits of the North American Industry Classification System (NAICS) code. *[Some special facilities, such as oil and gas production fields will have separate definitions.]*

"Full verification" means all verification services as provided in section WCI.8(c).

"Global warming potential" or "GWP factor" means the radiative forcing impact of one mass-based unit of a given greenhouse gas relative to an equivalent unit of carbon dioxide over a given period of time.

"Greenhouse gas", "greenhouse gases" or "GHG" means carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), hydrofluorocarbons (HFCs), and perfluorocarbons (PFCs).

"Hydrofluorocarbons" or "HFCs" means a class of GHGs primarily used as refrigerants, consisting of hydrogen, fluorine, and carbon.

"Importer" means…*[To be defined later with input from the Electricity Subcommittee.]*

"Lead verifier" means a person that has met all of the requirements in section WCI.8 *[TBD]*, and who may act as the lead verifier of a verification team providing verification services or as a lead verifier providing an independent review of verification services rendered.

"Material misstatement" means one or more inaccuracies identified in the course of verification that result in the total reported emissions being outside the 95 percent accuracy required to receive a positive verification statement.

"Owner or operator" means any person who owns, leases, operates, controls, or supervises a facility or fuel supply operation; or who imports electricity into the WCI region.

"Perfluorocarbons" or "PFCs" means a class of greenhouse gases consisting on the molecular level of carbon and fluorine.

"Positive verification statement" means a verification statement rendered by a verification body stating that the verification body can say with reasonable assurance that the submitted emissions data report is free of material misstatement and includes a qualifying statement that the emissions data report conforms to the requirements of this article.

"Pure" means consisting of at least 97 percent by mass of a specified substance. For facilities burning biomass fuels, this means the fraction of biomass carbon accounts for at least 97 percent of the total amount of carbon in the fuel burned at the facility.

"Reasonable assurance" means a high degree of confidence that submitted data and statements are valid.

"Stationary combustion unit" means any boiler, heater, furnace, kiln, turbine, internal combustion engine, incinerator or other non-mobile source device that combusts any solid, liquid, or gaseous fuel for purposes of producing useful heat or energy for industrial, commercial, or institutional use; or for purposes of reducing the volume of waste by removing combustible material.

"Supplier" means . . . *[To be defined later for transportation and RCI fuels accounting.]*.

"Verification" means the process used to ensure that an operator's emissions data report is free of material misstatement and complies with WCI's reporting procedures and methods for calculating and reporting GHG emissions.

"Verification body" means a firm accredited by the jurisdiction or its designee, that is able to render a verification statement and provide verification services for operators subject to reporting under this article.

"Verification cycle" means one year of full verification and the next consecutive two years of less intensive verification for operators subject to annual verification. For operators subject to triennial verification, a verification cycle means one year of full verification, and if elected, the next consecutive two years of less intensive verification. A verification cycle cannot exceed three calendar years.

"Verification statement" means the final opinion rendered by a verification body attesting whether an operator's emissions data report is free of material misstatement and a qualifying statement whether the emissions data report conforms to the requirements of this article.

"Verification services" means services provided during verification as specified in section WCI.8, including but not limited to reviewing an owner's or operator's emissions data report, verifying its accuracy according to the standards specified in this section, assessing the owner's or operator's compliance with this section, and submitting a verification statement to the *[jurisdiction or its agent]*.

"Verification team" means all of those working for a verification body, including all subcontractors, to provide verification services for an operator. The lead verifier for the verification team shall be a lead verifier in the verification body.

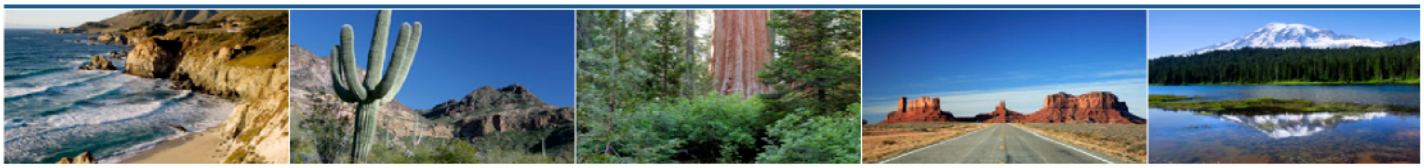
"Verifier" means an individual accredited by the jurisdiction or its designee to carry out verification services as specified in section WCI.8.

"Waste-derived fuel" means a fuel typically derived from waste and generally used as a substitute for conventional fossil fuels. Waste-derived fuels can include fossil fuels such as waste oil, plastics, or solvents; biomass such as dried sewage or impregnated saw dust; or fractions of both fossil fuels and biomass such as municipal solid waste or tires.

§ WCI.10 Global Warming Potentials

Owners and operators must use the global warming potential (GWP) values given in Table WCI.10-1 when converting emissions of greenhouse gases to metric tons of carbon dioxide equivalent (CO_2e), using Equation 1-1.

Table WCI.10-1. Global Warming Potential Factors for Greenhouse Gases			
Common Name	**Formula**	**Chemical Name**	**GWP**
Carbon dioxide	CO_2		1
Methane	CH_4		21
Nitrous oxide	N_2O		310
Sulfur hexafluoride	SF_6		23,900
Hydrofluorocarbons (HFCs)			
HFC-23	CHF_3	trifluoromethane	11,700
HFC-32	CH_2F_2	difluoromethane	650
HFC-41	CH_3F	fluoromethane	150
HFC-43-10mee	$C_5H_2F_{10}$	1,1,1,2,3,4,4,5,5,5- decafluoropentane	1,300
HFC-125	C_2HF_5	pentafluoroethane	2,800
HFC-134	$C_2H_2F_4$	1,1,2,2-tetrafluoroethane	1,000
HFC-134a	$C_2H_2F_4$	1,1,1,2-tetrafluoroethane	1,300
HFC-143	$C_2H_3F_3$	1,1,2-trifluoroethane	300
HFC-143a	$C_2H_3F_3$	1,1,1-trifluoroethane	3,800
HFC-152	$C_2H_4F_2$	1,2-difluoroethane	43
HFC-152a	$C_2H_4F_2$	1,1-difluoroethane	140
HFC-161	C_2H_5F	fluoroethane	12
HFC-227ea	C_3HF_7	1,1,1,2,3,3,3- heptafluoropropane	2,900
HFC-236cb	$C_3H_2F_6$	1,1,1,2,2,3-hexafluoropropane	1,300
HFC-236ea	$C_3H_2F_6$	1,1,1,2,3,3-hexafluoropropane	1,200
HFC-236fa	$C_3H_2F_6$	1,1,1,3,3,3-hexafluoropropane	6,300
HFC-245ca	$C_3H_3F_5$	1,1,2,2,3-pentafluoropropane	560
HFC-245fa	$C_3H_3F_5$	1,1,1,3,3-pentafluoropropane	950
HFC-365mfc	$C_4H_5F_5$	1,1,1,3,3-pentafluorobutane	890
Perfluorocarbons (PFCs)			
Perfluoromethane	CF_4	tetrafluoromethane	6,500
Perfluoroethane	C_2F_6	hexafluoroethane	9,200
Perfluoropropane	C_3F_8	octafluoropropane	7,000
Perfluorobutane	C_4F_{10}	decafluorobutane	7,000
Perfluorocyclobutane	$c\text{-}C_4F_8$	octafluorocyclobutane	8,700
Perfluoropentane	C_5F_{12}	dodecafluoropentane	7,500
Perfluorohexane	C_6F_{14}	tetradecafluorohexane	7,400



ATTACHMENT 2: GENERAL STATIONARY COMBUSTION

§ WCI.20 GENERAL STATIONARY COMBUSTION

§ WCI.21 Source Category Definition

General stationary fuel combustion sources are devices that combust solid, liquid, or gaseous fuel for the purpose of generating steam (or providing useful heat or energy) for industrial, commercial, or institutional use; or reducing the volume of waste by removing combustible matter. General stationary combustion sources are boilers, combustion turbines, engines, incinerators, and process heaters, and any other stationary combustion device that is not specifically addressed under the provisions for another source category in this rule.

Note: The source category definition may need to be revised after the remaining ER sections are completed.

§ WCI.22 Greenhouse Gas Reporting Requirements

The emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

(1) Total CO_2 emissions for fossil fuels, reported by fuel type.
(2) Total CO_2 emissions for all biomass fuels combined.
(3) Total CH_4 emissions for all fuels combined.
(4) Total N_2O emissions for all fuels combined.

(b) Annual fuel consumption:

(1) For gases, report in units of million cubic meters.
(2) For liquids, report in units of liters.
(3) For non-biomass solids, report in units of metric tons.
(4) For biomass-derived solid fuels, report in units of bone dry short tons or bone dry metric tons.

(c) Average carbon content of each fuel, if used to compute CO_2 emissions.

(d) Average high heating value of each fuel, as used to compute CO_2 emissions.

(e) Annual steam generation in pounds or kilograms, for units that burn biomass or municipal solid waste.

Please note that most of the calculation methodologies in this section currently accommodate inputs in English units, only, and not SI units. The section will be revised to allow inputs in SI units, as well as to provide applicable Canadian emission factors from "National Inventory Report 1990-2006: Greenhouse Gas Sources and Sinks in Canada – The Canadian

Government's Submission to the UN Framework Convention on Climate Change, April 2008." *(http://www.ec.gc.ca/pdb/ghg/inventory_e.cfm)]*

§ WCI.23 Calculation of CO_2 Emissions

For each fuel, calculate CO_2 mass emissions using one of the four calculation methodologies specified in this section, subject to the restrictions in §WCI.23 (e).

(a) Calculation Methodology 1. Calculate the annual CO_2 mass emissions by substituting a fuel-specific default CO_2 emission factor, a default high heating value, and the annual fuel consumption into the Equation 20-1:

$$CO_2 = Fuel \times HHV \times EF \times 0.001$$ **Equation 20-1**

Where:

CO_2 = Annual CO_2 mass emissions for the specific fuel type (metric tons).
Fuel = Mass or volume of fuel combusted per year (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).
HHV = Default high heat value of the fuel, from column 3 of Table 20-1 (mmBtu per mass or mmBtu per volume, as applicable).
EF = Fuel-specific default CO_2 emission factor, from column 5 of Table 20-1 (kg CO_2/mmBtu).
0.001 = Conversion factor from kilograms to metric tons.

(b) Calculation Methodology 2. Calculate the annual CO_2 mass emissions using a default CO_2 emission factor, and either Equation 20-2 or 20-3, as appropriate:

(1) Equation 20-2 of this section can be used for any type of fuel for which an emission factor is provided in Tables 20-1 or 20-2:

$$CO_2 = \sum_{p=1}^{n} Fuel_P \times HHV_P \times EF \times 0.001$$ **Equation 20-2**

Where:

CO_2 = Annual CO_2 mass emissions for a specific fuel type (metric tons).
n = Number of required heat content measurements for the year as specified in WCI.25.
$Fuel_p$ = Mass or volume of the fuel combusted during the measurement period "p" (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).
HHV_p = High heat value of the fuel for the measurement period (mmBtu per mass or volume).
EF = Fuel-specific default CO_2 emission factor, from column 5 of Table 20-1 or from Table 20-2 (kg CO_2/mmBtu).
0.001 = Conversion factor from kilograms to metric tons.

(2) Equation 20-3 of this section can be used for biomass solid fuels and municipal solid waste only:

$$CO_2 = Steam \times B \times EF \times 0.001$$ **Equation 20-3**

Where:

CO_2	=	Annual CO_2 mass emissions from MSW combustion (metric tons).
Steam	=	Total mass of steam generated by MSW combustion during the reporting year (lb steam).
B	=	Ratio of the boiler's maximum rated heat input capacity to its design rated steam output capacity (mmBtu/lb steam).
EF	=	Default carbon content for MSW, from column 5 of Table WCI.20-1 (kg CO_2/mmBtu).
0.001	=	Conversion factor from kilograms to metric tons.

(c) Calculation Methodology 3. Calculate the annual CO_2 mass emissions by substituting measurements of fuel carbon content, molecular weight (gaseous fuels, only), and the quantity of fuel combusted into the following equations. For solid fuels, the amount of fuel combusted is obtained from company records kept as provided in this rule. For liquid and gaseous fuels, the volume of fuel combusted is measured directly, using fuel flow meters (including gas billing meters). For fuel oil, tank drop measurements may also be used.

(1) For a solid fuel, use Equation 20-4 of this section:

$$CO_2 = \sum_{i=1}^{n} Fuel_i \times CC_i \times 3.664$$ **Equation 20-4**

Where:

CO_2	=	Annual CO_2 mass emissions from the combustion of the specific solid fuel (metric tons).
n	=	Number of monthly carbon content determinations for the year.
$Fuel_i$	=	Mass of the solid fuel combusted in month "n" (metric tons).
CC_i	=	Carbon content of the solid fuel, from the fuel analysis results for month "n"(percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).
3.664	=	Ratio of molecular weights, CO_2 to carbon.

(2) For a liquid fuel, use Equation 20-5 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \times 0.001$$ **Equation 20-5**

Where:

CO_2	=	Annual CO_2 mass emissions from the combustion of the specific liquid fuel (metric tons).
n	=	Number of required carbon content determinations for the year, as specified in WCI.25.

$Fuel_i$ = Volume of the liquid fuel combusted in month "n" (gallons).
CC_i = Carbon content of the liquid fuel, from the fuel analysis results for month "n" (kg C per gallon of fuel).
3.664 = Ratio of molecular weights, CO_2 to carbon.
0.001 = Conversion factor from kg to metric tons.

(3) For a gaseous fuel, use Equation 20-6 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \times \frac{MW}{MVC} \times 0.001 \qquad \textbf{Equation 20-6}$$

Where:

CO_2 = Annual CO_2 mass emissions from combustion of the specific gaseous fuel (metric tons).
n = Number of required carbon content and molecular weight determinations for the year, as specified in WCI.25.
$Fuel_i$ = Volume of the gaseous fuel combusted in a day or month, as applicable (scf).
CC_i = Average carbon content of the gaseous fuel, from the fuel analysis results for the day or month, as applicable (kg C per kg of fuel).
MW = Molecular weight of the gaseous fuel, from fuel analysis (kg/kg-mole).
MVC = Molar volume conversion factor (849.5 scf per kg-mole at standard conditions).
3.664 = Ratio of molecular weights, CO_2 to carbon.
0.001 = Conversion factor from kg to metric tons.

(d) Calculation Methodology 4. Calculate the annual CO_2 mass emissions from all fuels combusted in a unit, by using data from continuous emission monitoring systems (CEMS) as specified in (d)(1) through (d)(7).

(1) The operator of a facility that combusts fossil fuels or biomass and operates CEMS in response to federal, state, provincial, or local regulation, may use CO_2 or O_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in 40 CFR Part 75, Appendix F.

(A) The operator shall report CO_2 emissions for the report year in metric tons based on the sum of hourly CO_2 mass emissions over the year, converted to metric tons.
(B) If the operator of a facility that combusts biomass uses O_2 concentrations to calculate CO_2 concentrations, annual source testing must demonstrate that calculated CO_2 concentrations when compared to measured CO_2 concentrations meet the Relative Accuracy Test Audit (RATA) requirements in 40 CFR Part 60, Appendix B, Performance Specification 3.

(2) The operators of a facility that combusts municipal solid waste or other waste-derived fuels and operates a CEMS in response to federal, state, provincial, or local regulations must use CO_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in 40 CFR Part 75, Appendix F.

(A) Annual CO_2 emissions shall be reported in metric tons based on the sum of hourly CO_2 mass emissions over the year.

(B) Emissions calculations shall not be based on O_2 concentrations.

(3) The operator of a facility that combusts MSW or other waste-derived fuels and calculates CO_2 emissions using the methodology provided in WCI.23(d)(2) shall determine the portion of emissions associated with the combustion of biomass-derived fuels using the method provided in WCI.23(f).

(4) An operator who uses CEMS data to report CO_2 emissions from a facility that co-fires fossil fuels with biomass or waste-derived fuels that are partly biomass shall determine the portion of total CO_2 emissions separately assigned to the fossil fuel and the biomass-derived fuel using the method provided in WCI.23(f), if applicable. The operator who co-fires pure biomass with fossil fuels may elect to calculate CO_2 emissions for the fossil fuels using methods designated in WCI.23(b)(3) by fuel type and then subtract the fossil fuel related emissions from the total CO_2 emissions determined using the CEMS based methodology.

(5) For any units for which CO_2 emissions are reported using CEMS data, the operator is relieved of the requirement to separately report process emissions from combustion emissions or to report emissions separately for different fossil fuels when only fossil fuels are co-fired. In this circumstance, operators shall still report fuel use by fuel type as otherwise required.

(6) If a facility is subject to requirements in 40 CFR Part 60 or 40 CFR Part 75 and the operator chooses to add devices to an existing continuous monitoring system for the purpose of measuring CO_2 concentrations or flue gas flow, the operator shall select and operate the added devices pursuant to the requirements in 40 CFR Part 60 or Part 75 that apply to the facility. If the facility is subject to both 40 CFR Part 60 and 40 CFR Part 75, the operator shall select and operate the added devices pursuant to the requirements in 40 CFR Part 75.

(7) If a facility does not have a continuous emissions monitoring system and the operator chooses to add one in order to measure CO_2 concentrations, the operator shall select and operate the CEMS pursuant to the requirements in 40 CFR Part 75.

(A) The operator shall use CO_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in 40 CFR Part 75, Appendix F.
