Applying default values for project emissions baselines and reporting period emissions reductions that do not involve project-specific evaluation could lead to the over-compensation of offset projects, and the award of offset compliance units for emissions reductions that are not real. An example is the potential for confusion of the concepts of a standardized baseline scenario and a project-specific emissions baseline.[16] A standardized baseline scenario evaluates a sector or subsector of similar activities, arriving at an average level of performance or establishing a typical common activity. It is in effect a scenario of what would have occurred in the absence of a project under common practice — in this case a standardized metric applicable to multiple, similar project activities. In contrast, a project emissions baseline should be project-specific, as it should represent the *lesser*[17] of actual emissions prior to implementation of a project or the emissions that result from application of a baseline scenario to the specific emissions sources within a project boundary. In practice, the baseline scenario must be applied to the specific greenhouse gas emissions sources and sinks addressed by an offset project in order to derive a project-specific emissions or sequestration baseline.

If offset compliance units are calculated directly against a standardized baseline scenario, the baseline scenario must be emissions based (e.g., tons of carbon sequestered per acre, or emissions per unit of output), which limits the types of activity metrics that could be used as an activity baseline. Furthermore, a qualifying project could potentially have actual baseline emissions above or below those that would be calculated through application of the baseline scenario to the specific emissions sources and sinks addressed by the project (e.g., a forestry management offset project, where actual carbon sequestered per acre prior to implementation of the project exceeds that which would be derived through application of the activity baseline to the number of acres of land within the project boundary). If emissions reductions are credited against the

---

standard to qualify as eligible offset projects (the performance standard is an annual percentage emissions rate of total SF_6 used by the entity that is emitted per year). This emissions performance standard is one of the methods used to evaluate project additionality. However, while an emissions standard is used to evaluate additionality (the entity must have an emissions rate for its baseline year that is lower than the performance standard), actual baseline emissions as monitored for the entity are used as the basis against which emissions reductions are calculated and offset compliance units are awarded. This is because qualifying entities that meet the performance standard could have actual baseline year SF_6 emissions that are significantly lower than the performance standard. As a result, calculation of actual baseline emissions is necessary to ensure that a project is not over compensated with awarded offset compliance units.

[16] Activity baseline is a term used in current pending U.S. legislation, and is comparable to a baseline scenario.

[17] In the case of a sequestration offset project, the *greater* value of carbon sequestered would be used as the project baseline.

standardized baseline scenario, this would lead to over-crediting of offset compliance units for the project for the forestry management scenario above.

If emissions or sequestration baselines are not project-specific, the program could potentially issue offset compliance units for emissions reductions or removals that did not actually occur as a result of the project, due to the relative accuracy of the baseline scenario. This is because a standardized baseline scenario is a generalized proxy measure for evaluating project additionality for a category of projects and not necessarily a method for determining individual project baseline emissions. Avoiding this outcome requires quantification of baseline emissions or removals for all project emissions sources and sinks prior to the implementation of the project.

Western Climate Initiative

Auction Design Draft Recommendations

WCI Partners Meeting – Seattle, WA

May 20, 2010

Auction Design

- Released white paper on April 14, 2010
- Held stakeholder conference call on April 29, 2010
- Stakeholder comment period closed May 7, 2010
- Draft recommendations to be released Summer 2010

Auction Principles

- The following auction design principles inform decisions regarding the auction and guide the overall WCI market design effort.

The eight principles for auction design are:

Fairness	*Efficiency*
Effective Oversight	*Transparency & Openness*
Administrative Simplicity and Cost	*Accountability*
Compatibility with other markets	*Conflict of Interest*

Recommended Parameters

The following ten parameters were discussed in the white paper:

- *Auction Format*
- *Unsold Allowances*
- *Vintages*
- *Lot Size*
- *Avoiding Market Manipulation*
- *Timing and Frequency of Auctions*
- *Reserve Price*
- *Participant Access*
- *Financial Assurance*
- *Information and Transparency*

Draft Recommendations

Auction Format:

- Describes how participants can bid on allowances
- Majority stakeholder support for single round, sealed bid, uniform price auctions. Stakeholder suggestion to review the auction format after some time.

Draft Recommendations:

- *single round*
- *sealed bid*
- *uniform price*

Draft Recommendations

Reserve Price:

- Refers to the minimum allowance price that the seller will accept.
- Stakeholder comments indicate support as part of a price stability mechanism

Draft recommendation:

- *further analysis required*

Draft Recommendations

Unsold Allowances:

- Stakeholder support for use of unsold allowances for cost containment – unsold allowances released back into the market at certain prices.

Draft Recommendations:

- *partners will retire a fraction of the unsold allowances*
- *remaining fraction will be retained for use according to WCI partner direction.*

Draft Recommendations

Vintages:

- Vintage allowances refer to allowances sold prior to the compliance period for which they become valid.
- Stakeholder support for sale of vintages.

Draft Recommendations:

- *Include the sale of vintages.*
- *Separate auctions held for different vintages.*
- *Each auction day holds an auction for the current vintage year and a future vintage.*

Draft Recommendations

Lot Size:

- Refers to the number of allowances bundled together for offering as an auction unit.
- Stakeholder support for lot size of 1,000

Draft Recommendation:

- *lot size of 1,000*

Draft Recommendations

Timing and Frequency of Auctions:

- Stakeholder support for quarterly auctions, some support for auctions prior or post compliance period.

Draft Recommendation:

- *quarterly auctions*

Note: The last auction may be held at the end of the compliance period, prior to true-up.

Draft Recommendations

Participant Access:

- Stakeholders supported open access, and non-competitive bids. Limited support for consignment option.

Draft Recommendation:

- *auction open to anyone able to meet the qualification requirements.*

Note: Auction qualification requirements TBD.

Draft Recommendations

Financial Assurance:

- Stakeholders supported financial assurance

Draft Recommendation:

- *100% financial assurance*

Note: WCI will ensure a short time lag between the auction bid and settlement.

Draft Recommendations

Information and Transparency:

- Stakeholders supported information transparency but details varied.

Draft Recommendation:

- *public disclosure of auction results including:*
  - *the clearing price,*
  - *identity of winning bidders and*
  - *number of allowances awarded.*

Draft Recommendations

Avoiding Market Manipulation:

- Refers to options for minimizing collusion, manipulation and hoarding.

Draft Recommendation:

- *include auction monitoring, purchase limit (details TBD), and reserve price.*

Next Steps

- Finalize draft recommendations (May/June 2010)
- Brief partners on draft recommendations (June 2010)
- Post draft recommendations for stakeholder comment (June 2010)
- Incorporate stakeholder feedback
- Include final recommendations in the detailed program design document (Summer 2010)

Current Congressional Action on Climate

Judi Greenwald
Vice President of Innovative Solutions
Pew Center on Global Climate Change

Western Climate Initiative
May 20, 2010

Kerry-Lieberman Overview

- Result of several months of bipartisan negotiations
- Intended to be released April 26 as Kerry-Graham-Lieberman, though delayed after immigration controversy
- Eventually released on May 12 as Kerry-Lieberman
- Undergoing six-week EPA economic analysis, which should be finished in early June

Overview

- Coverage: 85% of U.S. GHG emissions under the cap
- Cap: 17% below 2005 levels by 2020; 83% below by 2050
- Threshold: Covers entities emitting >= 25K tons CO_2e; EPA may lower reporting threshold to 10K
- Offsets: 2 billion tons domestic & int'l
- Cost containment: Strategic reserve of 4 billion allowances available if allowance prices rise above trigger price
- Clean Air Act limitation: GHGs not regulated as criteria, hazardous, or international air pollutants under CAA
- State role: GHG cap-and-trade pre-empted; other state programs unaffected
- Allowance distribution: Multiple categories
- Bipartisan Senate Energy Committee ACELA bill may be incorporated in the future

Emissions Cap

- Reduction targets
  - 95.25% of 2005 levels by 2013
    - (slightly more aggressive than Waxman-Markey)
  - 83% of 2005 levels by 2020
  - 58% of 2005 levels by 2030
  - 17% of 2005 levels by 2050
- Mandatory reporting by 2011 for large sources with >25k tons/year of emissions; or lower at EPA's discretion
- EPA's discretion as to whether vehicle fleets with >25k tons/year must report

GHG Compliance Program

- Compliance begins in 2013 for:
  - Utilities
  - Refineries (onsite emissions)
  - Refined product providers (transportation fuel)

- Compliance begins in 2016 for:
  - Industrial sources
  - Natural gas local distribution companies

- Allowances are surrendered on an annual basis for all sources except for transportation fuels which is done on a quarterly basis.

- One-year compliance period with unlimited next year borrowing (similar in effect to two-year compliance period)

Transportation GHG Coverage

- 93% of GHG emissions from transportation are covered. Excludes ships and boats, pipelines, and lubricants.
- Transportation sector is covered under the cap but does not participate in the auction or trade with other sectors.
- EPA is ordered to set aside allowances from auctions by estimating the total need of the transport sector from existing data. Refined product providers don't compete with other sectors.
  - EPA can also borrow from one year ahead on a limited basis if needed.
- Refined product providers must pay the EPA quarterly for allowances as compliance
  - The amount is equal to the most recent auction clearing price for allowances in the cap-and-trade program for the other sectors X the attributable GHG emissions of the covered refined product during the previous quarter
  - Transportation sector may not trade, sell, bank or borrow allowances
  - The allowance price is announced at least 30 days before the beginning of the compliance quarter so that refined product providers can adjust future product prices accordingly

PEW CENTER ON Global CLIMATE CHANGE

Transportation GHG Coverage (cont'd)

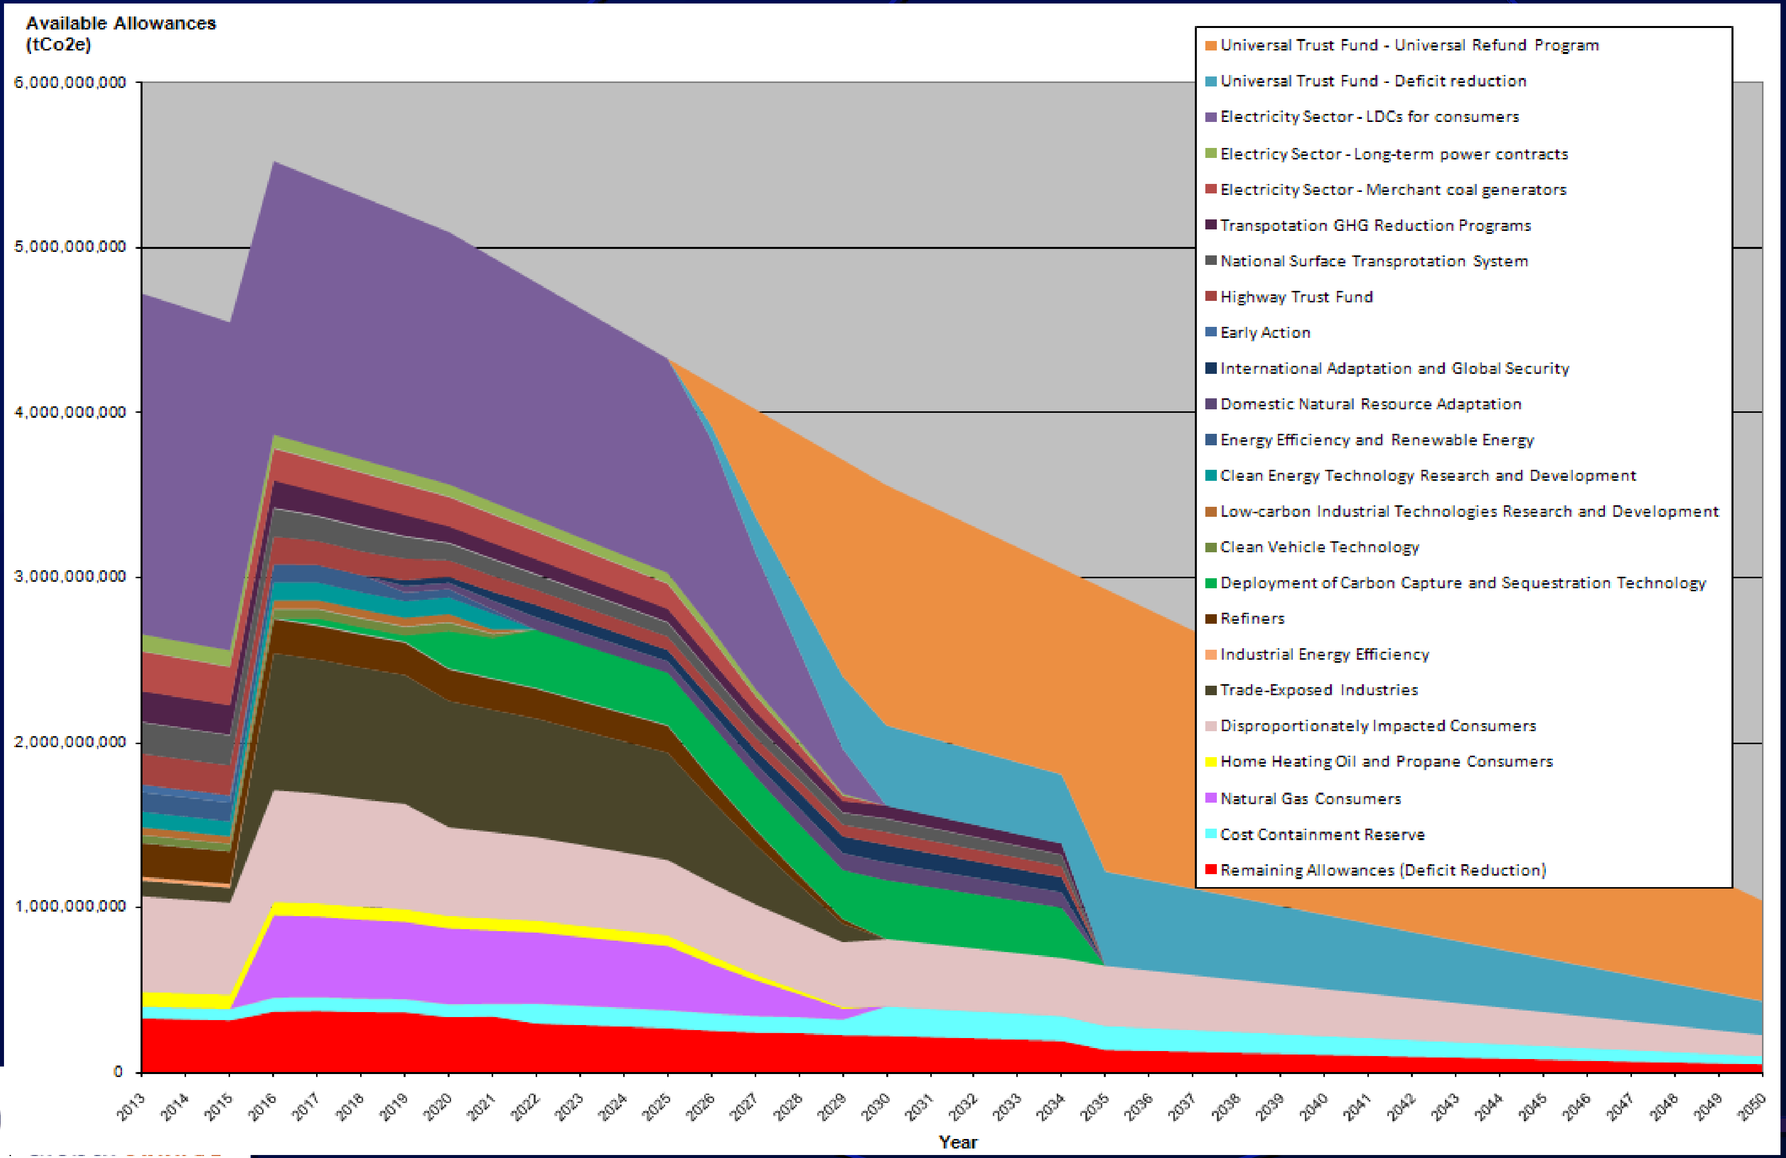
- EPA will set the percentage of allowances from the general auction pool that can be set aside for transportation. If EPA estimates of allowances for the transportation sector are too low, they can borrow from the following year's pool of allowances. If EPA overestimates, then those allowances are returned to the auction pool for the following quarter's auction.
- It is unclear what happens if transportation needs more allowances than what is available in the auction pool throughout the life of the program

Allowance Markets for other Sectors

- Unlimited banking
- Unlimited one-year borrowing w no interest
- Borrowing up to 15% of compliance obligation with vintage years 1-5 beyond calendar year at 8% interest per year
- Trading restricted to compliance entities and regulated carbon market participants
  - Restrictions to prevent excessive speculation
  - All allowances must be bought and sold on an exchange

PEW CENTER ON Global CLIMATE CHANGE

Allowance Distribution



EITE Provisions

- Allowance rebates for EITE ~ W-M
- Require surrender of allowances for imports in specified sectors, unless President determines otherwise

Credit for Early Action

- 1% of allowance value from 2013-2015 goes for early action
  - 2/3 of this amount goes to states with cap and trade programs
  - 1/3 of this amount goes to early action offset credits

Cost Containment

- Up to 2 billion tons of offsets system wide can be used for compliance (25% of which can come from international sources)
  - International limit may be increased up to 1 billion tons if the Administrator determines domestic supply is insufficient, but 2 billion ton overall limit still applies
- President may recommend to Congress to increase or decrease total number of offsets
- Domestic offset program similar to Stabenow bill

Cost Containment

- Price collar with a floor at $12/ton and a ceiling of $25/ton escalating respectively at 3% and 5% above inflation annually
- Strategic reserve contains 4 billion tons allowances over the life of the program pulled from future program years
  - Allowances are sold at the ceiling rate of that year
  - Covered entities can purchase reserve allowances up to 90 days before the date of compliance for up to 15% of their compliance obligation in that year
  - Must use strategic allowances within one year
  - Revenue from Strategic Reserve auction to be used to purchase REDD offsets which will be used to replenish the Reserve

Nuclear Provisions

- Increases nuclear loan guarantee funding to $54 billion (from $18.5 billion)
- Expands standby support regulatory risk insurance to cover up to 12 reactors (rather than 6)
- Includes provisions to expedite nuclear licensing
- Expands tax credits for nuclear power investments and generation

Offshore Oil and Gas

- Provides states with 37.5 percent of government revenue from drilling in offshore areas previously subject to drilling moratoria
- Allows states to prohibit offshore drilling within 75 miles of their coasts
  - Subject to Department of Interior impact analysis, any states directly impacted by potential oil spills in newly opened offshore areas can prevent leasing from proceeding

Coal Provisions

- Federal agencies to develop national CCS deployment strategy
- CCS trust fund to finance first 10 GW of commercial-scale demonstration projects
- Administrator to design legal framework for regulating geologic sequestration sites
- Authorizes bonus allowances in two phases
- Performance standards for new coal-fueled power plants. New facilities initially permitted after January 1, 2020 subject to a performance standard of a 65% reduction in CO_2 emissions. Plants permitted between 2009 and 2019 are subject to an annual CO_2 emission reduction of 50%
- Provides accelerated depreciation and investment tax credits for early replacement or retrofit of existing coal plants not subject to the CO_2 performance standard

Transportation Funding

- Most funds go to Highway Trust Fund and TIGER grant program;may or may not reduce GHG emissions
- Transportation Planning Program (up to $1.875 billion)
- Clean Vehicle Technology Fund (fixed % of allowances)
- Natural Gas Vehicle Support (separate funding mechanism)

PEW CENTER ON Global CLIMATE CHANGE

State Highlights

- Pre-empts state cap and trade programs; does not pre-empt other state actions
- Provides for exchange of state for federal allowances
- Less allowance value to states than under W-M
- States receive allowance value for consumer protection for home heating oil
- Offshore drilling: revenue sharing and veto power

State Highlights (cont'd)

- Directs Administrator to consult with regional initiatives in developing regulations for implementation
- Early action allowances available for states who have enacted cap and trade programs
- No money for state adaptation programs

What happens next?

- Reading, digesting, summarizing and analyzing K-L
- Senate Majority Leader Reid decides how to proceed
- Conditions for legislative success
  - Administration engagement
  - Senate Republican engagement

Market Oversight
Draft & Final Recommendations

Partner Meeting, Seattle, Washington

May 20, 2010

Market Oversight Objectives

- "The recommended design will provide opportunities to obtain low-cost emission reductions through emission trading, allowance banking, and inclusion of an offsets component."

WCI Design Recommendations, September 23, 2008

- "The WCI Partner jurisdictions and stakeholders want appropriate safeguards and oversight of the allowance and offset credit trading markets and want them to function efficiently."

Materials for Markets Workshop, April 9, 2009

Principles

- **Efficiency**: The market is designed to operate efficiently so that greenhouse gas (GHG) emission reductions can be achieved at the least cost. An efficient market means that allowance and offset credit prices reflect supply and demand, and accurately reveal the value of allowances and offset credits.

- **Effective Oversight**: The design and oversight of the market is effective in preventing or minimizing fraud, manipulation, and speculative excess.

Oversight Recommendations Process

- Public workshop April 9, 2009
- White Paper November 18, 2009
- Stakeholder call December 2, 2009
- Draft Recommendations paper April 1, 2010
- Stakeholder call April 20, 2010
- Holdings limit consultant’s report, May 14, 2010
- Stakeholder call May 25, 2010
- Final Recommendations paper
- Detailed Program Design Summary

Allowances, Offset Certificates, and Derivatives

- #1: Treat Compliance Instrument Derivatives as Commodity Derivatives for Market Oversight Purposes
- #2: Information on Derivatives Positions
- #3: Treat Allowances and Offset Certificates Identically for Market Oversight Purposes

Market Participants

- #4: Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System
- #5: Do Not Limit Market Participation to Compliance Entities
- #6: Do Not Require Registration of Intermediaries as Market Professionals

Holdings and Transfers

- #7: Holdings Limits
- #8: Require Use of a Central Limit Order Book for Secondary Market Transactions
- #9: Require Reporting of Beneficial Ownership
- #10: Information Required for Compliance Instrument Transfer
- #11: Holdings and Transfer Information Disclosed to Public
- #12 Market Monitoring

#2: Information on Derivatives Positions

- Mirror information to derivatives regulators for real-time monitoring
- Forensics
- Support for "providing appropriate technical and other compliance assistance" (Design Rec., §12.5)

- Data currently not collected
- Could not see whole market
- Infrastructure costs
- Debate over transparency benefits

#8 Central Limit Order Book

- Proposed as a way to get real-time transparency for prices, bids, and offers
- Stakeholder comment mixed, but largely unfavorable
- We have a refined proposal that addresses some concerns, but not all; still prescriptive in some ways
- Primary policy question is the value of real-time price transparency

Status

- Recommendations 1, 3 – 5, 6 (changed), 9 – 11 fairly solid
- #7 Holdings Limits: would need to work out details, but could likely be a final recommendation
- #12 Third-party market monitor: No final recommendation yet
- #2 Reporting to central derivatives repository: No final recommendation yet
- #8 Trading only on defined electronic platforms: No final recommendation yet

For More Information:

Western Climate Initiative

Public Comments
on
WCI Offset Criteria
Draft Recommendations

Seattle, Washington

May 20, 2010

Background

- May 12th, 2010 was the comment deadline for the WCI Offsets Criteria Draft Recommendations Paper
- Comments from 27 people/organizations were received
- This presentation summarizes the public comments by Offset Committee draft recommendation number

3.1 Offset Definition

- Add the term “avoidance” in the offsets definition.
- Include the notion that the reduction or removal is compensating for an emission elsewhere, and that the offset is a permit and does not create a new property right.
- Do not allow revoking a credit after certification otherwise you risk losing market confidence regarding the permanence and the value of a credit.

3.2.1 Offset Ownership

- Include guidance on who will have the authority to resolve ownership issues.
- Use a flexible approach to ownership based on the project proponent, similar to the approach used by CDM (“the focal point”) that does not have the program authority resolving issues of “ownership”.

3. 2.2. Use of Recommended Protocols

- Offset protocols should be fungible and harmonized across WCI.
- Provide further detail on the protocol review process.
- Create a central body to review and approve Partners' protocols.
- Have an open and timely process to adapt existing protocols and introduce new protocols.
- Protocols within sectors and within project types should use the same basic approaches to baseline determination, additionality, permanence, leakage, enforcement and environmental integrity.

3.2.3 Geographic Limits

- Allow WCI Partner jurisdictions to issue offset credits to qualified offset projects located outside of North America.
- Limit the geographic scope to just the WCI region.
- Clarify that offsets are fully fungible within the WCI structure

4.1 Real

- Consider recognizing reductions at sources not controlled by project developers under certain limited circumstances.
  - Indirect avoided deforestation
  - Electricity energy efficiency

4.2.1 Quantification

- Adopt only protocols with a high level of confidence that the reductions occurred can be establish.
- Develop procedures for re-evaluating quantification methodologies and publication of changes in advance
- Change the language in section 4.2.1.3 to "means erring on the side of caution, and it requires balancing of standards for accuracy with the need for cost-effective offset projects".
- Create an independent panel of scientists to review and make recommendations for updating each protocol. Accuracy should not be sacrificed in order to lower the cost of an offset.
- Clarify what is meant by "best available science".

4.2.2 Leakage

- Provide guidance to assess market leakage.
- Do not require leakage analysis for projects with no leakage risk.
- Provide clearly outlined policies and procedures for determining and quantifying leakage in each protocol.
- Qualify the use of “functional equivalence” evaluations in assessing leakage.

5.1 Additionality and Baseline

- Do not "reflect the most stringent regulatory requirements and legal requirements of any WCI Partner jurisdiction"; rather, evaluate on a case-by case basis the implications of using the most stringent legal requirements to set baselines and eligibility criteria.
- Do not rely exclusively on baselines as this would fail to comply with the rigorous definition of additionality.

5.2.1 Eligibility Date

- Move the eligibility date of September 23, 2008 to an earlier date, such as:
  - January 1st, 2000 to reward progressive companies
  - June 1st, 2005 Date of California Executive Order
  - January 1st, 2001 consistent with Waxman-Markey bill.
  - January 1st , 2006 as the proliferation of cap-and-trade opportunities reached a tipping point at that time
  - August 31, 2006 when California's AB 32 was signed into law
  - December 31, 2006 for consistency with the passage of California's Global Warming Solutions Act of 2006 (AB 32) and CARB preliminary draft regulations
  - Same as CAR or CCX
  - January 1, 2012

5.2.2 Crediting Period

- Do not limit the number of crediting period renewals.
- 15 years for sequestration projects.
- 50 year minimum for reforestation and improved forest management sequestration projects.
- 5 years for non-forestry projects.
- 10 years if project is subject to a comprehensive re-evaluation of additionality at the time of renewal
- Base the determination of crediting periods for certain project types on science and objective data.
- Allow an offset project to continue generating credits if a law is later enacted that makes the project activity mandatory.

6.1 Permanence

- intentional reversals should never be permitted and discounts or pro-rating should be consistent with this principle with strict penalties for reversals that are deemed intentional.
- Do not allow pro-rated short-term projects.
- Use measures that have proven to be successful in other areas to manage reversals and permanence, such as an assurance factor and a buffer reserve of credits.
- Have a shorter permanence requirement and investigate other means of achieving permanence that may be appropriate for some projects (e.g. a conservation easement).

7.1.1 Verification and 7.2.1 Validation

- Validation is absolutely necessary
- Do not require validation.
- Have consistent accreditation requirements across the WCI.
- Provide explicit guidance on what is a reasonable level of assurance down to the protocol level.

7.2.2 Enforcement

- Stringency of each jurisdiction's enforcement requirements should be designed to reduce opportunities for abuse.
- Apply penalties consistently across the WCI.

7.2.3.1 Material

- Errors in small projects may exceed materiality thresholds but only affect a small number of tons so could be exempted or subject to a different threshold.

8.1 Transparency

- A registry structure may facilitate disclosure for aggregated projects
- Timely public disclosure of project documents would allowing for public comments on proposed methodologies, projects, and credit issuance
- Regulators should explain why public comments were or were not taken into account.
- Establish registries that are ultimately linked to each other and contain standardized information.

8.2 Co-Benefits of Offsets

- Prioritize projects with positive co-benefits.
- Require a report on co-benefits as part of the offset registration and reporting process.

8.3 Assessment of Environmental or Social impacts

- Remove section 8.3.1
- Avoid additional assessment requirements to those already in place at the jurisdictional levels.
- Do not develop protocols that would require further analysis and mitigation of any negative environmental and socioeconomic impacts.
- Subject sequestration projects to further safeguards.
- Require offset projects to do no net harm

Other/General Comments

- Interest in how offsets/allowances from other systems are going to be considered
- Interest in the protocol and project approval processes
- Confusion over where WCI is including Market Oversight
- Establish a positive list (like the one included in the American Power Act).
- Include special program-wide provisions for small projects.

Next Steps

- WCI Offset Committee Task Team 1 will review and recommend where public comments should be incorporated into the revised recommendations for Partner Jurisdiction consideration

Western Climate Initiative

Proposed Harmonization of Essential Requirements for Mandatory Reporting with EPA Mandatory Reporting Rule

Partner Meeting, Seattle, Washington

May 20, 2010

Background

- July 16, 2009, Final ERs published
- As part of Summer 2009 re-prioritization, Partners directed Reporting Committee to harmonize ERs with EPA Mandatory Reporting Rule
- September 22, 2009, final EPA rule published

Principles

1. A U.S. facility should be able to comply with both the MRR and a WCI jurisdiction's reporting requirements by following a single set of monitoring, recordkeeping and reporting requirements.
2. The quantification methods included in the amended ERs must be sufficiently reliable and accurate to be employed in a (GHG) cap-and-trade program.
3. The amended ERs must remain suitable for use in Canadian WCI jurisdictions.

Process

- ERG prepared tables comparing each subpart of EPA rule to relevant ERs
- Committee reviewed each difference between the EPA rule and the ERs and decided whether:
  - The EPA approach could be adopted; or
  - The WCI approach need to be retained.

Process (cont'd)

- ERG and Committee prepared markup of EPA rules to conform to WCI requirements
- In most cases, the EPA rule could be modified without requiring a change to the EPA reporting system, e.g. by requiring a higher "tier" that is already available in and allowed by the EPA rule (next slide).
- During discussions of the GHG Data Exchange Integrated Project Team, EPA has indicated a willingness to augment its reporting system to accommodate additional data elements needed by state and regional programs.

Example Markup

(3) The Tier 3 Calculation Methodology:

(i) May be used for a unit of any size at any facility that combusts any type of fuel listed in Table C-1 of this subpart (except for MSW), unless the use of Tier 4 is required.

(ii) Shall be used for a unit ~~with~~ that has a maximum rated heat input capacity greater than 250 mmBtu/hr or is located at a facility subject to verification~~that combusts any type of fuel listed in Table C-1 of this subpart (except MSW)~~, unless either of the following conditions apply:

Subparts/Industries Covered

Subpart A—General Provisions
Subpart C—General Stationary Combustion
Subpart D—Electricity Generation
Subpart E—Adipic Acid Production
Subpart F—Aluminum Production
Subpart G—Ammonia Production
Subpart H—Cement Production
Subpart K—Ferroalloy Production
Subpart N—Glass Production
Subpart O—HCFC-22 Production and HFC-23 Destruction
Subpart P—Hydrogen Production

Subparts/Industries Covered (cont'd)

Subpart Q—Iron and Steel Production
Subpart R—Lead
Subpart V—Nitric Acid Production
Subpart X—Petrochemical Production
Subpart Y—Petroleum Refineries
Subpart Z—Phosphoric Acid Production
Subpart AA—Pulp and Paper
Subpart CC—Soda Ash Manufacturing
Subpart GG—Zinc Production

Next Steps

- U.S. jurisdictions to implement harmonized ERs by adopting incorporation-by-reference rules based on markup
- Canadian jurisdictions have determined that incorporation-by-reference of EPA rule or modified version of EPA rule is not feasible
- A version of the July 2009 ERs modified to conform in substance with the harmonized ERs is needed for the provinces

Western Climate Initiative

Final Complementary Policies White Paper

May 20, 2010

Table of Contents

1 Background and Purpose 3
1.1 The Role of Complementary Policies 4
1.2 Evaluating and Prioritizing Policies 5
1.3 Policies Recommended for Evaluation 6
1.4 Next Steps 8
2 Tier 1 Policies 9
2.1 Energy Production 9
2.1.1 Small-Scale Renewable Energy Resources 9
2.1.2 Combined Heat and Power 12
2.1.3 Hydropower 14
2.1.4 Emissions Performance Standards for Electric Generating Units 16
2.2 Energy Efficiency and Conservation 17
2.2.1 Energy Efficiency Targets 17
2.2.2 Energy Efficiency Programs and Incentives 18
2.3 Transportation 20
2.3.1 Low-Carbon Fuel Standard 20
2.3.2 Freight Transportation Infrastructure and Heavy Duty Vehicles 22
2.4 High Global Warming Potential (GWP) Gases 24
2.4.1 Regulatory Measures for High GWP Gases 24
3 Tier 2 Policies 25
3.1 Energy Production 25
3.1.1 Carbon Capture and Sequestration 25
3.1.2 Tradable Renewable Energy Certificates 27
3.2 Energy Efficiency and Conservation 29
3.2.1 Tradable Energy Savings Credits 29
3.3 Transportation 32

3.3.1 Pay-as-You-Drive Insurance 32
3.3.2 Electric and Alternative Fuel Vehicle Infrastructure 32
3.4 Agriculture 33
3.4.1 Agricultural Anaerobic Digesters 33
3.5 Waste 34
3.5.1 Landfill Methane Reduction 34

4 Tier 3 Policies 36
4.1 Transportation 36
4.1.1 Vehicle Emissions Labeling 36
4.1.2 Medium- and Heavy-duty Vehicle Hybridization 36
4.1.3 Transport Refrigeration Units 36
4.2 Industrial Sector 37
4.2.1 Emissions Performance Standards for Major Industrial Sources 37

5 Important Policies Addressed in Other Venues 38

Appendix 1: Complementary Policies: Capped vs. Uncapped Sources and Sectors 41

Appendix 2: Stakeholder Comments on Draft White Paper 42

Appendix 3: List of Acronyms 48

1 Background and Purpose

The Western Climate Initiative (WCI) Partners have recommended a comprehensive regional effort to reduce emissions of global warming pollution, combining a broad cap-and-trade program with complementary policies to achieve the WCI 2020 regional emissions goal.[1] Complementary policies can address market barriers that would otherwise limit the use of low-cost greenhouse gas (GHG) emission-reduction options and reduce emissions from sources excluded from the cap-and-trade program. Thus, complementary policies can lower the overall cost of reducing GHG emissions. This view is supported by the 2008 economic analysis of WCI's cap-and-trade design, which incorporated complementary policies related to energy efficiency and tailpipe emission standards. The analysis found that the WCI 2020 reduction goals can be achieved with small overall net savings due to reduced energy expenditures exceeding the direct costs of greenhouse gas emission reductions.[2]

As part of the WCI 2009-2010 Workplan, the WCI Partner jurisdictions formed the Complementary Policies Committee. The charge of the Committee is to recommend to the WCI Partner jurisdictions those policies which, if harmonized across multiple states and provinces both within and outside the WCI Partner jurisdictions, would help achieve the regional emissions reduction goals and assist with the transition to a low-carbon economy. By harmonizing complementary policies, the WCI Partner jurisdictions intend to foster increased market certainty, encourage trade among participating jurisdictions, reduce administrative costs and streamline regulatory procedures.

As a first step, the Committee prepared this white paper to solicit input from stakeholders on:

- the policies it recommends for further evaluation as outlined in its workplan;
- the Committee's recommended evaluation criteria;
- key issues or barriers to harmonization; and
- benefits that could accrue to the Partner jurisdictions and businesses that operate in more than one jurisdiction, if implementation is harmonized.

The Committee submitted the draft white paper for public review on December 1, 2009. The Committee held a webinar on December 7, 2009 to present the paper to stakeholders and clarify any questions they might have. At the end of the 60-day comment period on January 29, 2010, a total of 17 comments had been received. WCI carefully considered all public comments and amended the initial draft to produce a final white paper. Appendix 2 discusses

[1] The WCI GHG reduction goals, established in 2007, call for an aggregate reduction in the region of 15 percent below 2005 levels by 2020 and, over the long term, a reduction that significantly lowers the risk of dangerous threats to the climate. *See* http://www.westernclimateinitiative.org/component/remository/general/Emission-Reduction-Goal-Aug-2007/.

[2] *See* WCI, Appendix B: Economic Modeling Results, Sept. 23, 2008, at: http://www.westernclimateinitiative.org/component/remository/Economic-Modeling-Team-Documents/.

the comments received and provides WCI's responses. The specific comments can be reviewed at http://www.westernclimateinitiative.org/public-comments/document/14.

This paper also discusses why and when policies complementary to a cap-and-trade program are useful, how complementary policies help achieve the WCI's GHG reduction goals, and which policies would affect emissions under the cap and which would affect emissions from sectors and sources outside the cap.

1.1 The Role of Complementary Policies

The WCI Partner jurisdictions have designed an economy-wide, cap-and-trade program to reduce emissions in accordance with the WCI GHG reduction goals, while maximizing market efficiency in achieving those reductions. Putting a price on GHG emissions will result in investments in technologies and other actions that will reduce emissions. However, some activities that reduce emissions cost-effectively do not respond to this price signal: so-called market barriers prevent or impede the diffusion of cost-effective technologies and practices that could mitigate GHG emissions. The distribution of the costs and benefits of improving a building's energy performance is an instructive example of a market barrier. In commercial buildings, the cost of improvements is typically borne by the owners, however, the benefits are enjoyed by the tenants through lower energy bills. Because building owners do not realize directly the financial benefit from their efficiency investments, they are less likely to make those investments. A well designed energy efficiency program can provide the needed incentive to make those investments.

Complementary policies achieve a variety of objectives in addition to reducing GHG emissions and removing market barriers. They can:[3]

- Achieve reductions outside (or below) the cap
- Encourage investments in low-carbon technologies
- Lower the cost per metric ton of reductions in GHG emissions covered by the cap-and-trade program
- Lower the cost of transitioning to a low carbon economy
- Prevent emissions and economic leakage
- Create and retain clean energy jobs

Given the role complementary policies play in the transition to a low-carbon economy, a comprehensive program that combines a cap-and-trade program with targeted complementary policies will deliver emissions reductions at a lower cost to consumers, measured as the cost per ton of avoided GHG emissions.[4]

[3] Western Climate Initiative 2009-10 Workplan, updated June 23, 2009, p, 36.
[4] *See* Testimony of Richard Cowart, Regulatory Assistance Project, Before the Committee on Energy and Commerce Subcommittee on Energy and Environment, U.S. House of Representatives, April 23, 2009, "The Consumer

Complementary policies will interact with the GHG emissions cap differently at the start of the program than after it has begun. Prior to the commencement of the cap-and-trade program, complementary policies may reduce emissions at sources covered by the program, decreasing the overall emissions reductions required to be achieved by the cap-and-trade mechanism. As the cap-and-trade program begins in 2012, each partner's allowance budget will effectively incorporate prior reductions achieved through complementary policies.[5] Following the start of the cap-and-trade program, complementary policies can play an important role in helping facilities operate under the program in a cost-effective manner while also moderating allowance prices. For example, energy efficiency programs can address barriers to cost-effective investments and include programs that offer the following types of assistance:

- Information, education, marketing and technical assistance to make consumers aware of energy efficiency opportunities and the technical means to achieve energy reductions
- Grants and rebates to reduce the cost to the consumer of investing in energy efficiency products and services
- Financing to provide consumers with positive cash flow and the means to retrofit buildings or replace inefficient equipment that achieve future reductions and associated savings

The WCI Partners would also like to consider the potential benefits of harmonizing complementary programs among not only WCI jurisdictions, but also states and provinces that are not part of the WCI. This would require having them participate with the WCI organization as it moves forward in its evaluation of selected complementary policies.

1.2 Evaluating and Prioritizing Policies

The Committee's next step will be to more fully evaluate selected policies based on the following criteria, which are intended to help the Committee determine whether and how each policy should be harmonized and how each policy will help achieve WCI's emissions reduction goals:[6]

- The policy will reduce GHG emissions.
- The policy is expected to reduce costs associated with achieving the WCI goals for covered facilities.
- Administrative costs are expected to be manageable.
- Impacts on low-income communities or small businesses can be mitigated.
- Meaningful benefits to harmonizing implementation have been identified.

Allocation for Efficiency: How Allowance Allocations Can Protect Consumers, Mobilize Efficiency, and Contain the Costs of GHG Reduction," at http://energycommerce.house.gov/Press_111/20090423/testimony_cowart.pdf.

[5]Each jurisdiction's allowance budget will be calculated by using the best estimate of expected emissions for sources covered in the cap-and-trade program considering both voluntary and mandatory emission reductions through 2011, thus reductions achieved due to complementary policies will be reflected in each jurisdiction's starting allowance budget.

[6] Refinement of criteria in Western Climate Initiative 2009-2010 Workplan, p. 38.

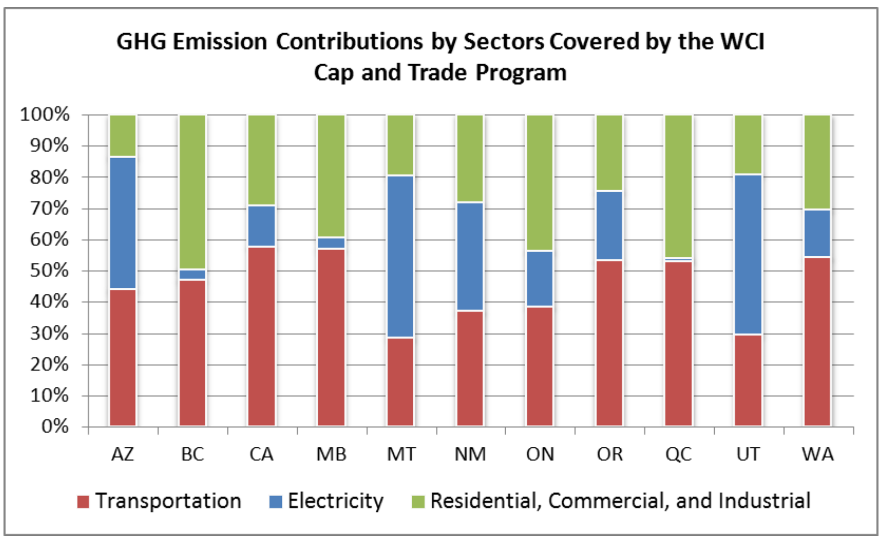
- Identified barriers to harmonizing implementation can be overcome.
- The policy addresses a perceived market failure.
- An opportunity to achieve collateral benefits (e.g., conserving water) has been identified.
- No collateral detriments (e.g., increased use of electricity that results in increased GHG emissions,[7] increased fine particulates or air toxics pollution) have been identified.
- The policy does not encourage leakage outside the cap.
- The policy has the potential to create or retain clean energy jobs or otherwise transition to a low-carbon economy.

These criteria are intended to help the Committee determine whether and how each policy should be harmonized and how each policy will help achieve WCI's emissions reduction goal.

After identifying an initial set of policies for further consideration, the Committee prioritized them using three tiers to assist with scheduling the Committee's work. Policies in the highest tier (Tier 1) will be evaluated first. The tiering of policies is based on the benefits of cross-jurisdictional harmonization, total GHG reduction benefits, and immediacy and ease of implementation (based on current or required efforts by jurisdictions). Tier 1 policies represent priority actions for the WCI Partners to consider because of their immediate impact in reducing GHG emissions and producing benefits from harmonization, and because they are currently underway or in development by multiple jurisdictions.

1.3 Policies Recommended for Evaluation

The accompanying graph shows for each WCI Partner jurisdiction the relative contribution of GHG emissions by each sector to be covered under the WCI cap-and-trade program.



Each of the WCI Partner jurisdictions has a climate action plan that delineates various policy instruments needed to achieve the jurisdiction's own emissions reduction goals or targets. The Committee used these plans to identify policies for consideration in this white paper. Listed below are the policies the Committee recommends for further evaluation.

[7] Where electricity substitutes for higher GHG-emitting transportation fuels, its increased use would be a benefit.

Energy Production

- Small-scale renewable energy resources (Tier 1)
- Combined heat and power (Tier 1)
- Hydropower (Tier 1)
- Emissions performance standards for electric generating units (Tier 1)
- Tradable renewable energy credits (Tier 2)
- Carbon capture and sequestration (Tier 2)

Energy Efficiency

- Energy efficiency targets (Tier 1)
- Energy efficiency programs and incentives (Tier 1)
- Energy savings credits (Tier 2)

Transportation

- Low-carbon fuel standard (Tier 1)
- Freight transportation infrastructure (Tier 1)
- Pay-as-you-drive insurance (Tier 2)
- Heavy-duty vehicle equipment (Tier 2)
- Electric and alternative fuel vehicle infrastructure (Tier 2)
- Vehicle emissions labeling (Tier 3)
- Medium- and heavy-duty vehicle hybridization (Tier 3)
- Transport refrigeration units (Tier 3)

Industrial Sector

- Emissions performance standards for major industrial sources (Tier 3)

High Global Warming Potential (GWP) Gases

- Regulatory measures for high GWP gases (Tier 1)

Agriculture

- Agricultural anaerobic digesters (Tier 2)

Waste Management

- Measures for landfill methane reduction (Tier 2)

Appendix A shows which of these complementary policies, if implemented, would reduce emissions from capped sources and sectors, and which policies would reduce emissions from uncapped sources and sectors.

It is important to note that many important complementary policy initiatives are not proposed to be evaluated by the Committee because they are being fully examined and developed in other venues. These other important policies are described briefly in Section 5 of this paper.

1.4 Next Steps

The Complementary Policies white paper was reviewed and approved by the WCI Partners on May 20, 2010 at their meeting in Seattle, Washington. The Complementary Policies Committee will next begin to evaluate the policies that are included in this paper to more fully identify the key issues and benefits. The Committee will evaluate necessary and available resources for next steps to address as many policies as practicable beginning with Tier 1 recommendations.

The Committee will also attempt to identify other related issues, such as needed jobs or skill sets to effectuate the policies. The outcome of the evaluation process will be design recommendations to facilitate regional harmonization of the policies.

The Committee will continue to engage stakeholders in future work and is currently developing an outreach plan to consider a number of options for doing so based on comments from stakeholders. The Committee also will produce reports that address two additional policy areas: 1) workforce transition, job creation, job retention and mitigation of community impacts associated with climate-related policies; and 2) climate change adaptation.

2 Tier 1 Policies

2.1 Energy Production

- Small-scale renewable energy resources
- Combined heat and power
- Hydropower
- Emissions performance standards for electric generating units

2.1.1 Small-Scale Renewable Energy Resources

Small-scale renewable resources include solar photovoltaic systems, solar water heating systems, community-scale wind turbines, geothermal systems, biomass digesters, micro-hydro systems, and generating systems that run on wood waste, agricultural waste, or waste gas from landfills or water treatment plants. These systems can help meet power and thermal energy needs and reduce GHG emissions. They can be installed at homes and businesses to supply on-site energy needs. In addition, utilities and third parties can build small-scale generating facilities as system resources for all customers.

Potential Policies. State/provincial policy options to address the barriers to small-scale renewable energy sources – many of which have been adopted in one or more WCI Partner jurisdictions – include the following:

Workforce training – Support for local and regional training programs may help ensure sufficient numbers of trained installers. Equipment and installer certification programs and random inspection of installations promote quality workmanship.

Public outreach and education – Public information can help consumers understand the benefits of small-scale renewable energy resources, how to undertake a project, and available assistance and funding options.

Uniform interconnection processes - Uniform technical standards, procedures and agreements can remove barriers and simplify the interconnection of small generators with utility systems, where appropriate. For projects with complex interconnection needs, reasonable timelines, fees and other requirements can be put in place for additional technical review and equipment that may be needed.

Power arrangements with the utility – Among the options:

- ‘‘Net metering” is a billing arrangement where the utility bills the customer only for the difference between the energy consumed at the premises and the energy produced by a qualifying system at the site. Any excess energy produced flows onto the utility grid for use by other customers, eliminating the need for the customer to have on-site storage or to to arrange for power sales to third parties. While net metering programs are widespread, many do not require all utilities in a state to participate or include all customer classes. Programs also may be constrained by low limits for individual project size and aggregate capacity, payment provisions for excess energy, insurance and equipment requirements, standby rates, and restrictions on third-party ownership of systems.[8]

- The Public Utility Regulatory Policies Act (PURPA)[9] requires utilities in the U.S. to interconnect with and purchase all capacity and energy from "Qualifying Facilities" up to 80 megawatts (MW) that use eligible renewable resources[10] at rates equal to the cost of the utility's avoided resource (for example, market purchases or a natural gas-fired power plant). States have broad discretion in implementing PURPA. Among the provisions for successful state programs are long-term contracts with fixed rates, standard avoided cost rates, commission-approved standard contract forms for small-scale projects, and methods for determining avoided costs that fully account for the value of the renewable energy to the utility system.
- Feed-in tariffs (FITs), also known as Advanced Renewable Tariffs, can provide rates that make it attractive for electricity to be produced by third parties (non-utilities) using renewable resources. Rates may vary by technology, geographic location and project size. FITs can encourage development of a variety of renewable energy projects. Like PURPA, FITs guarantee the right to interconnect and a buyer for the electricity, and payment is based on actual production. However, FIT rates are based on the cost of renewable energy generation, not the utility's avoided resource. Typically included in FIT rates is a return on investment sufficient to make the project worthwhile for investors.
- Targeted procurement of small-scale renewable energy resources that recognizes their unique benefits can incorporate many of the same features as a FIT, such as a must-take obligation and standard contract terms, but allow for market-based pricing through a reverse auction or similar mechanism.

Standby rates – Practices include cost-based rates, providing customer-generators choices for firm and non-firm service, including daily rates, allowing them to self-supply reserves and assure instantaneous load reductions to avoid standby charges, and providing supplemental power and maintenance service – with appropriate advance notice – at the customer's otherwise applicable tariff rate.

Utility resource planning and procurement – Utility resource planning and procurement often does not evaluate and include small-scale renewable resources for meeting generation and transmission needs. Similarly, the value of distributed generation typically is not considered in distribution system planning. Including distributed generation in utility

[8] A third party pays the upfront cost of the system; builds, installs and owns it for a specified term; takes advantage of tax, depreciation and other financial incentives; and sells the energy to the consumer hosting the system. The consumer reduces its bills through a net metering agreement with the utility. This financing model is especially important to local governments, schools, churches and others that cannot raise the capital for the project or take advantage of some government incentives.

[9] U.S. Public Utility Regulatory Policies Act, 16 U.S.C. § 824a-3.

[10] And qualifying cogeneration facilities of any size.

planning and acquisition processes helps states and provinces examine whether and how to use these resources to meet energy, capacity, distribution and transmission system needs.

Decouple utility sales from utility profits - "Decoupling" removes the link between utility sales and revenue so that the utility is indifferent to, rather than financially harmed by, customer-side distributed generation and efficiency measures.[11] Under decoupling, retail customer rates established to recover fixed utility costs are adjusted periodically to keep utility revenue at the level allowed by regulators.

Key issues to consider in developing small-scale renewable energy resources include:

- **Interconnection** – In the U.S., states generally have jurisdiction over interconnection (and sales) between customer-sited generation and retail electric utilities.[12] Utility interconnection processes may result in undue delays in gaining approval of applications, as well as undue costs associated with insurance and equipment which, upon closer examination, regulators may find unnecessary.

- **Power sales** – Utility procurement generally does not adequately consider small-scale distributed systems, despite their potential advantages, such as more rapid deployment and lower development risk compared to large projects. Small systems may not meet the minimum bid size for utility competitive bidding processes and wholesale markets, and the market for aggregation of small systems is immature. In addition, the prices utilities pay for renewable energy may be too low to drive significant development of small-scale systems.

- **Standby rates** – Unless prohibited by regulation, utilities may charge customer-generators special rates for back-up power when their on-site generator isn't running and for supplemental power to meet the customer's energy needs beyond the generator's capacity. Unless properly designed, standby rates can render a project uneconomic.

- **Utility planning** – Utility resource planning typically does not adequately evaluate and include small-scale renewable resources for meeting generation and transmission needs. Nor is the value of distributed generation typically considered in distribution system planning, where it could have especially high value in deferring costly upgrades to meet capacity needs in specific locations. Furthermore, those locations are not revealed to consumers or the marketplace.

---

[11] *See* National Action Plan for Energy Efficiency, *Aligning Utility Incentives With Investment in Energy Efficiency*, November 2007, at http://www.epa.gov/cleanenergy/energyprograms/napee/resources/guides.html; Regulatory Assistance Project, *Revenue Decoupling Standards and Criteria: A Report to the Minnesota Public Utilities Commission*, June 2008, at http://www.raponline.org/Pubs/MN-RAP_Decoupling_Rpt_6-2008.pdf.

[12] The Federal Energy Regulatory Commission has jurisdiction over interconnection of generating facilities for wholesale sales.

- **Utility disincentives** – Utilities recover a large amount of their fixed costs through volumetric rates. When customers develop on-site generation, utility revenue declines. Because so many of the costs of providing utility service do not change in the short run, a small reduction in sales due to customer-side resources can result in a disproportionately large reduction in utility earnings. Also, utilities typically do not earn a return on non-utility resources, nor can they make profits on them through operational efficiencies.

- **Cost** – Homeowners, businesses, local governments and others may have difficulty securing financing at favorable terms. And without subsidies, it may take too long for the investment to pay back.

- **Trained workforce** – Successful programs require a trained workforce to properly size, select and install equipment. If installers are in short supply, the consumer's interest in developing a project may pass.

- **Consumer awareness** – Most consumers are not aware of the benefits of small-scale renewable energy resources, how to undertake a project, and available assistance and funding options.

Benefits to harmonizing. Harmonizing these policies could build a larger market for small-scale renewable energy resources. It also would allow manufacturers to build equipment to meet a uniform set of standards accepted across a large region, make it easier for installers operating in multiple jurisdictions to understand interconnection and program requirements, and facilitate regional marketing of renewable energy systems.

2.1.2 Combined Heat and Power

This section was added after review of stakeholder comments.

About two-thirds of the energy content of the fuel used to generate power in the U.S. is wasted through conversion and line losses.[13] Combined heat and power (CHP), or cogeneration, sequentially produces both electric power and thermal energy.[14] Compared to traditional thermal electricity production, CHP can be viewed as an energy production or energy efficiency measure to reduce GHG emissions. Located at customer sites, CHP improves energy efficiency in two ways:[15]

1. Increasing fuel-use efficiency – Heat produced in the electric generation process that otherwise would be wasted is used for process or other thermal needs.

---

[13] Anna Shipley, Anne Hampson, Bruce Hedman, Patti Garland and Paul Bautista, *Combined Heat and Power: Effective Energy Solutions for a Sustainable Future*, Oak Ridge National Laboratory, Dec. 1, 2008, at http://www1.eere.energy.gov/industry/distributedenergy/pdfs/chp_report_12-08.pdf.

[14] Related, "waste energy recovery" generates additional electricity from waste heat from industrial processes.

[15] According to the U.S. Department of Energy, separately producing heat and power has a typical combined efficiency of 45 percent. CHP systems can operate at efficiency levels as high as 80 percent. *See* http://www1.eere.energy.gov/industry/distributedenergy/chp_basics.html.

2. Eliminating energy lost in delivering power – Electricity is produced on-site, so none is lost over transmission and distribution lines.

Compared to producing and delivering power from a remote power plant and separately producing steam or heat, overall energy required to produce the same amount of electric and thermal energy is reduced by about a third.[16] That efficiency savings translates into significant carbon savings.[17] Some states participating in the Regional Greenhouse Gas Initiative (RGGI) explicitly recognize the CO_2 emissions avoided by CHP units and reward them with allowances.[18]

CHP units are fueled by natural gas, other fossil fuels or local, renewable biomass resources. The units come in a wide range of sizes and technologies, including reciprocating engines, combustion or gas turbines, steam turbines, microturbines and fuel cells. The vast majority of CHP installations are in the industrial sector, but CHP also is used in commercial buildings and homes.

To advance CHP, WCI Partner jurisdictions can consider the policies discussed in this paper for small-scale renewable energy resources:

- Net metering programs can be applied to small-scale CHP.
- Federal PURPA law applies to CHP facilities of any size that meet efficiency requirements, as well as to renewable resources.
- Feed-in tariffs or targeted procurement could provide higher power purchase rates and long-term contracts for CHP, recognizing its energy efficiency and CO_2 benefits.
- Improvements in standby rates and interconnection processes are just as important for CHP as for renewable resources.
- CHP can be explicitly considered in utility planning and acquisition processes for energy, capacity, transmission and distribution.
- Decoupling can mitigate the disincentive for utilities to facilitate customer- or third party-owned CHP, which reduces utility sales and profits.

In addition, WCI Partner jurisdictions can consider including CHP as an eligible resource for meeting energy efficiency resource standards[19] and including waste energy recovery as an eligible resource for renewable portfolio standards – already the practice in some states.

---

[16] *See* http://www.energy.ca.gov/distgen/equipment/chp/performance.html.

[17] One analysis found that a small, energy-efficient gas-turbine CHP unit could reduce CO_2 emissions by about half, compared to generating power at the average U.S. fuel mix plus and separately producing heat from a natural gas-fired boiler. *See* Shipley, *et al.*

[18] For example, a certain amount of allowances are directly awarded or sold at a fixed price in Connecticut (5 percent) and Maine (13 percent). *See* section 22a-174-31, Control of Carbon Dioxide Emissions, at http://www.ct.gov/dep/lib/dep/air/regulations/mainregs/22a-174-31.pdf, and Chapter 156: CO_2 Budget Trading Program, at http://www.maine.gov/dep/air/greenhouse/rggi.htm. The RGGI model rule contains no formula for quantifying useful steam from CHP systems. Instead, a showing to environmental regulators is made in accordance with section XX-8.8 of the model rule. *See* http://www.rggi.org/docs/model_rule_corrected_1_5_07.pdf.

[19] *See* page [31].

Key issues to consider in promoting CHP resources include the same issues for small-scale renewable resources, such as:

- Interconnection barriers
- Difficulty selling power to utilities
- Standby rate design
- Lack of consideration in utility planning
- Utility financial disincentives to facilitate CHP
- Compatibility with non-industrial land uses and zoning

A number of issues are somewhat unique to CHP applications in the industrial sector and point to the need for financial incentives:[20]

- Cost – Industrial projects generally require a very short payback, and upfront costs for CHP are high compared to short-term savings. Installing CHP interrupts industrial processes, another project cost.
- Competition with other capital needs - Corporate capital budgeting processes place CHP in direct competition with investments that expand production, increase throughput or maintain overall plant reliability.
- Financing – Industrial companies often cannot finance CHP investments in-house and have limited outside financing options.

Benefits to harmonizing. CHP-related policies are similar to those for small-scale renewable resources. In addition, because most CHP is installed in industrial facilities, improving uniformity of regulatory and incentive programs across jurisdictions would facilitate CHP adoption by companies operating in multiple states and reduce competitiveness issues among states and provinces.

2.1.3 Hydropower

This section was added after review of stakeholder comments.

Hydropower uses stream flows and gravity to propel water through a turbine to generate electricity. Hydropower is typically a very low-cost form of electricity because there are no fuel costs and low operating costs, and it produces low or no emissions. However, due to the nature of dam construction and the potential disruption of natural stream flows, there are challenges regarding impacts to local populations, fish, wildlife and ecosystems are and must continue to be considered.

Hydropower plays a prominent role in the energy portfolios of many of the WCI jurisdictions. Emissions and economic benefits can be increased by acquiring incremental capacity from existing dams, improving efficiency at current hydropower facilities and examining the potential for new, small-scale or low impact, run-of-the-river facilities. In response to stakeholder

[20] *See* Bob Hinkle and Steve Schiller, *New Business Models for Energy Efficiency*, CalCEF Innovations whitepaper, March 2009, at http://eec1.ucdavis.edu/techsummit2-0/NewBusinessModelsforEE-WhitePaper.

comments, the Committee felt that a recommendation on hydropower should be included in this white paper for further consideration.

Potential Policies. Potential state/provincial policy options to address barriers to increased efficiency and production from hydropower facilities in an environmentally responsible manner include the following:

- Evaluate expanding eligibility for low-impact hydropower for state/provincial renewable portfolio standards; for example, including installing generation capability at dams that do not produce power today, increasing electricity generation efficiency at current hydropower facilities and developing small-scale, run-of-the-river facilities.
- Enhance coordination between state resource agencies issuing certifications under Section 401 of the U.S. Clean Water Act and the Federal Energy Regulatory Commission's licensing/exemption proceedings. Licensing of Canadian hydroelectric facilities will continue under processes administered by the Provinces.
- Consider the climate change benefits of hydropower projects when permitting agencies evaluate or consult on such projects.
- Consider a task force of state/provincial agencies on licensing for certain low-impact hydropower projects. For example, the task force could make recommendations regarding the addition of power generation to an existing non-hydroelectric dam, closed-loop hydropower storage and other types of projects deemed low impact by the state or province. The task force could facilitate state/provincial agency participation in any applicable state permitting processes and the federal licensing process.

Key issues to consider in developing these policies include:

- Mitigating adverse impacts to ecosystems and wildlife
- Administrative or legislative changes that may be needed to expand hydropower eligibility for state/provincial RPS and other renewable energy programs
- A coordinated approach with federal permitting agencies to ensure a consistent and streamlined process
- The potential impacts to hydropower from increased or decreased water supply due to climate change
- Potential options for low-impact hydropower and the potential role for organizations that certify such projects

Benefits to harmonizing. Harmonizing state/provincial policies on hydropower will provide a consistent market signal to potential developers on its role in programs such as RPS and securing low carbon renewable electricity to meet GHG reduction targets. The streamlining and standardizing of permitting requirements will reduce barriers to projects and the overall time needed for project completion. Forming a state/provincial task force to develop parameters and expectations for low-impact hydropower projects can help to identify innovative and transferable solutions to increasing hydropower production and efficiency in a manner that minimizes environmental impact.

2.1.4 Emissions Performance Standards for Electric Generating Units

An emissions performance standard (EPS) sets a maximum level of GHG emissions per unit of output. An EPS for electric generating units is designed to “raise the bar” for the emissions performance of each power plant, analogous to efficiency standards for appliances. Through the use of an EPS requirement, the construction of high-emitting generating resources with long expected useful lifetimes may be avoided. Similarly, new long-term contracts with existing high-emitting generating resources may be prevented. As a consequence, an EPS may reduce ratepayers’ financial and reliability risks associated with plant retirements, retrofits and emission allowance and offset costs under future emission control regulations. An EPS can also promote technological innovation to advance new power generation systems and to modify existing facilities in order to meet the standard.

An EPS should be considered in conjunction with a cap-and-trade program if:

1. Market prices for electricity increase to an unacceptable level to change the generation dispatch order or to induce new investments and technological advancements in clean generation at a sufficient rate or magnitude to meet GHG emissions reduction goals.
2. The level of carbon “leakage” outside the cap-and-trade region is unacceptable.

Key issues to address in designing an EPS for electric generating units include:

- The appropriate EPS performance level (emissions rate)
- The point of regulation e,g, generators or distribution companies that serve load;
- How broadly the EPS should be applied, e.g. electricity produced within the jurisdiction only or imported power as well
- The type of facility or commitment that should be subject to the EPS
- Whether it applies to new construction only, and/or new investments in existing facilities that expand rated capacity for their effective useful life
- Whether it applies only to facilities underlying long-term contracts or also to short-term contracts
- Determining the facility threshold, i.e. MW size or capacity factor
- The state of technology and the degree to which it can be pushed
- Start date and implications of building current-technology power plants that will not qualify under the EPS
- Calculation of net emissions for combined heat and power and biomass facilities
- Potential for carbon capture and storage

Benefits to harmonizing. Harmonized EPS policies and standards design would promote consistent signals to the market across a broad geographic region concerning GHG emissions performance for generating units. This would drive technological advancement in low-carbon solutions within a specific timetable linked directly to the carbon reduction goals for the electricity sector.

This policy has already seen a great deal of harmonization in the Western jurisdictions of the WCI. The states of California, Oregon and Washington have enacted similar EPS laws.[21] In addition, Montana has adopted a law imposing restraints on emissions from new coal plants in certain cases.[22] British Columbia requires carbon capture and storage for any new coal-based generating facility.[23]

2.2 Energy Efficiency and Conservation

- Energy efficiency targets
- Energy efficiency programs and incentives

2.2.1 Energy Efficiency Targets

Energy efficiency targets are used by policy makers to set performance goals – binding or voluntary – for energy efficiency investments and savings. The targets may apply to states or provinces, utility companies or third-party administrators of programs.

Energy efficiency targets take various forms. Energy Efficiency Resource Standards (EERS) establish long-term efficiency targets that are typically expressed as a percentage reduction compared to retail energy sales over a baseline period. Both annual and cumulative energy savings targets may be included. Standards may apply to both electricity and natural gas, and they may target reductions in peak electricity demand as well as energy usage overall. EERS are already in place in many states and federal standards have been proposed.[24]

Energy savings generally are achieved through end-use efficiency programs. In some states, savings from building codes, appliance efficiency standards, combined heat and power facilities, and distribution system efficiency improvements also may count toward meeting the standard.

Instead of expressing savings targets as percentages or absolute (e.g., megawatt-hour) savings figures, some states and provinces have made a commitment to acquire all cost-effective

[22] 69-8-421 MCA: http://data.opi.mt.gov/bills/mca/69/8/69-8-421.htm

[23] Bill 31: http://www.leg.bc.ca/38th4th/3rd_read/gov31-3.htm.

[24] In the U.S., for example, the American Council for an Energy-Efficient Economy (ACEEE) reports that 19 states have adopted an EERS requiring achievement of specified energy savings targets. In addition to strict EERS requirements, ACEEE includes states with Commission-ordered efficiency targets, states that allow efficiency to count toward renewable energy standards, and states with a rate cap triggering a relaxation of EERS requirements. *See* Laura A. Furrey, Steven Nadel, and John A. "Skip" Laitner, ACEEE, *Laying the Foundation for Implementing a Federal Energy Efficiency Resource Standard*, March 2009, at http://aceee.org/pubs/e091.htm. Bills pending in the 111th U.S. Congress would establish a national EERS. The United Kingdom and several Australian states are among jurisdictions outside the U.S. that have mechanisms similar to an EERS.

energy efficiency or achieve zero load growth through energy efficiency programs. Such efficiency targets can be articulated as part of a utility's integrated resource planning process and incorporated into applicable regulations. The suitability of subsequent utility acquisitions would be measured against that goal.

Energy efficiency targets also can be articulated in contracts or informal proceedings between the jurisdiction and a third-party efficiency provider. In some cases, the third-party provider is remunerated, in part, for achieving savings above the specified targets.

Key issues to consider in setting and achieving energy efficiency targets include:

- Savings potential (as assessed by a resource potential study)[25]
- Performance levels (e.g., percentage rate of savings)
- Baseline measurement (i.e., the starting point)
- Cost-effectiveness tests in screening individual efficiency programs or a portfolio of programs
- Utility disincentives to achieving stated goals[26]

Benefits to harmonizing. Energy efficiency targets include helping promote consistent signals to a broader market. Standardized requirements could be expected to reduce implementation barriers and costs for companies operating in multiple states.

2.2.2 Energy Efficiency Programs and Incentives

Energy efficiency programs are business plans or market mechanisms that address barriers to cost-effective investments. Programs can be run by the utility, the state or province, or a third-party administrator. Program costs can be integrated into the utility's cost of service, such as other resources, or be paid for through a separate charge on customer bills. The goal of a well-designed program is to motivate action by the targeted decision-makers – consumers, suppliers, stores or contractors – while minimizing program costs.

Energy efficiency investments can reduce total utility system costs[27] and avoid the use of fossil fuels and associated GHG emissions. Studies continue to find a vast potential of cost-effective

[25] A resource potential study assesses the technical and market potential for energy efficiency efforts and lays the foundation for developing appropriate savings targets. Results generally show achievable potential far in excess of current program scope.

[26] *See* decoupling discussion on page 7 and Regulatory Assistance Project, "The Role of Decoupling Where Energy Efficiency Is Required by Law," September 2009, at http://www.raponline.org/Pubs/RAP_Schwartz_IssuesletterSept09_2009_08_25.pdf.

[27] Preliminary research by ACEEE indicates average program costs of about 3 cents per kilowatt-hour saved and 29 cents per therm saved. (*See* Steven Nadel, ACEEE, Replies to Questions at the April 22, 2009, Hearing on Energy Efficiency Resource Standards, May 12, 2009, at http://aceee.org/tstimony/NadelQuestions04.22.09.pdf.) That's far less than the cost of new generating facilities. Efficiency investments also can avoid expensive upgrades to transmission and distribution systems.

efficiency remaining to be tapped.[28] Securing this potential could dramatically reduce electricity demand and significantly reduce the cost of meeting emissions reduction goals.

Policies include providing programs that offer the following types of assistance:[29]

- **Information, education, marketing and technical assistance** – Information on-line and at point of sale, branding (e.g., Energy Star), phone hotlines, workshops, multi-media advertising, on-site audits, field visits, training, certification and inspections are among the ways programs can increase awareness, knowledge and confidence among consumers, vendors and contractors.
- **Grants and rebates** – Financial incentives can reduce the cost to the consumer of investing in energy efficiency products and services. The incentive amounts are justified by a benefit-cost analysis and can be linked to the desired effect – for example, the number of targeted products installed by a certain date.
- **Financing** – Long-term financing of energy efficiency investments can provide consumers with positive cash flow. Financing strategies may focus on "lost opportunities," such as new buildings and new equipment, or they may provide consumers with the means to retrofit buildings or replace inefficient equipment. For example, some programs allow homeowners to add the cost of certain efficiency improvements to their mortgage, extending the repayment period.

Energy efficiency programs can include some form of "market transformation" – changing the way people make energy-related decisions or making efficient products and services widely available. Some programs are devoted exclusively to these purposes. Other programs focus on hard-to-reach sectors, such as multi-family housing and low-income households.

Programs to reduce energy consumption may be more compatible with a utility business structure that decouples utility sales from utility profits and includes performance incentives. Decoupling removes a utility's inherent *disincentive* to sell less of its product. Decoupling does not provide an *incentive* for the utility to acquire energy efficiency in lieu of supply-side alternatives that earn a return on investment. Where aggressive energy efficiency goals are in place, regulators may consider providing financial incentives to utilities for exceptional performance. Many utility commissions have adopted decoupling, incentive mechanisms, or both for electric and natural gas utilities.[30]

---

[28] For example, the recent McKinsey study found the U.S. has the potential to cost-effectively reduce non-transportation energy consumption roughly 23 percent by 2020. *See* www.mckinsey.com/USenergyefficiency. The Northwest Power and Conservation Council recently estimated achievable, cost-effective conservation in the four-state region (Idaho, Montana, Oregon and Washington) at 21percent of 20-year forecasted (medium-case) electric load – an amount that would meet about 85 percent of load growth in the region while significantly reducing both system cost and risk. *See* http://www.nwcouncil.org/energy/crac/Default.htm.

[29] Building codes, appliance standards, and new energy efficiency technologies are addressed briefly at the end of this paper.

[30] For maps showing status of decoupling in the U.S., *see* http://www.raponline.org/docs/NRDC_Decoupling%20Maps%20US_2009_08.pdf. For examples of incentive mechanisms and modeled results, *see* Chuck Goldman, Peter Cappers, Michele Chait, George Edgar, Jeff Schlegel and Wayne Shirley, "Financial Analysis of Incentive Mechanisms to Promote Energy Efficiency: Case Study of a Prototypical Southwest Utility," report to the Ernest Orlando Lawrence Berkeley National Laboratory, March 2009, at http://eetd.lbl.gov/EA/EMP/ee-pubs.html.

Key issues to consider in developing these policies include:

- High upfront cost, long payback on investment, and limited financing options
- Short windows of investment decision-making opportunity are easy to miss
- Trained workforce may be in short supply
- Limited public awareness, information and knowledge
- "Split incentives" between builders/building owners and tenants who pay the utility bills
- Resource planning and acquisition processes that don't evaluate energy efficiency on a par with supply-side alternatives
- Utility disincentives to encouraging energy efficiency

Benefits to harmonizing. Energy efficiency programs among the WCI jurisdictions and other states and provinces include reducing costs, helping to transform markets for energy efficiency products, technologies and practices, and achieving greater energy savings and GHG reductions. Regional programs can achieve economies of scale that are not possible with isolated programs. Working together, utilities and other program administrators can leverage personnel and funds for resource potential studies, regional marketing and training, developing a broad supply chain of products and services, robust evaluation of programs, and verification of estimated energy savings. Consistent program features and requirements also make it easier for vendors and contractors to participate.

Many programs rely on a common set of product and service specifications developed by the ENERGY STAR program. Some states already coordinate on energy efficiency assessments, strategy, model standards, programs, and common protocols for evaluating, measuring and verifying program results through such organizations as the Northwest Power and Conservation Council[31] and Northwest Energy Efficiency Alliance[32]. These efforts could be expanded to include a broader set of jurisdictions. Multi-state utilities offer similar programs throughout their service areas.

2.3 Transportation

- Low-carbon fuel standard
- Freight transportation infrastructure

2.3.1 Low-Carbon Fuel Standard

A Low Carbon Fuel Standard (LCFS) is a GHG emissions standard for transportation fuels. An LCFS provides a method for calculating the carbon intensity of fuels and requires fuel providers to reduce over time the carbon intensity of the fuels they sell. The carbon intensity calculation is typically based on *life-cycle carbon emissions* for each fuel type. An LCFS is designed to be technology-neutral across alternative transportation fuels, including electricity, biofuels and hydrogen, provided that it facilitates a reduction in GHGs (relative to a baseline target). Fuel

[31] http://www.nwcouncil.org/Default.htm
[32] http://www.nwalliance.org/

providers have the flexibility to provide the lowest priced mix of low-carbon fuels that achieves the intensity standard. This approach differs from a renewable fuel standard, which mandates production volumes of certain renewable fuels instead of a specified carbon intensity reduction target.

The State of California has adopted an LCFS program. Oregon recently passed legislation directing the Department of Environmental Quality to develop an LCFS. British Columbia's Greenhouse Gas Reductions (Renewable and Low Carbon Fuel Requirements) Act will be implemented through two regulations: 1) the Renewable Fuel Requirement Regulation, which requires fuel suppliers to meet an annual, provincial average of 5 percent renewable content for gasoline and diesel fuels; and 2) the proposed Low Carbon Fuel Requirement Regulation (LCFRR), which would require that the carbon intensity of transportation fuel sold in the province be reduced 10 percent by 2020. The LCFRR would require suppliers to provide transportation fuels with average carbon intensity less than or equal to annual target values beginning in 2010. The State of Washington is evaluating whether a LCFS should be adopted there.

Key issues to consider in designing an LCFS include:

- Carbon intensity reduction goals and schedule
- Interaction of an LCFS with the regional cap-and-trade system, including issues such as consistency of signals to industry under the two systems, potential for double counting of emissions reductions, and within-region vs. outside-region emissions reductions;
- Point of regulation (for example, should fuel companies be held responsible for increasing use of electric vehicles?)
- Cost to the public and businesses
- Current and expected regional capacity to produce sufficient low-carbon alternative fuels and opportunities for increasing capacity[33]
- Potential for commercialization of vehicles that can use low- or no-carbon fuels
- Development of a regional low-carbon fuel credit program
- Consistency in estimating lifecycle carbon intensities, considering fuel mixes, land use issues and other factors
- Options for minimizing the cost of compliance
- Potential use of compliance deferrals to address issues such as fuel shortages, fuel quality problems and significant spikes in fuel costs
- Refueling infrastructure to support an LCFS
- Environmental and health impacts beyond GHG reductions
- Local needs and conditions
- Fuel standards, certification and other product fungibility issues
- International trade agreements
- Coordinating with national mandates such as the revised U.S. Renewable Fuel Standard

[33] Regional capacity may be important from an economic impact perspective.

Benefits to harmonizing. LCFS policies and program design include consistent requirements among states and provinces that participate in the same fuel markets. Looking at the future needs for regional low-carbon fuel capacity may promote coordinated investment and economic opportunities. Regional harmonization could also provide a useful model for any national LCFS program.

2.3.2 Freight Transportation Infrastructure and Heavy Duty Vehicles

West Coast ports are North America's links to the rapidly growing Asian economies. The amount of goods imported and exported through these ports will continue to grow. Similarly, transborder freight transportation is a significant component of the economies of the WCI jurisdictions as U.S.-Canada surface transportation trade totalled $29.2 billion in May 2009. The continued growth in marine, air, rail and road transport activity poses a challenge to policy makers seeking to reduce GHG emissions. In addition, overlapping jurisdictions among many levels of government results in regulatory challenges for operators.

Many transport sectors have agreed that the solution lies in coordinating, rather than competing, on environmental issues. This is particularly relevant for areas such as the West Coast, where shippers have a choice among numerous air and marine ports of entry and land-based carriers. Through coordinated improvements and standards, states, provinces, port authorities and private carriers can justify investment in environmental improvements, without the fear that business will be lost to a higher-emitting, but lower cost competitor.

Examples of potential regional coordination on freight transportation and heavy-duty vehicles include the following:

- Jurisdictions could adopt requirements such as the U.S. Environmental Protection Agency (EPA) model rule to reduce heavy-duty truck idling during rest stops to facilitate a uniform approach. Outreach and financial assistance programs could promote energy-efficient and cost-effective alternatives such as auxiliary power units and truck stop electrification. A viable electrification network requires action by multiple jurisdictions to be effective.
- Ocean- and river-going vessels at dock usually run onboard diesel generators for "hotel" power. Using power from the electric utility grid is less expensive, but it may be necessary for multiple ports to provide connection facilities on-shore to make it cost-effective for vessels to install capability to connect to those facilities. WCI members California, Washington and British Columbia have installed on-shore power facilities using the best available and most compatible technology. A regional approach also could help eliminate competitiveness concerns among ports providing on-shore power.
- Smaller engines to provide hotel power, new engine technologies, and electronic start/stop controls are available to reduce pollution from locomotives, which often idle for extended periods of time. A regional approach could coordinate incentives and address jurisdictional issues for cleaning up switchyards and long haul locomotives.

- Most trucks built during the last decade are equipped with a speed limiter – an integrated circuit that allows for regulating maximum vehicle speed. Policies could include the mandatory use of speed-limiting devices, equipment for aerodynamic efficiency, supporting the introduction of new energy-efficient and GHG-reducing technologies, and instituting an inspection and maintenance program for heavy-duty trucks in jurisdictions throughout the WCI jurisdictions and in other states and provinces.

Key issues to consider for freight transportation infrastructure and heavy-duty vehicles include:

- Competitiveness among ports for docking of ocean and river-going vessels
- Lack of consistent regulations, penalties and funding programs among states and provinces with respect to anti-idling to encourage investment while avoiding impacts on trade competitiveness
- Standards for port electrification under development by the International Maritime Organization and their broader use with increasing certainty regarding the final standards
- High upfront cost, long payback on investment, and limited financial resources and incentives to fund research, development and implementation of new technologies
- Need for public-private partnerships and investments to develop a network of low-carbon fuel and electrififcation instrastructure to support heavy-duty trucks and port operations
- Programs developed by the American Trucking Association to reduce GHG emissions from freight movement, which can be implemented and enhanced through coordinated action by states and provinces
- The burden posed by differing requirements on the majority of heavy-duty vehicles, which travel between states and provinces or issues that may raise interstate commerce concerns
- Cost impacts of potential policies on individuals and small companies that own heavy-duty vehicles

Benefits to harmonizing. Policies include improving uniformity of regulatory and incentive programs, reducing competitiveness issues among states and provinces, leveraging incentives, and addressing jurisdictional issues with interstate freight movement. Because many trucking companies, trains and marine vessels operate between WCI Partner jurisdictions, regional coordination could also help identify or prevent instances where one jurisdiction's compliance mechanism may cause emissions increases in other jurisdictions. A regional approach to on-shore power would allow for pricing strategies to encourage its use, without affecting the competitive balance. Regional strategies to reduce GHG emissions from the freight transportation sector would produce multi-pollutant benefits, reducing toxins, sulfur dioxide, nitrogen oxides and fine particulates.

2.4 High Global Warming Potential (GWP) Gases

2.4.1 Regulatory Measures for High GWP Gases

High GWP gases are of growing concern due to their increasing rate of emissions and persistence in the atmosphere. These gases from anthropogenic sources are released as byproducts of industrial operations, primarily from electric power transmission and distribution, aluminum smelters, semiconductor manufacturing, production of insulating foam, and magnesium smelters and die-casters. High GWP chemicals also are used in many applications such as refrigeration, air conditioning and fire suppression. Typically, emissions of high GWP gases from processes and products are individually too small to be covered by the WCI cap-and-trade program. Nevertheless, just a few pounds of these materials can have the equivalent effect on global warming as several *tons* of CO_2.

Voluntary partnerships between EPA and industry are substantially reducing emissions of high GWP gases. For example, 81 utilities are participating in a voluntary program to reduce emissions from SF_6 used for insulation of electric transmission and distribution equipment. EPA publishes lists of acceptable substitutes for high GWP gases.

Key issues to consider for reducing emissions of high GWP gases include:

- Long timeframe for transitioning to safe and acceptable substitutes that offer lower overall risks to the environment and human health
- Removal and disposal of high-GWP gases
- Voluntary nature of existing programs
- Sizable expansion that is occurring in many industries that emit high-GWP gases

Benefits to harmonizing. Measures to reduce high GWP gases include reducing burdens on consumers and manufacturers while encouraging a broader market for lower-emitting substitutes. Regional programs can achieve economies of scale that are not possible with isolated programs. Regional harmonization may promote coordinated investments for research and development of alternatives. Harmonized policies could include design and funding of programs for capturing and disposing of high GWP gases, incentives for upgrading to newer products in order to more rapidly remove products with high GWP gases from circulation, and establishing specifications for the use of high GWP gases in newly manufactured products.

3 Tier 2 Policies

3.1 Energy Production

3.1.1 Carbon Capture and Sequestration

Carbon capture and sequestration (CCS) is a key technology that may for sustained emissions reductions in the electricity sector.[34] It involves four five steps: 1) separating CO2 before or after combustion of fossil fuels; 2) compressing the CO2 stream; 3) transporting it to an injection site; and 4) pumping it into underground geologic formations in a manner that prevents its release into the atmosphere and 5) long term monitoring and insurance to certify the sequestration.

Given the technical, institutional and legal risks, putting a price solely on CO_2 emissions may be insufficient to advance CCS deployment. Additional policies for the capture, transport, injection, monitoring and liability of the sequestered CO_2 are needed. Utility resource policies that mandate or promote CCS may be appropriate – such as emissions performance standards[35] – as well as innovative policies for siting and permitting, financing and rate-making.[36] State and provincial policy options to advance CCS include the following:[37]

Managing transport and sequestration – Current rules for transport and injection of CO_2 are for enhanced oil recovery and CCS pilot projects, not large-scale CCS deployment. Existing pipeline laws must be adapted for CO_2 transport. A standard template, such as the one produced by the Interstate Oil and Gas Compact Commission,[38] may be useful for the development of rules for geologic sequestration of CO_2. Further options could accelerate CCS deployment, such as pre-screening and pre-qualifying the best CO_2 pipeline and injection sites and simultaneously reviewing permit applications for the power plant, CO_2 pipeline and injection infrastructure.

Limiting liability for CO_2 releases – Large-scale CCS may not be deployed unless companies are able to manage liability associated with the escape or migration of CO_2 from pipelines and storage sites following permanent capping of the site and decommissioning of the injection facilities.[39] Policies designed to address liability must balance the goals of shielding companies from excessive liability, while maintaining a strong incentive for companies to minimize the chances of CO_2 release after decommissioning. In the absence of national legislation, states and provinces are beginning to address this issue on their own.

---

[34] Other strategies for sequestration also have been suggested, such as sequestration in biomass or in solid minerals.

[35] See pages 9-10.

[36] Jurisdictions also should consider whether any waivers may be warranted for power plant need determinations and competitive bidding requirements.

[37] For a complete discussion, see Richard Cowart and Shanna Vale, Regulatory Assistance Project, and Joshua Bushinsky and Pat Hogan, Pew Center on Global Climate Change, "Coal Initiative Reports: State Options for Low-Carbon Coal Policy," February 2008, at: http://www.pewclimate.org/docUploads/StateOptions-02-20-08.pdf.

[38] *See* http://iogcc.publishpath.com/Websites/iogcc/pdfs/Road-to-a-Greener-Energy-Future.pdf.

[39] Where those actions were taken in conformance with an approved plan for the cessation of operations.

Liability for releases during transport and injection (prior to decommissioning) also is an important issue. Insurance may adequately address liability during the operational period of a sequestration project, but clarifying legislation also could be beneficial. Other measures might be needed to compel the surrender of allowances for any CO_2 release.

Subsidies for CCS projects at fossil-fuel[40] plants – Among the options for funding are:

- A fee levied on generators or utilities on a per-megawatt-hour basis, or just on the portion attributable to fossil fuels
- A "feebate" system that charges fossil-fuel plants without CCS technology a per-megawatt-hour fee and distributes the funds collected for CCS equipment
- Direct expenditures or tax credits for CCS investments

Other financial incentives – Utilities could potentially receive higher rates of return or accelerated depreciation for CCS investments. Regulatory commissions or legislatures could grant bonding authority for CCS projects. Besides simply providing access to funds, such bonds could provide a lower interest rate.

Cost recovery support – Most regulatory commissions do not pre-approve power plants. Instead, they determine what costs may be included in a utility's retail rates only after the plant has reached commercial operation. Regulators can provide some type of cost recovery assurance for CCS projects even before construction begins, employing such strategies as:[41]

- Preapproval of CCS projects;
- Guaranteed buyer or must-take requirements for CCS-generated power;
- Cost recovery for power supply during unplanned outages of the CCS plant;
- Cost recovery even if the CCS plant is cancelled;
- Cost recovery for early retirement of existing coal plants if replaced with a CCS substitute.

Key issues to consider for CCS policies include the following:[42]

- *Acceleration:* Will it produce investment in CCS that would not otherwise occur?
- *Deterrence:* Will it deter investment in high-emitting technology options?
- *Prudence and accountability:* Will it promote prudent project management? Will those with responsibility be held accountable for performance?
- *Power supply costs:* Does it help to lower the cost premium for CCS power?
- *Administrative costs:* Does it help to lower administrative and regulatory costs for developers, government and other parties?
- *Risk and cost balance:* How well does it balance the interests of ratepayers and investors?

[40] Coal, natural gas, biomass, petroleum coke and other fossil fuel plants are candidates for CCS.
[41] State "used and useful" requirements (mandating that a plant be functioning and necessary to be included in the utility's revenue requirement) may need to be modified by statute to implement the last three options in this list.
[42] *See* Cowart, *et al.*

- *Innovation:* Will it promote further CCS research and technical innovation?
- *Standardization:* Will it promote CCS projects that could be replicated elsewhere?
- *Performance:* Does it secure significant carbon reductions? Are any incentives scaled to real-world performance, measured in tons of CO_2 permanently sequestered?

Benefits to harmonizing. Harmonizing CCS policies across jurisdictions might make sense for a number of reasons. First, successful CCS efforts require significant research, development and demonstration funding that is best spent in a coordinated manner. For example, coordinated mapping of potential sequestration sites and pipeline locations may reduce the need for redundant studies. Second, CCS projects may be developed by multi-state utilities, or developed jointly by utilities in multiple states and provinces, in order to achieve economies of scale and spread the costs and risks. Third, long-distance transmission lines for coal plants with CCS, as well as pipeline transport of CO_2 for sequestration at a remote location, may require cooperation among states and provinces.

In addition, consistent CCS policies could promote replicable CCS projects and reduce administrative costs for utilities and other project developers as well as stakeholders participating in regulatory processes. Further, absent a national policy, consistent policies across the region to address liability risks associated with potential CO_2 leakage could facilitate CCS projects where participating utilities, CO_2 pipeline transport and sequestration sites involve multiple jurisdictions.

3.1.2 Tradable Renewable Energy Certificates

This section was added after review of stakeholder comments.

To facilitate compliance with a Renewable Portfolio Standard (RPS), most jurisdictions allow renewable energy certificates[43] procured separately ("unbundled") from the associated electricity to satisfy at least a portion of the renewable resource obligation. These tradable certificates can reduce the cost of RPS compliance. However, differing requirements for certificates that may be used for RPS compliance hinder trading. Key differences across jurisdictions include:

- Eligible fuels and technologies
- The qualifying vintage of the generating unit (the date it began operation)
- Whether incremental power production at an existing unit qualifies
- Eligible project size
- Whether the power must be generated within – or delivered to – the jurisdiction
- Whether customer-sited resources are eligible
- Cost caps and alternative compliance mechanisms
- Limits on using certificates without also procuring the associated electricity
- The certificate definition itself, including any conveyed environmental attributes

[43] One certificate represents one megawatt-hour of electricity from a renewable energy generating unit.

Not all of these differences must be harmonized to make renewable energy certificates more fungible across WCI partner jurisdictions. And there are alternatives to developing common certificate requirements. Under multi-lateral agreements, for example, participating jurisdictions could accept certificates that qualify under each others' requirements on a reciprocal basis. A related approach would accept certificates that qualify in participating jurisdictions, but at a pre-determined discount instead of at par. In addition, jurisdictions could agree to expand geographic eligibility or relax energy delivery requirements under specified conditions indicating tight supplies of renewable resources.[44] Further, under any of these approaches, jurisdictions could limit the amount of otherwise non-qualifying certificates that may be used to meet renewable resource obligations.

States and provinces already have collaborated to establish a West-wide certificate tracking system. The Western Renewable Energy Generation Information System issues, registers and tracks all renewable energy certificates in the Western Interconnection. The system protects against multiple-counting and selling of certificates and verifies compliance with both RPS and voluntary renewable resource programs. The system can import (and export) certificates from (and to) other tracking systems in the U.S. and Canada. It provides the necessary infrastructure for certificate trading, but it is not a trading platform. Trading is generally through bilateral agreements.

Both of the major energy bills before Congress – the American Clean Energy and Security Act of 2009 (H.R. 2454) and the American Clean Energy Leadership Act of 2009 (S. 1462) – preserve the integrity of state renewable portfolio standards. Under both bills, federal renewable energy certificates would be entirely separate from state certificates and would have no purpose other than compliance with federal requirements. Federal certificates could be used nationwide for that purpose, but their use toward meeting state standards would be bound by individual state definitions and eligibility. H.R. 2454 includes explicit provisions for states to establish renewable energy certificate trading under higher state standards. Further, neither bill includes any apparent prohibitions against trading renewable energy certificates with Canadian provinces.

Key issues to consider in making renewable energy certificates more fungible include:

- Administrative or legislative changes that may be needed[45]
- Competing interests, e.g. renewable resource and economic development within the jurisdiction vs. lower RPS compliance costs through improved certificate trading
- Whether reducing climate change is among the jurisdiction's goals for its RPS program – CO_2 emissions reductions anywhere help meet that goal

[44] For a detailed review of potential approaches, *see* Edward A. Holt, *Increasing Coordination and Uniformity Among State Renewable Portfolio Standards,* prepared for Clean Energy States Alliance and the Northeast/Mid-Atlantic RPS Collaborative, December 2008, at http://www.cleanenergystates.org/Publications/CESA_Holt-RPS_Policy_Report_Dec2008.pdf.

[45] If an RPS was enacted through voter initiative, there may be restrictions on the legislature's ability to modify its provisions.

- Reduced local environmental benefits due to any reduction in local renewable energy development because the benefits of avoided air pollutants from a fossil-fuel power plant accrue primarily where *that* plant is located – except for for CO_2 – not necessarily in the vicinity of the renewable energy facilities that displace fossil-fuel generation
- The ability of jurisdictions to meet their highest RPS targets under today's differing certificate requirements
- In renewable-rich areas, the effect of increased use of unbundled certificates on the cost of balancing reserves, power prices, generation dispatch, and acquisition costs for RPS-qualifying resources[46]

Benefits to harmonizing. Trading renewable energy certificates across a broad region can increase competition and liquidity in the marketplace, lower prices for renewable resources and reduce the cost of RPS compliance.[47] In turn, lower prices may increase renewable energy development, leading to further reductions in greenhouse gas emissions. Because high-quality renewable resources are not dispersed evenly, trading among jurisdictions may increase the diversity of renewable resources that are developed. And tapping areas with better solar or wind potential, for example, may reduce acquisition costs. Renewable energy developers would benefit from increased certificate trading because their projects could comply with more RPS programs. Even if requirements for tradable certificates are not harmonized among WCI partner jurisdictions, the reciprocity approaches described above can provide significant benefits along these lines.

3.2 Energy Efficiency and Conservation

3.2.1 Tradable Energy Savings Credits

This section was added after review of stakeholder comments.

Energy savings credits[48] can be used like renewable energy credits.[49] They are issued, registered, tracked and retired. However, rather than representing one megawatt-hour (MWh) of renewable generation, an energy savings credit constitutes one MWh of energy not used. Energy savings credits present a greater challenge because their output cannot be metered. Instead, energy savings are estimated by comparing energy use after an energy savings

---

[46] The Northwest Power and Conservation Council is undertaking a study to examine the implications of an unbundled certificate market in western North America for meeting renewable resource obligations, focusing on implications for the Northwest.

[47] For example, a study for the Western Electric Industry Leaders Group on the transmission that will be needed to meet RPS and carbon requirements in the Western Interconnection estimated that certificate trading could reduce renewable resource procurement costs in 2020 by $351 million. Study by Energy and Environmental Economics, Inc. at http://weilgroup.org/E3_WEIL_Complete_Study_2008_082508.pdf. A study by Lawrence Berkeley National Laboratory also found large savings from this approach. *See* http://eetd.lbl.gov/ea/EMP/reports/lbnl-3077e.pdf.

[48] Also called energy savings certificates or "white tags," a term trademarked by Sterling Planet.

[49] See page 29.

measure is taken with business-as-usual energy use — i.e., assuming the measure had not been taken.[50]

Energy savings credits generally are used in conjunction with energy efficiency requirements, such as energy efficiency resource standards.[51] A central reason for the adoption of energy savings credits is that they monetize savings from energy efficiency projects and allow those savings to be traded. Trading creates the opportunity to not only track compliance but also to lower its cost, because credits can migrate to the highest valued use and provide additional funding for efficiency programs.

To be effective, a trading program for energy savings credits should meet the following prerequisites:[52]

- **Measures, projects and programs** – Credits should be based on savings claimed by approved measures, projects and programs.
- **Measurement of energy savings** – Programs should have approved measurement protocols, typically established by a utility commission or other regulator.
- **Verification and certification** – Savings claims should be verified by an independent entity and be consistent with established protocols for measures, projects and programs. While not requiring the action of a single entity, the process must be credible.
- **Issuance of credits** – Energy savings credits (and the attributes they represent[53]) must be issued in a way that ensures they are not double-counted by another entity or in another place, and that they are issued to the lawful recipients – e.g., the home owner or program administrator.
- **Tracking** – Systems must be in place to track and account for traded and retired credits, including the degree to which attributes vary among jurisdictions.
- **Price determination** – Because pricing of energy savings credits is a key element in trading, the pricing process should be transparent.

Key issues to consider in developing energy savings credits include the following:

- Whether energy savings credits will help meet the goals of energy efficiency requirements – One of the purposes of trading is to lower the cost of compliance, because trading locates and mobilizes reductions from less expensive measures, practices and programs in order to sell them to places where reductions are more expensive. However, if the goal of state or provincial energy efficiency requirements is saving energy locally (and lowering local energy bills), reducing air pollution in the area, or relieving electric system congestion within the jurisdiction, using energy savings credits may not be effective in matching resources and desired benefits. To the degree that there is a closer connection between the region from which energy savings credits

[50] Joe Loper, Steve Capanna and Rodney Sobin, Alliance to Save Energy, "Energy Savings Credits: Shining a Light on the Measurement Challenge," 2009 draft.

[51] See page 18

[52] *See* Loper, *et al*.

[53] For example, carbon emissions reductions or demand reductions for a specified time period.

are purchased and the place where the benefits are being sought, this problem would be less pronounced.

- Costs associated with credit certification, tracking and trading – While these costs can be significant, the incremental costs would be limited to the degree that states and provinces already participate in tracking systems for renewable energy credits. Costs include upgrade of existing systems to certify and track energy savings credits and personnel training associated with regulatory oversight.
- Stringency of energy efficiency requirements – Trading energy savings credits can make weak energy efficiency requirements even weaker. To the degree that energy efficiency requirements produce more business-as-usual savings (and credits) than one utility requires, a second utility can purchase the credits in lieu of meeting the requirements with more stringent measures. The purchasing utility also complies with the requirements, but with weaker savings – i.e., savings that utility one would have made anyway. This problem is exacerbated to the degree that credits from a jurisdiction with a weaker program are sold to a jurisdiction with a more stringent program. However, where programs are equally stringent, energy savings within the jurisdictions would not necessarily be compromised by trading of energy savings credits.[54]
- Combining energy savings credits with renewable portfolio standards – Because energy efficiency is cheaper, if combined with renewable portfolio standards, energy savings credits could dilute renewable resource obligations. From a least-cost strategy point of view this would be beneficial for consumers. To the degree that a renewable energy policy is designed with additional goals, such as promoting the local renewable energy industry, this interaction should be considered. Regardless, if the renewable resource obligation is based on a percentage of overall sales to retail customers (MWh), *any* energy efficiency gains will reduce that obligation. Therefore, there is no need to explicitly combine renewable energy and energy efficiency obligations to get those least-cost benefits.

Benefits to harmonizing. Establishing a system of tradable energy savings credits across WCI Partner jurisdictions may reduce the cost of compliance with energy efficiency requirements. If such requirements are stringent and lead to deep reductions in energy use, energy savings credits also may reduce the cost of meeting renewable portfolio standards – if renewable resource obligations are based on a percentage of overall retail sales or combined with energy efficiency requirements.

[54] Loper, *et al.* at 24.

3.3 Transportation

3.3.1 Pay-as-You-Drive Insurance

This section was added after review of stakeholder comments.

Pay-as-you-drive insurance (PAYD) bases vehicle insurance rates on miles driven. PAYD is typically a voluntary program designed to offer lower rates to drivers that drive below a mileage target for a given period, which provides an economic incentive to drivers to reduce their vehicle miles traveled (VMT). Because the program is voluntary, high-mileage drivers have the option to purchase conventional insurance policies. If properly structured, a PAYD program provides insurance companies with a more accurate correlation between individual policies and risk.

Key issues to consider in developing programs:

- Identifying qualitative and quantitative metrics to accurately quantify risk
- Ensuring that privacy is not infringed upon in tracking or verifying driving habits

Benefits to harmonizing. By coordinating state/provincial efforts with insurance companies, standard policies and procedures can be developed to encourage large-scale availability of PAYD policies.

3.3.2 Electric and Alternative Fuel Vehicle Infrastructure

Development of electric and alternative fuel vehicle infrastructure can take a variety of forms including:

- Consumer outreach and education
- Direct purchases of charging stations and alternative-fuel refueling stations by businesses and local, state/provincial or regional governments
- Addressing utility system impacts
- Development and implementation of policies that streamline the permitting and installation of alternative fuel vehicle infrastructure
- Creation of grant, loan or loan guarantee programs to help finance infrastructure
- Enactment of tax incentives to reduce the cost to developers of installing infrastructure

Key issues to consider in developing programs to accelerate the deployment of alternative fuel vehicle infrastructure include:

- How to pay for infrastructure, including revenue-positive public and commercial cost models
- Electric system impacts
- Removing service provider disincentives to supplying additional electric load and alternative fuels through such means as providing additional emissions allowances
- Policies to ensure interoperability of refueling across utility service territories and jurisdictions

- Coordination of these programs with a regional low-carbon fuel standard, if implemented
- Whether public agencies should provide free electric vehicle charging
- Public and private partnerships
- Deployment simultaneously with (or in advance of) alternative-fuel vehicle sales
- Distance between stations for charging/fueling

Benefits to harmonizing. By coordinating the development of electric and alternative fuel vehicle infrastructure, the WCI jurisdictions could foster sufficient market penetration of electric and alternative fuel vehicles to attain significant reductions in GHG emissions, create jobs, foster economic growth, reduce reliance on foreign fuels and reduce air pollution.

3.4 Agriculture

3.4.1 Agricultural Anaerobic Digesters

Anaerobic digesters capture the gases created as agricultural waste materials break down into methane and CO_2. Anaerobic digesters:

- Capture methane, a potent GHG that would otherwise be released into the atmosphere
- Displace CO_2 emissions by producing carbon-neutral electricity, pipeline-quality natural gas, transportation and boiler fuels, feedstocks for commercial chemicals (such as ammonia and methanol), and digested fiber that can be used as a substitute for mined peat moss
- Provide a valuable economic resource to farmers through renewable energy production and cogeneration

Key issues to consider in harmonizing policies to facilitate on-farm anaerobic digesters are:

- The level of necessary capital investment and ongoing transaction costs as well as payback periods, which depend in part on:
    - The amount of financial assistance available
    - The rates available from electric and natural gas utilities for sale of digester-produced power and gas
- The ease with which small independent power producers are able to meet the interconnection requirements of electric and natural gas utilities
- The proportion of agricultural and non-agricultural wastes allowed on-farm by government agencies for the purpose of anaerobic digestion
- Environmental regulation by state and local governments
- Local government requirements on the movement of agricultural and non-agricultural waste
- The degree to which energy production is accepted as a normal farming practice by the public and relevant government agencies, including:
    - Whether there are special rules about what activities can take place on farmland

- Whether energy production will remain ancillary to other types of agricultural production.

Benefits to harmonizing. Anaerobic digestion offers significant potential for permanent, real, additional and verifiable GHG emissions reductions. Removing permitting barriers and providing clarity and consistency in regulations would increase accessibility for states and provinces to realize these reduction opportunities.

3.5 Waste

3.5.1 Landfill Methane Reduction

Methane gas from landfills is a significant source of GHG emissions due to its high global warming potential and the sheer number of landfills. According to Environment Canada, landfill emissions account for more than a quarter of the anthropogenic methane in the atmosphere.[55] Landfills generate methane as the anaerobic bacteria break down organic waste, a process that usually begins within the first year of landfill operation and can continue for 50 years after landfill closure.

The U.S. EPA defines "large" municipal solid waste landfills and requires that they collect landfill gas and combust it.[56] The regulations do not mandate secondary energy recovery processes. The B.C. Government passed a Landfill Gas Regulation under the Greenhouse Gas Reduction Statutes Amendment Act, which requires that by Jan. 1, 2016, all landfills that are above a certain size and methane threshold must install (and properly operate) landfill gas management facilities.[57]

Collected landfill gas can be used for electricity, heat production and other applications. Beneficial use of collected landfill gas offers potentially significant benefits, including further reductions of GHG emissions by offsetting fossil fuels and producing energy from a renewable source. The EPA estimates that more than 450 municipal solid waste landfills in the U.S. operate landfill gas-to-energy programs, and approximately 520 more landfills could effectively do so, providing enough electricity to power 700,000 homes.[58] Environment Canada estimates that 600,000 homes could be powered by electricity generated from Canadian landfill gas sources.

The EPA operates a voluntary Landfill Methane Outreach Program (LMOP) to facilitate and provide assistance for landfill methane capture and conversion to energy. Canada and the U.S.

[56] *See* 2006 Standards of Performance for New Stationary Sources and Guidelines for Control of Existing Sources, and 2003 National Emission Standards for Hazardous Air Pollutants.
[57] *See* http://www.bclaws.ca/Recon/document/freeside/--%20e%20--/environmental%20management%20act%20%20sbc%202003%20%20c.%2053/05_regulations/28_391_2008.xml.
[58] *See Landfill Methane Outreach Program: Benefits of LFG Energy* at http://www.epa.gov/lmop/benefits.htm.

participate in the Methane to Markets partnership with 28 other countries that have interest or expertise in developing methane projects.

Key issues to consider in developing programs to capture landfill methane include:

- Identifying the entire inventory of potential methane-generating landfills;
- Closed landfills may be difficult to identify, but still have emissions;
- The type of outreach and targeting needed to successfully maximize program participation and how to coordinate that effort regionally
  - Targeting larger landfills that may qualify to participate in the LMOP but aren't yet taking action
  - Targeting a different population of landfills than federal programs
  - Quantifying the amount of methane produced to select target landfills using consistent procedures
- Funding of methane recovery projects, particularly for closed landfills or small municipal landfills
- Availability of electrical infrastructure and proximity of landfills to transmission lines
- Establishing effective and timely monitoring of landfill gas to identify problems or potential problems, including in the area between waste disposal sites and neighboring properties
- Difficulty of determining the percentage of landfill gas captured through a collection of wells and headers, with many uncertainties and variables
- Additional considerations that may explicitly address:
  - Organic waste diversion programs
  - Emission credits
  - Non-methane organic compounds (odors and air quality)
  - Recycling programs to recover energy-intensive materials, such as aluminum
  - Methane management opportunities for non-landfill organic waste – from dairies and pig farms, for example

Benefits to harmonization. Reaching out to landfills not subject to U.S. or Canadian regulations could further reduce landfill methane emissions and encourage energy recovery. Guidance for outreach at the regional level – possibly modeled after EPA's Landfill Methane Outreach Program – would reduce the level of jurisdictional effort necessary and provide a consistent message for the goals, benefits and procedures for a program that reduces landfill methane emissions reduction and promotes electricity production from landfill gas.

4 Tier 3 Policies

4.1 Transportation

4.1.1 Vehicle Emissions Labeling

Emissions labels provide consumers with information on GHG emissions from vehicles. This approach has the potential to influence vehicle market decisions by providing information for consumers who might have a preference for purchasing vehicles with lower GHG emissions. Harmonizing the content of emissions labels would provide standardized information for consumers while reducing burdens for manufacturers and regulators.

4.1.2 Medium- and Heavy-duty Vehicle Hybridization

Medium- and heavy-duty vehicles account for a significant portion of GHG emissions from the transportation sector. Hybridization reduces GHG and other emissions from these vehicles through greater fuel efficiency. Hybrid trucks and buses would likely achieve the greatest benefits in urban, stop-and-go applications, such as parcel delivery, transit and other short-range travel. A harmonized program of standards and incentives could help encourage a broader market for medium- and heavy-duty vehicle technology.

4.1.3 Transport Refrigeration Units

Transport Refrigeration Units (TRUs) are gasoline- or diesel-powered cooling units that are installed on containers used to transport produce, meat, dairy and other perishable goods. TRUs are capable of both cooling and heating and are found on refrigerated vans, trucks, trailers, railcars and shipping containers. Although TRU engines are relatively small, ranging from 9 horsepower to 36 horsepower, significant numbers of these engines congregate at distribution centers, truck stops and other facilities. Some companies use TRUs for extended cold storage and store overflow goods in TRU-equipped trucks and trailers for several weeks before holiday periods, or for more than a 24-hour period throughout the year. Harmonized policies and standards design would encourage more energy-efficient operations that reduce GHG emissions from systems using internal combustion engines. Harmonization also would encourage advancements in electrically driven refrigeration systems and cryogenic systems.

4.2 Industrial Sector

4.2.1 Emissions Performance Standards for Major Industrial Sources

Emissions performance standards for industrial facilities would set a maximum level of GHG emissions per unit of product produced.[59] These standards would be established by sector, by product, or in some cases by industrial process within a sector.

[59] For example, tons of CO_2 equivalent emitted per unit of product produced at the facility. For energy-related emissions, both direct use of fossil fuels on-site as well as off-site production of electricity consumed at the plant would be included.

5 Important Policies Addressed in Other Venues

A comprehensive program to achieve significant GHG emissions reductions and transition to a low-carbon economy will require a broad range of actions and investments by business, consumers and all levels of government. In addition to the three tiers of policies discussed above, other important initiatives are being examined and developed in other venues. These policies are expected to make critical contributions to achieving the WCI Partner jurisdictions' goals for greenhouse gas reductions. These other polcies, not being evaluated by the Complementary Policies Committee, include the following:

- **Renewable portfolio standards in the electricity sector.** Already adopted by each of the WCI Partner jurisdictions, renewable portfolio standards direct retail electricity providers to generate or purchase a portion of their power from renewable sources. These requirements promote multiple objectives, including diversifying electricity supply and encouraging deployment of low-carbon technology in the electricity sector. Included in this paper for further consideration is improving the ability to trade renewable energy certificates across WCI Partner jurisdictions.

  This section was added after review of stakeholder comments.
- **Transmission for renewable and other low-carbon resources.** Several regional efforts are underway to identify and prioritize necessary transmission lines to facilitate increased electric generation from renewable resouces. A substantial amount of these resources are located in areas remote from load centers. The Federal Energy Regulatory Commission (FERC) has jurisdiction over transmission of electric power in the U.S., however, states retain authority over siting transmission facilities. The Western interconnection serves all or portions of 14 U.S. states; Alberta; British Columbia; and the northern portion of Baja California, Mexico. The Western Electricity Coordinating Council (WECC) is responsible for coordinating and promoting bulk electric system reliability and open and non-discriminatory transmission access, subject to oversight by FERC and Canadian authorities. Advisory groups to WECC, the Western Governors' Association (WGA) and its energy arm, the Western Interstate Energy Board, support cooperative reliability and transmission efforts. The Western Renewable Energy Zones initiative promotes the efficient development, procurement and delivery of energy from renewable-rich zones to population centers while balancing other state objectives. In addition, with funding from the U.S. Department of Energy, WECC is developing 10-year and 20-year regional transmission plans – due in 2011 and 2013, respectively – to provide guidance for decisionmakers and facilitate expansion of needed transmission infrastructure, including transmission to accelerate development of renewable and other low-carbon resources.

- **Energy efficiency standards for new buildings and appliances.** State and provincial building and appliance standards ensure that manufacturers and builders bring energy-saving products to market. These standards have proven to be highly effective for reducing energy consumption and GHG emissions. Moreover, their implementation in a similar manner across jurisdictions is key to building larger markets for energy-saving products and green building techniques. States and provinces regularly update building standards. Most of the WCI Partner jurisdictions have adopted residential and commercial building codes consistent with the 2006 model International Energy Conservation Code, which itself provides a degree of harmonization. Most appliance standards in the U.S. are set by the federal government, including recent updates under the Energy Independence and Security Act of 2007. Pending U.S. Congressional bills would raise energy efficiency standards in building codes and increase energy efficiency requirements for lighting and appliances. Depending on any federal preemption provision, building codes and appliance standards in WCI Partner states may exceed these requirements.

- **Smart grid.** Smart grid infrastructure is under development in several of the WCI Partner jurisdictions in order to facilitate the dynamic transfer of information and electricity between the electric grid and retail customers. The smart grid will enable greater integration of intermittent renewable generation, demand-side resources and energy efficiency into the grid while improving reliability. Using funding authorized under the American Recovery and Investment Act of 2009, the U.S. Department of Energy is awarding some $4.5 billion to utilities, equipment suppliers, regional transmission organizations, states and research organizations to jump-start smart grid on a massive scale.[60] The National Institute for Standards and Technology is developing a framework, including protocols and model standards for information management, to ensure smart grid devices and systems work effectively with the many interconnected elements of the electric power grid. The Western Electricity Coordinating Council is likely to have a role in developing harmonized standards for the western states and provinces.

- Light-duty vehicle emissions standards. Light-duty vehicle emissions standards. In June 2009, EPA granted a waiver to California to proceed with implementation of its GHG emission reduction standards for new passenger cars, pickup trucks and sport utility vehicles beginning with the 2009 model year. This opened the way for the other 13 states and the District of Columbia that have adopted those standards to also proceed. Shortly thereafter, the Obama Administration announced its intent to adopt these emission standards at the national level. The final joint rule between EPA and the Department of Transportation's National Highway Safety Administration (NHTSA) was announced on April 10, 2010. In Canada, 2 Provinces that participate in the WCI have adopted these standards and the national government has committed to developing national vehicle GHG standards for 2011 and subsequent model year light duty vehicles

[60] *See* http://www.energy.gov/recovery/smartgrid_maps/SGIGSelections_State.pdf and http://www.energy.gov/news2009/documents2009/SG_Demo_Project_List_11.24.09.pdf.

that will mirror the US federal standards to create a more harmonized regulatory environment for automakers.

- **Vehicle miles traveled reductions.** Several WCI Partner jurisdictions have undertaken initiatives to encourage reductions in vehicle miles traveled (VMT) by fostering transit-oriented development or integrating climate change into transportation and land use planning. Pay-as-you-drive insurance, which will be evaluated as a Tier 2 policy as noted in this document, may indirectly impact VMT. VMT reductions can be an effective strategy to enhance mobility efficiency while reducing GHG emissions from the transportation sector.

- **Government leading by example.** Each WCI Partner jurisdiction has adopted goals or policies to save energy and reduce GHG emissions in its own operations. These policies build markets for low-GHG materials and equipment and set an important example for the private sector. By demonstrating exceptional emissions reductions in various areas, WCI Partner jurisdictions provide a laboratory for the development of innovative approaches.

- **Assistance for low-income households.** Results from the WCI economic analysis released in September 2008 indicate that the WCI emissions targets can be met through a broad based cap-and-trade program and complementary policies with a net savings to the economy. However, the WCI Partner jurisdictions are committed to understanding and addressing potential impacts on low-income households that, for example, spend a relatively high portion of their income on energy. Each WCI Partner jurisdiction is examining how best to address this issue, relying on the programs and approaches most suitable to each Partner's circumstances.

Appendix 1: Complementary Policies: Capped vs. Uncapped Sources and Sectors[61]

Policies to Reduce Emissions From Sources and Sectors Capped in 2012 *Energy Production* • Small-scale renewable energy resources (Tier 1) • Combined heat and power (Tier 1) • Hydropower (Tier 1) • Emissions performance standards for electric generating units (Tier 1) • Carbon capture and sequestration (Tier 2) • Tradable renewable energy certificates (Tier 2)
Energy Efficiency • Energy efficiency targets (Tier 1) • Energy efficiency programs and incentives (Tier 1) • Tradable energy savings credits (Tier 2)
Industrial Sector • Emissions performance standards for major industrial sources (Tier 3)
Policies to Reduce Emissions From Sources and Sectors Capped in 2015 *Transportation* • Low-carbon fuel standard (Tier 1) • Freight transportation infrastructure and heavy-duty vehicles (Tier 1) • Electric and alternative fuel vehicle infrastructure (Tier 2) • Pay-as-you-drive insurance (Tier 2) • Vehicle emissions labeling (Tier 3) • Medium- and heavy-duty vehicle hybridization (Tier 3) • Transport refrigeration units (Tier 3)
Policies to Reduce Emissions From *Uncapped* Sources and Sectors *High-Global Warming Potential Gases* • Regulatory measures for high-global warming potential gases (Tier 1)
Agriculture • Agricultural anaerobic digesters (Tier 2)
Waste Management • Measures for landfill methane reduction (Tier 2)

[61] This table only includes policies the Committee will evaluate for further consideration; it does not include policy initiatives underway in other venues.

Appendix 2: Stakeholder Comments on Draft White Paper

The Complementary Policies Committee prepared a draft of this white paper to solicit input from stakeholders on:

- *Recommended Policies:* Which policies should be recommended for further evaluation, how those policies should be prioritized, key issues associated with the policies, and benefits to harmonizing policies across WCI Partner jurisdictions, as well as other states and provinces
- *Evaluation Criteria and Indicators:* How the Committee's recommended evaluation criteria and qualitative indicators can be used to verify that criteria have been met
- *Continued Stakeholder Engagement:* How the Committee can best engage with stakeholders as the evaluation process evolves

The Committee received 17 sets of written comments on its draft white paper during the 60-day public comment period. Some comments were submitted on behalf of numerous organizations. The Committee carefully reviewed all comments. Following is an overview of the public comments received and WCI's responses, including changes in this final paper.

Comments on Policy Recommendations

Energy Production

Renewable portfolio standards (RPS) and tradable renewable energy credits. One stakeholder recommended that WCI Partners procure out-of-state renewable resources – or renewable energy credits from out-of-state projects – to meet state RPS requirements. Another commenter recommended that WCI Partners establish a system of tradable energy efficiency credits, in combination with tradable renewable energy credits. Other stakeholders recommended that all WCI Partner jurisdictions have strong RPS requirements, or that WCI Partner jurisdictions harmonize RPS requirements. On RPS generally and treatment of out-of-state resources, each WCI Partner already has established an RPS that specifies renewable resource obligations, geographic or deliverability requirements, and other standards in accordance with state objectives. However, WCI agrees that the concept of improving trading of renewable energy credits should be further explored. A section on this topic has been added to the final paper. We discuss energy efficiency credits under "Energy Efficiency," below.

Hydropower. Several comments were received on the economic and GHG benefits of hydropower. WCI agrees that acquiring incremental capacity from existing dams and potentially new, small-scale, run-of-the-river facilities present a valuable opportunity. A section on this topic has been added to the final paper.

Emissions performance standards. Some stakeholders are opposed to emissions performance standards for electric generating units, maintaining that they do not comport with a cap-and-trade system and that low-carbon solutions may not exist for a number of generating technologies. In its white paper, the Committee notes several key issues related to implementation and technology availability. Further, this paper is the Committee's initial review of policies for consideration. As described in the "Next Steps" section, WCI will evaluate these policies in more depth in the future, beginning with tier 1 policies.

Transmission. Several stakeholders recommended that the Committee explore policies related to the expansion of interstate transmission to access low-carbon resources. WCI acknowledges that this is a priority action for consideration, however, several interjurisdictional efforts are already underway to address this need. A section describing these efforts has been added to the paper under "Important Policies Addressed in Other Venues."

Combined heat and power facilities. Several stakeholders recommended that WCI consider policies to promote combined heat and power (cogeneration) facilities. They noted that many of the policies considered in the white paper for small-scale renewable resources also could apply to combined heat and power. WCI agrees that policies to promote combined heat and power facilities should be a high priority. A section on such policies has been added to the final paper.

Energy Efficiency

Building codes and appliance standards. Some stakeholders recommended that WCI Partners coordinate on building energy codes and appliance standards that exceed national requirements. WCI agrees that these are important efforts, but notes that they are being addressed through other avenues. See revisions in this paper under "Important Policies Addressed in Other Venues."

Industrial efficiency measures. The Committee received a comment that the policies proposed for consideration put insufficient emphasis on industrial energy efficiency measures, noting in particular energy efficiency audits for large industrial emitters. In response, the Committee points out that the policies described under "Energy Efficiency Targets" and "Energy Efficiency Programs and Incentives" span all sectors of the economy, including industry. Regarding audits specifically, large industrial facilities typically have in-house energy expertise. For small- and medium-size manufacturers in the U.S., the Department of Energy provides free, in-depth assessments of facilities, services and manufacturing operations. The audits examine potential savings from energy efficiency improvements, waste minimization and pollution prevention, and productivity improvement.[62]

[62] *See* http://iac.rutgers.edu/.

Energy savings credits. As described above, one stakeholder recommended that WCI Partners establish a system of tradable energy efficiency credits. WCI agrees to further explore this concept. This potential policy has been added to the final paper.

Smart grid. The Committee was asked to address policies to develop a "smart grid." WCI recognizes that smart grid technologies can enable GHG emissions reductions, if the requisite complementary policies are in place, e.g., policies that promote energy efficiency, renewable energy and clean distributed resources. However, WCI believes its appropriate role in this area is education and outreach that supports the significant federal and regional efforts already underway. The "Important Policies Addressed in Other Venues" section has been revised to further describe these federal and regional efforts.

Transportation

Stakeholders noted significant opportunities for reducing GHG emissions in the transportation sector through a reduction in Vehicle Miles Traveled (VMT) and increased efficiencies in driving habits. The WCI economic analysis affirmed that these policies will be critical to meeting GHG reduction goals.

Pay-as-you-drive insurance. Several jurisdictions are pursuing policies that promote pay-as-you-drive insurance. WCI agrees to further consider this policy and has added an initial discussion to this paper.

Reduced speed limits. One stakeholder suggested reducing highway speed limits as a strategy to reduce GHG emissions. Lower speed limits and mandatory use of speed regulators for heavy duty trucks are among the possible policies included in this paper for further consideration by WCI.

Low-carbon fuel standard (LCFS). Some stakeholders recommended that transportation fuels be included in the WCI cap-and-trade program or that alternative policies, such as a federal renewable fuel standard, should be considered. When it approved its cap-and-trade program design, WCI determined that transportation fuels will come under the cap beginning in 2015. Other stakeholders stated their concerns about implementation and economic impacts of an LCFS. WCI will continue to explore these issues as it moves forward with evaluating an LCFS.

Vehicle efficiency. Stakeholders recommended WCI Partner jurisdictions adopt vehicle efficiency standards. On April 1, 2010, EPA and the Department of Transportation's National Highway Safety Administration (NHTSA) announced a joint final rule establishing a national program to reduce greenhouse gas emissions and improve fuel economy for new cars and trucks sold in the United States. These standards were simultaneously adopted by the Canadian national government.

Electrification of the transportation sector. Some stakeholders suggested that the white paper include the electrification of transportation as a tier 1 policy. There are a number of options for diversifying the transportation fuel mix in WCI Partner jurisdictions. The draft white paper included development of electric and alternative-fuel infrastructure for freight transportation and vehicles as Tier 2 policies for further evaluation. Several WCI Partner jurisdictions, particularly on the West Coast, already have efforts underway to develop infrastructure for electric vehicles.

Another stakeholder recommended that the Committee consider additional transportation policies such as replacement tire standards, feebates for highly efficient vehicles, and an accelerated vehicle retirement program. Several WCI jurisdictions currently offer incentives for high-efficiency or alternative-fuel vehicles and have other programs underway to reduce emissions from the transportation sector.

High-Global Warming Potential Gases

Some stakeholders suggested that ozone-depleting substance destruction should be eligible under the WCI cap-and-trade program as a GHG offset. Because this recommendation deals specifically with offsets under the program, the Complementary Policies Committee referred this recommendation to the Offsets Committee.

Waste Management

One stakeholder suggested that the Complementary Policies Committee should drop from further consideration policies on anaerobic digesters and landfill methane reductions, and that these policies instead be addressed by the WCI Offsets Committee as it develops offset protocols. The white paper has been amended to clarify that the proposed complementary policies for anaerobic digesters are targeted towards streamlining permitting processes and increasing the accessibility of this technology. In the case of landfills, the proposed policy is coordinated regional outreach to landfills that are not subject to U.S. or Canadian regulations for methane reduction. The Complementary Policies Committee will coordinate with the Offsets Committee in any further evaluation of such outreach.

Other stakeholders asked the Committee to explore *additional* policies that address emissions from the waste sector, including mandating landfill gas-to-electricity (or landfill gas-to-fuel) processes for large landfills; requiring small landfills to collect and combust waste gas; and flaring methane from other organic waste sources, such as dairies, pig farms and food processing facilities. To address large waste sources, some stakeholders recommended using waste gas to generate electricity and produce transportation fuels, and increasing recycling of aluminum and other discarded materials.

The white paper includes a variety of policy approaches to help coordinate and encourage broader adoption of methane management practices to reflect the diversity of landfills (e.g., size, construction and composition); the variability in methane yields among regions (e.g., wet vs. dry); and the various complex and, in some cases, novel technologies employed for methane capture and flaring/electricity generation. Such policy tools include funding of methane recovery projects, particularly for closed landfills or small municipal landfills; evaluation of requisite electrical infrastructure; outreach to maximize program participation; and improved inventorying.

Other Sectors

Forestry. Some stakeholders recommended that WCI Partners require standardized, sector-wide accounting of forest carbon, including flows between sectors and permanent conversion of forest land to other uses. Stakeholders also recommended that WCI use state and provincial inventory information to develop a regional forest carbon policy that includes no net loss or a "floor" for forest carbon and continued sequestration at or above current levels, with a goal of maintaining forest carbon stores in natural forests and increasing total terrestrial carbon stores in the forest sector over time. The Committee referred these recommendations to the WCI Partners for consideration. The Partners determined that these recommendations address areas beyond the Committee's scope, as outlined in its workplan.

Other land uses. WCI should consider developing a regional mitigation program, potentially implemented at the state or provincial level, for the net climate impact of emissions from other land uses (e.g., peat extraction) and conversion of natural and working landscapes to developed or other uses. While the Committee is aware of the potential impact of land use changes on greenhouse gas emissions, it also recognizes that land use is typically a local government decision.

Workforce strategies. The Committee received a comment that any strategy proposals to address workforce issues related to the cap-and-trade program should align state assets, such as community colleges and apprenticeship, rather than create new and perhaps duplicative programs. The Committee appreciates this advance comment for its future report in this area.

Evaluation Criteria

Stakeholders provided comments on the draft criteria for evaluating recommended policies for harmonization, suggesting either revisions to the criteria or additional criteria. The Committee has revised the criteria to include "The policy addresses a perceived market failure" and to clarify that the increased use of electricity is not a collateral detriment, unless it results in higher GHG emissions. Other revisions recommended by stakeholders were deemed to be similar to those already put forth by the Committee.

Stakeholders provided the following suggestions for how policies should be prioritized (tiered) and evaluated:

- The ranking of some policies, including small-scale renewable resources and development of algae biofuels, should be lowered. In the case of biofuels, a stakeholder commented that "supporting research of a single technology does not seem to be the proper role for the WCI complementary policies committee."

- Carbon capture and sequestration, transportation electrification, smart grid, and industrial emissions performance standards should be tier 1 policies.

The Committee agrees that barriers to algae biofuels fall under the purview of a broader policy, such as an LCFS. With regard to the other comments, the Committee re-evaluated the tiering of policies before publishing the final white paper to ensure consistency with the evaluation criteria.

Stakeholder Engagement

Stakeholders were asked to provide suggestions as to how the Complementary Policies Committee can better engage stakeholders and increase participation. The Committee sincerely appreciates these suggestions and will take them up as it continues its work.

General Comments

GHG reductions from complementary policies vs. cap-and-trade program. Some stakeholders maintain that GHG reductions from complementary policies should be counted towards the emissions cap under the cap-and-trade program. Additions to the white paper under "The Role of Complementary Policies" further clarify the interaction between GHG emission reductions from complementary policies and the cap-and-trade program.

Vehicle emissions labeling. The Committee received a comment that the benefits of vehicle emissions labeling would be nullified by combining that program with tradable credits for vehicle emissions. The purpose of vehicle emission labeling is to provide consumers with information about the particular vehicle. It does not purport to share information about overall greenhouse gas emissions. In an emissions trading program, emission reductions achieved in one sector may indeed be traded to another sector that is unable to make reductions. However, the declining cap will ensure the needed reductions are made.

WCI focus. One stakeholder recommended that WCI focus its efforts on its core directives – particularly the implementation of the regional cap-and-trade program – and limit its engagement in complementary policies to those critical to the cap-and-trade program's success, at least until after the program's implementation in 2012. The section "The Role of Complementary Policies" explains the importance of both efforts to achieve WCI's GHG emissions reduction goals at least cost.

Regulatory and trade agreement conflicts. One commenter recommended that the Committee evaluate potential conflicts between complementary policies under consideration and regulations and trade agreements. That type of analysis is envisioned in the next phase of the Committee's work, as explained in further detail in the amended "Next Steps" section of this paper.

Appendix 3: List of Acronyms

CCS	Carbon capture and sequestration
CHP	Combined heat and power
EERS	Energy efficiency resource standard
EPA	U.S. Environmental Protection Agency
EPS	Emissions performance standard
FIT	Feed-in tariff
GHG	Greenhouse gas
GWP	Global warming potential
LCFRR	Low Carbon Fuel Requirement Regulation
LCFS	Low carbon fuel standard
LMOP	Landfill Methane Outreach Program
MW	Megawatt
MWh	Megawatt-hour
ODS	Ozone depleting substances
PAYD	Pay-as-you-drive
PURPA	Public Utility Regulatory Policies Act
RPS	Renewable portfolio standard
TRU	Transport Refrigeration Units
WCI	Western Climate Initiative
VMT	Vehicle miles traveled

WCI.8 Verification WCI.8-1

1 Introduction

On July 16, 2009, The WCI published the Final Essential Requirements for Mandatory Reporting (the "ERs") to be implemented by the WCI Partner jurisdictions. On September 22, 2009, U.S. EPA adopted its final Mandatory Reporting Rule (the "EPA rule") for greenhouse gas emissions. Many U.S. facilities in the WCI region will be subject to both reporting programs. Specifically, most facilities with emissions of CO_2e greater than or equal to 25,000 metric tons per year in WCI states will be subject to both programs.

The WCI Partners were concerned that the existence of two different reporting systems in a WCI state could result in the imposition of duplicative or conflicting reporting obligations on facilities subject to both programs. Unless steps were taken to reconcile the WCI ERs with the EPA rule, a facility in a WCI state and with CO_2e emissions of 25,000 metric tons per year or greater could be required to prepare and submit two reports containing different data values in different formats to two jurisdictions.

In order to avoid the imposition of this burden on reporting facilities, the Partners directed the WCI Reporting Committee to develop amended ERs that are harmonized with the EPA rule.

Both the EPA rule and the WCI ERs require the filing of initial reports for the 2010 reporting year by Spring 2011 (March 31, 2011, and April 1, 2011, respectively). The goal of the Reporting Committee is to issue amended ERs in time for implementation in the 2011 reporting year. The adoption and implementation of interim measures to harmonize existing reporting requirements with the EPA rule has been left to the discretion of individual WCI jurisdictions.

This document and its Appendices contain the WCI's proposal for harmonizing the ERs and the EPA rule in U.S. jurisdictions (the "harmonized ERs"). As explained below, the WCI is also working on the development of amended ERs that are methodologically consistent with the harmonized ERs but appropriate for use in the Canadian Partner jurisdictions.

WCI stakeholders are invited to submit written comments on this proposal by no later than June 28, 2010.

2 Harmonization Principles

2.1 For U.S. Jurisdictions

In developing harmonized ERs for use in U.S. jurisdictions, the WCI Reporting Committee adhered to the following principles:

1. A U.S. facility should be able to comply with both the MRR and a WCI jurisdiction's reporting requirements by following a single set of monitoring, recordkeeping and reporting requirements.

2. The quantification methods included in the harmonized ERs must be sufficiently reliable and accurate to be employed in a greenhouse gas (GHG) cap-and-trade program.

The most straightforward way to follow the first principle would be to adopt the EPA rule without change. Unfortunately, it is not possible to do so and also adhere to the second principle. As EPA has acknowledged, the EPA rule, unlike the WCI ERs, has not been specifically designed to meet the needs of a cap-and-trade program:

> A key difference between the Federal mandatory GHG reporting rule and the RGGI and WCI programs is that the Federal mandatory GHG rule is solely a reporting requirement. It does not in any way regulate GHG emissions or require any emissions reductions.

74 Fed. Reg. 16448, 16460 (2009); see also 74 Fed. Reg. 56260, 56369 (2009) (EPA rule designed to gather data needed to "inform future climate change policies").

Fortunately, in nearly all cases where the Reporting Committee determined that a modification to the EPA rule was necessary for implementation of a cap-and-trade program or to achieve other WCI objectives, the modification could be implemented without requiring any alteration to the EPA program. For example, Subpart C of EPA's general stationary combustion rule establishes essentially the same four-tiered approach as section WCI.20 of the ERs. In some cases, WCI.20 requires the use of a higher tier than the EPA rule. Because the EPA rule generally *allows* the use of higher tier for any facility, however, a facility may use the methodology required by WCI.20 and still submit a report conforming to the EPA rule.

In a few cases, the Reporting Committee identified additional data elements that the EPA rule does not require but that WCI jurisdictions will need for cap-and-trade or other purposes.[1] In order to avoid imposing a requirement to file a supplemental report addressing these data elements, the Reporting Committee has been working with EPA and the National Data Exchange to secure changes to the EPA GHG reporting schema that will allow submission of reports containing these data elements directly to EPA. In addition, EPA has indicated that it may be possible to make adjustments to the online reporting tool it is developing for the federal GHG reporting program to accommodate state and regional reporting requirements.

[1] For example, gathering data related to cogeneration.

WCI intends to follow the same principles with regard to future additions or amendments to the EPA rule, such as the recently re-proposed Subpart W for the oil and gas industry.

2.2 For Canadian Jurisdictions

In developing harmonized ERs for use in Canadian jurisdictions that modify the existing ERs, the WCI Reporting Committee is adhering to the following principles:

1. A Canadian facility should apply the same functions, equations, sampling protocols and measurement criteria as U.S. facilities subject to the U.S. version of the harmonized ERs. This means that the harmonized ERs will achieve the same level of reporting accuracy for Canadian and U.S. facilities, but the U.S. version may require more data elements to be reported to harmonize with the EPA rule.

2. The quantification methods included in the harmonized ERs must remain sufficiently reliable and accurate to be employed in a greenhouse gas (GHG) cap-and-trade program.

3. The WCI reporting system must remain suitable for use in Canadian jurisdictions. For example, it must allow reporting in metric as well as English units and must where necessary include Canada-specific emission factors.

4. The harmonized ERs should facilitate harmonization with Canadian federal reporting. Some Canadian jurisdictions are working with Environment Canada to develop a one-window reporting tool for provincial and national GHG reporting requirements.

3 Harmonization Approach

3.1 For U.S. Jurisdictions

The WCI proposes to achieve harmonization in U.S. jurisdictions by adopting incorporation-by-reference rules that modify the EPA rule in a manner consistent with the harmonization principles set forth in section 2.1. The new WCI ERs for U.S. jurisdictions, which are attached to this document as appendices, therefore take the form of a markup of the EPA rule. The partners anticipate that each U.S. Partner will adopt an incorporation-by-reference rule consistent with this markup.

The WCI chose this approach for U.S. jurisdictions, rather than attempting to amend the existing WCI ERs to achieve harmonization, for the following reasons:

- Although the WCI ERs and EPA rule for the most part follow similar approaches to GHG quantification, they vary widely in organization and formatting and in the details of the monitoring, recordkeeping and reporting requirements imposed. It would therefore be extraordinarily difficult to amend the ERs to conform to the EPA rule without inadvertently introducing inconsistencies between the two programs. Any inconsistency would subject U.S. facilities to the risk of noncompliance with one program or the other.

- An incorporation-by-reference rule will make it much easier for a facility subject to both WCI and EPA requirements to assure itself that it is complying with both programs.

3.2 For Canadian Jurisdictions

For the Canadian jurisdictions, the key requirement is that the WCI reporting system as a whole require the use of comparable methodologies and produce comparable results for facilities of the same type, so that a “ton is a ton” in both the U.S. and Canada. For Canadian jurisdictions it is not nearly as important to avoid small differences between the ERs and the EPA rule as it is for the U.S. jurisdictions, where differences create a risk of inadvertent non-compliance.

Canadian Partners have invested substantial resources in developing regulations to implement the existing WCI ERs. In addition, the provinces face technical and legal issues with the incorporation by reference of the EPA rule that do not apply to the states. The WCI is therefore working on the development of amendments to the existing WCI ERs to assure that they conform in substance with the U.S. version of the harmonized ERs. These amendments will also take into account the interest provinces have in harmonizing their reporting programs with Environment Canada’s.

The Reporting Committee is currently undertaking the Canadian ER harmonization work, and expects to have harmonized ERs prepared for stakeholder review in July.

3.3 Verification

Consistent with the Design Recommendations for the WCI Regional Cap-and-Trade Program, the harmonized ERs will continue to require third party verification of emission reports by entities and facilities included in the cap. A version of the verification rule, WCI.8, revised to cross reference the U.S. version of the harmonized ERs is included as an appendix.

Because the EPA rule does not require third-party verification, it generally requires reporting of substantially more data than the existing WCI ERs. In the absence of third-party verification, EPA must require the submission of sufficient data to enable the agency to implement its own audit program. In order to assure consistency with the first harmonization principle—allowing compliance with both programs through preparation of a single report—the WCI markup of the

EPA rule does not attempt to reduce the amount of data required in a report for U.S. jurisdictions.

The amount of data to be reported for Canadian jurisdictions will be modified to reflect that third party verification is required for emissions reports at a certain threshold of emissions, so less data is required to be reported to the Canadian jurisdictions as compared to that which is required to be reported to the EPA for their internal verification.

3.4 Missing Data Procedures

The EPA rule includes procedures in each subpart for replacing missing data resulting from monitoring failures. With the exception of methodologies for facilities subject to 40 C.F.R. Part 75 (the acid rain program), these missing data procedures do not appear to be sufficiently rigorous to support a cap-and-trade system. There is no limitation on the amount of data that may be missing, and replacement methods appear to be both inadequate (for example, many use only one or two available data points) and inequitable (for example, Part 75 power plants have to apply punitive methods, while other facilities do not).

In order to move forward with a harmonization proposal in time to allow implementation for the 2011 reporting year, the proposed harmonized ERs retain the EPA missing data procedures. Before implementation of the cap-and-trade program, however, the WCI intends to revisit this issue. The WCI will investigate whether the EPA missing data procedures can be modified to be more consistent with the needs of a cap-and-trade program while adhering to the harmonization principles in section 2.1.

As a partial measure to address the possibility of gaming, the harmonized ERs include a provision making it clear that the use of a missing data procedure does not excuse a facility's failure to follow the monitoring requirements of the rule.

4 Summary of Changes to EPA Rule

The following table summarizes the changes to the EPA rule that the WCI is proposing to implement in WCI jurisdictions. The specific language for the changes is set forth in the Appendices.

The table also identifies potential differences in approach that may be employed by the Canadian WCI jurisdictions.

§	Change to EPA Rule	Rationale
Subpart A—General Provisions		
98.1	Added new (c) substituting jurisdiction for EPA and EPA administrator throughout rule.	Clarifies who is responsible for administering the incorporated-by-reference version of the EPA rule. Since the EPA rule does not provide delegation, EPA will remain responsible for administering the original 40 C.F.R. Part 98 requirements.
98.1 and passim[2]	Added new (d) providing for identification of data that will be reported for informational purposes only and will not be subject to cap and trade. Added "reporting only" label to certain EPA subparts and specific quantification methods.	Not all quantification methods specified by the harmonized ERs are suitable for a cap-and-trade system. The "reporting only" label provides notice to stakeholders on WCI's current view on which emissions should not be subject to the cap-and-trade program.
98.1	Added new (e) to authorize a WCI jurisdiction to allow submission of a report to EPA to meet the requirements of the harmonized ERs.	As discussed above, WCI is working with EPA to allow reporting entities to use EPA's system to meet the requirements of both the EPA rule and the harmonized ERs.

[2] Occurring in various places.

§	Change to EPA Rule	Rationale
98.2 passim	Changed threshold for reporting from 25,000 metric tons to 10,000 metric tons.	Consistent with WCI design recommendation for reporting. EPA has indicated that it may be able to accommodate reports by facilities with emissions below the EPA rule threshold.
98.2(a)(3)(iii)	Changed heat input threshold for fuel combustion units from 30 mmBtu/hr to 12 mmBtu/hr.	The 30 mmBtu/hr threshold is designed to provide facilities whose only regulated GHG source is fuel combustion an easy method for determining whether they are above the 25,000 metric tons emission threshold. For WCI's 10,000 metric tons threshold, the equivalent heat input threshold is 12 mmBtu/hr.
98.2(b)(2)	Added exclusions from the applicability determination for certain emissions from the combustion of biomass.	Consistent with WCI Design Recommendations and existing WCI.1(b)(2).
98.2(i)	Added new (4) providing additional off-ramp for facilities required to report to WCI jurisdiction but not EPA (i.e. emissions between 10,000 and 25,000 metric tons per year) that subsequently fall below the 10,000- metric-tons-per-year threshold.	Consistent with existing WCI.1(e)(2).
98.3(g), 98.3(g)(5)(iv)	Added requirement to submit records within 10 days of a request from a WCI jurisdiction.	Consistent with existing WCI.4(b). Failure of EPA rule to specify a time period for responding may make enforcement difficult.
98.3(h)	Added a new (2) requiring facilities subject to WCI but not EPA reporting requirements to submit correction only if cumulative errors exceed 5 % of total CO_2e emissions.	Consistent with WCI.2(f). This change cannot be applied to facilities subject to the EPA rule, since EPA requires the correction of any errors.

§	Change to EPA Rule	Rationale
98.3(i) (6)	Modified to require calibration during any outage of sufficient duration to allow performance of the calibration procedure, not just during scheduled maintenance.	If outages occur for reasons other than scheduled maintenance (e.g. for repairs necessitated by unforeseen equipment failure), and the outages last long enough to complete a new calibration, there is no reason to put calibration off until the next schedule maintenance.
98.3	Added a method for calculating weighted averages as new (j).	In some cases, the harmonized ERs require more frequent sampling than the EPA rule. This subsection provides a method for reducing the data obtained from the additional samples to fit the EPA reporting system.
98.3	Added new (k) requiring a jurisdiction's approval before a facility may switch from a CEMS to a mass- or fuel-based monitoring method or vice versa.	This provision is designed to prevent facilities from using changes in monitoring methods to create an artificial reduction in GHG emissions.
98.3	Added a modified version of the de minimis provision in WCI.2(d) as new (l). Instead of allowing the use of any alternative method approved by the verifier, as in the current ERs, the modified version requires the use of a method permitted by 40 C.F.R. Part 98 for the facility. So, for example, a facility subject to verification could use Tiers 1 or 2, rather than Tier 3, for up to 3 percent of its combustion emissions.	The EPA rule does not include a de minimis provision. Allowing U.S. facilities to employ methods that are not specified by the EPA rule therefore would be inconsistent with harmonization. In some cases, however, the harmonized ERs require the use of a higher tier than would otherwise be required by the EPA rule. In these cases, it is consistent with harmonization to allow the use of the lower tier for emissions determined to be de minimis.

§	Change to EPA Rule	Rationale
98.3	Added new (m) to make it clear the missing data procedures included in the EPA rule (and therefore the harmonized ERs) do not excuse facilities from possible enforcement action for failure to conduct the monitoring required by the rule.	See section 3.4.
Subpart C—General Stationary Combustion		
98.32(b), 98.33(f)	Added requirement to report fugitive HFC emissions from cooling units.	Consistent with existing WCI.42(h) and WCI.42(d).
98.33(a)(2)(iii)	Limit availability of Equation C-2c (ratio of heat input to steam method) to municipal solid waste and solid biomass, rather than allowing its use for any other solid fuel listed in Table C-1.	Consistent with existing WCI.23(b)(2).
98.33(a)(4)(iv)	Require CEMS installed after beginning of first reporting year subject to rule to include a CO2 monitor, rather than an oxygen monitor.	Although it may make sense not to require the retrofit of grandfathered CEMS with a CO2 monitor, there is no reason for newly installed CEMS not to include such a monitor.
98.33(b)(1)	Limit use of Tier 1 (default emission factors and HHV) to units that are both (1) below both EPA's 250 mmBtu/hr heat input threshold and (2) located at facilities that are not subject to verification (i.e., emissions < 25,000 metric tons/yr).	Consistent with existing WCI.23(e)(1).
98.33(b)(1)(iv)	Require use of Tier 2 when a facility can obtain HHV from the fuel supplier, even if this information is not currently "routinely received."	If a facility is able to obtain this information, it should use the more accurate method.

§	Change to EPA Rule	Rationale
98.33(b)(2)	Limit use of Tier 2 (default emission factors and measured HHV) to units that are both (1) below both EPA's 250 mmBtu/hr heat input threshold and (2) located at facilities that are not subject to verification (i.e., emissions < 25,000 metric tons/yr), except for facilities that burn pipeline quality natural gas or distillate fuel oil.	Consistent with existing WCI.23(e)(2).
98.33(b)(3)	Require the use of Tier 3 (measured carbon content) for all units at a facility subject to verification (i.e. emissions > 25,000 metric tons/yr). Require Tier 3 for the combustion of *all* fuels that are not listed in Table C-1, not just for unlisted fuels that provide 10 % or more of a unit's annual heat input.	Consistent with existing WCI.23(e)(3). Exempting unlisted fuels that provide less than 10 % of a unit's heat input could result in a significant gap in a facility's reported emissions.
98.33(c)	Add new (6) to allow an operator use a source-specific emission factor to calculate CH4 and N2O emissions.	Consistent with existing WCI.24(d). Since this is optional, it does not conflict with harmonization principle 1.
98.33(e)(2)	Require the use of 98.33(e)(3) for the combustion of any fossil fuel/biomass mixture containing an undeterminable quantity of fossil fuels, not just MSW.	The method specified in 98.33(e)(2) assumes that the amount of fossil fuel in a fossil fuel/biomass mixture can be determined and that a mass balance approach is therefore possible. Its use therefore must be limited to fuels where the amount of fossil fuel in a mixture can in fact be determined. Other mixtures must as a practical matter be subject to 98.33(e)(3).

§	Change to EPA Rule	Rationale
98.34(b)(3)(ii)(E)	Require installation of equipment necessary to perform daily sampling and analysis of carbon content and molecular weight for refinery fuel gas by beginning of first reporting year subject to harmonized ERs.	Consistent with existing WCI.34.
98.36(b), (d)	Added provisions requiring reporting of nameplate capacity and net power generated for EGUs and cogeneration data, as well as certain fuel data if not reported under 40 C.F.R. Part 75.	Consistent with existing WCI.40.
Subpart D—Electricity Generation		
98.46	Corrected cross-reference.	Clarification.
Subpart E—Adipic Acid Production		
No change.		
Subpart F—Aluminum Production		
98.64(a)	Changed to require re-measurement of smelter-specific slope coefficients every 36 months, rather than every 10 years. Inserted additional conditions that would trigger the obligation to re-measure the coefficients before the expiration of the 36-month period.	Consistent with WCI.74(b).
98.64(a), (d)	Changed to require the use of smelter-specific measurements rather than the default values specified in table F-1.	Consistent with WCI.74.
98.64(b)	Changed minimum measurement frequency from annually to monthly for all parameters.	Consistent with WCI.74(a).
Subpart G—Ammonia Production		
No change.		

§	Change to EPA Rule	Rationale
Subpart H—Cement Production		
No change to EPA rule for U.S. jurisdictions. Unlike the EPA rule, existing WCI.090 allows emissions to be calculated on a facility-wide basis. The harmonized ERs for U.S. jurisdictions will retain the EPA requirement to calculate emissions for each kiln in order to assure harmonization. Canadian jurisdictions, however, may continue to allow facility-based calculations.		
Subpart K—Feroalloy Production		
No change.		
Subpart N—Glass Production		
Passim	Changed to apply to batch as well as continuous processes.	Consistent with draft WCI method. This change may require facilities not subject to the EPA rule to report but should not result in a facility subject to both the WCI and EPA programs being subject to inconsistent reporting obligations.
Subpart O—HCFC-22 Production and HFC-23 Destruction		
No change.		
Subpart P—Hydrogen Production		
98.160(a)	Changed to apply subpart to production of hydrogen for use on site as well as hydrogen sold as a product.	Consistent with WCI.131. This change may require facilities not subject to the EPA rule to report but should not result in a facility subject to both the WCI and EPA programs being subject to inconsistent reporting obligations.
98.163(b), 98.164(b)(2)-(4)	Require daily, rather than monthly or weekly, analysis of carbon feedstocks other than natural gas.	Consistent with WCI.134(b)(1). Higher frequency sampling required to insure accuracy adequate for a cap-and-trade program.

<table>
<tr><th>§</th><th>Change to EPA Rule</th><th>Rationale</th></tr>
<tr><td>98.166(b)</td><td>Added (7) requiring reporting of carbon in unconverted feedstock for which GHG emissions are calculated and reported by the facility using other methods.</td><td>In order to avoid possible double counting of emissions, WCI.133, Equation 130-1 allows subtraction of carbon “accounted for elsewhere” from the amount of feedstock, before calculation of the mass balance. EPA’s equations P-1, P-2 and P-3 do not allow for such a deduction. The equations themselves cannot be modified in the harmonized ERs, because that would require reporting different emissions to EPA and a U.S. WCI jurisdiction. The harmonized ERs therefore provide for the reporting of carbon accounted for elsewhere in bulk, which can then be subtracted from a facility’s total emissions by the WCI data system.</td></tr>
<tr><td colspan="3">Subpart Q—Iron and Steel Production</td></tr>
<tr><td colspan="3">No change to EPA rule for U.S. jurisdictions.

The EPA rule requires the reporting of CO2 from the combustion of coke oven gases at the point of combustion under Subpart C. Existing WCI.153 requires the reporting of emissions attributable to coke oven gases and blast furnace gases at the point of generation using a mass balance method. U.S. jurisdictions will employ the EPA method in order to assure harmonization. Canadian jurisdictions may continue to employ existing WCI.153. It is anticipated that the methods will produce substantially similar results.

Jurisdictions also may choose not to allow the use of the site-specific emission factor method established by 98.173(b)(2) for process emissions.</td></tr>
<tr><td colspan="3">Subpart R—Lead Production</td></tr>
<tr><td colspan="3">No change.</td></tr>
<tr><td colspan="3">Subpart S—Lime Production</td></tr>
<tr><td colspan="3">No change.</td></tr>
</table>

§	Change to EPA Rule	Rationale
Subpart V—Nitric Acid Production		
No change.		
Subpart X—Petrochemical Production		
No change.		
Subpart Y—Petroleum Refineries		
98.253(b)(1)(iii) 98.256(e)(8)	Amended to allow use of alternative equation Y-3 for flare emissions only during periods of startup, shutdown or malfunction.	The more accurate methods specified in equations Y-1 and Y-2 should be used for periods of normal operations.
98.253(c)(2) 98.256(f)(9)	Require calculation of emissions from catalytic cracking units that do not use CEMS and have rated capacities less than 10,000 barrels per stream day using this method (no less than hourly monitoring of O2, CO2 and CO), rather than 98.173(c)(3), which is deleted.	The EPA TSD for this sector states that the method specified in 98.173(c)(3) for units that do not have the necessary monitors is highly uncertain.
98.253(h), (l), (m), (n)	Identified as reporting only.	WCI does not believe the methods specified in these sections are sufficiently accurate to support a cap-and-trade program.
98.253(i)	Rather than allowing the use of default factors in Equation Y-18 for CO2 emissions from delayed coking units, require (1) the volumetric void fraction of the coking vessel prior to steaming to be based on engineering calculations and (2) the mole fraction of methane in coking vessel gas to be based on two samples per year.	Greater accuracy required for cap-and-trade.
98.253(k) 98.256(m)	Require the use the same method for process vents (paragraph (j)) and uncontrolled blowdown systems.	Consistent with WCI.200.

§	Change to EPA Rule	Rationale
98.254	New (m) added to require installation of equipment needed for daily sampling of carbon content and molecular weight of gaseous fuels (other than natural gas and biogas) by no later than first reporting year of harmonized ERs.	Needed to insure Tier 3 calculations of emissions from refinery gas are sufficiently accurate for cap-and-trade.
98.257(m)	New (b) added to require retention of records of the method used to demonstrate that the thresholds in §98.253(j) are not exceeded.	Needed for third-party verification.
Subpart Z—Phosphoric Acid Production		
No change.		
Subpart AA—Pulp and Paper		
98.273(a)(1), (b)(1), (c)(1)	Require use of applicable Subpart C methodology rather than specifying the use of Tier 1 for combustion at chemical recovery furnaces and pulp mill lime kilns.	Consistent with WCI.212(c). There does not appear to be any reason to treat combustion at these sources differently from combustion elsewhere. Note: Although Subpart C generally allows the use of higher tiers, even when a lower tier is specified for a particular unit or fuel, section 98.273 could be read as *requiring* the use of Tier 1. WCI is seeking clarification of the correct interpretation of section 98.273 in order to assure that the proposed changes are consistent with harmonization principle 1.
Subpart CC—Soda Ash Manufacturing		
98.294(d), 98.296(a)(5), (b)(12)	Added requirement to determine CO2 recycled to carbonation tower.	Consistent with WCI.232(f).

§	Change to EPA Rule	Rationale
Subpart GG—Zinc Production		
No change.		

Subpart A—General Provisions

§ 98.1 Purpose and scope.

(a) This part establishes mandatory greenhouse gas (GHG) reporting requirements for owners and operators of certain facilities that directly emit GHG as well as for certain fossil fuel suppliers and industrial GHG suppliers. For suppliers, the GHGs reported are the quantity that would be emitted from combustion or use of the products supplied.[1]

(b) Owners and operators of facilities and suppliers that are subject to this part must follow the requirements of subpart A and all applicable subparts of this part. If a conflict exists between a provision in subpart A and any other applicable subpart, the requirements of the subparts B through PP of this part shall take precedence.

(c) Except as otherwise specifically provided:

(1) Wherever the term "Administrator" is used in the rules incorporated by reference in this Article,[2] the term [director/secretary/administrator] of the [jurisdiction] shall be substituted.

(2) Wherever the term "EPA" is used in the rules incorporated by reference in this Article, the term [jurisdiction] shall be substituted.

(d) The following emissions data shall be submitted for information only and may not be subject to cap-and-trade requirements:[3]

(1) Data submitted by a source category designated as "reporting only." This provision does not apply to emissions from general stationary combustion at a source in a "reporting only" category.

(2) Emissions data calculated with a methodology identified as "reporting only."

(3) Data submitted by a facility not subject to verification under WCI.8.

[1] WCI jurisdictions will require reporting by fuel suppliers for reporting year 2012 and later and may in part rely on EPA methods

[2] "Article" is a placeholder for a jurisdiction-specific cross reference to whatever subdivision of its administrative code contains the WCI's Essential Requirements for Mandatory Reporting in their entirety. Any WCI methodologies that are not sufficiently accurate for cap-and-trade purposes, such as the coal storage method, should be designated "reporting only" in the jurisdiction's rules.

[3] The identification of data as "reporting only" will be subject to review possible revision before the adoption of a cap-and-trade program. On adoption of a cap-and-trade program, the jurisdiction will want to substitute a citation to the rules implementing the program for the words "cap-and-trade requirements." Any WCI methodologies that are not sufficiently accurate for cap-and-trade purposes, such as the coal storage method, should also be designated "reporting only" in the jurisdiction's rules.

(e) On approval by [jurisdiction], reports that conform to this Article and that are submitted to the EPA GHG reporting system shall be deemed to satisfy, in whole or in part,[4] the requirement to submit a report to [jurisdiction] under this Article.[5]

§ 98.2 Who must report?

(a) The GHG reporting requirements and related monitoring, recordkeeping, and reporting requirements of this part apply to the owners and operators of any facility that is located in the United States and that meets the requirements of either paragraph (a)(1), (a)(2), or (a)(3) of this section; and any supplier that meets the requirements of paragraph (a)(4) of this section:

(1) A facility that contains any source category (as defined in subparts C through JJ of this part) that is listed in this paragraph (a)(1) in any calendar year starting in ~~2010~~2011.[6] [7] For these facilities, the annual GHG report must cover all source categories and GHGs for which calculation methodologies are provided in subparts C through JJ of this part and sections – of this Article.

(i) Electricity generation (units that report CO2 emissions year-round through 40 CFR part 75).

(ii) Adipic acid production.

(iii) Aluminum production.

(iv) Ammonia manufacturing.

(v) Cement production.

(vi) HCFC–22 production.

(vii) HFC–23 destruction processes that are not collocated with a HCFC–22 production facility and that destroy more than 2.14 metric tons of HFC–23 per year.

---

[4] Supplemental reports may be needed for facilities subject to both EPA reporting requirements and WCI-only quantification methodologies, e.g. facilities that include coal storage (subject to WCI.100).

[5] Applies in U.S. jurisdictions only. Procedures for approval will be established by the jurisdiction.

[6] Alternatively, the calendar year after adoption of these essential requirements for a WCI jurisdiction adopting them after 2011. The same change would be made to other instances below where an initial reporting year of 2011 is specified.

[7] No threshold is specified for these source categories, because EPA has determined that the overwhelming majority of facilities in these categories would have emissions greater than 25,000 metric tons per year. It is highly likely that all such facilities would have emissions greater than 10,000 metric tons per year. Thus, omitting a threshold simplifies the rule without departing from the WCI's policy of requiring reporting only for facilities with emissions exceeding 10,000 metric tons per year. Canadian jurisdictions may choose to impose the 10,000 metric tons per year threshold to some or all of these categories so long as the coverage is not altered.

(viii) Lime manufacturing.

(ix) Nitric acid production.

(x) Petrochemical production.

(xi) Petroleum refineries.

(xii) Phosphoric acid production.

(xiii) Silicon carbide production.

(xiv) Soda ash production.

(xv) Titanium dioxide production.

(xvi) Municipal solid waste landfills that generate CH4 in amounts equivalent to 25,000 metric tons CO2e or more per year, as determined according to subpart HH of this part [Reporting only].

(xvii) Manure management systems with combined CH4 and N2O emissions in amounts equivalent to metric tons CO2e or more per year, as determined according to subpart JJ of this part [Reporting only].

(2) A facility that contains any source category (as defined in subparts C through JJ of this part) that is listed in this paragraph (a)(2) in any calendar year starting in 2010 and that emits ~~25,000~~10,000 metric tons CO2e or more per year in combined emissions from stationary fuel combustion units, miscellaneous uses of carbonate, and all source categories that are listed in this paragraph. For these facilities, the annual GHG report must cover all source categories and GHGs for which calculation methodologies are provided in subparts C through JJ of this part and sections – of this Article.

(i) Ferroalloy Production.

(ii) Glass Production.

(iii) Hydrogen Production.

(iv) Iron and Steel Production.

(v) Lead Production.

(vi) Pulp and Paper Manufacturing.

(vii) Zinc Production.

(3) A facility that in any calendar year starting in 2010 meets all three of the conditions listed in this paragraph (a)(3). For these facilities, the annual GHG report must cover emissions from stationary fuel combustion sources only.

(i) The facility does not meet the requirements of either paragraph (a)(1) or (a)(2) of this section.

(ii) The aggregate maximum rated heat input capacity of the stationary fuel combustion units at the facility is ~~30~~ 12 mmBtu/hr or greater.[8]

(iii) The facility emits ~~25,000~~10,000 metric tons CO2e or more per year in combined emissions from all stationary fuel combustion sources.

(4) A supplier (as defined in subparts KK through PP of this part) that provides products listed in this paragraph (a)(4) in any calendar year starting in 2010. For these suppliers, the annual GHG report must cover all applicable products for which calculation methodologies are provided in subparts KK through PP of this part.

(i) Coal-to-liquids suppliers, as specified in this paragraph (a)(4)(i).

(A) All producers of coal-to-liquid products.

(B) Importers of an annual quantity of coal-to-liquid products that is equivalent to 25,000 metric tons CO2e or more.

(C) Exporters of an annual quantity of coal-to-liquid products is equivalent to 25,000 metric tons CO2e or more.

(ii) Petroleum product suppliers, as specified in this paragraph (a)(4)(ii):

(A) All petroleum refineries that distill crude oil.

(B) Importers of an annual quantity of petroleum products that is equivalent to 25,000 metric tons CO2e or more.

(C) Exporters of an annual quantity of petroleum products that is equivalent to 25,000 metric tons CO2e or more.

(iii) Natural gas and natural gas liquids suppliers, as specified in this paragraph (a)(4)(iii):

(A) All natural gas fractionators.

(B) All local natural gas distribution companies.

(iv) Industrial greenhouse gas suppliers, as specified in this paragraph (a)(4)(iv):

(A) All producers of industrial greenhouse gases.

(B) Importers of industrial greenhouse

[8] 30 mmBtu/hr * 10,000/25,000.

gases with annual bulk imports of N_2O, fluorinated GHG, and CO_2 that in combination are equivalent to 25,000 metric tons CO_2e or more.

(C) Exporters of industrial greenhouse gases with annual bulk exports of N_2O, fluorinated GHG, and CO_2 that in combination are equivalent to 25,000 metric tons CO_2e or more.

(v) Carbon dioxide suppliers, as specified in this paragraph (a)(4)(v).

(A) All producers of CO_2.

(B) Importers of CO_2 with annual bulk imports of N_2O, fluorinated GHG, and CO_2 that in combination are equivalent to 25,000 metric tons CO_2e or more.

(C) Exporters of CO_2 with annual bulk exports of N_2O, fluorinated GHG, and CO_2 that in combination are equivalent to 25,000 metric tons CO_2e or more.

(5) Research and development activities are not considered to be part of any source category defined in this part.

(b) To calculate GHG emissions for comparison to the ~~25,000~~10,000 metric ton CO_2e per year emission threshold in paragraph (a)(2) of this section, the owner or operator shall calculate annual CO_2e emissions, as described in paragraphs (b)(1) through (b)(4) of this section.

(1) Calculate the annual emissions of CO_2, CH_4, N_2O, and each fluorinated GHG in metric tons from all applicable source categories listed in paragraph (a)(2) of this section. The GHG emissions shall be calculated using the calculation methodologies specified in each applicable subpart and available company records. Include emissions from only those gases listed in Table A– 1 of this subpart.

(2) For each general stationary fuel combustion unit, calculate the annual CO_2 emissions in metric tons using any of the four calculation methodologies specified in § 98.33(a). Calculate the annual CH_4 and N_2O emissions from the stationary fuel combustion sources in metric tons using the appropriate equation in § 98.33(c). ~~Exclude carbon dioxide emissions from the combustion of biomass, but include emissions of CH4 and N2O from biomass combustion.~~

(i) For stationary combustion units, carbon dioxide emissions from the combustion of biomass fuels shall be included in determining whether a facility is subject to the reporting requirements of this Article with the following exceptions:

(1) Until such time as [jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, a maximum of 15,000 metric tons of carbon dioxide emissions from the combustion of pure solid biomass fuel may be excluded from calculation of GHG emissions for comparison to the 10,000 metric ton CO2e per year emission threshold in paragraph (a)(2) of this section, provided that total GHG emissions including emissions from solid biomass fuel are less than 25,000 metric tons CO2e.

(2) After such time as [jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, the carbon dioxide emissions from the combustion of those fuels may be excluded from calculation of GHG emissions for determining whether the 10,000 metric tons CO2e per year emission threshold in paragraph (a)(1) of this section has been met.

(ii) The exceptions in paragraphs (b)(2)(i) of this section shall not apply in determining whether a facility is subject to the reporting requirements of 40 C.F.R. Part 98.

(3) For miscellaneous uses of carbonate, calculate the annual CO2 emissions in metric tons using the procedures specified in subpart U of this part.

(4) Sum the emissions estimates from paragraphs (b)(1), (b)(2), and (b)(3) of this section for each GHG and calculate metric tons of CO2e using Equation A– 1 of this section.

$$CO_2e = \sum_{i=1}^{n} GHG_i \times GWP_i \qquad \text{(Eq. A-1)}$$

Where:

CO2e = Carbon dioxide equivalent, metric tons/year.

GHGi = Mass emissions of each greenhouse gas listed in Table A–1 of this subpart, metric tons/year.

GWPi = Global warming potential for each greenhouse gas from Table A–1 of this subpart.

n = The number of greenhouse gases emitted.

(5) For purpose of determining if an emission threshold has been exceeded, include in the emissions calculation any CO2 that is captured for transfer off site.

(c) To calculate GHG emissions for comparison to the ~~25,000~~10,000 metric ton CO_2e/year emission threshold for stationary fuel combustion under paragraph (a)(3) of this section, calculate CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit by following the methods specified in paragraph (b)(2) of this section. Then, convert the emissions of each GHG to metric tons CO_2e per year using Equation A–1 of this section, and sum the emissions for all units at the facility.

(d) To calculate GHG quantities for comparison to the 25,000 metric ton CO_2 per year threshold for importers and exporters of coal-to-liquid products under paragraph (a)(4)(i) of this section, calculate the mass in metric tons per year of CO_2 that would result from the complete combustion or oxidation of the quantity of coal-to-liquid products that are imported during the reporting year and that are exported during the reporting year. Calculate the emissions using the methodology specified in subpart LL of this part.

(e) To calculate GHG quantities for comparison to the 25,000 metric ton CO_2e per year threshold for importers and exporters of petroleum products under paragraph (a)(4)(ii) of this section, calculate the mass in metric tons per year of CO_2 that would result from the complete combustion or oxidation of the volume of petroleum products and natural gas liquids that are imported during the reporting year and that are exported during the reporting year. Calculate the emissions using the methodology specified in subpart MM of this part.

(f) To calculate GHG quantities for comparison to the 25,000 metric ton CO_2e per year threshold under paragraph (a)(4) of this section for importers and exporters of industrial greenhouse gases and for importers and exporters of CO_2, the owner or operator shall calculate the mass in metric tons per year of CO_2e imports and exports as described in paragraphs (f)(1) through (f)(3) of this section.

(1) Calculate the mass in metric tons per year of CO_2, N_2O, and each fluorinated GHG that is imported and the mass in metric tons per year of CO_2, N_2O, and each fluorinated GHG that is exported during the year. Include only those gases listed in Table A–1 of this subpart.

(2) Convert the mass of each imported and each GHG exported from paragraph (f)(1) of this section to metric tons of CO_2e using Equation A–1 of this section.

(3) Sum the total annual metric tons of CO_2e in paragraph (f)(2) of this section for all imported GHGs. Sum the total annual metric tons of CO_2e in paragraph (f)(2) of this section for all exported GHGs.

(g) If a capacity or generation reporting threshold in paragraph (a)(1) of this section applies, the owner or operator shall review the appropriate records and perform any necessary calculations to determine whether the threshold has been exceeded.

(h) An owner or operator of a facility or supplier that does not meet the applicability requirements of paragraph (a) of this section is not subject to this rule. Such owner or operator would become subject to the rule and reporting requirements § 98.3(b)(3), if a facility or supplier exceeds the applicability requirements of paragraph (a) of this section at a later time. Thus, the owner or operator should reevaluate the applicability to this part (including the revising of any relevant emissions calculations or other calculations) whenever there is any change that could cause a facility or supplier to meet the applicability requirements of paragraph (a) of this section. Such changes include but are not limited to process modifications, increases in operating hours, increases in production, changes in fuel or raw material use, addition of equipment, and facility expansion.

(i) Except as provided in this paragraph, once a facility or supplier is subject to the requirements of this part, the owner or operator must continue for each year thereafter to comply with all requirements of this part, including the requirement to submit annual GHG reports, even if the facility or supplier does not meet the applicability requirements in paragraph (a) of this section in a future year.

(1) If reported emissions are less than 25,000 metric tons CO2e per year for five consecutive years, then the owner or operator may discontinue complying with this part provided that the owner or operator submits a notification to the Administrator that announces the cessation of reporting and explains the reasons for the reduction in emissions. The notification shall be submitted no later than March 31 of the year immediately following the fifth consecutive year of emissions less than 25,000 tons CO2e per year. The owner or operator must maintain the corresponding records required under § 98.3(g) for each of the five consecutive years and retain such records for three years following the year that reporting was discontinued. The owner or operator must resume reporting if annual emissions in any future calendar year increase to 25,000 metric tons CO2e per year or more.

(2) If reported emissions are less than ~~15,000~~ 10,000 metric tons CO2e per year for three consecutive years, then the owner or operator may discontinue complying with this part provided that the owner or operator submits a notification to the Administrator that announces

the cessation of reporting and explains the reasons for the reduction in emissions. The notification shall be submitted no later than March 31 of the year immediately following the third consecutive year of emissions less than ~~15,000~~10,000 tons CO2e per year. The owner or operator must maintain the corresponding records required under § 98.3(g) for each of the three consecutive years and retain such records for three years following the year that reporting was discontinued. The owner or operator must resume reporting if annual emissions in any future calendar year increase to ~~25,000~~10,000 metric tons CO2e per year or more.

(3) If the operations of a facility or supplier are changed such that all applicable GHG-emitting processes and operations listed in paragraphs (a)(1) through (a)(4) of this section cease to operate, then the owner or operator is exempt from reporting in the years following the year in which cessation of such operations occurs, provided that the owner or operator submits a notification to the Administrator that announces the cessation of reporting and certifies to the closure of all GHG emitting processes and operations. This paragraph (i)(2) does not apply to seasonal or other temporary cessation of operations. This paragraph (i)(2) does not apply to facilities with municipal solid waste landfills. The owner or operator must resume reporting for any future calendar year during which any of the GHG-emitting processes or operations resume operation.[9]

(4) If in the prior year a facility was required to report under this Article but was not required to report under 40 C.F.R. Part 98, and the operations of the facility change such that emissions fall below 10,000 metric tons CO2e per year during the prior year, then in lieu of submitting a report under this Article the owner or operator shall submit to [jurisdiction] a signed statement certifying that emissions were less than 10,000 metric tons CO2e during the prior year. After certifying that emissions are below 10,000 metric tons CO2e per year for three consecutive years under this paragraph, the owner or operator shall be exempted from further reporting until CO2e emissions again exceed 10,000 metric tons in any future calendar year.

(j) Table A–2 of this subpart provides a conversion table for some of the common units of measure used in part 98.

[9] This provision may require modification to meet the needs of the cap-and-trade program.

§ 98.3 What are the general monitoring, reporting, recordkeeping and verification requirements of this part?

The owner or operator of a facility or supplier that is subject to the requirements of this part must submit GHG reports to the Administrator, as specified in this section.

(a) General. Except as provided in paragraph (d) of this section, follow the procedures for emission calculation, monitoring, quality assurance, missing data, recordkeeping, and reporting that are specified in each relevant subpart of this part.

(b) Schedule. The annual GHG report must be submitted no later than March 31 of each calendar year for GHG emissions in the previous calendar year.

(1) For an existing facility or supplier that began operation before January 1, 2010, report emissions for calendar year 2010 and each subsequent calendar year.

(2) For a new facility or supplier that begins operation on or after January 1, 2010, report emissions beginning with the first operating month and ending on December 31 of that year. Each subsequent annual report must cover emissions for the calendar year, beginning on January 1 and ending on December 31.

(3) For any facility or supplier that becomes subject to this rule because of a physical or operational change that is made after January 1, 2010, report emissions for the first calendar year in which the change occurs, beginning with the first month of the change and ending on December 31 of that year. For a facility or supplier that becomes subject to this rule solely because of an increase in hours of operation or level of production, the first month of the change is the month in which the increased hours of operation or level of production, if maintained for the remainder of the year, would cause the facility or supplier to exceed the applicable threshold. Each subsequent annual report must cover emissions for the calendar year, beginning on January 1 and ending on December 31.

(c) Content of the annual report. Except as provided in paragraph (d) of this section, each annual GHG report shall contain the following information:

(1) Facility name or supplier name (as appropriate) and physical street address including the city, state, and zip code.

(2) Year and months covered by the report.

(3) Date of submittal.

(4) For facilities, report annual emissions of CO_2, CH_4, N_2O, and each fluorinated GHG (as defined in § 98.6) as follows:

(i) Annual emissions (excluding biogenic CO_2) aggregated for all GHG from all applicable source categories in subparts C through JJ of this part and expressed in metric tons of CO_2e calculated using Equation A–1 of this subpart.

(ii) Annual emissions of biogenic CO_2 aggregated for all applicable source categories in subparts C through JJ of this part.

(iii) Annual emissions from each applicable source category in subparts C through JJ of this part, expressed in metric tons of each GHG listed in paragraphs (c)(4)(iii)(A) through (c)(4)(iii)(E) of this section.

(A) Biogenic CO_2.

(B) CO_2 (excluding biogenic CO_2).

(C) CH_4.

(D) N_2O.

(E) Each fluorinated GHG (including those not listed in Table A–1 of this subpart).

(iv) Emissions and other data for individual units. processes, activities, and operations as specified in the ‘‘Data reporting requirements’’ section of each applicable subpart of this part.

(5) For suppliers, report annual quantities of CO_2, CH_4, N_2O, and each fluorinated GHG (as defined in § 98.6) that would be emitted from combustion or use of the products supplied, imported, and exported during the year. Calculate and report quantities at the following levels:

(i) Total quantity of GHG aggregated for all GHG from all applicable supply categories in subparts KK through PP of this part and expressed in metric tons of CO_2e calculated using Equation A–1 of this subpart.

(ii) Quantity of each GHG from each applicable supply category in subparts KK through PP of this part, expressed in metric tons of each GHG. For fluorinated GHG, report emissions of all fluorinated GHG, including those not listed in Table A–1 of this subpart.

(iii) Any other data specified in the ‘‘Data reporting requirements’’ section of each applicable subpart of this part.

(6) A written explanation, as required under § 98.3(e), if you change emission calculation methodologies during the reporting period.

(7) A brief description of each ‘‘best available monitoring method’’ used according to paragraph (d) of this section, the parameter measured using the method, and the time period during which the ‘‘best available monitoring method’’ was used.

(8) Each data element for which a missing data procedure was used according to the procedures of an applicable subpart and the total number of hours in the year that a missing data procedure was used for each data element.

(9) A signed and dated certification statement provided by the designated representative of the owner or operator, according to the requirements of § 98.4(e)(1).

(d) Special provisions for reporting year 2010.

(1) Best available monitoring methods. During January 1, 2010 through March 31, 2010, owners or operators may use best available monitoring methods for any parameter (e.g., fuel use, daily carbon content of feedstock by process line) that cannot reasonably be measured according to the monitoring and QA/QC requirements of a relevant subpart. The owner or operator must use the calculation methodologies and equations in the ‘‘Calculating GHG Emissions’’ sections of each relevant subpart, but may use the best available monitoring method for any parameter for which it is not reasonably feasible to acquire, install, and operate a required piece of monitoring equipment by January 1, 2010. Starting no later than April 1, 2010, the owner or operator must discontinue using best available methods and begin following all applicable monitoring and QA/QC requirements of this part, except as provided in paragraphs (d)(2) and (d)(3) of this section. Best available monitoring methods means any of the following methods specified in this paragraph:

(i) Monitoring methods currently used by the facility that do not meet the specifications of an relevant subpart.

(ii) Supplier data.

(iii) Engineering calculations.

(iv) Other company records.

(2) Requests for extension of the use of best available monitoring methods. The owner or operator may submit a request to the Administrator to use one or more best available monitoring methods beyond March 31, 2010.

(i) Timing of request. The extension request must be submitted to EPA no later than 30 days after the effective date of the GHG reporting rule.

(ii) Content of request. Requests must contain the following information:

(A) A list of specific item of monitoring instrumentation for which the request is being made and the locations where each piece of monitoring instrumentation will be installed.

(B) Identification of the specific rule requirements (by rule subpart, section, and paragraph numbers) for which the instrumentation is needed.

(C) A description of the reasons why the needed equipment could not be obtained and installed before April 1, 2010.

(D) If the reason for the extension is that the equipment cannot be purchased and delivered by April 1, 2010, include supporting documentation such as the date the monitoring equipment was ordered, investigation of alternative suppliers and the dates by which alternative vendors promised delivery, backorder notices or unexpected delays, descriptions of actions taken to expedite delivery, and the current expected date of delivery.

(E) If the reason for the extension is that the equipment cannot be installed without a process unit shutdown, include supporting documentation demonstrating that it is not practicable to isolate the equipment and install the monitoring instrument without a full process unit shutdown. Include the date of the most recent process unit shutdown, the frequency of shutdowns for this process unit, and the date of the next planned shutdown during which the monitoring equipment can be installed. If there has been a shutdown or if there is a planned process unit shutdown between promulgation of this part and April 1, 2010, include a justification of why the equipment could not be obtained and installed during that shutdown.

(F) A description of the specific actions the facility will take to obtain and install the equipment as soon as reasonably feasible and the expected date by which the equipment will be installed and operating.

(iii) Approval criteria. To obtain approval, the owner or operator must demonstrate to the Administrator's satisfaction that it is not reasonably feasible to acquire, install, and operate a required piece of monitoring equipment by April 1, 2010. The use of best available methods will not be approved beyond December 31, 2010.

(3) Abbreviated emissions report for facilities containing only general stationary fuel combustion sources. In lieu of the report required by paragraph (c) of this section, the owner or operator of an existing facility that is in operation on January 1, 2010 and that meets the conditions of § 98.2 (a)(3) may submit an abbreviated GHG report for the facility for GHGs emitted in 2010. The abbreviated report must be submitted by March 31, 2011. An owner or operator that submits an abbreviated report must submit a full GHG report according to the requirements of paragraph (c) of this section beginning in calendar year 2011. The abbreviated facility report must include the following information:

(i) Facility name and physical street address including the city, state and zip code.

(ii) The year and months covered by the report.

(iii) Date of submittal.

(iv) Total facility GHG emissions aggregated for all stationary fuel combustion units calculated according to any method specified in § 98.33(a) and expressed in metric tons of CO2, CH4, N2O, and CO2e.

(v) Any facility operating data or process information used for the GHG emission calculations.

(vi) A signed and dated certification statement provided by the designated representative of the owner or operator, according to the requirements of paragraph (e)(1) of this section.

(e) Emission calculations. In preparing the GHG report, you must use the calculation methodologies specified in the relevant subparts, except as specified in paragraph (d) of this section. For each source category, you must use the same calculation methodology throughout a reporting period unless you provide a written explanation of why a change in methodology was required.

(f) Verification. To verify the completeness and accuracy of reported GHG emissions, the Administrator may review the certification statements described in paragraphs (c)(8) and (d)(3)(vi) of this section and any other credible evidence, in conjunction with a comprehensive review of the GHG reports and periodic audits of selected reporting facilities. Nothing in this section prohibits the Administrator from using additional information to verify the completeness and accuracy of the reports.

(g) Recordkeeping. An owner or operator that is required to report GHGs under this part must keep records as specified in this paragraph. Retain all required records for at least ~~3~~ 7 years. The records shall be kept in an electronic or hard-copy format (as appropriate) and recorded in a form that is suitable for expeditious inspection and review. Upon request by the Administrator, the records required under this section must be made available to EPA within 10 days after the request. Records may be retained off site if the records are readily available for expeditious inspection and review. For records that are electronically generated or maintained, the equipment or software necessary to read the records shall be made available, or, if requested by EPA, electronic records shall be converted to paper documents. You must retain the following records, in addition to those records prescribed in each applicable subpart of this part:

(1) A list of all units, operations, processes, and activities for which GHG emission were calculated.

(2) The data used to calculate the GHG emissions for each unit, operation, process, and activity, categorized by fuel or material type. These data include but are not limited to the following information in this paragraph (g)(2):

(i) The GHG emissions calculations and methods used.

(ii) Analytical results for the development of site-specific emissions factors.

(iii) The results of all required analyses for high heat value, carbon content, and other required fuel or feedstock parameters.

(iv) Any facility operating data or process information used for the GHG emission calculations.

(3) The annual GHG reports.

(4) Missing data computations. For each missing data event, also retain a record of the duration of the event, actions taken to restore malfunctioning monitoring equipment, the cause of the event, and the actions taken to prevent or minimize occurrence in the future.

(5) For sources subject to reporting under 40 C.F.R. Part 98, ~~A~~ a written GHG Monitoring Plan.[10]

[10] WCI jurisdictions may elect to require a GHG Monitoring Plan from all sources. This provision is optional for Canadian jurisdictions.

(i) At a minimum, the GHG Monitoring Plan shall include the elements listed in this paragraph (g)(5)(i).

(A) Identification of positions of responsibility (i.e., job titles) for collection of the emissions data.

(B) Explanation of the processes and methods used to collect the necessary data for the GHG calculations.

(C) Description of the procedures and methods that are used for quality assurance, maintenance, and repair of all continuous monitoring systems, flow meters, and other instrumentation used to provide data for the GHGs reported under this part.

(ii) The GHG Monitoring Plan may rely on references to existing corporate documents (e.g., standard operating procedures, quality assurance programs under appendix F to 40 CFR part 60 or appendix B to 40 CFR part 75, and other documents) provided that the elements required by paragraph (g)(5)(i) of this section are easily recognizable.

(iii) The owner or operator shall revise the GHG Monitoring Plan as needed to reflect changes in production processes, monitoring instrumentation, and quality assurance procedures; or to improve procedures for the maintenance and repair of monitoring systems to reduce the frequency of monitoring equipment downtime.

(iv) Upon request by the Administrator, the owner or operator shall make all information that is collected in conformance with the GHG Monitoring Plan available for review during an audit within 10 days after the request. Electronic storage of the information in the plan is permissible, provided that the information can be made available in hard copy upon request during an audit.

(6) The results of all required certification and quality assurance tests of continuous monitoring systems, fuel flow meters, and other instrumentation used to provide data for the GHGs reported under this part.

(7) Maintenance records for all continuous monitoring systems, flow meters, and other instrumentation used to provide data for the GHGs reported under this part.

(h) Annual GHG report revisions.

(1) The owner or operator of a facility subject to reporting under both this Article and 40 C.F.R. Part 98 shall submit a revised report within 45 days of discovering or being notified by EPA of errors in an annual GHG report. The revised report must correct all identified errors.

The owner or operator shall retain documentation for ~~3~~ 7 years to support any revisions made to an annual GHG report.

(2) The owner or operator of a facility subject to reporting under this Article but not 40 C.F.R. Part 98 shall submit a revised report within 30 days of finding that a report contains an error, or accumulation of errors, greater than 5 percent of the total CO_2e emissions reported. To the extent possible, the revised report must correct all identified errors. A revised report will be accepted only if approved by [jurisdiction]. The owner or operator shall retain documentation for 7 years to support any revisions made to an annual GHG report.

(i) Calibration accuracy requirements. The owner or operator of a facility or supplier that is subject to the requirements of this part must meet the calibration accuracy requirements of this paragraph (i).

(1) Except as provided paragraphs (i)(4) through (i)(6) of this section, flow meters and other devices (e.g., belt scales) that measure data used to calculate GHG emissions shall be calibrated prior to April 1, 2010 using the procedures specified in this paragraph and each relevant subpart of this part. All measurement devices must be calibrated according to the manufacturer's recommended procedures, an appropriate industry consensus standard, or a method specified in a relevant subpart of this part. All measurement devices shall be calibrated to an accuracy of 5 percent. For facilities and suppliers that become subject to this part after April 1, 2010, the initial calibration shall be conducted on the date that data collection is required to begin. Subsequent calibrations shall be performed at the frequency specified in each applicable subpart.[11]

(2) For flow meters, perform all calibrations at measurement points that are representative of normal operation of the meter. Except for the orifice, nozzle, and venturi flow meters described in paragraph (i)(3) of this section, calculate the calibration error at each measurement point using Equation A–2 of this section. The terms ''R'' and ''A'' in Equation A–2 must be expressed in consistent units of measure (e.g., gallons/minute, ft 3/min). The calibration error at each measurement point shall not exceed 5.0 percent of the reference value.

[11] Canadian jurisdictions may grant an exemption for the combustion of solid biomass or biomass fuels determined to be carbon neutral.

$$CE = \frac{R - A}{R} \times 100 \qquad \text{(Eq. A-2)}$$

Where:

CE = Calibration error (%)

R = Reference value

A = Flow meter response to the reference value

(3) For orifice, nozzle, and venturi flow meters, the initial quality assurance consists of in-situ calibration of the differential pressure (delta-P), total pressure, and temperature transmitters. Calibrate each transmitter at a zero point and at least one upscale point. Fixed reference points, such as the freezing point of water, may be used for temperature transmitter calibrations. Calculate the calibration error of each transmitter at each measurement point, using Equation A–3 of this subpart. The terms ‘‘R’’, ‘‘A’’, and ‘‘FS’’ in Equation A–3 of this subpart must be in consistent units of measure (e.g., milliamperes, inches of water, psi, degrees). For each transmitter, the CE value at each measurement point shall not exceed 2.0 percent of full-scale. Alternatively, the results are acceptable if the sum of the calculated CE values for the three transmitters at each calibration level (i.e., at the zero level and at each upscale level) does not exceed 5.0 percent.

$$CE = \frac{R - A}{FS} \times 100 \qquad \text{(Eq. A-3)}$$

Where:

CE = Calibration error (%)

R = Reference value

A = Transmitter response to the reference value

FS = Full-scale value of the transmitter

(4) Fuel billing meters are exempted from the calibration requirements of this section, provided that the fuel supplier and any unit combusting the fuel do not have any common owners and are not owned by subsidiaries or affiliates of the same company.

(5) For a flow meter or other measurement device that has been previously calibrated in accordance with this part, an initial calibration is not required by the date specified in paragraph (i)(1) of this section if, as of the date required for the initial calibration, the previous calibration is still active (i.e., the device is not yet due for recalibration because the time interval between successive calibrations, as required by this part, has not elapsed).

(6) For units and processes that operate continuously with infrequent outages, it may not be possible to meet the April 1, 2010 deadline for the initial calibration of a flow meter or other measurement device without removing the device from service and shipping it to a remote location, thereby disrupting normal process operation. In such cases, the owner or operator may postpone the initial calibration until the next scheduled maintenance outage or any other outage of sufficient duration to complete the calibration, and may similarly postpone the subsequent recalibrations. Such postponements shall be documented in the monitoring plan that is required under § 98.3(g)(5).

(j) Where a rule in this Article requires sampling of a parameter on a more frequent basis than the corresponding rule in 40 C.F.R. Part 98, the following shall apply:

(1) The samples must be spaced apart as evenly as possible over time, taking into account the operating schedule of the relevant unit or facility.

(2) You must calculate and report a weighted average of the values derived from the samples by using the following formula:

$$V_E = \frac{\sum_{j=1}^{n}(V_j \times M_j)}{\sum_{j=1}^{n} M_j}$$

Where:

V_E = The value of the parameter to be reported under 40 C.F.R. Part 98 for period E.

j = Each period during period E for which a sample is required by [jurisdiction] under the applicable rule in this Article.

n = The number of periods j in period E.

Vj = The value of the sample for period j.

Mj = The mass of the sampled material processed or otherwise used by the relevant unit or facility in period j.

(3) You must keep records of the date and result for each sample and mass measurement used in the equation in subsection (2) and of the calculation of each weighted average included in your report.

(k)Where this Article specifies a choice between use of a fuel-based or mass balance-based calculation or use of a continuous emissions monitoring system (CEMS) to calculate CO2 emissions, the operator shall make this choice and continue to use the method chosen for all future emissions data reports, unless the use of the alternative calculation method is approved in advance by [the jurisdiction].[12]

(l) The owner or operator may elect to designate as de minimis one or more sources or pollutants that collectively emit no more than 3 percent of the facility's total CO2e emissions, but not to exceed 20,000 metric tons CO2e. Where this Article otherwise requires the use of a more stringent method for monitoring and reporting emissions than the method required by 40 C.F.R. Part 98, the owner or operator may elect to use any other method allowed under 40 C.F.R. Part 98 for the sources or pollutants designated as de minimis.[13]

(m) Notwithstanding the missing data procedures specified in this Article, the failure to conduct monitoring in accordance with the schedules established in this Article shall constitute a violation.

§ 98.4 Authorization and responsibilities of the designated representative.[14]

(a) General. Except as provided under paragraph (f) of this section, each facility, and each supplier, that is subject to this part, shall have one and only one designated representative, who shall be responsible for certifying, signing, and submitting GHG emissions reports and any other submissions for such facility and supplier respectively to the Administrator under this part. If the

[12] Approval may be granted by rule or by other general authorization. A case-by-case approval process may not be required.
[13] Canadian jurisdictions may include de minimis provisions consistent with WCI.2(d).
[14] In Canadian jurisdictions, the responsibilities specified in this section will ordinarily fall on the "operator's representative" as defined in Canadian law.

facility is required under any other part of title 40 of the Code of Federal Regulations to submit to the Administrator any other emission report that is subject to any requirement in 40 CFR part 75, the same individual shall be the designated representative responsible for certifying, signing, and submitting the GHG emissions reports and all such other emissions reports under this part.

(b) Authorization of a designated representative. The designated representative of the facility or supplier shall be an individual selected by an agreement binding on the owners and operators of such facility or supplier and shall act in accordance with the certification statement in paragraph (i)(4)(iv) of this section.

(c) Responsibility of the designated representative. Upon receipt by the Administrator of a complete certificate of representation under this section for a facility or supplier, the designated representative identified in such certificate of representation shall represent and, by his or her representations, actions, inactions, or submissions, legally bind each owner and operator of such facility or supplier in all matters pertaining to this part, notwithstanding any agreement between the designated representative and such owners and operators. The owners and operators shall be bound by any decision or order issued to the designated representative by the Administrator or a court.

(d) Timing. No GHG emissions report or other submissions under this part for a facility or supplier will be accepted until the Administrator has received a complete certificate of representation under this section for a designated representative of the facility or supplier. Such certificate of representation shall be submitted at least 60 days before the deadline for submission of the facility's or supplier's initial emission report under this part.

(e) Certification of the GHG emissions report. Each GHG emission report and any other submission under this part for a facility or supplier shall be certified, signed, and submitted by the designated representative or any alternate designated representative of the facility or supplier in accordance with this section and § 3.10 of this chapter.

(1) Each such submission shall include the following certification statement signed by the designated representative or any alternate designated representative: ''I am authorized to make this submission on behalf of the owners and operators of the facility or supplier, as applicable, for which the submission is made. I certify under penalty of law that I have personally examined, and am familiar with, the statements and information submitted in this document and all its attachments. Based on my inquiry of those individuals with primary

responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment.''

(2) The Administrator will accept a GHG emission report or other submission for a facility or supplier under this part only if the submission is certified, signed, and submitted in accordance with this section.

(f) Alternate designated representative. A certificate of representation under this section for a facility or supplier may designate one alternate designated representative, who shall be an individual selected by an agreement binding on the owners and operators, and may act on behalf of the designated representative, of such facility or supplier. The agreement by which the alternate designated representative is selected shall include a procedure for authorizing the alternate designated representative to act in lieu of the designated representative.

(1) Upon receipt by the Administrator of a complete certificate of representation under this section for a facility or supplier identifying an alternate designated representative.

(i) The alternate designated representative may act on behalf of the designated representative for such facility or supplier.

(ii) Any representation, action, inaction, or submission by the alternate designated representative shall be deemed to be a representation, action, inaction, or submission by the designated representative.

(2) Except in this section, whenever the term ‘‘designated representative’’ is used in this part, the term shall be construed to include the designated representative or any alternate designated representative.

(g) Changing a designated representative or alternate designated representative. The designated representative or alternate designated representative identified in a complete certificate of representation under this section for a facility or supplier received by the Administrator may be changed at any time upon receipt by the Administrator of another later signed, complete certificate of representation under this section for the facility or supplier. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous designated representative or the previous alternate designated representative of the facility or supplier before the time and date when the Administrator receives such later signed certificate of representation shall be binding on the new designated representative and the owners and operators of the facility or supplier.

(h) Changes in owners and operators. In the event an owner or operator of the facility or supplier is not included in the list of owners and operators in the certificate of representation under this section for the facility or supplier, such owner or operator shall be deemed to be subject to and bound by the certificate of representation, the representations, actions, inactions, and submissions of the designated representative and any alternate designated representative of the facility or supplier, as if the owner or operator were included in such list. Within 90 days after any change in the owners and operators of the facility or supplier (including the addition of a new owner or operator), the designated representative or any alternate designated representative shall submit a certificate of representation that is complete under this section except that such list shall be amended to reflect the change. If the designated representative or alternate designated representative determines at any time that an owner or operator of the facility or supplier is not included in such list and such exclusion is not the result of a change in the owners and operators, the designated representative or any alternate designated representative shall submit, within 90 days of making such determination, a certificate of representation that is complete under this section except that such list shall be amended to include such owner or operator.

(i) Certificate of representation. A certificate of representation shall be complete if it includes the following elements in a format prescribed by the Administrator in accordance with this section:

(1) Identification of the facility or supplier for which the certificate of representation is submitted.

(2) The name, address, e-mail address (if any), telephone number, and facsimile transmission number (if any) of the designated representative and any alternate designated representative.

(3) A list of the owners and operators of the facility or supplier identified in paragraph (i)(1) of this section, provided that, if the list includes the operators of the facility or supplier and the owners with control of the facility or supplier, the failure to include any other owners shall not make the certificate of representation incomplete.

(4) The following certification statements by the designated representative and any alternate designated representative:

(i) ‘‘I certify that I was selected as the designated representative or alternate designated representative, as applicable, by an agreement binding on the owners and operators of the facility or supplier, as applicable.’’

(ii) ‘‘I certify that I have all the necessary authority to carry out my duties and responsibilities under 40 CFR part 98 on behalf of the owners and operators of the facility or supplier, as applicable, and that each such owner and operator shall be fully bound by my representations, actions, inactions, or submissions.’’

(iii) ‘‘I certify that the owners and operators of the facility or supplier, as applicable, shall be bound by any order issued to me by the Administrator or a court regarding the facility or supplier.’’

(iv) ‘‘If there are multiple owners and operators of the facility or supplier, as applicable, I certify that I have given a written notice of my selection as the ‘designated representative’ or ‘alternate designated representative’, as applicable, and of the agreement by which I was selected to each owner and operator of the facility or supplier.’’

(5) The signature of the designated representative and any alternate designated representative and the dates signed.

(j) Documents of agreement. Unless otherwise required by the Administrator, documents of agreement referred to in the certificate of representation shall not be submitted to the Administrator. The Administrator shall not be under any obligation to review or evaluate the sufficiency of such documents, if submitted.

(k) Binding nature of the certificate of representation. Once a complete certificate of representation under this section for a facility or supplier has been received, the Administrator will rely on the certificate of representation unless and until a later signed, complete certificate of representation under this section for the facility or supplier is received by the Administrator.

(l) Objections Concerning a Designated Representative

(1) Except as provided in paragraph (g) of this section, no objection or other communication submitted to the Administrator concerning the authorization, or any representation, action, inaction, or submission, of the designated representative or alternate designated representative shall affect any representation, action, inaction, or submission of the

designated representative or alternate designated representative, or the finality of any decision or order by the Administrator under this part.

(2) The Administrator will not adjudicate any private legal dispute concerning the authorization or any representation, action, inaction, or submission of any designated representative or alternate designated representative.

(m) Delegation by designated representative and alternate designated representative.

(1) A designated representative or an alternate designated representative may delegate his or her own authority, to one or more individuals, to submit an electronic submission to the Administrator provided for or required under this part, except for a submission under this paragraph.

(2) In order to delegate his or her own authority, to one or more individuals, to submit an electronic submission to the Administrator in accordance with paragraph (m)(1) of this section, the designated representative or alternate designated representative must submit electronically to the Administrator a notice of delegation, in a format prescribed by the Administrator, that includes the following elements:

(i) The name, address, e-mail address (if any), telephone number, and facsimile transmission number (if any) of such designated representative or alternate designated representative.

(ii) The name, address, e-mail address, telephone number, and facsimile transmission number (if any) of each such individual (referred to as an ‘‘agent’’).

(iii) For each such individual, a list of the type or types of electronic submissions under paragraph (m)(1) of this section for which authority is delegated to him or her.

(iv) For each type of electronic submission listed in accordance with paragraph (m)(2)(iii) of this section, the facility or supplier for which the electronic submission may be made.

(v) The following certification statements by such designated representative or alternate designated representative:

(A) ‘‘I agree that any electronic submission to the Administrator that is by an agent identified in this notice of delegation and of a type listed, and for a facility or supplier designated, for such agent in this notice of delegation and that is made when I am a designated representative or alternate designated representative, as applicable, and before this notice of delegation is superseded by another notice of delegation under § 98.4(m)(3) shall be deemed to be an electronic submission certified, signed, and submitted by me.''

(B) ''Until this notice of delegation is superseded by a later signed notice of delegation under § 98.4(m)(3), I agree to maintain an e-mail account and to notify the Administrator immediately of any change in my e-mail address unless all delegation of authority by me under § 98.4(m) is terminated.''

(vi) The signature of such designated representative or alternate designated representative and the date signed.

(3) A notice of delegation submitted in accordance with paragraph (m)(2) of this section shall be effective, with regard to the designated representative or alternate designated representative identified in such notice, upon receipt of such notice by the Administrator and until receipt by the Administrator of another such notice that was signed later by such designated representative or alternate designated representative, as applicable. The later signed notice of delegation may replace any previously identified agent, add a new agent, or eliminate entirely any delegation of authority.

(4) Any electronic submission covered by the certification in paragraph (m)(2)(iv)(A) of this section and made in accordance with a notice of delegation effective under paragraph (m)(3) of this section shall be deemed to be an electronic submission certified, signed, and submitted by the designated representative or alternate designated representative submitting such notice of delegation.

§ 98.5 How is the report submitted?

Each GHG report and certificate of representation for a facility or supplier must be submitted electronically in accordance with the requirements of § 98.4 and in a format specified by the Administrator.

Subpart C—General Stationary Combustion

§98.30 Definition of the source category.

(a) Stationary fuel combustion sources are devices that combust solid, liquid, or gaseous fuel, generally for the purposes of producing electricity, generating steam, or providing useful heat or energy for industrial, commercial, or institutional use, or reducing the volume of waste by removing combustible matter. Stationary fuel combustion sources include, but are not limited to, boilers, simple and combined-cycle combustion turbines, engines, incinerators, and process heaters.

(b) This source category does not include:

(1) Portable equipment, as defined in §98.6.

(2) Emergency generators and emergency equipment, as defined in §98.6.

(3) Irrigation pumps at agricultural operations.

(4) Flares, unless otherwise required by provisions of another subpart of 40 CFR part 98 to use methodologies in this subpart.

(5) Electricity generating units that are subject to subpart D of this part.

(c) For a unit that combusts hazardous waste (as defined in 40 CFR 261.3), reporting of GHG emissions is not required unless either of the following conditions apply:

(1) Continuous emission monitors (CEMS) are used to quantify CO_2 mass emissions.

(2) Any fuel listed in Table C-1 of this subpart is also combusted in the unit. In this case, report GHG emissions from combustion of all fuels listed in Table C-1 of this subpart.

§98.31 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains one or more stationary fuel combustion sources and the facility meets the applicability requirements of either §§98.2(a)(1), 98.2(a)(2), or 98.2(a)(3).

§98.32 GHGs to report.

(a) You must report CO_2, CH_4, and N_2O mass emissions from each stationary fuel combustion unit.

(b) [Reporting only] Units that generate electricity either for sale or for use onsite must also report fugitive HFC emissions from cooling units by following the requirements of §98.33(f).

§98.33 Calculating GHG emissions.

You must calculate CO_2 emissions according to paragraph (a) of this section, and calculate CH_4 and N_2O emissions according to paragraph (c) of this section.

Subpart C—General Stationary Combustion

(a) CO₂ emissions from fuel combustion. Calculate CO_2 emissions by using one of the four calculation methodologies in this paragraph (a) subject to the conditions, requirements, and restrictions set forth in paragraph (b) of this section. If you co-fire biomass fuels with fossil fuels, report CO_2 emissions from the combustion of biomass separately using the methods in paragraph (e) of this section.

(1) Tier 1 Calculation Methodology. Calculate the annual CO_2 mass emissions for each type of fuel by using Equation C-1 of this section.

$$CO_2 = 1 x 10^{-3} * Fuel * HHV * EF \qquad \text{(Eq. C-1)}$$

Where:

CO_2 = Annual CO_2 mass emissions for the specific fuel type (metric tons).

Fuel = Mass or volume of fuel combusted per year, from company records as defined in §98.6 (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).

HHV = Default high heat value of the fuel, from Table C-1 of this subpart (mmBtu per mass or mmBtu per volume, as applicable).

EF = Fuel-specific default CO_2 emission factor, from Table C-1 of this subpart (kg CO_2/mmBtu).

$1 \text{ x } 10^{-3}$ = Conversion factor from kilograms to metric tons.

(2) Tier 2 Calculation Methodology. Calculate the annual CO_2 mass emissions for each type of fuel by using either Equation C2a or C2c of this section, as appropriate.

(i) Equation C-2a of this section applies to any type of fuel listed in Table C-1 of the subpart, except for municipal solid waste (MSW). For MSW combustion, use Equation C-2c of this section.

$$CO_2 = 1x10^{-3} * Fuel * HHV * EF \qquad \text{(Eq. C-2a)}$$

Where:

CO_2 = Annual CO_2 mass emissions for a specific fuel type (metric tons).

Fuel = Mass or volume of the fuel combusted during the year, from company records as defined in §98.6 (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).

HHV = Annual average high heat value of the fuel from all valid samples for the year (mmBtu per mass or volume). The average HHV shall be calculated according to the requirements of paragraph (a)(2)(ii) of this section.

EF = Fuel-specific default CO_2 emission factor, from Table C-1 of this subpart (kg CO_2/mmBtu).

1×10^{-3} = Conversion factor from kilograms to metric tons.

(ii) The minimum number of HHV samples for determining annual average HHV is specified (e.g., monthly, quarterly, semi-annually, or by lot) in §98.34. The method for computing the annual average HHV is a function of how frequently you perform or receive from the fuel supplier the results of fuel sampling for HHV. The method is specified in paragraph (a)(2)(ii)(A) or (a)(2)(ii)(B) of this section, as applicable.

(A) If the results of fuel sampling are received monthly or more frequently, then the annual average HHV shall be calculated using Equation C-2b of this section. If multiple HHV determinations are made in any month, average the values for the month arithmetically.

$$(HHV)_{annual} = \frac{\sum_{i=1}^{n}(HHV)_i * (Fuel)_i}{\sum_{i=1}^{n}(Fuel)_i} \qquad \text{(Eq. C-2b)}$$

Where:

$(HHV)_{annual}$	=	Weighted annual average high heat value of the fuel (mmBtu per mass or volume).
$(HHV)_i$	=	High heat value of the fuel, for month "i" (mmBtu per mass or volume).
$(Fuel)_i$	=	Mass or volume of the fuel combusted during month "i" (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).
n	=	Number of months in the year that fuel is burned in the unit.

(B) If the results of fuel sampling are received less frequently than monthly, then the annual average HHV shall be computed as the arithmetic average HHV for all values for the year (including valid samples and substitute data values under 98.35).

(iii) For units that combust municipal solid waste (MSW) and that produce steam, use Equation C-2c of this section. Equation C-2c of this section may also be used for any ~~other~~ solid biomass fuel listed in Table C-1 of this subpart provided that steam is generated by the unit.

$$CO_2 = 1 \times 10^{-3} \text{ Steam} * B * EF \qquad \text{(Eq. C-2c)}$$

Where:

CO_2	=	Annual CO_2 mass emissions from MSW or solid fuel combustion (metric tons).
Steam	=	Total mass of steam generated by MSW or solid fuel combustion during the reporting year (lb steam).
B	=	Ratio of the boiler's maximum rated heat input capacity to its design rated steam output capacity (mmBtu/lb steam).
EF	=	Fuel-specific default CO_2 emission factor, from Table C-1 of this subpart (kg CO_2/mmBtu)[1].
1×10^{-3}	=	Conversion factor from kilograms to metric tons.

(3) Tier 3 Calculation Methodology. Calculate the annual CO_2 mass emissions for each fuel by using either Equation C3, C4, or C5 of this section, as appropriate.

(i) For a solid fuel, use Equation C-3 of this section.

[1] The ER required development of a site-specific emission factor for MSW. For harmonization with the MRR, this requirement was deleted. However, jurisdictions may allow or require testing to develop a site-specific emission factor as an alternative to the default emission factors in Table C-1.

$$CO_2 = \frac{44}{12} * Fuel * CC * 0.91 \qquad \text{(Eq. C-3)}$$

Where:

CO_2 = Annual CO_2 mass emissions from the combustion of the specific solid fuel (metric tons).

Fuel = Annual mass of the solid fuel combusted, from company records as defined in §98.6 (short tons).

CC = Annual average carbon content of the solid fuel (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.

44/12 = Ratio of molecular weights, CO_2 to carbon.

0.91 = Conversion factor from short tons to metric tons.

(ii) For a liquid fuel, use Equation C-4 of this section.

$$CO_2 = \frac{44}{12} * Fuel * CC * 0.001 \qquad \text{(Eq. C-4)}$$

Where:

CO_2 = Annual CO_2 mass emissions from the combustion of the specific liquid fuel (metric tons).

Fuel = Annual volume of the liquid fuel combusted (gallons). The volume of fuel combusted must be measured directly, using fuel flow meters calibrated according to §98.3(i). Fuel billing meters may be used for this purpose. Tank drop measurements may also be used.

CC = Annual average carbon content of the liquid fuel (kg C per gallon of fuel). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.

44/12 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to metric tons.

(iii) For a gaseous fuel, use Equation C-5 of this section.

$$CO_2 = \frac{44}{12} * Fuel * CC * \frac{MW}{MVC} * 0.001 \qquad \text{(Eq. C-5)}$$

Where:

CO_2	=	Annual CO_2 mass emissions from combustion of the specific gaseous fuel (metric tons).
Fuel	=	Annual volume of the gaseous fuel combusted (scf). The volume of fuel combusted must be measured directly, using fuel flow meters calibrated according to §98.3(i). Fuel billing meters may be used for this purpose.
CC	=	Annual average carbon content of the liquid fuel (kg C per gallon of fuel). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.
MW	=	Annual average molecular weight of the gaseous fuel (kg/kg-mole). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.
MVC	=	Molar volume conversion factor (849.5 scf per kg-mole at standard conditions, as defined in §98.6).
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(iv) Fuel flow meters that measure mass flow rates may be used for liquid fuels, provided that the fuel density is used to convert the readings to volumetric flow rates. The density shall be measured at the same frequency as the carbon content, using ASTM D1298-99 (Reapproved 2005) "Standard Test Method for Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and

Liquid Petroleum Products by Hydrometer Method” (incorporated by reference, see §98.7).

(v) The following default density values may be used for fuel oil, in lieu of using the ASTM method in paragraph (a)(3)(iv) of this section: 6.8 lb/gal for No. 1 oil; 7.2 lb/gal for No. 2 oil; 8.1 lb/gal for No. 6 oil.

(4) Tier 4 Calculation Methodology. Calculate the annual CO_2 mass emissions from all fuels combusted in a unit, by using quality-assured data from continuous emission monitoring systems (CEMS).

(i) This methodology requires a CO_2 concentration monitor and a stack gas volumetric flow rate monitor, except as otherwise provided in paragraph (a)(4)(iv) of this section. Hourly measurements of CO_2 concentration and stack gas flow rate are converted to CO_2 mass emission rates in metric tons per hour.

(ii) When the CO_2 concentration is measured on a wet basis, Equation C-6 of this section is used to calculate the hourly CO_2 emission rates:

$$CO_2 = 5.18x10^{-7} * C_{CO2} * Q \qquad \text{(Eq. C-6)}$$

Where:

CO_2 = CO_2 mass emission rate (metric tons/hr).
C_{CO2} = Hourly average CO_2 concentration (% CO_2).

Q = Hourly average stack gas volumetric flow rate (scfh).

5.18×10^{-7} = Conversion factor (metric tons/scf/% CO_2).

(iii) If the CO_2 concentration is measured on a dry basis, a correction for the stack gas moisture content is required. You shall either continuously monitor the stack gas moisture content as described in §75.11(b)(2) of this chapter or, for certain types of fuel, use a default moisture percentage from §75.11(b)(1) of this chapter. For each unit operating hour, a moisture correction must be applied to Equation C-6 of this section as follows:

$$CO_2^* = CO_2\left(\frac{100 - \%H_2O}{100}\right) \qquad \text{(Eq. C-7)}$$

Where:

CO_2^* = Hourly CO_2 mass emission rate, corrected for moisture (metric tons/hr).

CO_2 = Hourly CO_2 mass emission rate from Equation C-6 of this section, uncorrected (metric tons/hr).

$\%H_2O$ = Hourly moisture percentage in the stack gas (measured or default value, as appropriate).

(iv) An oxygen (O_2) concentration monitor may be used in lieu of a CO_2 concentration monitor in a CEMS installed before January 1, 2012,[2] to determine the hourly CO_2 concentrations, in accordance with Equation F-14a or F-14b (as applicable) in appendix F to 40 CFR part 75, if the

[2] A jurisdiction may want to modify this date depending on the effective date of the jurisdiction's reporting regulations.

effluent gas stream monitored by the CEMS consists solely of combustion products (i.e., no process CO_2 emissions are mixed with the combustion products) and if only fuels that are listed in Table 1 in section 3.3.5 of appendix F to 40 CFR part 75 are combusted in the unit. If the O_2 monitoring option is selected, the F-factors used in Equations F-14a and F-14b shall be determined according to section 3.3.5 or section 3.3.6 of appendix F to 40 CFR part 75, as applicable. If Equation F-14b is used, the hourly moisture percentage in the stack gas shall be either a measured value in accordance with §75.11(b)(2) of this chapter, or, for certain types of fuel, a default moisture value from §75.11(b)(1) of this chapter.

(v) Each hourly CO_2 mass emission rate from Equation C-6 or C-7 of this section is multiplied by the operating time to convert it from metric tons per hour to metric tons. The operating time is the fraction of the hour during which fuel is combusted (e.g., the unit operating time is 1.0 if the unit operates for the whole hour and is 0.5 if the unit operates for 30 minutes in the hour). For common stack configurations, the operating time is the fraction of the hour during which effluent gases flow through the common stack.

(vi) The hourly CO_2 mass emissions are then summed over each calendar quarter and the quarterly totals are summed to determine the annual CO_2 mass emissions.

(vii) If both biomass and fossil fuel are combusted during the year, determine and report the biogenic CO_2 mass emissions separately, as described in paragraph (e) of this section.

(5) Alternative methods for units with continuous monitoring systems. Units not subject to the Acid Rain Program that report data to EPA according to 40 CFR part 75 may use the alternative methods in this paragraph in lieu of using any of the four calculation methodology tiers.

(i) For a unit that combusts only natural gas and/or fuel oil, is not subject to the Acid Rain Program, monitors and reports heat input data year-round according to appendix D to 40 CFR part 75, but is not required by the applicable 40 CFR part 75 program to report CO_2 mass emissions data, calculate the annual CO_2 mass emissions for the purposes of this part as follows:

(A) Use the hourly heat input data from appendix D to 40 CFR part 75, together with Equation G-4 in appendix G to 40 CFR part 75 to determine the hourly CO_2 mass emission rates, in units of tons/hr;

(B) Use Equations F-12 and F-13 in appendix F to 40 CFR part 75 to calculate the quarterly and cumulative annual CO_2 mass emissions, respectively, in units of short tons; and

(C) Divide the cumulative annual CO_2 mass emissions value by 1.1 to convert it to metric tons.

(ii) For a unit that combusts only natural gas and/or fuel oil, is not subject to the Acid Rain Program, monitors and reports heat input data year-round according to 40 CFR 75.19 of this chapter but is not required by the applicable 40 CFR part 75 program to report CO_2 mass emissions data, calculate the annual CO_2 mass emissions for the purposes of this part as follows:

(A) Calculate the hourly CO_2 mass emissions, in units of short tons, using Equation LM-11 in 40 CFR 75.19(c)(4)(iii).

(B) Sum the hourly CO_2 mass emissions values over the entire reporting year to obtain the cumulative annual CO_2 mass emissions, in units of short tons.

(C) Divide the cumulative annual CO_2 mass emissions value by 1.1 to convert it to metric tons.

(iii) For a unit that is not subject to the Acid Rain Program, uses flow rate and CO_2 (or O_2) CEMS to report heat input data year-round according to 40 CFR part 75, but is not required by the applicable 40 CFR part 75 program to report CO_2 mass emissions data, calculate the annual CO_2 mass emissions as follows:

(A) Use Equation F-11 or F-2 (as applicable) in appendix F to 40 CFR part 75 to calculate the hourly CO_2 mass emission rates from the CEMS data. If an O_2 monitor is used, convert the hourly average O_2 readings to CO_2 using Equation F-14a or F-14b in appendix F to 40 CFR part 75 (as applicable), before applying Equation F-11 or F-2.

(B) Use Equations F-12 and F-13 in appendix F to 40 CFR part 75 to calculate the quarterly and cumulative annual CO_2 mass emissions, respectively, in units of short tons.

(C) Divide the cumulative annual CO_2 mass emissions value by 1.1 to convert it to metric tons.

(D) If both biomass and fossil fuel are combusted during the year, determine and report the biogenic CO_2 mass emissions separately, as described in paragraph (e) of this section.

(b) Use of the four tiers. Use of the four tiers of CO_2 emissions calculation methodologies described in paragraph (a) of this section is subject to the following conditions, requirements, and restrictions:

(1) The Tier 1 Calculation Methodology:

(i) May be used for any fuel listed in Table C-1 of this subpart that is combusted in a unit with a maximum rated heat input capacity of 250 mmBtu/hr or less at a facility that is not subject to verification.

(ii) ~~May be used for MSW in a unit of any size that does not produce steam, if the use of Tier 4 is not required.~~[Reserved]

(iii) ~~May be used for solid, gaseous, or liquid biomass fuels in a unit of any size provided that the fuel is listed in Table C-1 of this subpart.~~[Reserved]

(iv) May not be used if you routinely perform fuel sampling and analysis for the fuel high heat value (HHV) or ~~routinely receives~~can obtain the results of HHV sampling and analysis from the fuel supplier at the minimum frequency specified in §98.34(a), or at a greater frequency. In such cases, Tier 2 or higher shall be used.

(2) The Tier 2 Calculation Methodology:

(i) May be used for the combustion of any type of fuel in a unit with a maximum rated heat input capacity of 250 mmBtu/hr or less at a facility that is not subject to verification provided that the fuel is listed in Table C-1 of this subpart.

(ii) May be used in a unit with a maximum rated heat input capacity greater than 250 mmBtu/hr or that is located at a facility subject to verification for the combustion of pipeline quality natural gas and distillate fuel oil.

(iii) May be used for MSW or solid biomass fuel[3] in a unit of any size that produces steam, if Equation C-2c is employed and if the use of Tier 4 is not required.

(3) The Tier 3 Calculation Methodology:

(i) May be used for a unit of any size at any facility that combusts any type of fuel listed in Table C-1 of this subpart (except for MSW), unless the use of Tier 4 is required.

(ii) Shall be used for a unit ~~with~~ that has a maximum rated heat input capacity greater than 250 mmBtu/hr or is located at a facility subject to verification~~that combusts any type of fuel listed in Table C-1 of this subpart (except MSW)~~, unless either of the following conditions apply:

(A) The use of Tier ~~1 or~~ 2 is permitted, as described in paragraph~~s (b)(1)(iii) and~~ (b)(2)(ii) of this section.

(B) The use of Tier 4 is required.

~~(iii) Shall be used for a fuel not listed in Table C-1 of this subpart if the fuel is combusted in a unit with a maximum rated heat input capacity greater than 250 mmBtu/hr provided that both of the following conditions apply:~~

---

[3] Consistent with 98.33(a)(2)(iii).

~~(A) The use of Tier 4 is not required.~~

~~(B) The fuel provides 10% or more of the annual heat input to the unit or, if §98.36(c)(3)applies, to a group of units served by common supply pipe.~~

(4) The Tier 4 Calculation Methodology:

(i) May be used for a unit of any size, combusting any type of fuel.

(ii) Shall be used if the unit meets all six of the conditions specified in paragraphs (b)(4)(ii)(A) through (b)(4)(ii)(F) of this section:

(A) The unit has a maximum rated heat input capacity greater than 250 mmBtu/hr, or if the unit combusts municipal solid waste and has a maximum rated input capacity greater than 250 tons per day of MSW.

(B) The unit combusts solid fossil fuel or MSW, either as a primary or secondary fuel.

(C) The unit has operated for more than 1,000 hours in any calendar year since 2005.

(D) The unit has installed CEMS that are required either by an applicable Federal or State regulation or the unit’s operating permit.

(E) The installed CEMS include a gas monitor of any kind or a stack gas volumetric flow rate monitor, or both and the monitors have been certified, either in accordance with the requirements of 40 CFR part 75, part 60 of this chapter, or an applicable State continuous monitoring program.

(F) The installed gas or stack gas volumetric flow rate monitors are required, either by an applicable Federal or State regulation or by the unit's operating permit, to undergo periodic quality assurance testing in accordance with either appendix B to 40 CFR part 75, appendix F to 40 CFR part 60, or an applicable State continuous monitoring program.

(iii) Shall be used for a unit with a maximum rated heat input capacity of 250 mmBtu/hr or less and for a unit that combusts municipal solid waste with a maximum rated input capacity of 250 tons of MSW per day or less, if the unit meets all of the following three conditions:

(A) The unit has both a stack gas volumetric flow rate monitor and a CO_2 concentration monitor.

(B) The unit meets the conditions specified in paragraphs (b)(4)(ii)(B) through (b)(4)(ii)(D) of this section.

(C) The CO_2 and stack gas volumetric flow rate monitors meet the conditions specified in paragraphs (b)(4)(ii)(E) and (b)(4)(ii)(F) of this section.

(5) The Tier 4 Calculation Methodology shall be used beginning on:

(i) January 1, 2010, for a unit that is required to report CO_2 mass emissions beginning on that date, if all of the monitors needed to measure CO_2 mass emissions have been installed and certified by that date.

(ii) January 1, 2011, for a unit that is required to report CO_2 mass emissions beginning on January 1, 2010, if all of the monitors needed to measure CO_2 mass emissions have not been installed and certified by January 1, 2010. In this case, you may use Tier 2 or Tier 3 to report GHG emissions for 2010.

(6) You may elect to use any applicable higher tier for one or more of the fuels combusted in a unit. For example, if a 100 mmBtu/hr unit combusts natural gas and distillate fuel oil, you may elect to use Tier 1 for natural gas and Tier 3 for the fuel oil, even though Tier 1 could have been used for both fuels. However, for units that use either the Tier 4 or the alternative calculation methodology specified in paragraph (a)(5) of this section, CO_2 emissions from the combustion of all fuels shall be based solely on CEMS measurements.

(c) Calculation of CH_4 and N_2O emissions from stationary combustion sources. You must calculate annual

CH_4 and N_2O mass emissions only for units that are required to report CO_2 emissions using the calculation methodologies of this subpart and for only those fuels that are listed in Table C-2 of this subpart.

(1) Use Equation C-8 of this section to estimate CH_4 and N_2O emissions for any fuels for which you use the Tier 1 or Tier 3 calculation methodologies for CO_2. Use the same values for fuel combustion that you use for the Tier 1 or Tier 3 calculation.

$$CH_4 \text{ or } N_2O = 1 \, x \, 10^{-3} * Fuel * HHV * EF \qquad \text{(Eq. C-8)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (metric tons).

Fuel = Mass or volume of the fuel combusted, either from company records or directly measured by a fuel flow meter, as applicable (mass or volume per year).

HHV = Default high heat value of the fuel from Table C-1 of this subpart (mmBtu per mass or volume).

EF = Fuel-specific default emission factor for CH_4 or N_2O, from Table C-2 of this subpart (kg CH_4 or N_2O per mmBtu).

$1 \text{ x } 10^{-3}$ = Conversion factor from kilograms to metric tons.

(2) Use Equation C-9a of this section to estimate CH_4 and N_2O emissions for any fuels for which you use the Tier 2 Equation C-2a of this section to estimate CO_2 emissions.

Use the same values for fuel combustion and HHV that you use for the Tier 1 or Tier 3 calculation.

$$CH_4 \text{ or } N_2O = 1 \text{ x } 10^{-3} * HHV * EF * Fuel \qquad \text{(Eq. C-9a)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (metric tons).

Fuel = Mass or volume of the fuel combusted during the reporting year.

HHV = High heat value of the fuel, averaged for all valid measurements for the reporting year (mmBtu per mass or volume).

EF = Fuel-specific default emission factor for CH_4 or N_2O, from Table C-2 of this subpart (kg CH_4 or N_2O per mmBtu).

1 x 10^{-3} = Conversion factor from kilograms to metric tons.

(3) Use Equation C-9b of this section to estimate CH_4 and N_2O emissions for any fuels for which you use Equation C-2c of this section to calculate the CO_2 emissions. Use the same values for steam generation and the ratio "B" that you use for Equation C-2c.

$$CH_4 \text{ or } N_2O = 1 \text{ x } 10^{-3} \text{ Steam} * B * EF \qquad \text{(Eq. C-9b)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a solid fuel (metric tons).

Steam = Total mass of steam generated by solid fuel combustion during the reporting year (lb steam).

B = Ratio of the boiler's maximum rated heat input capacity to its design rated steam output (mmBtu/lb steam).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Table C-2 of this subpart (kg CH_4 or N_2O per mmBtu).

1×10^{-3} = Conversion factor from kilograms to metric tons.

(4) Use Equation C-10 of this section for units in the Acid Rain Program, units that monitor and report heat input on a year-round basis according to 40 CFR part 75, and units that use the Tier 4 Calculation Methodology.

$$CH_4 \text{ or } N_2O = 0.001 * (HI)_A * EF \qquad \text{(Eq. C-10)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (metric tons).

$(HI)_A$ = Cumulative annual heat input from the fuel, derived from the electronic data reports required under §75.64 of this chapter or, for Tier 4 units, from the best available information as described in paragraph (c)(4)(ii) of this section(mmBtu).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Table C-2 of this section (kg CH_4 or N_2O per mmBtu).

0.001 = Conversion factor from kg to metric tons.

(i) If only one type of fuel listed in Table C-2 of this subpart is combusted during normal operation, substitute the cumulative annual heat input from combustion of the fuel into Equation C-10 of this section to calculate the annual CH_4 or N_2O emissions.

(ii) If more than one type of fuel listed in Table C-2 of this subpart is combusted during normal operation, use Equation C-10 of this section separately for each type of fuel. If flow rate and diluent gas monitors are used to measure the unit heat input, use the best available information (e.g., fuel feed rate measurements, fuel heating values, engineering analysis) to estimate the annual heat input from each type of fuel.

(5) When multiple fuels are combusted during the reporting year, sum the fuel-specific results from Equations C-8, C-9a, C-9b, or C-10 of this section (as applicable) to obtain the total annual CH_4 and N_2O emissions, in metric tons.

(6) The operator may elect to calculate CH_4 or N_2O emissions using source-specific emission factors derived from source tests conducted at least annually under the supervision of [jurisdiction]. Upon approval of a source test plan, the source test procedures in that plan shall be repeated in each future year to update the source specific emission factors annually.

(d) Calculation of CO_2 from sorbent.

(1) When a unit is a fluidized bed boiler, is equipped with a wet flue gas desulfurization system, or uses other acid gas emission controls with sorbent injection, use Equation C-11 of this section to calculate the CO_2 emissions from the sorbent, if those CO_2 emissions are not monitored by CEMS:

$$CO_2 = 0.91 * S * R * \left(\frac{MW_{CO2}}{MW_S}\right) \qquad \text{(Eq. C-11)}$$

Where:

CO_2 = CO_2 emitted from sorbent for the reporting year (metric tons).

S = Limestone or other sorbent used in the reporting year, from company records (short tons).

R = 1.00, the calcium-to-sulfur stoichiometric ratio.

MW_{CO2} = Molecular weight of carbon dioxide (44).

MW_S = Molecular weight of sorbent (100 if calcium carbonate).

0.91 = Conversion factor from short tons to metric tons

(2) The annual CO_2 mass emissions for the unit shall be the sum of the CO_2 emissions from the combustion process and the CO_2 emissions from the sorbent.

(e) <u>CO_2 emissions from combustion of biomass</u>. Use the procedures of this paragraph (e) to estimate biogenic CO_2 emissions from units that combust a combination of biomass and fossil fuels. Reporting of CO_2 emissions from combustion of biomass is required only for those biomass fuels listed in Table C-1 of this section, unless emissions are measured using CEMS.

(1) If CEMS are not used to measure CO_2, use Equation C-1 or C-2c of this subpart to calculate the annual CO_2 mass emissions from the combustion of biomass (except MSW) for a unit of any size. Determine the mass of biomass combusted using one of the following procedures in this paragraph (e)(1), as appropriate.

(i) Use company records.

(ii) Follow the procedures in paragraph (e)(5) of this section.

(iii) For premixed fuels that contain biomass and fossil fuels (e.g., mixtures containing biodiesel), use best available information to determine the mass of biomass fuels and document the procedure used in the GHG Monitoring Plan required by §98.3(g)(5).

(2) If a CO_2 CEMS (or a surrogate O_2 monitor) and a stack gas flow rate monitor are used to determine the annual CO_2 mass emissions either according to 40 CFR part 75, the Tier 4 Calculation Methodology, or the alternative calculation methodology specified in paragraph (a)(5)(iii); and if both fossil fuel and biomass (except for MSW) are combusted in the unit during the reporting year, you may use the following procedure to determine the annual

biogenic CO_2 mass emissions. If MSW or a fossil fuel/biomass mixture containing an undeterminable quantity of fossil fuels is combusted in the unit, follow the procedures in paragraph (e)(3) of this section.

(i) For each operating hour, use Equation C-12 of this section to determine the volume of CO_2 emitted.

$$V_{CO2h} = \frac{(\%CO_2)_h}{100} * Q_h * t_h \qquad \text{(Eq. C-12)}$$

Where:

V_{CO2h} = Hourly volume of CO_2 emitted (scf).

$(\%CO_2)_h$ = Hourly average CO_2 concentration, measured by the CO_2 concentration monitor, or, if applicable, calculated from the hourly average O_2 concentration ($\%CO_2$).

Q_h = Hourly average stack gas volumetric flow rate, measured by the stack gas volumetric flow rate monitor (scfh).

t_h = Source operating time (decimal fraction of the hour during which the source combusts fuel, i.e., 1.0 for a full operating hour, 0.5 for 30 minutes of operation, etc.).

100 = Conversion factor from percent to a decimal fraction.

(ii) Sum all of the hourly V_{CO2h} values for the reporting year, to obtain V_{total}, the total annual volume of CO_2 emitted.

(iii) Calculate the annual volume of CO_2 emitted from fossil fuel combustion using Equation C-13 of this section. If two or more types of fossil fuel are combusted during the year, perform a separate calculation with Equation C-13 of this section for each fuel and sum the results.

$$V_{ff} = \frac{Fuel * F_c * HHV}{10^6} \qquad \text{(Eq. C-13)}$$

Where:

V_{ff} = Annual volume of CO_2 emitted from combustion of a particular fossil fuel (scf).

Fuel = Total quantity of the fossil fuel combusted in the reporting year, from company records, as defined in §98.6 (lb for solid fuel, gallons for liquid fuel, and scf for gaseous fuel).

F_c = Fuel-specific carbon based F-factor, either a default value from Table 1 in section 3.3.5 of appendix F to 40 CFR part 75 or a site-specific value determined under section 3.3.6 of appendix F to 40 CFR part 75 (scf CO_2/mmBtu).

HHV = High heat value of the fossil fuel, from fuel sampling and analysis (annual average value in Btu/lb for solid fuel, Btu/gal for liquid fuel and Btu/scf for gaseous fuel, sampled as specified (e.g., monthly, quarterly, semi-annually, or by lot) in §98.34(a)(2)). The average HHV shall be calculated according to the requirements of paragraph (a)(2)(ii) of this section.

10^6 = Conversion factor, Btu per mmBtu.

(iv) Subtract V_{ff} from V_{total} to obtain V_{bio}, the annual volume of CO_2 from the combustion of biomass. If a CEMS is being used to measure the combined combustion and process emissions from a unit that is subject to another subpart of part 98, then also subtract CO_2 process emissions from V_{total} to determine V_{bio}. The CO_2 process emissions must be calculated according to the requirements of the applicable subpart.

(v) Calculate the biogenic percentage of the annual CO_2 emissions,expressed as a decimal fraction, using Equation C-14 of this section:

$$\% \, Biogenic = \frac{V_{bio}}{V_{total}} \qquad \text{(Eq. C-14)}$$

(vi) Calculate the annual biogenic CO_2 mass emissions, in metric tons, by multiplying the results obtained from Equation C-14 of this section by the annual CO_2 mass emissions in metric tons, as determined:

(A) Under paragraph (a)(4)(vi) of this section, for units using the Tier 4 Calculation Methodology.

(B) Under paragraph (a)(5)(iii)(B) of this section, for units using the alternative calculation methodology specified in paragraph (a)(5)(iii).

(C) From the electronic data report required under §75.64 of this chapter, for units in the Acid Rain Program and other units using CEMS to monitor and report CO_2 mass emissions according to 40 CFR part 75. However, before calculating the annual biogenic CO_2 mass emissions, multiply the cumulative annual CO_2 mass emissions by 0.91 to convert from short tons to metric tons.

(3) For a unit that combusts MSW, the annual biogenic CO_2 emissions shall be calculated using the procedures in this paragraph (3).

(i) If the Tier 1 or Tier 2 Calculation Methodology is used to quantify CO_2 mass emissions:

(A) Use Equation C-1 or C-2c of this subpart, as appropriate, to calculate the annual CO_2 mass emissions from MSW combustion.

(B) Determine the relative proportions of biogenic and non-biogenic CO_2 emissions on a quarterly basis using the method specified in §98.34(d).

(C) Determine the annual biogenic CO_2 mass emissions from MSW combustion by multiplying the annual CO_2 mass emissions by the annual average biogenic decimal fraction obtained from §98.34(d).

(ii) If the unit uses Tier 4 to quantify CO_2 emissions:

(A) Follow the procedures in paragraphs (e)(2)(i) and (ii) of this section, to determine V_{total}.

(B) If any fossil fuel was combusted during the year, follow the procedures in paragraph (e)(2)(iii) of this section, to determine V_{ff}.

(C) Subtract V_{ff} from V_{total}, to obtain V_{MSW} , the annual volume of CO_2 emissions from MSW combustion.

(D) Determine the annual volume of biogenic CO_2 emissions (V_{bio}) from MSW combustion as follows. Multiply the annual volume of CO_2 emissions from MSW combustion (V_{MSW})

by the annual average biogenic decimal fraction obtained from ASTM D6866-08 and ASTM D7459-08.

(E) Calculate the biogenic percentage of the annual CO_2 emissions from the unit, using Equation C-14 of this section. For the purposes of this calculation, the term "V_{bio}" in the numerator of Equation C-14 of this section shall be the results of the calculation performed under paragraph (e)(3)(ii)(D) of this section.

(F) Calculate the annual biogenic CO_2 mass emissions according to paragraph (e)(2)(vi)(A) of this section.

(4) As an alternative to the procedures in paragraph (e)(2) of this section, use ASTM Methods D7459-08 and D6866-08 to determine the biogenic portion of the annual CO_2 emissions, as described in §98.34(e). If this option is selected, the results of each determination shall be expressed as a decimal fraction (e.g., 0.30, if 30 percent of the CO_2 is biogenic), and the values shall be averaged over the reporting year. The annual biogenic CO_2 mass emissions shall be calculated by multiplying the the total annual CO_2 mass emissions by the annual average biogenic fraction obtained from ASTM D6866-08 and ASTM D7459-08.

(5) If Equation C-1 of this section is selected to calculate the annual biogenic mass emissions for wood, wood waste, or other solid biomass-derived fuel, Equation C-15

of this section may be used to quantify biogenic fuel consumption, provided that all of the required input parameters are accurately quantified. Similar equations and calculation methodologies based on steam generation and boiler efficiency may be used, provided that they are documented in the GHG Monitoring Plan required by §98.3(g)(5).

$$(Fuel)_p = \frac{[H * S] - (HI)_{nb}}{2000\,(HHV)_{bio}\,(Eff)_{bio}} \quad \text{(Eq. C-15)}$$

Where:

$(Fuel)_p$	=	Quantity of biomass consumed during the measurement period "p" (tons/year or tons/month, as applicable).
H	=	Average enthalpy of the boiler steam for the measurement period (Btu/lb).
S	=	Total boiler steam production for the measurement period (lb/month or lb/year, as applicable).
$(HI)_{nb}$	=	Heat input from co-fired fossil fuels and non-biomass-derived fuels for the measurement period, based on company records of fuel usage and default or measured HHV values (Btu/month or Btu/year, as applicable).
$(HHV)_{bio}$	=	Default or measured high heat value of the biomass fuel (Btu/lb).
$(Eff)_{bio}$	=	Percent efficiency of biomass-to-energy conversion, expressed as a decimal fraction.
2000	=	Conversion factor (lb/ton).

(f) [Reporting only] Calculating fugitive HFC emissions from cooling units.[4] Operators of electricity generating facilities shall calculate fugitive HFC emissions for each HFC compound used in cooling units that support power generation or are used in heat transfers to cool stack gases using either the methodology in paragraph (f)(1) or (f)(2). The Operator is not required to report GHG emissions from air or water cooling systems or condensers that do not contain HFCs.

(1) Use Equation C-16 to calculate annual HFC emissions:

$$HFC = HFC_{inventory} + HFC_{purchases/acquisitions} - HFC_{sales/disbursements} + HFC_{\Delta capacity} \qquad \text{Eqn. C-16}$$

Where:

HFC = Annual fugitive HFC emission, metric tons;

$HFC_{inventory}$ = The difference between the quantity of HFC in storage at the beginning of the year and the quantity in storage at the end of the year. Stored HFC includes HFC contained in cylinders (such as 115-pound storage cylinders), gas carts, and other storage containers. It does not include HFC gas held in operating equipment. The change in inventory will be negative if the quantity of HFC in storage increases over the course of the year.

$HFC_{purchases/acquisitions}$ = The sum of all HFC acquired from other entities during the year either in storage containers or in equipment.

$HFC_{sales/disbursements}$ = The sum of all the HFC sold or otherwise transferred offsite to other entities during the year either in storage containers or in equipment.

[4] Taken from WCI.43(d).

$HFC_{\Delta capacity}$ = The net change in the total nameplate capacity (i.e. the full and proper charge) of the cooling equipment). The net change in capacity will be negative if the total nameplate capacity at the end of the year is less than the total nameplate capacity at the beginning of the year.

(2) Use service logs to document HFC usage and emissions from each cooling unit. Service logs should document all maintenance and service performed on the unit during the report year, including the quantity of HFCs added to or removed from the unit, and include a record at the beginning and end of each report year. The operator may use service log information along with the following simplified material balance equations to quantify fugitive HFCs from unit installation, servicing, and retirement, as applicable. The operator shall include the sum of HFC emissions from the applicable equations in the greenhouse gas emissions data report.

$$HFC_{Install} = R_{new} - C_{new}$$

$$HFC_{Service} = R_{recharge} - R_{Recover}$$

$$HFC_{Retire} = C_{retire} - R_{retire}$$

Where:

$HFC_{Install}$ = HFC emitted during initial charging/installation of the unit, kilograms;

$HFC_{Service}$ = HFC emitted during use and servicing of the unit for the report year, kilograms;

HFC_{Retire} = HFC emitted during the removal from service/retirement of the unit, kilograms;

R_{new} = HFC used to fill new unit (omit if unit was pre-charged by the manufacturer), kilograms;

C_{new} = Nameplate capacity of new unit (omit if unit was pre-charged by the manufacturer), kilograms;

$R_{recharge}$ = HFC used to recharge the unit during maintenance and service, kilograms;

$R_{recover}$ = HFC recovered from the unit during maintenance and service, kilograms;

C_{retire} = Nameplate capacity of the retired unit, kilograms; and

R_{retire} = HFC recovered from the retired unit, kilograms.

§98.34 Monitoring and QA/QC requirements.

The CO_2 mass emissions data for stationary fuel combustion sources shall be monitored as follows:

(a) For the Tier 2 Calculation Methodology:

(1) All fuel samples shall be taken at a location in the fuel handling system that provides a sample representative of the fuel combusted. The fuel sampling and analysis may be performed by either the owner or operator or the supplier of the fuel.

(2) The minimum required frequency of the HHV sampling and analysis for each type of fuel is specified in this paragraph. When the specified frequency is based on a specified time period (i.e., weekly, monthly, quarterly, or semiannually), fuel sampling and analysis is required only for those periods in which the unit operates.

(i) For natural gas, semiannual sampling and analysis is required (i.e., twice in a calendar year, with consecutive samples taken at least four months apart).

(ii) For coal and fuel oil, analysis of at least one representative sample from each fuel lot is required. For the purposes of this section, a fuel lot is defined as a shipment or delivery of a single fuel (e.g., ship load, barge load, group of trucks, group of railroad cars, etc.).

(iii) For liquid fuels other than fuel oil, for fossil fuel-derived gaseous fuels, and for biogas; sampling and analysis is required at least once per calendar quarter. To the extent practicable, consecutive quarterly samples shall be taken at least 30 days apart.

(iv) For solid fuels other than coal and MSW, weekly sampling is required to obtain composite samples, which are then analyzed monthly.

(3) If different types of fuel (e.g., different ranks of coal or different grades of fuel oil) are blended prior to combustion, use one of the following procedures in this paragraph.

(i) Use a weighted HHV value in the emission calculations, based on the relative proportions of each fuel in the blend.

(ii) Take a representative sample of the blend and analyze it for HHV.

(4) If, for a particular type of fuel, HHV sampling and analysis is performed more often than the minimum frequency specified in paragraphs (a)(2)of this section, the results of all valid fuel analyses shall be used in the GHG emission calculations.

(5) If, for a particular type of fuel, valid HHV values are obtained at less than the minimum frequency specifed in paragraphs (a)(2) of this section, appropriate substitute data values shall be used in the emissions calculations, in accordance with missing data procedures of §98.35.

(6) Use any applicable fuel sampling and analysis methods in this paragraph (a)(6) to determine the high heat values. Alternatively, for gaseous fuels, the HHV may be calculated using chromatographic analysis together with standard heating values of the fuel constituents, provided that the gas chromatograph is operated, maintained, and calibrated according to the manufacturer's instructions.

(i) ASTM D4809-06 Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (Precision Method) (incorporated by reference, see §98.7).

(ii) ASTM D240-02 (Reapproved 2007) Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (incorporated by reference, see §98.7).

(iii) ASTM D1826-94 (Reapproved 2003) Standard Test Method for Calorific (Heating) Value of Gases in Natural Gas Range by Continuous Recording Calorimeter (incorporated by reference, see §98.7).

(iv) ASTM D3588-98 (Reapproved 2003) Standard Practice for Calculating Heat Value, Compressibility Factor, and Relative Density of Gaseous Fuels (incorporated by reference, see §98.7).

(v) ASTM D4891-89 (Reapproved 2006) Standard Test Method for Heating Value of Gases in Natural Gas Range by Stoichiometric Combustion (incorporated by reference, see §98.7).

(vi) GPA Standard 2172–09 Calculation of Gross Heating Value, Relative Density, Compressibility and Theoretical Hydrocarbon Liquid Content for Natural Gas Mixtures for Custody Transfer (incorporated by reference, see §98.7).

(vii) GPA Standard 2261–00, Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography (incorporated by reference, see §98.7).

(viii) ASTM D5865-07a, Standard Test Method for Gross Calorific Value of Coal and Coke (incorporated by reference, see §98.7).

(b) For the Tier 3 Calculation Methodology:

(1) Calibrate each oil and gas flow meter according to §98.3(i) and the provisions of paragraph (b).

(i) Perform calibrations using any of the test methods and procedures in this paragraph (b)(1)(i):

(A) An applicable flow meter test method listed in paragraphs (b)(4)(i) through (b)(4)(viii) of this section.

(B) The calibration procedures specified by the flow meter manufacturer.

(C) An industry-accepted or industry standard calibration practice.

(ii) In addition to the initial calibration required by §98.3(i), recalibrate each fuel flow meter (except for qualifying billing meters under paragraph (b)(1)(iii) of this section) either annually, at the minimum frequency specified by the manufacturer, or at the interval specified by the industry consensus standard practice used.

(iii) Fuel billing meters are exempted from the initial and ongoing calibration requirements of this paragraph, provided that the fuel supplier and the unit combusting the fuel do not have any common owners and are not owned by subsidiaries or affiliates of the same company.

(iv) For the initial calibration of an orifice, nozzle, or venturi meter; in-situ calibration of the transmitters is sufficient. A primary element inspection (PEI) shall be performed at least once every three years.

(v) For the continuously-operating units and processes described in §98.3(i)(6), the required flow meter recalibrations and, if necessary, the PEIs may be postponed until the next scheduled maintenance outage.

(vi) If a mixture of fuels is transported by a common pipe (e.g., still gas and supplementary natural gas), you must either separately meter each of the fuels prior to mixing using flow meters calibrated according to §98.3(i), or use flow meters calibrated according to §98.3(i) to measure the mixed fuel at the common pipe and to separately meter an appropriate subset of the fuels prior to mixing. If the latter option is chosen, quantify the fuels that are not measured prior to mixing by subtracting out the fuels measured prior to mixing from the fuel measured at the common pipe.

(2) Oil tank drop measurements (if used to determine liquid fuel use volume) shall be performed according to any an appropriate method published by a consensus-based standards organization (e.g., the American Petroleum Institute).

(3) The carbon content and, if applicable, molecular weight of the fuels shall be determined according to the procedures in paragraph (b)(3).

(i) All fuel samples shall be taken at a location in the fuel handling system that provides a sample representative of the fuel combusted. The fuel sampling and analysis may be performed by either the owner or operator or by the supplier of the fuel.

(ii) At a minimum, fuel samples shall be collected at the frequency specified in this paragraph. When sampling is required at a specified time interval (e.g., weekly, monthly, quarterly, or semiannually), fuel sampling and analysis is required for only those specified periods in which the unit operates.

(A) For natural gas, semiannual sampling and analysis is required (i.e., twice in a calendar year, with consecutive samples taken at least four months apart).

(B) For coal and fuel oil, analysis of at least one representative sample from each fuel lot is required. For the purposes of this section, a fuel lot is defined as a shipment or delivery of a single fuel (e.g., ship load, barge load, group of trucks, group of railroad cars, etc.).

(C) For other liquid fuels other than fuel oil, for fossil fuel-derived gaseous fuels, and for biogas; sampling and analysis is required at least once per calendar quarter. To the extent practicable, consecutive quarterly samples shall be taken at least 30 days apart.

(D) For solid fuels other than coal, weekly sampling is required to obtain composite samples, which are then analyzed monthly.

(E) For gaseous fuels other than natural gas and biogas (e.g., refinery gas), daily sampling and analysis to determine the carbon content and molecular weight of the fuel is required if the necessary equipment is in place to make these measurements. Otherwise, weekly sampling and analysis shall be performed. The equipment necessary to perform daily sampling and analysis of carbon content and molecular weight for refinery fuel gas must be installed no later than January 1, 2012.

(iii) If, for a particular type of fuel, sampling and analysis for carbon content and molecular weight is performed more often than the minimum frequency specified in paragraph (b)(3) of this section, the results of all valid fuel analyses shall be used in the GHG emission calculations.

(iv) If, for a particular type of fuel, sampling and analysis for carbon content and molecular weight is performed at less than the minimum frequency specifed in paragraph (b)(3) of this section, appropriate substitute data values shall be used in the emissions calculations, in accordance with the missing data procedures of §98.35.

(v) The procedures of paragraphs (a)(3) of this section apply to carbon content and molecular weight determinations.

(4) Use any applicable standard method from the following list to quality assure the data from each fuel flow meter.

(i) AGA Report No. 3, Orifice Metering of Natural Gas and Other Related Hydrocarbon Fluids, Part 1: General Equations and Uncertainty Guidelines (1990) and Part 2: Specification and Installation Requirements (2000)(incorporated by reference, see §98.7).

(ii) AGA Transmission Measurement Committee Report No. 7, Measurement of Gas by Turbine Meters (2006) (incorporated by reference, see §98.7).

(iii) ASME MFC-3M-2004 Measurement of Fluid Flow in Pipes Using Orifice, Nozzle, and Venturi (incorporated by reference, see §98.7).

(iv) ASME MFC-4M-1986 (Reaffirmed 1997), Measurement of Gas Flow by Turbine Meters (incorporated by reference, see §98.7).

(v) ASME MFC-5M-1985 (Reaffirmed 1994), Measurement of Liquid Flow in Closed Conduits Using Transit-Time Ultrasonic Flowmeters (incorporated by reference, see §98.7).

(vi) ASME MFC-6M-1998 Measurement of Fluid Flow in Pipes Using Vortex Flowmeters (incorporated by reference, see §98.7).

(vii) ASME MFC–7M–1987 (Reaffirmed 1992), Measurement of Gas Flow by Means of Critical Flow Venturi Nozzles (incorporated by reference, see §98.7).

(viii) ASME MFC–9M–1988 (Reaffirmed 2001), Measurement of Liquid Flow in Closed Conduits by Weighing Method (incorporated by reference, see §98.7).

(5) Use any applicable methods from the following list to determine the carbon content and molecular weight (for gaseous fuel) of the fuel. Alternatively, the results of chromatographic analysis of the fuel may be used, provided that the gas chromatograph is operated, maintained, and calibrated according to the manufacturer's instructions.

(i) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see §98.7).

(ii) ASTM D1946-90 (Reapproved 2006) Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see §98.7).

(iii) ASTM D2502-04 (Reapproved 2002) Standard Test Method for Estimation of Molecular Weight (Relative Molecular Mass) of Petroleum Oils from Viscosity Measurements (incorporated by reference, see §98.7).

(iv) ASTM D2503-92 (Reapproved 2007) Standard Test Method for Relative Molecular Mass (Relative Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure (incorporated by reference, see §98.7).

(v) ASTM D3238-95 (Reapproved 2005) Standard Test Method for Calculation of Carbon Distribution and Structural Group Analysis of Petroleum Oils by the n-d-M Method (incorporated by reference, see §98.7).

(vi) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, see §98.7).

(vii) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7).

(c) For the Tier 4 Calculation Methodology, the CO_2 and flow rate monitors must be certified prior to the applicable deadline specified in §98.33(b)(5).

(1) For initial certification, you may use any one of the following three procedures in this paragraph.

(i) §75.20(c)(2) and (4) and appendix A to 40 CFR part 75.

(ii) The calibration drift test and relative accuracy test audit (RATA) procedures of Performance Specification 3 in appendix B to part 60 (for the CO_2 concentration monitor) and Performance Specification 6 in appendix B to part 60 (for the continuous emission rate monitoring system (CERMS)).

(iii) The provisions of an applicable State continuous monitoring program.

(2) If an O_2 concentration monitor is used to determine CO_2 concentrations, the applicable provisions of 40 CFR part 75, 40 CFR part 60, or an applicable State continuous monitoring program shall be followed for initial certification and on-going quality assurance, and all required RATAs of the monitor shall be done on a percent CO_2 basis.

(3) For ongoing quality assurance, follow the applicable procedures in either appendix B to 40 CFR part 75, appendix F to 40 CFR part 60, or an applicable State continuous monitoring program. If appendix F to 40 CFR part 60 is selected for on-going quality assurance, perform daily calibration drift assessments for both the CO_2 monitor (or surrogate O_2 monitor) and the flow rate monitor, conduct cylinder gas audits of the CO_2 concentration monitor in three of the four quarters of each year (except for non-

operating quarters), and perform annual RATAs of the CO_2 concentration monitor and the CERMS.

(4) For the purposes of this part, the stack gas volumetric flow rate monitor RATAs required by appendix B to 40 CFR part 75 and the annual RATAs of the CERMS required by appendix F to 40 CFR part 60 need only be done at one operating level, representing normal load or normal process operating conditions, both for initial certification and for ongoing quality assurance.

(5) If, for any source operating hour, quality assured data are not obtained with a CO_2 monitor (or surrogate O_2 monitor), flow rate monitor, or (if applicable) moisture monitor, use appropriate substitute data values in accordance with the missing data provisions of §98.35.

(d) When municipal solid waste (MSW) is combusted in a unit, determine the biogenic portion of the CO_2 emissions from MSW combustion using ASTM D6866-08 Standard Test Methods for Determining the Biobased Content of Solid, Liquid, and Gaseous Samples Using Radiocarbon Analysis (incorporated by reference, see §98.7) and ASTM D7459-08 Standard Practice for Collection of Integrated Samples for the Speciation of Biomass (Biogenic) and Fossil-Derived Carbon Dioxide Emitted from Stationary Emissions Sources (incorporated by reference, see §98.7). Perform the ASTM

D7459-08 sampling and the ASTM D6866-08 analysis at least once in every calendar quarter in which MSW is combusted in the unit. Collect each gas sample during normal unit operating conditions while MSW is the only fuel being combusted for at least 24 consecutive hours or for as long as is necessary to obtain a sample large enough to meet the specifications of ASTM D6866-08. Separate CO_2 emissions into the biogenic and non-biogenic fraction using the average proportion of biogenic emissions of all samples analyzed during the reporting year. Express the results as a decimal fraction (e.g., 0.30, if 30 percent of the CO_2 from MSW combustion is biogenic). If there is a common fuel source of MSW that feeds multiple units at the facility, performing the testing at only one of the units is sufficient.

(e) For units that use CEMS to measure the total CO_2 mass emissions and combust a combination of biogenic fuels (other than MSW) with a fossil fuel, ASTM D6866-08 and ASTM D7459-08 may be used to determine the biogenic portion of the CO_2 emissions. Perform the ASTM D7459-08 sampling and the ASTM D6866-08 analysis at least once in every calendar quarter in which biogenic and non-biogenic fuels are co-fired in the unit. The relative proportions of the biogenic and non-biogenic fuels during the sampling shall be representative of the average fuel blend for a typical operating year. Collect each gas sample using ASTM D7459-08 during normal unit operation for at least 24 consecutive hours or for as long as is necessary to obtain a sample large enough to meet the specifications of ASTM D6866-08.

(f) Whenever company records are used in the calculation of CO_2 emissions, the records required under §98.3(g) shall include both the company records and an explanation of how those records are used to estimate the following parameters:

(1) Fuel consumption, when the Tier 1 and Tier 2 Calculation Methodologies are used.

(2) Fuel consumption, when solid fuel is combusted and the Tier 3 Calculation Methodology is used.

(3) Fossil fuel consumption when §98.33(e) applies to a unit that uses CEMS to quantify CO_2 emissions and that combusts both fossil and biomass fuels.

(4) Sorbent usage, when §98.33(d) applies.

(5) Quantity of steam generated by a unit when §98.33(a)(2) applies.

(6) Biogenic fuel consumption under §98.33(e)(5).

(g) As part of the GHG Monitoring Plan required under §98.3(g)(5), you must document the procedures used to ensure the accuracy of the estimates of fuel usage, sorbent usage, steam production, and boiler efficiency (as applicable) in paragraph (f) of this section, including but not limited to calibration of weighing equipment, fuel flow meters, steam flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices shall also be recorded, and the technical basis for these estimates shall be provided.

§98.35 Procedures for estimating missing data.

Required in U.S. jurisdictions only. Canadian jurisdictions may impose data substitution procedures that differ from the following.

Whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For all units subject to the requirements of the Acid Rain Program, and all other stationary combustion units subject to the requirements of this part that monitor and report emissions and heat input data in accordance with 40 CFR part 75, the missing data substitution procedures in 40 CFR part 75 shall be followed for CO_2 concentration, stack gas flow rate, fuel flow rate, high heating value, and fuel carbon content.

(b) For units that use the Tier 1, Tier 2, Tier 3, and Tier 4 Calculation Methodologies, perform missing data substitution as follows for each parameter:

(1) For each missing value of the high heating value, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the “after” value has not been obtained by the time that the GHG emissions report is due, you may use the “before” value for missing data substitution or the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production, operating hours). If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(2) For missing records of CO_2 concentration, stack gas flow rate, percent moisture, fuel usage, and sorbent usage, the substitute data value shall be the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production,

operating hours, etc.). You must document and retain records of the procedures used for all such estimates.

§98.36 Data reporting requirements.

Canadian jurisdictions may allow or require aggregation of emissions data up to the facility level.

(a) In addition to the facility-level information required under §98.3, the annual GHG emissions report shall contain the unit-level or process-level emissions data in paragraphs (b) through (d) of this section (as applicable) and the emissions verification data in paragraph (e) of this section.

(b) Units that use the four tiers. You shall report the following information for stationary combustion units that use the Tier 1, Tier 2, Tier 3, or Tier 4 methodology in §98.33(a) to calculate CO_2 emissions, except as otherwise provided in paragraphs (c) and (d) of this section:

(1) The unit ID number.

(2) A code representing the type of unit.

(3) Maximum rated heat input capacity of the unit, in mmBtu/hr for boilers and process heaters only and relevant units of measure for other combustion sources.

(4) Each type of fuel combusted in the unit during the report year.

(5) The tier used to calculate the CO_2 emissions for each type of fuel combusted (i.e., Tier 1, 2, 3, or 4).

(6) For a unit that uses Tiers 1, 2, and 3; the CO_2, CH_4, and N_2O emissions for each type of fuel combusted, expressed in metric tons of each gas and in metric tons of CO_2e.

(7) For a unit that uses Tier 4:

(i) For units that burn fossil fuels only, the annual CO_2 emissions for all fuels combined. Reporting CO_2 emissions by type of fuel is not required.

(ii) For units that burn both fossil fuels and biomass, the annual CO_2 emissions from combustion of all fossil fuels combined and the annual CO_2 emissions from combustion of all biomass fuels combined. Reporting CO_2 emissions by type of fuel is not required.

(iii) Annual CH_4 and N_2O emissions for each type of fuel combusted expressed in metric tons of each gas and in metric tons of CO_2e.

(8) Annual CO_2 emissions from sorbent (if calculated using Equation C-11 of this subpart), expressed in metric tons.

(9) Annual GHG emissions from all fossil fuels burned in the unit (i.e., the sum of the CO_2 , CH_4, and N_2O emissions), expressed in metric tons of CO_2e.

(10) Customer meter number for units that combust natural gas.

(11) For units that generate electricity, nameplate generating capacity (MW) and net power generated (MWh) during the reporting year.

(12) For each cogeneration unit, indicate whether topping or bottoming cycle and provide useful thermal output as applicable, in mmBtu. Where steam or heat is acquired from another facility for the generation of electricity, report the provider and amount of acquired steam or heat in mmBtu. Where supplemental firing has been applied to support electricity generation or industrial output, report this purpose and fuel consumption by fuel type using the following units:[5]

(i) For gases, report in units of million standard cubic feet.
(ii) For liquids, report in units of gallons.
(iii) For non-biomass solids, report in units of short tons.
(iv) For biomass-derived solid fuels, report in units of bone dry short tons.

(c) Reporting alternatives for units using the four Tiers. You may use any of the applicable reporting alternatives of this paragraph to simplify the unit-level reporting required under paragraph (b) of this section:

[5] Taken from WCI.42(b).

Subpart C—General Stationary Combustion

(1) Aggregation of units. If a facility contains two or more units (e.g., boilers or combustion turbines), each of which has a maximum rated heat input capacity of 250 mmBtu/hr or less, you may report the combined GHG emissions for the group of units in lieu of reporting GHG emissions from the individual units, provided that the use of Tier 4 is not required or elected for any of the units and the units use the same tier for any common fuels combusted. If this option is selected, the following information shall be reported instead of the information in paragraph (b) of this section:

(i) Group ID number, beginning with the prefix "GP".

(ii) An identification number for each unit in the group.

(iii) Cumulative maximum rated heat input capacity of the group (mmBtu/hr).

(iv) The highest maximum rated heat input capacity of any unit in the group (mmBtu/hr).

(v) Each type of fuel combusted in the group of units during the reporting year.

(vi) Annual CO_2, CH_4, and N_2O mass emissions aggregated for each type of fuel combusted in the group of units during the year, expressed in metric tons of each gas and in metric tons of CO_2e. If any of the units burn both fossil fuels and biomass, report also the annual CO_2 emissions from combustion of all fossil fuels combined and annual CO_2 emissions from combustion of all biomass fuels combined, expressed in metric tons.

(vii) The tier used to calculate the CO_2 mass emissions for each type of fuel combusted in the units (i.e., Tier 1, Tier 2, or Tier 3).

(viii) The calculated CO_2 mass emissions (if any) from sorbent.

(ix) Annual GHG emissions from all fossil fuels burned in the group (i.e., the sum of the CO_2 , CH_4, and N_2O emissions), expressed in metric tons of CO2e.

(2) Monitored common stack or duct configurations. When the flue gases from two or more stationary combustion units at a facility are discharged through a common stack or duct before exiting to the atmosphere and if CEMS are used to continuously monitor CO_2 mass emissions at the common stack or duct according to the Tier 4 Calculation Methodology, you may report the combined emissions from the units sharing the common stack or duct, in lieu of separately reporting the GHG emissions from the individual units. The following information shall be reported instead of the information in paragraph (b) of this section:

(i) Common stack or duct identification number, beginning with the prefix "CS".

(ii) Identification numbers of the units sharing the common stack or duct.

(iii) Maximum rated heat input capacity of each unit sharing the common stack or duct (mmBtu/hr).

(iv) Each type of fuel combusted in the units during the year.

(v) The methodology used to calculate the CO_2 mass emissions, i.e., Tier 4.

(vi) If the any of the units burn both fossil fuels and biomass, annual CO_2 mass emissions, annual CO_2 emissions from combustion of fossil fuels, and annual CO_2 emissions from combustion of biomass measured at the common stack or duct, expressed in metric tons.

(vii) The annual CH_4 and N_2O emissions from the units sharing the common stack or duct, expressed in metric tons of each gas and in metric tons of CO_2e.

(viii) Annual GHG emissions from all fossil fuels burned in the group (i.e., the sum of the CO_2 , CH_4, and N_2O emissions), expressed in metric tons of CO2e.

(3) <u>Common pipe configurations</u>. When two or more liquid-fired or gaseous-fired stationary combustion units at a facility combust the same type of fuel and the fuel is

fed to the individual units through a common supply line or pipe, you may report the combined emissions from the units served by the common supply line, in lieu of separately reporting the GHG emissions from the individual units, provided that the total amount of fuel combusted by the units is accurately measured at the common pipe or supply line using a fuel flow meter that is calibrated in accordance with §98.34(a). If a portion of the fuel measured at the common pipe is diverted to a chemical or industrial process where it is used but not combusted, you may subtract the diverted fuel from the fuel measured at the common pipe prior to performing the GHG emissions calculations, provided that the amount of fuel diverted is also measured with a calibrated flow meter per §98.3(i). If the common pipe option is selected, the applicable tier shall be used based on the maximum rated heat input capacity of the largest unit served by the common pipe configuration. The following information shall be reported instead of the information in paragraph (b) of this section:

(i) Common pipe identification number, beginning with the prefix "CP".

(ii) The identification numbers of the units served by the common pipe.

(iii) Maximum rated heat input capacity of each unit served by the common pipe (mmBtu/hr).

(iv) The fuels combusted in the units during the reporting year.

(v) The methodology used to calculate the CO_2 mass emissions (i.e., Tier 1, Tier 2, or Tier 3).

(vi) If the any of the units burns both fossil fuels and biomass, the annual CO_2 mass emissions from combustion of all fossil fuels and annual CO_2 emissions from combustion of all biomass fuels from the units served by the common pipe, expressed in metric tons.

(vii) Annual CH_4 and N_2O emissions from the units served by the common pipe, expressed in metric tons of each gas and in metric tons of CO_2e.

(viii) Annual GHG emissions from all fossil fuels burned in units served by the common pipe (i.e., the sum of the CO_2, CH_4, and N_2O emissions), expressed in metric tons of CO_2e.

(d) Units subject to 40 CFR part 75.

(1) For stationary combustion units that are either subject to the Acid Rain Program or not in the Acid Rain Program but monitor and report CO_2 mass emissions year-round according to 40 CFR part 75, you shall report the following unit-level information:

(i) Unit or stack identification numbers. Use exact same unit, common stack, or multiple stack identification numbers that represent the monitored locations (e.g., 1, 2, CS001, MS1A, etc.) that are reported under §75.64 of this chapter.

(ii) Annual CO_2, CH_4, and N_2O emissions at each monitored location, expressed in metric tons of CO_2e.

(iii) Identification of the Part 75 methodology used to determine the CO_2 mass emissions.

(iv) Annual fuel consumption, if not reported under 40 CFR part 75.

(A) For gases, report in units of thousands of standard cubic feet.

(B) For liquids, report in units of gallons.

(C) For non-biomass solids, report in units of short tons.

(D) For biomass solid fuels, report in units of bone dry short tons or bone dry metric tons.

(v) Average carbon content of each fuel, if used to compute CO_2 emissions but not reported under 40 CFR part 75.

(vi) Average high heating value of each fuel, if used to compute CO_2 emissions but not reported under 40 CFR part 75.

(vii) For units that burn both fossil fuels and biomass, the annual CO2 emissions from combustion of all fossil fuels combined and the annual CO2 emissions from combustion of all biomass fuels combined. Reporting CO2 emissions by type of fuel is not required.

(viii) For units that generate electricity, nameplate generating capacity (MW) and net power generated (MWh) during the reporting year.

(ix) For each cogeneration unit, indicate whether topping or bottoming cycle and provide useful thermal output as applicable, in mmBtu. Where steam or heat is acquired from another facility for the generation of electricity, report the provider and amount of acquired steam or heat in mmBtu. Where supplemental firing has been applied to support electricity generation or industrial output, report this purpose and fuel consumption by fuel type using the units in WCI.42(b).

(2) For units that use the alternative CO_2 mass emissions calculation methods for units with continuous monitoring systems provided in §98.33(a)(5), you shall report the following unit-level information:

(i) Unit, stack, or pipe ID numbers. Use exact same unit, common stack, or multiple stack identification numbers that represent the monitored locations (e.g., 1, 2, CS001, MS1A, etc.) that are reported under §75.64 of this chapter.

(ii) For units that use the alternative methods specified in §98.33(a)(5)(i) and (ii) to monitor and report heat input data year-round according to appendix D to 40 CFR part 75 or 40 CFR 75.19:

(A) Each type of fuel combusted in the unit during the reporting year.

(B) The methodology used to calculate the CO_2 mass emissions for each fuel type.

(C) A code or flag to indicate whether heat input is calculated according to appendix D to 40 CFR part 75 or 40 CFR 75.19.

(D) Annual CO_2, CH_4, and N_2O emissions at each monitored location, across all fuel types, expressed in metric tons of CO_2e.

(iii) For units with continuous monitoring systems that use the alternative method for units with continuous monitoring systems in §98.33(a)(5)(iii) to monitor heat input year-round according to 40 CFR part 75:

(A) Fuel combusted during the reporting year.

(B) Methodology used to calculate the CO_2 mass emissions.

(C) A code or flag to indicate that the heat input data is derived from CEMS measurements.

(D) The total annual CO_2, CH_4, and N_2O emissions at each monitored location, expressed in metric tons of CO_2e.

(iv) The information required in paragraphs (d)(1)(iv) through (d)(1)(ix) of this section, as applicable.

(e) Verification data. You must keep on file, in a format suitable for inspection and auditing, sufficient data to verify the reported GHG emissions. This data and information must, where indicated in this paragraph (e), be included in the annual GHG emissions report.

(1) The applicable verification data specified in this paragraph (e) are not required to be kept on file or reported for units that meet any one of the three following conditions:

(i) Are subject to the Acid Rain Program.

(ii) Use the alternative methods for units with continuous monitoring systems provided in §98.33(a)(5).

(iii) Are not in the Acid Rain Program, but are required monitor and report CO_2 mass emissions and heat input data year-round, in accordance with 40 CFR part 75.

(2) For stationary combustion sources using the Tier 1, Tier 2, Tier 3, and Tier 4 Calculation Methodologies in

Subpart C—General Stationary Combustion

§98.33(a) to quantify CO_2 emissions, the following additional information shall be kept on file and included in the GHG emissions report, where indicated:

(i) For the Tier 1 Calculation Methodology, report the total quantity of each type of fuel combusted in the unit or group of aggregated units (as applicable) during the reporting year, in short tons for solid fuels, gallons for liquid fuels and standard cubic feet for gaseous fuels.

(ii) For the Tier 2 Calculation Methodology, report:

(A) The total quantity of each type of fuel combusted in the unit or group of aggregated units (as applicable) during each month of the reporting year. Express the quantity of each fuel combusted during the measurement period in short tons for solid fuels, gallons for liquid fuels, and scf for gaseous fuels.

(B) The frequency of the HHV determinations (e.g., once a month, once per fuel lot).

(C) The high heat values used in the CO_2 emissions calculations for each type of fuel combusted, in mmBtu per short ton for solid fuels, mmBtu per gallon for liquid fuels, and mmBtu per scf for gaseous fuels. Specify the date on which each fuel sample was taken. Indicate whether each HHV is a measured value of a substitute data value.

(D) If Equation C-2c of this subpart is used to calculate CO_2 mass emissions, report the total quantity (i.e., pounds) of steam produced from MSW or solid fuel combustion during the year, and the ratio of the maximum rate heat input capacity to the design rated steam output capacity of the unit, in mmBtu per lb of steam.

(iii) For the Tier 2 Calculation Methodology, keep records of the methods used to determine the HHV for each type of fuel combusted and the date on which each fuel sample was taken.

(iv) For the Tier 3 Calculation Methodology, report:

(A) The quantity of each type of fuel combusted in the unit or group of units (as applicable) during the year, in short tons for solid fuels, gallons for liquid fuels, and scf for gaseous fuels.

(B) The frequency of carbon content and, if applicable, molecular weight determinations for each type of fuel for the reporting year (e.g., daily, weekly, monthly, semiannually, once per fuel lot).

(C) The carbon content and, if applicable, gas molecular weight values used in the emission calculations (including both valid and substitute data values). Report all measured values if the fuel is sampled monthly or less frequently. Otherwise, for daily and weekly sampling, report monthly average values determined using the calculation procedures in Equation C-2b for each variable. Express carbon content as a decimal fraction for solid fuels, kg C per gallon for liquid fuels, and kg C per kg of fuel for gaseous fuels. Express the gas molecular weights in units of kg per kg-mole.

(D) The total number of valid carbon content determinations and, if applicable, molecular weight determinations made during the reporting year, for each fuel type.

(E) The number of substitute data values used for carbon content and, if applicable, molecular weight used in the annual GHG emissions calculations.

(v) For the Tier 3 Calculation Methodology, keep records of the following:

(A) For liquid and gaseous fuel combustion, the dates and results of the initial calibrations and periodic recalibrations of the required fuel flow meters.

(B) For fuel oil combustion, the method from §98.34(b) used to make tank drop measurements (if applicable).

(C) The methods used to determine the carbon content for each type of fuel combusted.

(D) The methods used to calibrate the fuel flow meters).

(vi) For the Tier 4 Calculation Methodology, report:

(A) The total number of source operating hours in the reporting year.

(B) The cumulative CO_2 mass emissions in each quarter of the reporting year, i.e., the sum of the hourly values calculated from Equation C-6 or C-7 of this subpart (as applicable), in metric tons.

(C) For CO_2 concentration, stack gas flow rate, and (if applicable) stack gas moisture content, the percentage of source operating hours in which a substitute data value of each parameter was used in the emissions calculations.

(vii) For the Tier 4 Calculation Methodology, keep records of:

(A) Whether the CEMS certification and quality assurance procedures of 40 CFR part 75, 40 CFR part 60, or an applicable State continuous monitoring program were used.

(B) The dates and results of the initial certification tests of the CEMS.

(C) The dates and results of the major quality assurance tests performed on the CEMS during the reporting year, i.e., linearity checks, cylinder gas audits, and relative accuracy test audits (RATAs).

(viii) If CO_2 emissions that are generated from acid gas scrubbing with sorbent injection are not captured using CEMS, report:

(A) The total amount of sorbent used during the report year, in short tons.

(B) The molecular weight of the sorbent.

(C) The ratio ("R") in Equation C-11 of this subpart.

(ix) For units that combust both fossil fuel and biomass, when CEMS are used to quantify the annual CO_2 emissions and biogenic CO_2 is determined according to §98.33(e)(2), you shall report the following additional information, as applicable:

(A) The annual volume of CO_2 emitted from the combustion of all fuels, i.e., V_{total}, in scf.

(B) The annual volume of CO_2 emitted from the combustion of fossil fuels, i.e., V_{ff}, in scf. If more than one type of fossil fuel was combusted, report the combustion volume of CO_2 for each fuel separately as well as the total.

(C) The annual volume of CO_2 emitted from the combustion of biomass, i.e., V_{bio}, in scf.

(D) The carbon-based F-factor used in Equation C-13 of this subpart, for each type of fossil fuel combusted, in scf CO_2 per mmBtu.

(E) The annual average HHV value used in Equation C-13 of this subpart, for each type of fossil fuel combusted, in Btu/lb, Btu/gal, or Btu/scf, as appropriate.

(F) The total quantity of each type of fossil fuel combusted during the reporting year, in lb, gallons, or scf, as appropriate.

(G) Annual biogenic CO_2 mass emissions, in metric tons.

(x) When ASTM methods D7459-08 and D6866-08 are used to determine the biogenic portion of the annual CO_2 emissions from MSW combustion, report:

(A) The results of each quarterly sample analysis, expressed as a decimal fraction (e.g., if the biogenic fraction of the CO_2 emissions from MSW combustion is 30 percent, report 0.30).

(B) Annual combined biomass and fossil fuel CO_2 emissions from MSW combustion, in metric tons of CO_2e.

(C) The quantities V_{ff}, V_{total}, and V_{MSW} from §98.33(e)(4)(ii), if CEMS are used to measure CO_2 emissions.

(D) The annual volume of biogenic CO_2 emissions from MSW combustion, in metric tons.

(xi) When ASTM methods D7459-08 and D6866-08 are used to determine the biogenic portion of the annual CO_2 emissions from a unit that co-fires biogenic (other than MSW) and non-biogenic fuels, you shall report the results of each quarterly sample analysis, expressed as a decimal fraction (e.g., if the biogenic fraction of the CO_2 emissions is 30 percent, report 0.30).

(3) Within 30 days of receipt of a written request from the Administrator, you shall submit explanations of the following:

(i) An explanation of how company records are used to quantify fuel consumption, if the Tier 1 or Tier 2 Calculation Methodology is used to calculate CO_2 emissions.

(ii) An explanation of how company records are used to quantify fuel consumption, if solid fuel is combusted and the Tier 3 Calculation Methodology is used to calculate CO_2 emissions.

(iii) An explanation of how sorbent usage is quantified.

(iv) An explanation of how company records are used to quantify fossil fuel consumption in units that uses CEMS to quantify CO_2 emissions and combusts both fossil fuel and biomass.

(v) An explanation of how company records are used to measure steam production, when it is used to calculate CO_2 mass emissions under §98.33(a)(2)(iii) or to quantify solid fuel usage under §98.33(c)(3).

(4) Within 30 days of receipt of a written request from the Administrator, you shall submit the verification data and information described in paragraphs (e)(2)(iii), (e)(2)(v), and (e)(2)(vii) of this section.

§98.37 Records That Must be Retained.

In addition to the requirements of §98.3(g), you must retain the applicable records specified in §§98.34(f) and (g), 98.35(b), and 98.36(e).

§98.38 Definitions.

Except as specified in this section, all~~All~~ terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

"Bottoming cycle plant" means a cogeneration plant in which the energy input to the system is first applied to a useful thermal energy application or process, and at least some of the reject heat emerging from the application or process is then used for electricity production.

"Cogeneration unit" means a stationary fuel combustion device which simultaneously generates electrical and thermal energy that is (i) used by the operator of the facility where the cogeneration unit is located; or (ii) transferred to another facility for use by that facility.

"Cogeneration system" means individual cogeneration components including the prime mover (heat engine), generator, heat recovery, and electrical interconnection, configured into an integrated system that provides sequential generation of multiple forms of useful energy (usually electrical and thermal), at least one form of which the facility consumes on-site or makes available to other users for an end-use other than electricity generation.

"Topping cycle plant" means a cogeneration plant in which the energy input to the plant is first used to produce electricity, and at least some of the reject heat from the electricity production process is then used to provide useful thermal output.

Canadian jurisdictions will substitute tables that contain Canada-specific emission factors for Tables C-1 and C-2 below:

Table C-1 of Subpart C—Default CO_2 Emission Factors and High Heat Values for Various Types of Fuel

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Coal and Coke	**mmBtu/short ton**	**kg CO_2 /mmBtu**
Anthracite	25.09	103.54

Subpart C—General Stationary Combustion

Table C-1 of Subpart C—Default CO_2 Emission Factors and High Heat Values for Various Types of Fuel

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Bituminous	24.93	93.40
Subbituminous	17.25	97.02
Lignite	14.21	96.36
Coke	24.80	102.04
Mixed (Commercial sector)	21.39	95.26
Mixed (Industrial coking)	26.28	93.65
Mixed (Industrial sector)	22.35	93.91
Mixed (Electric Power sector)	19.73	94.38
Natural Gas	**mmBtu/scf**	**kg CO_2 /mmBtu**
Pipeline (Weighted U.S. Average)	1.028×10^{-3}	53.02
Petroleum Products	**mmBtu/gallon**	**kg CO_2 /mmBtu**
Distillate Fuel Oil No. 1	0.139	73.25
Distillate Fuel Oil No. 2	0.138	73.96
Distillate Fuel Oil No. 4	0.146	75.04
Residual Fuel Oil No. 5	0.140	72.93
Residual Fuel Oil No. 6	0.150	75.10
Still Gas	0.143	66.72
Kerosene	0.135	75.20
Liquefied petroleum gases (LPG)	0.092	62.98
Propane	0.091	61.46
Propylene	0.091	65.95
Ethane	0.096	62.64
Ethylene	0.100	67.43
Isobutane	0.097	64.91
Isobutylene	0.103	67.74
Butane	0.101	65.15
Butylene	0.103	67.73
Naphtha (<401 deg F)	0.125	68.02
Natural Gasoline	0.110	66.83
Other Oil (>401 deg F)	0.139	76.22
Pentanes Plus	0.110	70.02
Petrochemical Feedstocks	0.129	70.97
Petroleum Coke	0.143	102.41
Special Naphtha	0.125	72.34
Unfinished Oils	0.139	74.49
Heavy Gas Oils	0.148	74.92
Lubricants	0.144	74.27
Motor Gasoline	0.125	70.22
Aviation Gasoline	0.120	69.25
Kerosene-Type Jet Fuel	0.135	72.22
Asphalt and Road Oil	0.158	75.36
Crude Oil	0.138	74.49
Fossil Fuel-derived Fuels (Solid)	**mmBtu/short ton**	**kg CO_2 /mmBtu**
Municipal Solid Waste[1]	9.95	90.7
Tires	26.87	85.97
Fossil Fuel-derived Fuels (Gaseous)	**mmBtu/scf**	**kg CO_2 /mmBtu**

Subpart C—General Stationary Combustion

Table C-1 of Subpart C—Default CO_2 Emission Factors and High Heat Values for Various Types of Fuel

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Blast Furnace Gas	0.092×10^{-3}	274.32
Coke Oven Gas	0.599×10^{-3}	46.85
Biomass Fuels - Solid	**mmBtu/short Ton**	**kg CO_2 /mmBtu**
Wood and Wood Residuals	15.38	93.80
Agricultural Byproducts	8.25	118.17
Peat	8.00	111.84
Solid Byproducts	25.83	105.51
Biomass Fuels - Gaseous	**mmBtu/scf**	**kg CO_2 /mmBtu**
Biogas (Captured methane)	0.841×10^{-3}	52.07
Biomass Fuels - Liquid	**mmBtu/gallon**	**kg CO_2 /mmBtu**
Ethanol (100%)	0.084	68.44
Biodiesel (100%)	0.128	73.84
Rendered Animal Fat	0.125	71.06
Vegetable Oil	0.120	81.55

[1]Allowed only for units that do not generate steam and use Tier 1.

Table C-2 of Subpart C—Default CH_4 and N_2O Emission Factors for Various Types of Fuel.

Fuel Type	Default CH_4 Emission Factor (kg CH_4 /mmBtu)	Default N_2O Emission Factor (kg N_2O/mmBtu)
Coal and Coke (All fuel types in Table C-1)	1.1×10^{-2}	1.6×10^{-03}
Natural Gas	1.0×10^{-03}	1.0×10^{-04}
Petroleum (All fuel types in Table C-1)	3.0×10^{-03}	6.0×10^{-04}
Municipal Solid Waste	3.2×10^{-02}	4.2×10^{-03}
Tires	3.2×10^{-02}	4.2×10^{-03}
Blast Furnace Gas	2.2 x 10-05	1.0×10^{-04}
Coke Oven Gas	4.8 x 10-04	1.0×10^{-04}
Biomass Fuels - Solid (All fuel types in Table C-1)	3.2×10^{-02}	4.2×10^{-03}
Biogas	3.2×10^{-03}	6.3×10^{-04}
Biomass Fuels - Liquid (All fuel types in Table C-1)	1.1×10^{-03}	1.1×10^{-04}

Note: Those employing this table are assumed to fall under the IPCC definitions of the "Energy Industry" or "Manufacturing Industries and Construction". In all fuels except for coal the values for these two categories are identical. For coal combustion, those who fall within the IPCC "Energy Industry" category may employ a value of 1 g of CH_4/MMBtu.

[1]Allowed only for units that do not generate steam and use Tier 1.

Table C-2 of Subpart C—Default CH_4 and N_2O Emission Factors for Various Types of Fuel.

Fuel Type	Default CH_4 Emission Factor (kg CH_4 /mmBtu)	Default N_2O Emission Factor (kg N_2O/mmBtu)
Coal and Coke (All fuel types in Table C-1)	1.1×10^{-2}	1.6×10^{-03}
Natural Gas	1.0×10^{-03}	1.0×10^{-04}
Petroleum (All fuel types in Table C-1)	3.0×10^{-03}	6.0×10^{-04}
Municipal Solid Waste	3.2×10^{-02}	4.2×10^{-03}
Tires	3.2×10^{-02}	4.2×10^{-03}
Blast Furnace Gas	2.2×10^{-05}	1.0×10^{-04}
Coke Oven Gas	4.8×10^{-04}	1.0×10^{-04}
Biomass Fuels - Solid (All fuel types in Table C-1)	3.2×10^{-02}	4.2×10^{-03}
Biogas	3.2×10^{-03}	6.3×10^{-04}
Biomass Fuels – Liquid (All fuel types in Table C-1)	1.1×10^{-03}	1.1×10^{-04}

Note: Those employing this table are assumed to fall under the IPCC definitions of the "Energy Industry" or "Manufacturing Industries and Construction". In all fuels except for coal the values for these two categories are identical. For coal combustion, those who fall within the IPCC "Energy Industry" category may employ a value of 1 g of CH_4/MMBtu.

Subpart D—Electricity Generation

§98.40 Definition of the source category.

(a) The electricity generation source category comprises electricity generating units that are subject to the requirements of the Acid Rain Program and any other electricity generating units that are required to monitor and report to EPA CO_2 emissions year-round according to 40 CFR part 75.

(b) This source category does not include portable equipment, emergency equipment, or emergency generators, as defined in §98.6.[1]

§98.41 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains one or more electricity generating units and the facility meets the requirements of §98.2(a)(1).

§98.42 GHGs to report[2].

(a) For each electricity generating unit that is subject to the requirements of the Acid Rain Program or is otherwise required to monitor and report to EPA CO_2 emissions year-round according to 40 CFR part 75, you must

[1] Retain for U.S. rules. Canadians will decide whether or not to retain for their jurisdictions.

[2] Reporting of fugitive CO2 by geothermal facilities is in the ERMRs but not in the MRR. Flag for Partners decision on whether or not to retain reporting by geothermal facilities. If geothermal is retained, it may be clearer to publish the requirement as a separate WCI subpart rather than be included in MRR subpart D.

report under this subpart the annual mass emissions of CO_2, N_2O, and CH_4 by following the requirements of this subpart.

(b) For each electricity generating unit that is not subject to the Acid Rain Program or otherwise required to monitor and report to EPA CO_2 emissions year-round according to 40 CFR part 75, you must report under subpart C of this part (General Stationary Fuel Combustion Sources) the emissions of CO_2, CH_4, and N_2O by following the requirements of subpart C.

(c) For each stationary fuel combustion unit that does not generate electricity, you must report under subpart C of this part (General Stationary Fuel Combustion Sources) the emissions of CO_2, CH_4, and N_2O by following the requirements of subpart C of this part.

§98.43 Calculating GHG emissions.

Continue to monitor and report CO_2 mass emissions as required under §75.13 or section 2.3 of apppendix G to 40 CFR part 75, and §75.64. Calculate CO_2, CH_4, and N_2O emissions as follows:

(a) Convert the cumulative annual CO_2 mass emissions reported in the fourth quarter electronic data report required under §75.64 from units of short tons to metric tons. To convert tons to metric tons, divide by 1.1023.

(b) Calculate and report annual CH_4 and N_2O mass emissions under this subpart by following the applicable method specified in §98.33(c).

§98.44 Monitoring and QA/QC requirements

Follow the applicable quality assurance procedures for CO_2 emissions in appendices B, D, and G to 40 CFR part 75.

§98.45 Procedures for estimating missing data.

Follow the applicable missing data substitution procedures in 40 CFR part 75 for CO_2 concentration, stack gas flow rate, fuel flow rate, high heating value, and fuel carbon content.

§98.46 Data reporting requirements.

The annual report shall comply with the data reporting requirements specified in §98.36(d~~b~~)[3] and, if applicable, §98.36(c)(2) or (c)(3).

§98.47 Records that must be retained.

You shall comply with the recordkeeping requirements of §§98.3(g) and 98.37.

§98.48 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

[3] This corrects an error in the MRR that EPA is in the process of correcting.

Subpart F—Aluminum Production

§98.60 Definition of the source category.

(a) A primary aluminum production facility manufactures primary aluminum using the Hall-Héroult manufacturing process. The primary aluminum manufacturing process comprises the following operations:

(1) Electrolysis in prebake and Søderberg cells.

(2) Anode baking for prebake cells.

(b) This source category does not include experimental cells or research and development process units.

§98.61 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains an aluminum production process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.62 GHGs to report.

You must report:

(a) Perfluoromethane (CF_4), and perfluoroethane (C_2F_6) emissions from anode effects in all prebake and Søderberg electolysis cells.

(b) CO_2 emissions from anode consumption during electrolysis in all prebake and Søderberg electolysis cells.

(c) CO_2 emissions from on-site anode baking.

(d) You must report under subpart C of this part (General Stationary Fuel Combustion Sources) the emissions of CO_2, N_2O, and CH_4 emissions from each stationary fuel combustion unit by following the requirements of subpart C.

§98.63 Calculating GHG emissions.

(a) The annual value for PFC emissions shall be estimated from the sum of monthly values using Equation F-1 of this section:

$$E_{PFC} = \sum_{m=1}^{m=12} E_m \qquad \text{(Eq. F-1)}$$

Where:

E_{PFC} = Annual PFC emissions from aluminum production (metric tons PFC).

E_m = PFC emissions from aluminum production for the month "m" (metric tons PFC).

(b) Use Equation F-2 of this section to estimate CF_4 emissions from anode effect duration or Equation F-3 of this section to estimate CF_4 emissions from overvoltage, and use Equation F-4 of this section to estimate C_2F_6 emissions from anode effects from each prebake and Søderberg electolysis cell.

$$E_{CF4} = S_{CF4} \times AEM \times MP \times 0.001 \qquad \text{(Eq. F-2)}$$

Where:

E_{CF4} = Monthly CF_4 emissions from aluminum production (metric tons CF_4).

S_{CF4} = The slope coefficient ((kg CF_4/metric ton Al)/(AE-Mins/cell-day)).

AEM = The anode effect minutes per cell-day (AE-Mins/cell-day).

MP = Metal production (metric tons Al), where AEM and MP are calculated monthly.

$$E_{CF4} = EF_{CF4} \times MP \times 0.001 \qquad \text{(Eq. F-3)}$$

Where:

E_{CF4} = Monthly CF_4 emissions from aluminum production (metric tons CF_4).

EF_{CF4} = The overvoltage emission factor (kg CF_4/metric ton Al).

MP = Metal production (metric tons Al), where MP is calculated monthly.

$$E_{C2F6} = E_{CF4} \times F_{C2F6/CF4} \times 0.001 \qquad \text{(Eq. F-4)}$$

Where:

E_{C2F6} = Monthly C_2F_6 emissions from aluminum production (metric tons C_2F_6).

E_{CF4} = CF_4 emissions from aluminum production(kg CF_4).

$F_{C2F6/CF4}$ = The weight fraction of C_2F_6/CF_4 (kg C_2F_6/kg CF_4).

0.001 = Conversion factor from kg to metric tons, where E_{CF4} is calculated monthly.

(c) You must calculate and report the annual process CO_2 emissions from anode consumption during electrolysis and anode baking of prebake cells using either the procedures in paragraph (d) of this section or the procedures in paragraphs (e) and (f) of this section.

(d) Calculate and report under this subpart the process CO_2 emissions by operating and maintaining CEMS according to the Tier 4 Calculation Methodology in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(e) Use the following procedures to calculate CO_2 emissions from anode consumption during electrolysis:

(1) For Prebake cells: you must calculate CO_2 emissions from anode consumption using Equation F-5 of this section:[1]

$$E_{CO2} = NAC \times MP \times ([100 - S_a - Ash_a] / 100) \times (44/12) \quad \text{(Eq. F-5)}$$

Where:

E_{CO2} = Annual CO_2 emissions from prebaked anode consumption (metric tons CO_2).

NAC = Net annual prebaked anode consumption per metric ton Al (metric tons C/metric tons Al).

MP = Annual metal production (metric tons Al).

S_a = Sulfur content in baked anode (percent weight).

Ash_a = Ash content in baked anode(percent weight).

44/12 = Ratio of molecular weights, CO_2 to carbon.

(2) For Søderberg cells you must calculate CO_2 emissions using Equation F-6 of this section:[2]

$$E_{CO2} = (PC \times MP - [CSM \times MP] / 1000 - BC / 100 \times PC \times MP \times [S_p + Ash_p + H_p] / 100 - [100 - BC] / 100 \times PC \times MP \times [S_c + Ash_c] / 100 - MP \times CD) \times (44/12) \quad \text{(Eq. F-6)}$$

Where:

E_{CO2} = Annual CO_2 emissions from paste consumption (metric ton CO_2).

PC = Annual paste consumption (metric ton/metric ton Al).

MP = Annual metal production (metric ton Al).

[1]The WCI equivalents for equations F-5, F-6 and F-8 in the existing ERs for aluminum production include a deduction for impurities in the baked anode, pitch and packing coke respectively. Allowing such a deduction, however, would be inconsistent with harmonization, since it would require reporting different amounts for these processes to EPA and the WCI. WCI solicits stakeholder input on the significance of this omission.

[2]WCI discussed removing the factor for carbon removed as skimmed dust (CD) since it is not included in the WCI methodology. It has been retained to assure harmonization.

CSM = Annual emissions of cyclohexane soluble matter (kg/metric ton Al).

BC = Binder content of paste (percent weight).

S_p = Sulfur content of pitch (percent weight).

Ash_p = Ash content of pitch (percent weight).

H_p = Hydrogen content of pitch (percent weight).

S_c = Sulfur content in calcined coke (percent weight).

Ash_c = Ash content in calcined coke (percent weight).

CD = Carbon in skimmed dust from Søderberg cells (metric ton C/metric ton Al).

44/12 = Ratio of molecular weights, CO_2 to carbon.

(e) Use the following procedures to calculate CO_2 emissions from anode baking of prebake cells:

(1) Use Equation F-7 of this section to calculate emissions from pitch volatiles combustion.

$$E_{CO2PV} = (GA - H_w - BA - WT) \times (44/12) \qquad \text{(Eq. F-7)}$$

Where:

E_{CO2PV} = Annual CO_2 emissions from pitch volatiles combustion (metric tons CO_2).

GA = Initial weight of green anodes (metric tons).

H_w = Annual hydrogen content in green anodes (metric tons).

BA = Annual baked anode production (metric tons).

WT = Annual waste tar collected (metric tons).

44/12 = Ratio of molecular weights, CO_2 to carbon.

(2) Use Equation F-8 of this section to calculate emissions from bake furnace packing material.

$$E_{CO2PC} = PCC \times BA \times ([100 - S_{pc} - Ash_{pc}] / 100) \times (44/12) \qquad \text{(Eq. F-8)}$$

Where:

E_{CO2PC} = Annual CO_2 emissions from bake furnace packing material (metric tons CO_2).

PCC = Annual packing coke consumption (metric tons/metric ton baked anode).

BA = Annual baked anode production (metric tons).
S_{pc} = Sulfur content in packing coke (percent weight).
Ash_{pc} = Ash content in packing coke (percent weight).
44/12 = Ratio of molecular weights, CO_2 to carbon.

(f) If process CO_2 emissions from anode consumption during electrolysis or anode baking of prebake cells are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part (General Stationary Fuel Combustion Sources), then the calculation methodology in paragraphs (d) and (e) of this section shall not be used to calculate those process emissions. The owner or operation shall report under this subpart the combined stack emissions according to the Tier 4 Calculation Methodology in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

§98.64 Monitoring and QA/QC requirements.

(a) Effective one year after publication of the rule for smelters with no prior measurement or effective three years after publication for facilities with historic measurements, the smelter-specific slope coefficients used in Equations F-2, F-3, and F-4 of this subpart must be measured in accordance with the recommendations of the

EPA/IAI Protocol for Measurement of Tetrafluoromethane (CF_4) and Hexafluoroethane (C_2F_6) Emissions from Primary Aluminum Production (2008), except the minimum frequency of measurement shall be every ~~10 years~~ 36 months ~~unless~~ and when a change occurs in the control algorithm that affects the mix of types of anode effects or the nature of the anode effect termination routine or when changes occur in the distribution or duration of anode effects (i.e., when the percentage of manual kills changes or if the number of anode effects decreases and results in a fewer number of longer anode effects) or for Rio Tinto Alcan control technology (i.e., when the algorithm for bridge movements and anode effect overvoltage accounting changes). Facilities which operate at less than 0.2 anode effect minutes per cell day or operate with less than 1.4mV anode effect overvoltage ~~can~~ must use ~~either~~ smelter-specific slope coefficients ~~or the technology specific default values in Table F-1 of this subpart~~.

(b) The minimum frequency of the measurement and analysis is ~~annually except as follows: Monthly – anode effect minutes per cell day (or anode effect overvoltage and current efficiency), production~~monthly.

(c) Sources ~~may~~ must use ~~either~~ smelter-specific values from annual measurements of parameters needed to complete the equations in §98.63 (e.g., sulfur, ash, and hydrogen contents)~~ or the default values shown in Table F-2 of this subpart~~.

§98.65 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required sample measurement is not taken), a substitute data value for the missing parameter shall be used in the calculations, according to the following requirements:

(a) Where anode or paste consumption data are missing, CO_2 emissions can be estimated from aluminum production using Tier 1 method per Equation F-8 of this section.

$$ECO_2 = EF_p \times MP_p + EF_s \times MP_s \qquad \text{(Eq. F-8)}$$

Where:

ECO_2 = CO_2 emissions from anode and/or paste consumption, metric tons CO_2.

EF_p = Prebake technology specific emission factor (1.6 metric tons CO_2/metric ton aluminum produced).

MP_p = Metal production from prebake process (metric tons Al).

EF_s = Søderberg technology specific emission factor (1.7 metric tons CO_2/metric ton Al produced).

MP_s = Metal production from Søderberg process (metric tons Al).

(b) For other parameters, use the average of the two most recent data points after the missing data.

§98.66 Data reporting requirements.

In addition to the information required by §98.3(c), you must report the following information at the facility level:

(a) Annual aluminum production in metric tons.

(b) Type of smelter technology used.

(c) The following PFC-specific information on an annual basis:

(1) Perfluoromethane emissions and perfluoroethane emissions from anode effects in all prebake and all Søderberg electolysis cells combined.

(2) Anode effect minutes per cell-day (AE-mins/cell-day), anode effect frequency (AE/cell-day), anode effect duration (minutes). (Or anode effect overvoltage factor ((kg CF_4/metric ton Al)/(mV/cell day)), potline overvoltage (mV/cell day), current efficiency (%).)

(3) Smelter-specific slope coefficients (or overvoltage emission factors) and the last date when the smelter-specific-slope coefficients (or overvoltage emission factors) were measured.

(d) Method used to measure the frequency and duration of anode effects (or overvoltage).

(e) The following CO_2-specific information for prebake cells:

(1) Annual anode consumption.

(2) Annual CO_2 emissions from the smelter.

(f) The following CO_2-specific information for Søderberg cells:

(1) Annual paste consumption.

(2) Annual CO_2 emissions from the smelter.

(g) Smelter-specific inputs to the CO_2 process equations (e.g., levels of sulfur and ash) that were used in the calculation, on an annual basis.

(h) Exact data elements required will vary depending on smelter technology (e.g., point-feed prebake or Søderberg) and process control technology (e.g., Pechiney or other).

§98.67 Records that must be retained.

In addition to the information required by §98.3(g), you must retain the following records:

(a) Monthly aluminum production in metric tons.

(b) Type of smelter technology used.

(c) The following PFC-specific information on a monthly basis:

(1) Perfluoromethane and perfluoroethane emissions from anode effects in prebake and Søderberg electolysis cells.

(2) Anode effect minutes per cell-day (AE-mins/cell-day), anode effect frequency (AE/cell-day), anode effect duration (minutes). (Or anode effect overvoltage factor ((kg CF_4/metric ton Al)/(mV/cell day)), potline overvoltage (mV/cell day), current efficiency (%).))

(3) Smelter-specific slope coefficients and the last date when the smelter-specific-slope coefficients were measured.

(d) Method used to measure the frequency and duration of anode effects (or to measure anode effect overvoltage and current efficiency).

(e) The following CO_2-specific information for prebake cells:

(1) Annual anode consumption.

(2) Annual CO_2 emissions from the smelter.

(f) The following CO_2-specific information for Søderberg cells:

(1) Annual paste consumption.

(2) Annual CO_2 emissions from the smelter.

(g) Smelter-specific inputs to the CO_2 process equations (e.g., levels of sulfur and ash) that were used in the calculation, on an annual basis.

(h) Exact data elements required will vary depending on smelter technology (e.g., point-feed prebake or Søderberg) and process control technology (e.g., Pechiney or other).

§98.68 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Table F-1 of Subpart F—Slope and Overvoltage Coefficients for the Calculation of PFC Emissions from Aluminum Production

Technology	**CF_4 Slope Coefficient [(kg CF_4/metric ton Al)/(AE-Mins/cell-day)]**	**CF_4 Overvoltage Coefficient [(kg CF_4/metric ton Al)/(mV)]**	**Weight Fraction C_2F_6/CF_4 [(kg C_2F_6/kg CF_4)]**
CWPB	0.143	1.16	0.121
SWPB	0.272	3.65	0.252
VSS	0.092	NA	0.053
HSS	0.099	NA	0.085

Table F-2 of Subpart F—Default Data Sources for Parameters Used for CO_2 Emissions

CO_2 Emissions from Prebake Cells (CWPB and SWPB)	
Parameter	Data Source
MP: metal production (metric tons Al)	Individual facility records
NAC: net annual prebaked anode consumption per metric ton Al (metric tons C/metric tons Al)	Individual facility records
S_a: sulfur content in baked	2.0

anode (percent weight)	
Ash_a: ash content in baked anode(percent weight)	0.4
CO_2 Emissions from Søderberg Cells (VSS and HSS)	
Parameter	Data Source
MP: metal production (metric tons Al)	Individual facility records
PC: annual paste consumption (metric ton/metric ton Al)	Individual facility records
CSM: annual emissions of cyclohexane soluble matter (kg/metric ton Al)	HSS: 4.0 VSS: 0.5
BC: binder content of paste (percent weight)	Dry Paste: 24 Wet Paste: 27
S_p: sulfur content of pitch (percent weight)	0.6
Ash_p: ash content of pitch (percent weight)	0.2
H_p: hydrogen content of pitch (percent weight)	3.3
S_c: sulfur content in calcined coke (percent weight)	1.9
Ash_c: ash content in calcined coke (percent weight)	0.2
CD: carbon in skimmed dust from Søderberg cells (metric ton C/metric ton Al)	0.01
CO_2 Emissions from Pitch Volatiles Combustion (VSS and HSS)	
Parameter	Data Source
GA: initial weight of green anodes (metric tons)	Individual facility records
H_w: annual hydrogen content in green anodes (metric tons)	0.005 × GA
BA: annual baked anode production (metric tons)	Individual facility records
WT: annual waste tar collected (metric tons) (a) Riedhammer furnaces (b) all other furnaces	(a) 0.005 × GA (b) insignificant
CO_2 Emissions from Bake Furnace Packing Materials (CWPB	

and SWPB)	
Parameter	Data Source
PCC: annual packing coke consumption (metric tons/metric ton baked anode)	0.015
BA: annual baked anode production (metric tons)	Individual facility records
S_{pc}: sulfur content in packing coke (percent weight)	2
Ash_{pc}: ash content in packing coke (percent weight)	2.5

Subpart N—Glass Production

§98.140 Definition of the source category.

(a) A glass manufacturing facility manufactures flat glass, container glass, pressed and blown glass, or wool fiberglass by melting a mixture of raw materials to produce molten glass and form the molten glass into sheets, containers, fibers, or other shapes. A glass manufacturing facility uses one or more continuous or batch glass melting furnaces to produce glass.[1]

(b) A glass melting furnace that is an experimental furnace or a research and development process unit is not subject to this subpart.

§98.141 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a glass production process and the facility meets the requirements of either §98.2(a)(1) or (2).

§98.142 GHGs to report.

You must report:

(a) CO_2 process emissions from each continuous or batch glass melting furnace.

[1]EPA's definition of a glass manufacturing facility is limited to only continuous glass melting furnaces. WCI has requested that batch furnaces be included as well. Expanded definition included in §98.140(a). All references in Subpart N to "continuous glass melting furnace" have been changed to "continuous or batch glass melting furnace" or "continuous and batch glass melting furnace", depending upon the specific text.

(b) CO_2 combustion emissions from each continuous or batch glass melting furnace.

(c) CH_4 and N_2O combustion emissions from each continuous or batch glass melting furnace. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(d) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit other than continuous or batch glass melting furnaces. You must report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

§98.143 Calculating GHG emissions.

You must calculate and report the annual process CO_2 emissions from each continuous or batch glass melting furnace using the procedure in paragraphs (a) and (b) of this section.

(a) For each continuous or batch glass melting furnace that meets the conditions specified in §98.33(b)(4)(ii) or (iii), you must calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(b) For each continuous or batch glass melting furnace that is not subject to the requirements in paragraph (a) of this section, calculate and report the process and combustion CO_2 emissions from the glass melting furnace by using either the procedure in paragraph (b)(1) of this section or the procedure in paragraphs (b)(2) through (b)(7) of this section, except as specified in paragraph (c) of this section.

(1) Calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(2) Calculate and report the process and combustion CO_2 emissions separately using the procedures specified in paragraphs (b)(2)(i) through (b)(2)(vi) of this section.

(i) For each carbonate-based raw material charged to the furnace, obtain from the supplier of the raw material the carbonate-based mineral mass fraction.

(ii) Determine the quantity of each carbonate-based raw material charged to the furnace.

(iii) Apply the appropriate emission factor for each carbonate-based raw material charged to the furnace, as shown in Table N-1 to this subpart.

(iv) Use Equation N-1 of this section to calculate process mass emissions of CO_2 for each furnace:

$$E_{CO2} = \sum_{i=1}^{n} MF_i \bullet (M_i \bullet \frac{2000}{2205}) \bullet EF_i \bullet F_i \qquad \text{(Eq. N-1)}$$

Where:

E_{CO2}	=	Process emissions of CO_2 from the furnace (metric tons).
n	=	Number of carbonate-based raw materials charged to furnace.
MF_i	=	Annual average mass fraction of carbonate-based mineral i in carbonate-based raw material i (percentage, expressed as a decimal).
M_i	=	Annual amount of carbonate-based raw material i charged to furnace (tons).
2000/2205	=	Conversion factor to convert tons to metric tons.
EF_i	=	Emission factor for carbonate-based raw material i (metric ton CO_2 per metric ton carbonate-based raw material as shown in Table N-1 to this subpart).
F_i	=	Fraction of calcination achieved for carbonate-based raw material i, assumed to be equal to 1.0 (percentage, expressed as a decimal).

(v) You must calculate the total process CO_2 emissions from continuous and batch glass melting furnaces at the facility using Equation N-2 of this section:

$$CO_2 = \sum_{i=1}^{k} E_{CO_2 i} \qquad \text{(Eq. N-2)}$$

Where:

CO_2	=	Annual process CO_2 emissions from glass manufacturing facility (metric tons).
E_{CO2i}	=	Annual CO_2 emissions from glass melting furnace i (metric tons).
k	=	Number of continuous and batch glass melting furnaces.

(vi) Calculate and report under subpart C of this part (General Stationary Fuel Combustion Sources) the combustion CO_2 emissions in the glass furnace according to the applicable requirements in subpart C.

(c) As an alternative to data provided by the raw material supplier, a value of 1.0 can be used for the mass fraction (MF_i) of carbonate-based mineral i in Equation N-1 of this section.

§98.144 Monitoring and QA/QC requirements.

(a) You must measure annual amounts of carbonate-based raw materials charged to each continuous or batch glass melting furnace from monthly measurements using plant instruments used for accounting purposes, such as calibrated scales or weigh hoppers. Total annual mass charged to glass melting furnaces at the facility shall be compared to records of raw material purchases for the year.

(b) You must measure carbonate-based mineral mass fractions at least annually to verify the mass fraction data provided by the supplier of the raw material; such measurements shall be based on sampling and chemical analysis conducted by a certified laboratory using ASTM D3682-01 (Reapproved 2006) Standard Test Method for Major and Minor Elements in Combustion Residues from Coal Utilization Processes (incorporated by reference, see §98.7).

(c) You must determine the annual average mass fraction for the carbonate-based mineral in each carbonate-based raw material by calculating an arithmetic average of the monthly data obtained from raw material suppliers or sampling and chemical analysis.

(d) You must determine on an annual basis the calcination fraction for each carbonate consumed based on sampling and chemical analysis using an industry consensus standard. This chemical analysis must be conducted using an x-ray fluorescence test or other enhanced testing method published by an industry consensus standards organization (e.g., ASTM, ASME, API, etc.).

§98.145 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., carbonate raw materials consumed, etc.). If the monitoring and quality assurance procedures in §98.144 cannot be followed and data is missing, you must use the most appropriate of the missing data procedures in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such missing value estimates.

(a) For missing data on the monthly amounts of carbonate-based raw materials charged to any continuous or batch glass melting furnace use the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes, such as purchase records.

(b) For missing data on the mass fractions of carbonate-based minerals in the carbonate-based raw materials assume that the mass fraction of each carbonate based mineral is 1.0.

§98.146 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information specified in paragraphs (a) and (b) of this section, as applicable.

Subpart N—Glass Production

(a) If a CEMS is used to measure CO_2 emissions, then you must report under this subpart the relevant information required under §98.37 for the Tier 4 Calculation Methodology and the following information specified in paragraphs (a)(1) and (a)(2) of this section:

(1) Annual quantity of each carbonate-based raw material charged to each continuous or batch glass melting furnace and for all furnaces combined (tons).

(2) Annual quantity of glass produced (tons).

(b) If a CEMS is not used to determine CO_2 emissions from continuous or batch glass melting furnaces, and process CO_2 emissions are calculated according to the procedures specified in §98.143(b), then you must report the following information as specified in paragraphs (b)(1) through (b)(9) of this section:

(1) Annual process emissions of CO_2 (metric tons) for each continuous or batch glass melting furnace and for all furnaces combined.

(2) Annual quantity of each carbonate-based raw material charged (tons) to each continuous or batch glass melting furnace and for all furnaces combined.

(3) Annual quantity of glass produced (tons) from each continuous or batch glass melting furnace and from all furnaces combined.

(4) Carbonate-based mineral mass fraction (percentage, expressed as a decimal) for each carbonate-based raw material charged to a continuous or batch glass melting furnace.

(5) Results of all tests used to verify the carbonate-based mineral mass fraction for each carbonate-based raw material charged to a continuous or batch glass melting furnace, as specified in paragraphs (b)(5)(i) through (b)(5)(iii) of this section.

(i) Date of test.

(ii) Method(s) and any variations used in the analyses.

(iii) Mass fraction of each sample analyzed.

(6) The fraction of calcination achieved for each carbonate-based raw material, if a value other than 1.0 is used to calculate process mass emissions of CO_2.

(7) Method used to determine fraction of calcination (percentage, expressed as a decimal).

(8) Total number of continuous or batch glass melting furnaces.

(9) The number of times in the reporting year that missing data procedures were followed to measure monthly quantities of carbonate-based raw materials any continuous

or batch glass melting furnace or mass fraction of the carbonate-based minerals (months).

§98.147 Records that must be retained.

In addition to the information required by §98.3(g), you must retain the records listed in paragraphs (a), (b), and (c) of this section.

(a) If a CEMS is used to measure emissions, then you must retain the records required under §98.37 for the Tier 4 Calculation Methodology and the following information specified in paragraphs (a)(1) and (a)(2) of this section:

(1) Monthly glass production rate for each continuous or batch glass melting furnace (tons).

(2) Monthly amount of each carbonate-based raw material charged to each continuous or batch glass melting furnace (tons).

(b) If process CO_2 emissions are calculated according to the procedures specified in §98.143(b), you must retain the records in paragraphs (b)(1) through (b)(5) of this section.

(1) Monthly glass production rate for each continuous or batch glass melting furnace (metric tons).

(2) Monthly amount of each carbonate-based raw material charged to each continuous or batch glass melting furnace (metric tons).

(3) Data on carbonate-based mineral mass fractions provided by the raw material supplier for all raw materials consumed annually and included in calculating process emissions in Equation N-1 of this subpart.

(4) Results of all tests used to verify the carbonate-based mineral mass fraction for each carbonate-based raw material charged to a continuous or batch glass melting furnace, including the data specified in paragraphs (b)(4)(i) through (b)(4)(v) of this section.

(i) Date of test.

(ii) Method(s), and any variations of the methods, used in the analyses.

(iii) Mass fraction of each sample analyzed.

(iv) Relevant calibration data for the instrument(s) used in the analyses.

(v) Name and address of laboratory that conducted the tests.

(5) The fraction of calcination achieved for each carbonate-based raw material (percentage, expressed as a decimal), if a value other than 1.0 is used to calculate process mass emissions of CO_2.

(c) All other documentation used to support the reported GHG emissions.

§98.148 Definitions.

Subpart N—Glass Production

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Table N-1 of Subpart N—CO_2 Emission Factors for Carbonate-Based Raw Materials

Carbonate-Based Raw Material – Mineral	CO_2 Emission Factor[a]
Limestone – $CaCO_3$	0.440
Dolomite – $CaMg(CO_3)_2$	0.477
Sodium carbonate/soda ash – Na_2CO_3	0.415

[a] Emission factors in units of metric tons of CO_2 emitted per metric ton of carbonate-based raw material charged to the furnace.

Subpart P—Hydrogen Production

§98.160 Definition of the source category.

(a) A hydrogen production source category consists of facilities that produce hydrogen gas for use onsite or sold as a product to other entities.

(b) This source category comprises process units that produce hydrogen by reforming, gasification, oxidation, reaction, or other transformations of feedstocks.

(c) This source category includes merchant hydrogen production facilities located within a petroleum refinery if they are not owned by, or under the direct control of, the refinery owner and operator.

§98.161 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a hydrogen production process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.162 GHGs to report.

You must report:

(a) CO_2 process emissions from each hydrogen production process unit.

(b) CO_2, CH_4 and N_2O combustion emissions from each hydrogen production process unit. You must calculate and report these combustion emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(c) CO_2, CH_4, and N_2O emissions from each stationary combustion unit other than hydrogen production process units. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(d) For CO_2 collected and transferred off site, you must follow the requirements of subpart PP of this part.

§98.163 Calculating GHG emissions.

You must calculate and report the annual process CO_2 emissions from each hydrogen production process unit using the procedures specified in either paragraph (a) or (b) of this section.

(a) Continuous Emissions Montoring Systems (CEMS). Calculate and report under this subpart the process CO_2 emissions by operating and maintaining CEMS according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(b) Fuel and feedstock material balance approach. Calculate and report process CO_2 emissions as the sum of the annual emissions associated with each fuel and feedstock used for hydrogen production by following paragraphs (b)(1) through (b)(3) of this section.

(1) Gaseous fuel and feedstock. You must calculate the annual CO_2 process emissions from gaseous fuel and feedstock according to Equation P-1 of this section:

$$CO_2 = (\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n * \frac{MW}{MVC}) * 0.001 \qquad \text{(Eq. P-1)}$$

Where:

CO_2	=	Annual CO_2 process emissions arising from fuel and feedstock consumption (metric tons/yr).
$Fdstk_n$	=	Volume of the gaseous fuel and feedstock used in month n(scf (at standard conditions of 68 °F and atmospheric pressure) of fuel and feedstock).
CC_n	=	Weighted ~~A~~average carbon content of the gaseous fuel and feedstock, from the results of one or more analyses for month n for natural gas or from daily analysis for gasseous feedstocks other than natural gas(kg carbon per kg of fuel and feedstock).
MW	=	Molecular weight of the gaseous fuel and feedstock (kg/kg-mole).
MVC	=	Molar volume conversion factor (849.5 scf per kg-mole at standard conditions).
k	=	Months in the year.
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(2) Liquid fuel and feedstock. You must calculate the annual CO_2 process emissions from liquid fuel and feedstock according to Equation P-2 of this section:

$$CO_2 = (\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n) * 0.001 \qquad \text{(Eq. P-2)}$$

Where:

CO_2 = Annual CO_2 emissions arising from fuel and feedstock consumption (metric tons/yr).

$Fdstk_n$ = Volume of the liquid fuel and feedstock used in month n (gallons of fuel and feedstock).

CC_n = Weighted Average carbon content of the liquid fuel and feedstock, from the results of daily ~~one or more~~ analyses for month n (kg carbon per gallon of fuel and feedstock).

k = Months in the year.

44/12 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to metric tons.

(3) Solid fuel and feedstock. You must calculate the annual CO_2 process emissions from solid fuel and feedstock according to Equation P-3 of this section:

$$CO_2 = \sum_{n=1}^{k} \frac{44}{12} * (Fdstk_n * CC_n) * 0.001 \qquad \text{(Eq.P-3)}$$

Where:

CO_2 = Annual CO_2 emissions from fuel and feedstock consumption in metric tons per year ~~month~~ ~~(~~(metric tons/yr).

$Fdstk_n$ = Mass of solid fuel and feedstock used in month n (kg of fuel and feedstock).

CC_n = Weighted ~~A~~average carbon content of the solid fuel and feedstock, from the results of daily~~one or more~~ analyses for month n (kg carbon per kg of fuel and feedstock).

k = Months in the year.

44/12 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to metric tons.

(c) If GHG emissions from a hydrogen production process unit are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part (General Stationary Fuel Combustion Sources), then the calculation methodology in paragraph (b) of this section shall not be used to calculate process emissions. The owner or operator shall report under this subpart the combined stack emissions according to the Tier 4 Calculation Methodology in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

§98.164 Monitoring and QA/QC requirements.

The GHG emissions data for hydrogen production process units must be quality-assured as specified in paragraphs (a) or (b) of this section, as appropriate for each process unit:

(a) If a CEMS is used to measure GHG emissions, then the facility must comply with the monitoring and QA/QC procedures specified in §98.34(c).

(b) If a CEMS is not used to measure GHG emissions, then you must:

(1) Calibrate all oil and gas flow meters (except for gas billing meters), solids weighing equipment, and oil tank drop measurements (if used to determine liquid fuel and feedstock use volume) according to the calibration accuracy requirements in §98.3(i) of this part .

(2) Determine the carbon content and the molecular weight monthly ~~annually~~ for ~~of standard gaseous hydrocarbon fuels and feedstocks having consistent composition (e.g.,~~ natural gas~~)~~. For other gaseous fuels and feedstocks (e.g., biogas, refinery gas, or process gas), daily ~~weekly~~ sampling and analysis is required to determine the carbon content and molecular weight of the fuel and feedstock.

(3) Determine the carbon content of fuel oil, naphtha, and other liquid fuels and feedstocks at least ~~monthly~~daily~~,~~. ~~except annually for standard liquid hydrocarbon fuels and feedstocks having consistent composition, or upon delivery for liquid fuels delivered by bulk transport (e.g., by truck or rail).~~

(4) Determine the carbon content of coal, coke, and other solid fuels and feedstocks at least ~~monthly,~~daily ~~except annually for standard solid hydrocarbon fuels and feedstocks having consistent composition, or upon delivery for solid fuels delivered by bulk transport (e.g., by truck or rail)~~.

(5) You must use the following applicable methods to determine the carbon content for all fuels and feedstocks, and molecular weight of gaseous fuels and feedstocks.

(i) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see §98.7).

(ii) ASTM D1946-90 (Reapproved 2006), Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see §98.7).

(iii) ASTM D2013-07 Standard Practice of Preparing Coal Samples for Analysis (incorporated by reference, see §98.7).

(iv) ASTM D2234/D2234M-07 Standard Practice for Collection of a Gross Sample of Coal (incorporated by reference, see §98.7).

(v) ASTM D2597-94 (Reapproved 2004) Standard Test Method for Analysis of Demethanized Hydrocarbon Liquid Mixtures Containing Nitrogen and Carbon Dioxide by Gas Chromatography (incorporated by reference, see §98.7).

(vi) ASTM D3176-89 (Reapproved 2002), Standard Practice for Ultimate Analysis of Coal and Coke (incorporated by reference, see §98.7).

(vii) ASTM D3238-95 (Reapproved 2005), Standard Test Method for Calculation of Carbon Distribution and

Structural Group Analysis of Petroleum Oils by the n-d-M Method (incorporated by reference, see §98.7).

(viii) ASTM D4057-06 Standard Practice for Manual Sampling of Petroleum and Petroleum Products (incorporated by reference, see §98.7).

(ix) ASTM D4177-95 (Reapproved 2005) Standard Practice for Automatic Sampling of Petroleum and Petroleum Products (incorporated by reference, see §98.7).

(x) ASTM D5291-02 (Reapproved 2007), Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, see §98.7).

(xi) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7).

(xii) ASTM D6609-08 Standard Guide for Part-Stream Sampling of Coal (incorporated by reference, see §98.7).

(xiii) ASTM D6883-04 Standard Practice for Manual Sampling of Stationary Coal from Railroad Cars, Barges, Trucks, or Stockpiles (incorporated by reference, see §98.7).

(xiv) ASTM D7430-08ae1 Standard Practice for Mechanical Sampling of Coal (incorporated by reference, see §98.7).

(xv) ASTM UOP539-97 Refinery Gas Analysis by Gas Chromatography (incorporated by reference, see §98.7).

(xvi) GPA 2261–00 Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography (incorporated by reference, see §98.7).

(xvii) ISO 3170: Petroleum Liquids -- Manual sampling – Third Edition (incorporated by reference, see §98.7).

(xviii) ISO 3171: Petroleum Liquids -- Automatic pipeline sampling – Second Edition (incorporated by reference, see §98.7).

(c) For units using the calculation methodologies described in this section, the records required under §98.3(g) must include both the company records and a detailed explanation of how company records are used to estimate the following:

(1) Fuel and feedstock consumption, when solid fuel and feedstock is combusted and a CEMS is not used to measure GHG emissions.

(2) Fossil fuel consumption, when, pursuant to §98.33(e), the owner or operator of a unit that uses CEMS to quantify CO_2 emissions and that combusts both fossil and

biogenic fuels separately reports the biogenic portion of the total annual CO_2 emissions.

(3) Sorbent usage, if the methodology in §98.33(d) is used to calculate CO_2 emissions from sorbent.

(d) The owner or operator must document the procedures used to ensure the accuracy of the estimates of fuel and feedstock usage and sorbent usage (as applicable) in paragraph (b) of this section, including, but not limited to, calibration of weighing equipment, fuel and feedstock flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices must also be recorded, and the technical basis for these estimates must be provided.

§98.165 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation), a substitute data value for the missing parameter must be used in the calculations as specified in paragraphs (a), (b), and (c) of this section:

(a) For each missing value of the monthly fuel and feedstock consumption, the substitute data value must be the best available estimate of the fuel and feedstock consumption, based on all available process data (e.g., hydrogen production, electrical load, and operating hours). You must document and keep records of the procedures used for all such estimates.

(b) For each missing value of the carbon content or molecular weight of the fuel and feedstock, the substitute data value must be the arithmetic average of the quality-assured values of carbon contents or molecular weight of the fuel and feedstock immediately preceding and immediately following the missing data incident. If no quality-assured data on carbon contents or molecular weight of the fuel and feedstock are available prior to the missing data incident, the substitute data value must be the first quality-assured value for carbon contents or molecular weight of the fuel and feedstock obtained after the missing data period. You must document and keep records of the procedures used for all such estimates.

(c) For missing CEMS data, you must use the missing data procedures in §98.35.

§98.166 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information specified in paragraphs (a) or (b) of this section, as appropriate:

Subpart P—Hydrogen Production

(a) If a CEMS is used to measure CO_2 emissions, then you must report the relevant information required under §98.36 for the Tier 4 Calculation Methodology and the following information in this paragraph (a):

(1) Unit identification number and annual CO_2 process emissions.

(2) Annual quantity of hydrogen produced (metric tons) for each process unit and for all units combined.

(3) Annual quantity of ammonia produced (metric tons), if applicable, for each process unit and for all units combined.

(b) If a CEMS is not used to measure CO_2 emissions, then you must report the following information for each hydrogen production process unit:

(1) Unit identification number and annual CO_2 process emissions (2) Monthly consumption of each fuel and feedstock used for hydrogen production and its type (scf of gaseous fuels and feedstocks, gallons of liquid fuels and feedstocks, kg of solid fuels and feedstocks).

(3) Annual quantity of hydrogen produced (metric tons).

(4) Annual quantity of ammonia produced, if applicable (metric tons).

(5) Monthly or daily analyses of carbon content for each fuel and feedstock used in hydrogen production (kg carbon/kg of gaseous and solid fuels and feedstocks, (kg carbon per gallon of liquid fuels and feedstocks).

(6) Monthly or daily analyses of the molecular weight of gaseous fuels and feedstocks (kg/kg-mole) used, if any.

(7) Amount of carbon in unconverted feedstock for which GHG emissions are calculated and reported by your facility using other calculation methods provided in this regulation. For example, carbon in waste diverted to a fuel system or flare, where the CO_2 and CH_4 emissions are calculated and reported using other methods provided in this regulation. (metric tons CO_2e/year).

(c) Quarterly quantity of CO_2 collected and transferred off site in either gas, liquid, or solid forms (kg), following the requirements of subpart PP of this part.

(d) Annual quantity of carbon other than CO_2 collected and transferred off site in either gas, liquid, or solid forms (kg carbon).

§98.167 Records that must be retained.

In addition to the information required by §98.3(g), you must retain the records specified in paragraphs (a) through (b) of this section for each hydrogen production facility.

(a) If a CEMS is used to measure CO_2 emissions, then you must retain under this subpart the records required for the Tier 4 Calculation Methodology in §98.37.

(b) If a CEMS is not used to measure CO_2 emissions, then you must retain records of all analyses and calculations conducted as listed in §§98.166(b), (c), and (d).

§98.168 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Subpart Y—Petroleum Refineries

§98.250 Definition of Source Category.

(a) A petroleum refinery is any facility engaged in producing gasoline, gasoline blending stocks, naphtha, kerosene, distillate fuel oils, residual fuel oils, lubricants, or asphalt (bitumen) through distillation of petroleum or through redistillation, cracking, or reforming of unfinished petroleum derivatives, except as provided in paragraph (b) of this section.

(b) For the purposes of this subpart, facilities that distill only pipeline transmix (off-spec material created when different specification products mix during pipeline transportation) are not petroleum refineries, regardless of the products produced.

(c) This source category consists of the following sources at petroleum refineries: catalytic cracking units; fluid coking units; delayed coking units; catalytic reforming units; coke calcining units; asphalt blowing operations; blowdown systems; storage tanks; process equipment components (compressors, pumps, valves, pressure relief devices, flanges, and connectors) in gas service; marine vessel, barge, tanker truck, and similar loading operations; flares; sulfur recovery plants; and non-merchant hydrogen plants (i.e., hydrogen plants that are owned or under the direct control of the refinery owner and operator).

Subpart Y—Petroleum Refineries

§98.251 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a petroleum refineries process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.252 GHGs to report.

You must report:

(a) CO_2, CH_4, and N_2O combustion emissions from stationary combustion units and from each flare. Calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C, except for CO_2 emissions from combustion of refinery fuel gas. For CO_2 emissions from combustion of fuel gas, use either equation C-5 in subpart C of this part or the Tier 4 methodology in subpart C of this part. You may aggregate units, monitor common stacks, or monitor common (fuel) pipes as provided in §98.36(c) when calculating and reporting emissions from stationary combustion units.

(b) CO_2, CH_4, and N_2O coke burn-off emissions from each catalytic cracking unit, fluid coking unit, and catalytic reforming unit under this subpart.

(c) CO_2 emissions from sour gas sent off site for sulfur recovery operations under this subpart. You must follow the calculation methodologies from §98.253(f)and the monitoring and

QA/QC methods, missing data procedures, reporting requirements, and recordkeeping requirements of this subpart.

(d) CO_2 process emissions from each on-site sulfur recovery plant under this subpart.

(e) CO_2, CH_4, and N_2O emissions from each coke calcining unit under this subpart.

(f) CO_2 and CH_4 emissions from asphalt blowing operations under this subpart.

(g) CH_4 emissions from equipment leaks, storage tanks, loading operations, delayed coking units, and uncontrolled blowdown systems under this subpart.

(h) CO_2, CH_4, and N_2O emissions from each process vent not specifically included in paragraphs (a) through (g) of this section under this subpart.

(i) CO_2 and CH_4 emissions from non-merchant hydrogen production under this subpart. You must follow the calculation methodologies, monitoring and QA/QC methods, missing data procedures, reporting requirements, and recordkeeping requirements of subpart P of this part.

§98.253 Calculating GHG emissions.

(a) Calculate GHG emissions required to be reported in §98.252(b) through (i) using the applicable methods in paragraphs (b) through (n) of this section.

(b) For flares, calculate GHG emissions according to the requirements in paragraphs (b)(1) through (b)(3) of this section.

(1) Calculate the CO_2 emissions according to the applicable requirements in paragraphs (b)(1)(i) through (b)(1)(iii) of this section.

(i) Flow measurement. If you have a continuous flow monitor on the flare, you must use the measured flow rates when the monitor is operational and the flow rate is within the calibrated range of the measurement device to calculate the flare gas flow. If you do not have a continuous flow monitor on the flare and for periods when the monitor is not operational or the flow rate is outside the calibrated range of the measurement device, you must use engineering calculations, company records, or similar estimates of volumetric flare gas flow.

(ii) Heat value or carbon content measurement. If you have a continuous higher heating value monitor or gas composition monitor on the flare or if you monitor these parameters at least weekly, you must use the measured heat value or carbon content value in calculating the CO_2 emissions from the flare using the applicable methods in paragraphs (b)(1)(ii)(A) and (b)(1)(ii)(B).

(A) If you monitor gas composition, calculate the CO_2 emissions from the flare using Equation Y-1 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation Y-1 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[\frac{44}{12} \times (Flare)_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right) \qquad \text{(Eq.Y-1)}$$

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
n	=	Number of measurement periods. The minimum value for n is 52 (for weekly measurements); the maximum value for n is 366 (for daily measurements during a leap year).
p	=	Measurement period index.
44	=	Molecular weight of CO_2 (kg/kg-mole).
12	=	Atomic weight of C (kg/kg-mole).
$(Flare)_p$	=	Volume of flare gas combusted during measurement period (standard cubic feet per period, scf/period). If a mass flow meter is used, measure flare gas flow rate in kg/period and replace the term "$(MW)_p$/MVC" with "1".
$(MW)_p$	=	Average molecular weight of the flare gas combusted during measurement period (kg/kg-mole). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.
MVC	=	Molar volume conversion factor (849.5 scf/kg-mole).
$(CC)_p$	=	Average carbon content of the flare gas combusted during measurement period (kg C per kg flare gas). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.

(B) If you monitor heat content but do not monitor gas composition, calculate the CO_2 emissions from the flare using Equation Y-2 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation Y-2 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \sum_{p=1}^{n} \left[(Flare)_p \times (HHV)_p \times EmF \right] \qquad \text{(Eq.Y-2)}$$

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
n	=	Number of measurement periods. The minimum value for n is 52 (for weekly measurements); the maximum value for n is 366 (for daily measurements during a leap year).
p	=	Measurement period index.
$(Flare)_p$	=	Volume of flare gas combusted during measurement period (million (MM) scf/period). If a mass flow meter is used, you must also measure molecular weight and convert the mass flow to a volumetric flow as follows: Flare[MMscf] = 0.000001 × Flare[kg] × MVC/$(MW)_p$, where MVC is the molar volume conversion factor (849.5 scf/kg-mole) and $(MW)_p$ is the average molecular weight of the flare gas combusted during measurement period (kg/kg-mole).
$(HHV)_p$	=	Higher heating value for the flare gas combusted during measurement period (British thermal units per scf, Btu/scf = MMBtu/MMscf). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.
EmF	=	Default CO_2 emission factor of 60 kilograms CO_2/MMBtu (HHV basis).

(iii) Alternative Method for Startup, Shutdown, and Malfunctions~~to heat value or carbon content measurements~~. For startup, shutdown, and malfunctions during which you were unable to measure the parameters required by Equations Y-1 and Y-2 of this section, ~~If you do not measure the~~ you must ~~higher heating value or carbon content of the flare gas at least weekly,~~ determine the quantity of gas discharged to the flare separately for each ~~periods of routine flare operation and for periods of~~ start-up, shutdown, or malfunction, and calculate the CO_2 emissions as specified in paragraphs (b)(1)(iii)(A) ~~through~~ and (b)(1)(iii)(C) of this section.

(A) For periods of start-up, shutdown, or malfunction, use engineering calculations and process knowledge to estimate the carbon content of the flared gas for each start-up, shutdown, or malfunction event. ~~exceeding 500,000 scf/day.~~

(B) ~~For periods of normal operation, use the average heating value measured for the fuel gas for the heating value of the flare gas. If heating value is not measured, the heating value may be estimated from historic data or engineering calculations.~~

Reserved.

(C) Calculate the CO_2 emissions using Equation Y-3 of this section.

$$\cancel{CO_2 = 0.98 \times 0.001 \times \left(Flare_{Norm} \times HHV \times EmF + \sum_{p=1}^{n} \left[\frac{44}{12} \times (Flare_{SSM})_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right)}$$ ~~(Eq.Y-3)~~

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[\frac{44}{12} \times (Flare_{SSM})_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right) \quad \text{(Eq.Y-3)}$$ [1]

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
~~$Flare_{Norm}$~~	~~=~~	~~Annual volume of flare gas combusted during normal operations from company records, (million (MM) standard cubic feet per year, MMscf/year).~~
~~HHV~~	~~=~~	~~Higher heating value for fuel gas or flare gas from company records (British thermal units per scf, Btu/scf = MMBtu/MMscf).~~
~~EmF~~	~~=~~	~~Default CO_2 emission factor for flare gas of 60 kilograms CO_2/MMBtu (HHV basis).~~
n	=	Number of start-up, shutdown, and malfunction events during the reporting year exceeding 500,000 scf/day.
p	=	Start-up, shutdown, and malfunction event index.
44	=	Molecular weight of CO_2 (kg/kg-mole).
12	=	Atomic weight of C (kg/kg-mole).
$(Flare_{SSM})_p$	=	Volume of flare gas combusted during indexed start-up, shutdown, or malfunction event from engineering calculations, (scf/event).
$(MW)_p$	=	Average molecular weight of the flare gas, from the analysis results or engineering calculations for the event (kg/kg-mole).
MVC	=	Molar volume conversion factor (849.5 scf/kg-mole).

[1] Equation Y-3 was revised to delete the factors used to calculate CO_2 emissions during normal operation of the flare. For normal operation of flares, ERMR proposes that CO_2 emissions be calcualted using either Equation Y-1 or Y-2.

$(CC)_p$ = Average carbon content of the flare gas, from analysis results or engineering calculations for the event (kg C per kg flare gas).

(2) Calculate CH_4 using Equation Y-4 of this section.

$$CH_4 = \left(CO_2 \times \frac{EmF_{CH4}}{EmF} \right) + CO_2 \times \frac{0.02}{0.98} \times \frac{16}{44} \times f_{CH4} \qquad \text{(Eq. Y-4)}$$

Where:

CH_4 = Annual methane emissions from flared gas (metric tons CH_4/year).

CO_2 = Emission rate of CO_2 from flared gas calculated in paragraph (b)(1) of this section (metric tons/year).

EmF_{CH4} = Default CH_4 emission factor for "PetroleumProducts" from Table C-2 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CH_4/MMBtu).

EmF = Default CO_2 emission factor for flare gas of 60 kg CO_2/MMBtu (HHV basis).

0.02/0.98 = correction factor for flare combustion efficiency.

16/44 = correction factor ratio of the molecular weight of CH_4 to CO_2

f_{CH4} = Weight fraction of carbon in the flare gas prior to combustion that is contributed by methane from measurement values or engineering calculations (kg C in methane in flare gas/kg C in flare gas); default is 0.4.

(3) Calculate N_2O emissions using Equation Y-5 of this section.

$$N_2O = \left(CO_2 \times \frac{EmF_{N2O}}{EmF} \right) \qquad \text{(Eq. Y-5)}$$

Where:

N_2O = Annual nitrous oxide emissions from flared gas (metric tons N_2O/year).

CO_2 = Emission rate of CO_2 from flared gas calculated in paragraph (b)(1) of this section (metric tons/year).
EmF_{N2O} = Default N_2O emission factor for "PetroleumProducts" from Table C-2 of subpart C of this part (General Stationary Fuel Combustion Sources)(kg N_2O/MMBtu).
EmF = Default CO_2 emission factor for flare gas of 60 kg CO_2/MMBtu (HHV basis).

(c) For catalytic cracking units and traditional fluid coking units, calculate the GHG emissions using the applicable methods described in paragraphs (c)(1) through (c)(5) of this section.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part (General Stationary Fuel Combustion Sources), you must calculate and report CO_2 emissions as provided in paragraphs (c)(1)(i) and (c)(1)(ii) of this section. Other catalytic cracking units and traditional fluid coking units must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part (General Stationary Combustion Souces), or follow the requirements of paragraphs (c)(2) or (3) of this section.

(i) Calculate CO_2 emissions by following the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(ii) If a CO boiler or other post-combustion device is used, you must also calculate the CO_2 emissions from the fuel fired to the CO boiler or post-combustion device using the applicable methods for stationary combustion units in subpart C of this part. Calculate the process emissions from the catalytic cracking unit or fluid coking unit as the difference in the CO_2 CEMS emissions and the calculated combustion emissions associated with the CO boiler.

(2) For catalytic cracking units and fluid coking units ~~with rated capacities greater than 10,000 barrels per stream day (bbls/sd)~~ that do not use a continuous CO_2 CEMS for the final exhaust stack, you must continuously or no less frequently than hourly monitor the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels and calculate the CO_2 emissions according to the requirements of paragraphs (c)(2)(i) through (c)(2)(iii) of this section:

(i) Calculate the CO_2 emissions from each catalytic cracking unit and fluid coking unit using Equation Y-6 of this section.

$$CO_2 = \sum_{p=1}^{n}\left[\left(Q_r\right)_p \times \frac{\left(\%CO_2 + \%CO\right)_p}{100\%} \times \frac{44}{MVC} \times 0.001\right] \qquad \text{(Eq. Y-6)}$$

Where:

CO_2 = Annual CO_2 mass emissions (metric tons/year).

Q_r = Volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels (dry standard cubic feet per hour, dscfh).

$\%CO_2$ = Hourly average percent CO_2 concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis).

$\%CO$ = Hourly average percent CO concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis). When there is no post-combustion device, assume %CO to be zero.

44 = Molecular weight of CO_2 (kg/kg-mole).

MVC = Molar volume conversion factor (849.5 scf/kg-mole).

0.001 = Conversion factor (metric ton/kg).

n = Number of hours in calendar year.

(ii) Either continuously monitor the volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels or calculate the volumetric flow rate of this exhaust gas stream using Equation Y-7 of this section.

$$Q_r = \frac{\left(79 * Q_a + (100 - \%O_{oxy}) * Q_{oxy}\right)}{100 - \%CO_2 - \%CO - \%O_2} \quad \text{(Eq. Y-7)}$$

Where:

Q_r = Volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels (dscfh).

Q_a = Volumetric flow rate of air to the fluid catalytic cracking unit regenerator or fluid coking unit burner, as determined from control room instrumentation (dscfh).

Q_{oxy} = Volumetric flow rate of oxygen enriched air to the fluid catalytic cracking unit regenerator or fluid coking unit burner as determined from control room instrumentation (dscfh).

$\%O_2$	=	Hourly average percent oxygen concentration in exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis).
$\%O_{oxy}$	=	O_2 concentration in oxygen enriched gas stream inlet to the fluid catalytic cracking unit regenerator or fluid coking unit burner based on oxygen purity specifications of the oxygen supply used for enrichment (percent by volume – dry basis).
$\%CO_2$	=	Hourly average percent CO_2 concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis).
%CO	=	Hourly average percent CO concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis). When no auxiliary fuel is burned and a continuous CO monitor is not required under 40 CFR part 63 subpart UUU, assume %CO to be zero.

(iii) If you have a CO boiler that uses auxiliary fuels or combusts materials other than catalytic cracking unit or fluid coking unit exhaust gas, you must determine the CO_2 emissions resulting from the combustion of these fuels or other materials following the requirements in subpart C and report those emissions by following the requirements of subpart C of this part.

(3) ~~For catalytic cracking units and fluid coking units with rated capacities of 10,000 barrels per stream day (bbls/sd) or less that do not use a continuous CO_2 CEMS for the final exhaust stack, comply with the requirements in paragraphs (c)(3)(i) of this section or paragraphs (c)(3)(ii) and (c)(3)(iii) of this section, as applicable.~~

Reserved.

~~(i) If you continuously or no less frequently than daily monitor the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels, you must calculate the CO_2 emissions according to the requirements of paragraphs (c)(2)(i) through (c)(2)(iii) of this section, except that daily averages are allowed and the summation can be performed on a daily basis.~~

~~(ii) If you do not monitor at least daily the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels, calculate the CO_2 emissions from each catalytic cracking unit and fluid coking unit using Equation Y-8 of this section.~~

$$\cancel{CO_2 = Q_{unit} \times (CBF \times 0.001) \times CC \times \frac{44}{12}} \qquad \text{(Eq. Y-8)}$$

~~Where:~~

~~CO_2 = Annual CO_2 mass emissions (metric tons/year).~~

~~Q_{unit} = Annual throughput of unit from company records (barrels (bbls) per year, bbl/yr).~~

~~CBF = Coke burn-off factor from engineering calculations (kg coke per barrel of feed); default for catalytic cracking units = 7.3; default for fluid coking units = 11.~~

~~0.001 = Conversion factor (metric ton/kg).~~

~~CC = Carbon content of coke based on measurement or engineering estimate (kg C per kg coke); default = 0.94.~~

~~44/12 = Ratio of molecular weight of CO_2 to C (kg CO_2 per kg C).~~

~~(iii) If you have a CO boiler that uses auxiliary fuels or combusts materials other than catalytic cracking unit or fluid coking unit exhaust gas, you must determine the CO_2 emissions resulting from the combustion of these fuels or other materials following the requirements in subpart C of this part (General Stationary Fuel Combustion Sources) and report those emissions by following the requirements of subpart C of this part.~~

(4) Calculate CH_4 emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation Y-9 of this section.

$$CH_4 = \left(CO_2 * \frac{EmF_2}{EmF_1} \right) \qquad \text{(Eq. Y-9)}$$

Where:

CH_4 = Annual methane emissions from coke burn-off (metric tons CH_4/year).

CO_2 = Emission rate of CO_2 from coke burn-off calculated in paragraphs (c)(1), (c)(2), (e)(1), (e)(2), (g)(1), or (g)(2) of this section, as applicable (metric tons/year).

EmF_1 = Default CO_2 emission factor for petroleum coke from Table C-1 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CO_2/MMBtu).

EmF_2 = Default CH_4 emission factor for "PetroleumProducts" from Table C-2 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CH_4/MMBtu).

(5) Calculate N_2O emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation Y-10 of this section.

$$N_2O = \left(CO_2 * \frac{EmF_3}{EmF_1} \right) \quad \text{(Eq. Y-10)}$$

Where:

N_2O = Annual nitrous oxide emissions from coke burn-off (mt N_2O/year).

CO_2 = Emission rate of CO_2 from coke burn-off calculated in paragraphs (c)(1), (c)(2), (e)(1), (e)(2), (g)(1), or (g)(2) of this section, as applicable (metric tons/year).

EmF_1 = Default CO_2 emission factor for petroleum coke from Table C-1 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CO_2/MMBtu).

EmF_3 = Default N_2O emission factor for ”PetroleumProducts” from Table C-2 of subpart C of this part (kg N_2O/MMBtu).

(d) For fluid coking units that use the flexicoking design, the GHG emissions from the resulting use of the low value fuel gas must be accounted for only once. Typically, these emissions will be accounted for using the methods described in subpart C of this part (General Stationary Fuel Combustion Sources). Alternatively, you may use the methods in paragraph (c) of this section provided that you do not otherwise account for the subsequent combustion of this low value fuel gas.

(e) For catalytic reforming units, calculate the CO_2 emissions using the applicable methods described in paragraphs (e)(1) through (e)(3) of this section and calculate the CH_4 and N_2O emissions using the methods described in paragraphs (c)(4) and (c)(5) of this section, respectively.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part (General Stationary Fuel Combustion Sources), you must calculate CO_2 emissions as provided in paragraphs (c)(1)(i) and (c)(1)(ii) of this section. Other catalytic reforming units must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part, or follow the requirements of paragraph (e)(2) or (e)(3) of this section.

(2) If you continuously or no less frequently than daily monitor the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic reforming unit catalyst regenerator prior to the combustion of other fossil fuels, you must calculate the CO_2 emissions according to the requirements of paragraphs (c)(2)(i) through (c)(2)(iii) of this section.

(3) Calculate CO_2 emissions from the catalytic reforming unit catalyst regenerator using Equation Y-11 of this section.

$$CO_2 = \sum_{1}^{n} \left[\left(CB_Q\right)_n \times CC \times \frac{44}{12} \times 0.001 \right] \qquad \text{(Eq. Y-11)}$$

Where:

CO_2	=	Annual CO_2 emissions (metric tons/year).
CB_Q	=	Coke burn-off quantity per regeneration cycle from engineering estimates (kg coke/cycle).
n	=	Number of regeneration cycles in the calendar year.
CC	=	Carbon content of coke based on measurement or engineering estimate (kg C per kg coke); default = 0.94.
44/12	=	Ratio of molecular weight of CO_2 to C (kg CO_2 per kg C).
0.001	=	Conversion factor (metric ton/kg).

(f) For on-site sulfur recovery plants, calculate and report CO_2 process emissions from sulfur recovery plants according to the requirements in paragraphs (f)(1) through (f)(5) of this section. Combustion emissions from the sulfur recovery plant (e.g., from fuel combustion in the Claus burner or the tail gas treatment incinerator) must be reported under subpart C of this part (General Stationary Fuel Combustion Sources). For the purposes of this subpart, the sour gas stream for which monitoring is required according to paragraphs (f)(2) through (f)(5) of this section is not considered a fuel.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part, you must calculate CO_2 emissions under this subpart by following the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources). You must monitor fuel use in the Claus burner, tail gas incinerator, or other

combustion sources that discharge via the final exhaust stack from the sulfur recovery plant and calculate the combustion emissions from the fuel use according to subpart C of this part. Calculate the process emissions from the sulfur recovery plant as the difference in the CO_2 CEMS emissions and the calculated combustion emissions associated with the sulfur recovery plant final exhaust stack. Other sulfur recovery plants must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C, or follow the requirements of paragraphs (f)(2) through (f)(5) of this section.

(2) Flow measurement. If you have a continuous flow monitor on the sour gas feed to the sulfur recovery plant, you must use the measured flow rates when the monitor is operational to calculate the sour gas flow rate. If you do not have a continuous flow monitor on the sour gas feed to the sulfur recovery plant, you must use engineering calculations, company records, or similar estimates of volumetric sour gas flow.

(3) Carbon content. If you have a continuous gas composition monitor capable of measuring carbon content on the sour gas feed to the sulfur recovery plant or if you monitor gas composition for carbon content on a routine basis, you must use the measured carbon content value. Alternatively, you may develop a site-specific carbon content factor using limited

measurement data or engineering estimates or use the default factor of 0.20.

(4) Calculate the CO_2 emissions from each sulfur recovery plant using Equation Y-12 of this section.

$$CO_2 = F_{SG} * \frac{44}{MVC} * MF_C * 0.001 \quad \text{(Eq. Y-12)}$$

Where:

CO_2 = Annual CO_2 emissions (metric tons/year).

F_{SG} = Volumetric flow rate of sour gas feed (including sour water stripper gas) to the sulfur recovery plant (scf/year).

44 = Molecular weight of CO_2 (kg/kg-mole).

MVC = Molar volume conversion factor (849.5 scf/kg-mole).

MF_C = Mole fraction of carbon in the sour gas to the sulfur recovery plant (kg-mole C/kg-mole gas); default = 0.20.

0.001 = Conversion factor, kg to metric tons

(5) If tail gas is recycled to the front of the sulfur recovery plant and the recycled flow rate and carbon content is included in the measured data under paragraphs (f)(2) and (f)(3) of this section, respectively, then the annual CO_2 emissions calculated in paragraph (f)(4) of this section must be corrected to avoid double counting these emissions. You may use engineering estimates to perform this correction or assume that the corrected CO_2 emissions are 95 percent of the uncorrected value calculated using Equation Y-12 of this section.

(g) For coke calcining units, calculate GHG emissions according to the applicable provisions in paragraphs (g)(1) through (g)(3) of this section.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part, you must calculate and report CO_2 emissions under this subpart by following the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources). You must monitor fuel use in the coke calcining unit that discharges via the final exhaust stack from the coke calcining unit and calculate the combustion emissions from the fuel use according to subpart C of this part. Calculate the process emissions from the coke calcining unit as the difference in the CO_2 CEMS emissions and the calculated combustion emissions associated with the coke calcining unit final exhaust stack. Other coke calcining units must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part, or follow the requirements of paragraph (g)(2) of this section.

(2) Calculate the CO_2 emissions from the coke calcining unit using Equation Y-13 of this section.

$$CO_2 = \frac{44}{12} * \left(M_{in} * CC_{GC} - \left(M_{out} + M_{dust}\right) * CC_{MPC}\right) \quad \text{(Eq. Y-13)}$$

Where:

CO_2	=	Annual CO_2 emissions (metric tons/year).
M_{in}	=	Annual mass of green coke fed to the coke calcining unit from facility records (metric tons/year).
CC_{GC}	=	Average mass fraction carbon content of green coke from facility measurement data (metric ton carbon/metric ton green coke).
M_{out}	=	Annual mass of marketable petroleum coke produced by the coke calcining unit from facility records (metric tons petroleum coke/year).
M_{dust}	=	Annual mass of petroleum coke dust collected in the dust collection system of the coke calcining unit from facility records (metric ton petroleum coke dust/year)
CC_{MPC}	=	Average mass fraction carbon content of marketable petroleum coke produced by the coke calcining unit from facility measurement data (metric ton carbon/metric ton petroleum coke).
44	=	Molecular weight of CO_2 (kg/kg-mole).
12	=	Atomic weight of C (kg/kg-mole).

(3) For all coke calcining units, use the CO_2 emissions from the coke calcining unit calculated in paragraphs (g)(1) or (g)(2), as applicable, and calculate CH_4 using the methods described in paragraph (c)(4) of this section and N_2O emissions using the methods described in paragraph (c)(5) of this section.

(h) [Reporting only.] For asphalt blowing operations, calculate GHG emissions according to the requirements in paragraph (j) of this section or according to the applicable provisions in paragraphs (h)(1) and (h)(2) of this section.

(1) For uncontrolled asphalt blowing operations or asphalt blowing operations controlled by vapor scrubbing, calculate CO_2

and CH_4 emissions using Equations Y-14 and Y-15 of this section, respectively.

$$CO_2 = (Q_{AB} \times EF_{AB.CO2}) \quad \text{(Eq. Y-14)}$$

Where:

CO_2 = Annual CO_2 emissions from uncontrolled asphalt blowing (metric tons CO_2/year).

Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).

$EF_{AB,CO2}$ = Emission factor for CO_2 from uncontrolled asphalt blowing from facility-specific test data (metric tons CO_2/MMbbl asphalt blown); default = 1,100.

$$CH_4 = (Q_{AB} \times EF_{AB,CH4}) \quad \text{(Eq. Y-15)}$$

Where:

CH_4 = Annual methane emissions from uncontrolled asphalt blowing (metric tons CH_4/year).

Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).

$EF_{AB,CH4}$ = Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (metric tons CH_4/MMbbl asphalt blown); default = 580.

(2) For asphalt blowing operations controlled by thermal oxidizer or flare, calculate CO_2 and CH_4 emissions using Equations Y-16 and Y-17 of this section, respectively, provided these emissions are not already included in the flare emissions calculated in paragraph (b) of this section or in the stationary combustion unit emissions required under subpart C of this part (General Stationary Fuel Combustion Sources).

$$CO_2 = 0.98 \times \left(Q_{AB} \times CEF_{AB} \times \frac{44}{12} \right) \quad \text{(Eq. Y-16)}$$

Where:

CO_2 = Annual CO_2 emissions from controlled asphalt blowing (metric tons CO_2/year).

0.98 = Assumed combustion efficiency of thermal oxidizer or flare.

Q_{AB} = Quantity of asphalt blown (MMbbl/year).

CEF_{AB} = Carbon emission factor from asphalt blowing from facility-specific test data (metric tons C/MMbbl asphalt blown); default = 2,750.

44 = Molecular weight of CO_2 (kg/kg-mole).

12 = Atomic weight of C (kg/kg-mole).

$$CH_4 = 0.02 \times (Q_{AB} \times EF_{AB,CH4}) \qquad \text{(Eq. Y-17)}$$

Where:

CH_4 = Annual methane emissions from controlled asphalt blowing (metric tons CH_4/year).

0.02 = Fraction of methane uncombusted in thermal oxidizer or flare based on assumed 98% combustion efficiency.

Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).

$EF_{AB,CH4}$ = Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (metric tons CH_4/MMbbl asphalt blown); default = 580.

(i) For delayed coking units, calculate the CH_4 emissions from the depressurization of the coking unit vessel (i.e., the "coke drum") to atmosphere using either of the methods provided in paragraphs (i)(1) or (i)(2), provided no water or steam is added to the vessel once it is vented to the atmosphere. You must use the method in paragraph (i)(1) of this section if you add water or steam to the vessel after it is vented to the atmosphere.

(1) Use the process vent method in paragraph (j) of this section and also calculate the CH_4 emissions from the subsequent opening of the vessel for coke cutting operations using Equation Y-18 of this section. If you have coke drums or vessels of different dimensions, use Equation Y-18 for each set of coke drums or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

$$CH_4 = \left(N \times H \times \frac{(P_{CV} + 14.7)}{14.7} \times f_{void} \times \frac{\pi \times D^2}{4} \times \frac{16}{MVC} \times MF_{CH4} \times 0.001 \right) \quad \text{(Eq. Y-18)}$$

Where:

CH_4	=	Annual methane emissions from the delayed coking unit vessel opening (metric ton/year).
N	=	Cumulative number of vessel openings for all delayed coking unit vessels of the same dimensions during the year.
H	=	Height of coking unit vessel (feet).
P_{CV}	=	Gauge pressure of the coking vessel when opened to the atmosphere prior to coke cutting or, if the alternative method provided in paragraph (i)(2) of this section is used, gauge pressure of the coking vessel when depressurization gases are first routed to the atmosphere (pounds per square inch gauge, psig)
14.7	=	Assumed atmospheric pressure (pounds per square inch, psi)
f_{void}	=	Volumetric void fraction of coking vessel prior to steaming based on engineering calculations(cf gas/cf of vessel)~~; default = 0.6~~.
D	=	Diameter of coking unit vessel (feet).
16	=	Molecular weight of CH_4 (kg/kg-mole).
MVC	=	Molar volume conversion factor (849.5 scf/ kg-mole).
MF_{CH4}	=	Average ~~M~~mole fraction of methane in coking vessel gas based on the analysis of at least two samples per

year, collected at least four months a part (kg-mole CH_4/kg-mole gas, wet basis)~~; default value is 0.01~~.

0.001 = Conversion factor (metric ton/kg).

(2) Calculate the CH_4 emissions from the depressurization vent and subsequent opening of the vessel for coke cutting operations using Equation Y-18 of this section and the pressure of the coking vessel when the depressurization gases are first routed to the atmosphere. If you have coke drums or vessels of different dimensions, use Equation Y-18 for each set of coke drums or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

(j) For each process vent not covered in paragraphs (a) through (i) of this section that can be reasonably expected to contain greater than 2 percent by volume CO_2 or greater than 0.5 percent by volume of CH_4 or greater than 0.01 percent by volume (100 parts per million) of N_2O, calculate GHG emissions using the Equation Y-19 of this section. You must use Equation Y-19 of this section for catalytic reforming unit depressurization and purge vents when methane is used as the purge gas or if you elected this method as an alternative to the methods in paragraphs (h)(1) or (h)(2) of this section.

$$E_x = \sum_{p=1}^{N}\left((VR)_p \times (MF_x)_p \times \frac{MW_x}{MVC} \times (VT)_p \times 0.001\right) \qquad \text{(Eq. Y-19)}$$

Where:

E_x = Annual emissions of each GHG from process vent (metric ton/yr).

N = Number of venting events per year.

P = Index of venting events.

$(VR)_p$ = Average volumetric flow rate of process gas during the event (scf per hour).

$(MF_x)_p$ = Mole fraction of GHG x in process vent during the event (kg-mol of GHG x/kg-mol vent gas).

MW_x = Molecular weight of GHG x (kg/kg-mole); use 44 for CO_2 or N_2O and 16 for CH_4.

MVC = Molar volume conversion factor (849.5 scf/kg-mole).

$(VT)_p$ = Venting time for the event, (hours).

0.001 = Conversion factor (metric ton/kg)

(k) For uncontrolled blowdown systems, you must ~~either~~ use the methods for process vents in paragraph (j) of this section. ~~or calculate CH_4 emissions using Equation Y-20 of this section. Blowdown systems where the uncondensed gas stream is routed to a flare or similar control device is considered to be controlled and is not required to estimate emissions under this paragraph (k).~~

$$CH_4 = \left(Q_{Ref} \times EF_{BD} \times \frac{16}{MVC} \times 0.001 \right) \qquad \text{(Eq. Y-20)}$$

~~Where:~~

~~CH_4 = Methane emission rate from blowdown systems (mt CH_4/year).~~

~~Q_{Ref} = Quantity of crude oil plus the quantity of intermediate products received from off site that are processed at the facility (MMbbl/year).~~

~~EF_{BD} = Methane emission factor for uncontrolled blown systems (scf CH_4/MMbbl); default is 137,000.~~

~~16 = Molecular weight of CH_4 (kg/kg-mole).~~

~~MVC = Molar volume conversion factor (849.5 scf/kg-mole).~~
~~0.001 = Conversion factor (metric ton/kg).~~

(l) [Reporting only.] For equipment leaks, calculate CH_4 emissions using the method specified in either paragraph (l)(1) or (l)(2) of this section.

(1) Use process-specific methane composition data (from measurement data or process knowledge) and any of the emission estimation procedures provided in the Protocol for Equipment Leak Emissions Estimates (EPA-453/R-95-017, NTIS PB96-175401).

(2) Use Equation Y-21 of this section.

$$CH_4 = \left(0.4 \times N_{CD} + 0.2 \times N_{PU1} + 0.1 \times N_{PU2} + 4.3 \times N_{H2} + 6 \times N_{FGS}\right) \quad \text{(Eq. Y-21)}$$

Where:

CH_4 = Annual methane emissions from equipment leaks (metric tons/year)

N_{CD} = Number of atmospheric crude oil distillation columns at the facility.

N_{PU1} = Cumulative number of catalytic cracking units, coking units (delayed or fluid), hydrocracking, and full-range distillation columns (including depropanizer and debutanizer distillation columns) at the facility.

N_{PU2} = Cumulative number of hydrotreating/hydrorefining units, catalytic reforming units, and visbreaking units at the facility.

N_{H2} = Total number of hydrogen plants at the facility.

N_{FGS} = Total number of fuel gas systems at the facility.

(m) [Reporting only.] For storage tanks, except as provided in paragraph (m)(3) of this section, calculate CH_4 emissions using the applicable methods in paragraphs (m)(1) and (m)(2) of this section.

(1) For storage tanks other than those processing unstabilized crude oil, you must either calculate CH_4 emissions from storage tanks that have a vapor-phase methane concentration of 0.5 volume percent or more using tank-specific methane composition data (from measurement data or product knowledge) and the AP-42 emission estimation methods provided in Section 7.1 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources", including TANKS Model (Version 4.09D) or similar programs, or estimate CH_4 emissions from storage tanks using Equation Y-22 of this section.

$$CH_4 = \left(0.1 \times Q_{Ref}\right) \qquad \text{(Eq. Y-22)}$$

Where:

CH_4 = Annual methane emissions from storage tanks (metric tons/year).

0.1 = Default emission factor for storage tanks (metric ton CH_4/MMbbl).

Q_{Ref} = Quantity of crude oil plus the quantity of intermediate products received from off site that are processed at the facility (MMbbl/year).

(2) For storage tanks that process unstabilized crude oil, calculate CH_4 emissions from the storage of unstabilized crude oil using either tank-specific methane composition data (from measurement data or product knowledge) and direct measurement of the gas generation rate or by using Equation Y-23 of this section.

$$CH_4 = (995{,}000 \times Q_{un} \times \Delta P) \times MF_{CH4} \times \frac{16}{MVC} \times 0.001 \qquad \text{(Eq. Y-23)}$$

Where:

CH_4 = Annual methane emissions from storage tanks (metric tons/year).

Q_{un} = Quantity of unstabilized crude oil received at the facility (MMbbl/year).

ΔP = Pressure differential from the previous storage pressure to atmospheric pressure (pounds per square inch, psi).

MF_{CH4} = Mole fraction of CH_4 in vent gas from the unstabilized crude oil storage tank from facility measurements (kg-mole CH_4/kg-mole gas); use 0.27 as a default if measurement data are not available.

995,000 = Correlation Equation factor (scf gas per MMbbl per psi)

16 = Molecular weight of CH_4 (kg/kg-mole).

MVC = Molar volume conversion factor (849.5 scf/kg-mole).

0.001 = Conversion factor (metric ton/kg).

(3) You do not need to calculate CH_4 emissions from storage tanks that meet any of the following descriptions:

(i) Units permanently attached to conveyances such as trucks, trailers, rail cars, barges, or ships;

(ii) Pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere;

(iii) Bottoms receivers or sumps;

(iv) Vessels storing wastewater; or

(v) Reactor vessels associated with a manufacturing process unit.

(n) [Reporting only.] For crude oil, intermediate, or product loading operations for which the equilibrium vapor-phase concentration of methane is 0.5 volume percent or more, calculate CH_4 emissions from loading operations using product-specific, vapor-phase methane composition data (from measurement data or process knowledge) and the emission estimation procedures provided in Section 5.2 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources." For loading operations in which the equilibrium vapor-phase concentration of methane is less than 0.5 volume percent, you may assume zero methane emissions.

§98.254 Monitoring and QA/QC requirements.

(a) Fuel flow meters, gas composition monitors, and heating value monitors associated with stationary combustion sources must follow the monitoring and QA/QC requirements in §98.34.

(b) All flow meters, gas composition monitors, and heating value monitors that are used to provide data for the GHG emissions calculations in this subpart for sources other than stationary combustion sources shall be calibrated according to the procedures in the applicable methods specified in paragraphs (c) through (e) of this section, the procedures specified by the manufacturer, or §§98.3(i). Recalibrate each flow meter either biennially (every two years) or at the minimum frequency specified by the manufacturer. Recalibrate each gas composition monitor and heating value monitor either annually or at the minimum frequency specified by the manufacturer.

(c) For flare or sour gas flow meters, operate and maintain the flow meter using any of the following methods, a method published by a consensus-based standards organization (e.g., ASTM, API, etc.) or follow the procedures specified by the flow meter manufacturer. Flow meters must have a rated accuracy of ±5 percent or lower.

(1) ASME MFC–3M–2004 Measurement of Fluid Flow in Pipes Using Orifice, Nozzle, and Venturi (incorporated by reference, see §98.7).

(2) ASME MFC–4M–1986 (Reaffirmed 1997) Measurement of Gas Flow by Turbine Meters (incorporated by reference, see §98.7).

(3) ASME MFC–6M–1998 Measurement of Fluid Flow in Pipes Using Vortex Flowmeters (incorporated by reference, see §98.7).

(4) ASME MFC–7M–1987 (Reaffirmed 1992) Measurement of Gas Flow by Means of Critical Flow Venturi Nozzles (incorporated by reference, see §98.7).

(5) ASME MFC-11M-2006 Measurement of Fluid Flow by Means of Coriolis Mass Flowmeters (incorporated by reference, see §98.7).

(6) ASME MFC-14M-2003 Measurement of Fluid Flow Using Small Bore Precision Orifice Meters (incorporated by reference, see §98.7).

(7) ASME MFC-18M-2001 Measurement of Fluid Flow Using Variable Area Meters (incorporated by reference, see §98.7).

(8) AGA Report No. 11 Measurement of Natural Gas by Coriolis Meter (2003) (incorporated by reference, see §98.7).

(d) Determine flare gas composition using any of the following methods.

(1) Method 18 at 40 CFR part 60, appendix A-6.

(2) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see §98.7).

(3) ASTM D1946-90 (Reapproved 2006) Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see §98.7).

(4) GPA 2261–00 Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography (incorporated by reference, see §98.7).

(5) UOP539-97 Refinery Gas Analysis by Gas Chromatography (incorporated by reference, see §98.7).

(e) Determine flare gas higher heating value using any of the following methods.

(1) ASTM D4809-06 Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (Precision Method) (incorporated by reference, see §98.7).

(2) ASTM D240-02 (Reapproved 2007) Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (incorporated by reference, see §98.7).

(3) ASTM D1826-94 (Reapproved 2003) Standard Test Method for Calorific (Heating) Value of Gases in Natural Gas Range by Continuous Recording Calorimeter (incorporated by reference, see §98.7).

(4) ASTM D3588-98 (Reapproved 2003) Standard Practice for Calculating Heat Value, Compressibility Factor, and Relative Density of Gaseous Fuels (incorporated by reference, see §98.7).

(5) ASTM D4891-89 (Reapproved 2006) Standard Test Method for Heating Value of Gases in Natural Gas Range by Stoichiometric Combustion (incorporated by reference, see §98.7).

(f) For exhaust gas flow meters used to comply with the requirements in §98.253(c)(2)(ii), install, operate, calibrate, and maintain exhaust gas flow meter according to the requirements in 40 CFR 63.1572(c) or according to the following requirements.

(1) Locate the flow meter(s) and other necessary equipment such as straightening vanes in a position that provides representative flow; reduce swirling flow or abnormal velocity distributions due to upstream and downstream disturbances.

(2) Use a flow rate meter with an accuracy within ±5 percent.

(3) Use a continuous monitoring system capable of correcting for the temperature, pressure, and moisture content to output flow in dry standard cubic feet (standard conditions as defined in §98.6).

(4) Install, operate, and maintain each continuous monitoring system according to the manufacturer's specifications and requirements.

(g) For exhaust gas CO_2/CO/O_2 composition monitors used to comply with the requirements in §98.253(c)(2), install, operate, calibrate, and maintain exhaust gas composition monitors according to the the requirements in 40 CFR 60.105a(b)(2) or 40 CFR 63.1572(a) or according to the manufacturer's specifications and requirements.

(h) Determine the mass of petroleum coke as required by Equation Y-13 of this subpart using mass measurement equipment meeting the requirements for commercial weighing equipment as described in Specifications, Tolerances, and Other Technical Requirements For Weighing and Measuring Devices, NIST Handbook 44 (2009) (incorporated by reference, see §98.7). Calibrate the measurement device according to the procedures specified by the method, the procedures specified by the manufacturer, or

§98.3(i). Recalibrate either biennially or at the minimum frequency specified by the manufacturer.

(i) Determine the carbon content of petroleum coke as required by Equation Y-13 of this subpart using any one of the following methods. Calibrate the measurement device according to procedures specified by the method or procedures specified by the measurement device manufacturer.

(1) ASTM D3176-89 (Reapproved 2002) Standard Practice for Ultimate Analysis of Coal and Coke (incorporated by reference, see §98.7).

(2) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, see §98.7).

(3) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7).

(j) Determine the quantity of petroleum process streams using company records. These quantities include the quantity of asphalt blown, quantity of crude oil plus the quantity of intermediate products received from off site, and the quantity of unstabilized crude oil received at the facility.

(k) The owner or operator shall document the procedures used to ensure the accuracy of the estimates of fuel usage, gas composition, and heating value including but not limited to calibration of weighing equipment, fuel flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices shall also be recorded, and the technical basis for these estimates shall be provided.

(l) All CO_2 CEMS and flow rate monitors used for direct measurement of GHG emissions must comply with the QA procedures in §98.34(c).

(m) For purposes of §98.34(b)(3)(ii)(E), the equipment necessary to take daily measurements of carbon content and molecular weight shall be in place for refinery fuel gas, and daily sampling and analysis shall therefore be required, by no later than January 1, 2012.

§98.255 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., concentrations, flow rates, fuel heating values, carbon content values). Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For stationary combustion sources, use the missing data procedures in subpart C of this part.

(b) For each missing value of the heat content, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the "after" value is not obtained by the end of the reporting year, you may use the "before" value for the missing data substitution. If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(c) For missing CO_2, CO, O_2, CH_4, or N_2O concentrations, gas flow rate, and percent moisture, the substitute data values shall be the best available estimate(s) of the parameter(s), based on all available process data (e.g., processing rates, operating hours, etc.). The owner or operator shall document and keep records of the procedures used for all such estimates.

(d) For hydrogen plants, use the missing data procedures in subpart P of this part.

§98.256 Data reporting requirements.

In addition to the reporting requirements of §98.3(c), you must report the information specified in paragraphs (a) through (q) of this section.

Subpart Y—Petroleum Refineries

(a) For combustion sources, follow the data reporting requirements under subpart C of this part (General Stationary Fuel Combustion Sources).

(b) For hydrogen plants, follow the data reporting requirements under subpart P of this part (Hydrogen Production).

(c) [RESERVED].

(d) [RESERVED].

(e) For flares, owners and operators shall report:

(1) The flare ID number (if applicable).

(2) A description of the type of flare (steam assisted, air-assisted).

(3) A description of the flare service (general facility flare, unit flare, emergency only or back-up flare).

(4) The calculated CO_2, CH_4, and N_2O annual emissions for each flare, expressed in metric tons of each pollutant emitted.

(5) A description of the method used to calculate the CO_2 emissions for each flare (e.g., reference section and equation number).

(6) If you use Equation Y-1 of this subpart, the annual volume of flare gas combusted (in scf/year) and the annual average molecular weight (in kg/kg-mole) and carbon content of the flare gas (in kg carbon per kg flare gas).

(7) If you use Equation Y-2 of this subpart, the annual volume of flare gas combusted (in million (MM) scf/year) and the

annual average higher heating value of the flare gas (in MMBtu per MMscf).

(8) If you use Equation Y-3 of this subpart, ~~the annual volume of flare gas combusted (in MMscf/year) during normal operations, the annual average higher heating value of the flare gas (in MMBtu/MMscf),~~ the number of SSM events, and ~~exceeding 500,000 scf/day, and~~ the volume of gas flared (in scf/event) and the average molecular weight (in kg/kg-mole) and carbon content of the flare gas (in kg carbon per kg flare) for each SSM event ~~over 500,000 scf/day~~.

(9) The fraction of carbon in the flare gas contributed by methane used in Equation Y-4 of this subpart and the basis for its value.

(f) For catalytic cracking units, traditional fluid coking units, and catalytic reforming units, owners and operators shall report:

(1) The unit ID number (if applicable).

(2) A description of the type of unit (fluid catalytic cracking unit, thermal catalytic cracking unit, traditional fluid coking unit, or catalytic reforming unit).

(3) Maximum rated throughput of the unit, in bbl/stream day.

(4) The calculated CO_2, CH_4, and N_2O annual emissions for each unit, expressed in metric tons of each pollutant emitted.

(5) A description of the method used to calculate the CO_2 emissions for each unit (e.g., reference section and equation number).

(6) If you use a CEMS, the relevant information required under §98.36(e)(2)(vi) for the Tier 4 Calculation Methodology, the CO_2 annual emissions as measured by the CEMS (unadjusted to remove CO_2 combustion emissions associated with a CO boiler, if present) and the process CO_2 emissions as calculated according to §98.253(c)(1)(ii). Report the CO_2 annual emissions associated with fuel combustion under subpart C of this part (General Stationary Fuel Combustion Sources).

(7) If you use Equation Y-6 of this subpart, the annual average exhaust gas flow rate, $\%CO_2$, and %CO.

(8) If you use Equation Y-7 of this subpart, the annual average flow rate of inlet air and oxygen-enriched air, $\%O_2$, $\%O_{oxy}$, $\%CO_2$, and %CO.

(9) ~~If you use Equation Y-8 of this subpart, the coke burn-off factor, annual throughput of unit, and the average carbon content of coke and the basis for the value.~~

Reserved.

(10) ~~Indicate whether you use a measured value, a unit-specific emission factor, or a default emission factor for CH_4 emissions. If you use a unit-specific emission factor for CH_4, report the units of measure for the unit-specific factor, the~~

~~activity data for calculating emissions (e.g., if the emission factor is based on coke burn-off rate, the annual quantity of coke burned), and the basis for the factor.~~

Reserved.

(11) Indicate whether you use a measured value, a unit-specific emission factor, or a default emission factor for N_2O emissions. If you use a unit-specific emission factor for N_2O, report the units of measure for the unit-specific factor, the activity data for calculating emissions (e.g., if the emission factor is based on coke burn-off rate, the annual quantity of coke burned), and the basis for the factor.

(12) If you use Equation Y-11 of this subpart, the number of regeneration cycles during the reporting year, the average coke burn-off quantity per cycle, and the average carbon content of the coke.

(g) For fluid coking unit of the flexicoking type, the owner or operator shall report:

(1) The unit ID number (if applicable).

(2) A description of the type of unit.

(3) Maximum rated throughput of the unit, in bbl/stream day.

(4) Indicate whether the GHG emissions from the low heat value gas are accounted for in subpart C of this part or §98.253(c).

(5) If the GHG emissions for the low heat value gas are calculated at the flexicoking unit, also report the calculated annual CO_2, CH_4, and N_2O emissions for each unit, expressed in metric tons of each pollutant emitted, and the applicable equation input parameters specified in paragraphs (f)(7) through (f)(11) of this section.

(h) For sulfur recovery plants and for emissions from sour gas sent off-site for sulfur recovery, the owner and operator shall report:

(1) The plant ID number (if applicable).

(2) Maximum rated throughput of each independent sulfur recovery plant, in metric tons sulfur produced/stream day.

(3) The calculated CO_2 annual emissions for each sulfur recovery plant, expressed in metric tons. The calculated annual CO_2 emissions from sour gas sent off-site for sulfur recovery, expressed in metric tons.

(4) If you use Equation Y-12 of this subpart, the annual volumetric flow to the sulfur recovery plant (in scf/year) and the annual average mole fraction of carbon in the sour gas (in kg-mole C/kg-mole gas).

(5) If you recycle tail gas to the front of the sulfur recovery plant, indicate whether the recycled flow rate and carbon content are included in the measured data under §98.253(f)(2) and (3). Indicate whether a correction for CO_2

emissions in the tail gas was used in Equation Y-12. If so, then report the value of the correction, the annual volume of recycled tail gas (in scf/year) and the annual average mole fraction of carbon in the tail gas (in kg-mole C/kg-mole gas). Indicate whether you used the default (95%) or a unit specific correction, and if used, report the approach used.

(6) If you use a CEMS, the relevant information required under §98.36(e)(2)(vi) for the Tier 4 Calculation Methodology, the CO_2 annual emissions as measured by the CEMS and the annual process CO_2 emissions calculated according to §98.253(f)(1). Report the CO_2 annual emissions associated with fuel combustion subpart C of this part (General Stationary Fuel Combustion Sources).

(i) For coke calcining units, the owner and operator shall report:

(1) The unit ID number (if applicable).

(2) Maximum rated throughput of the unit, in metric tons coke calcined/stream day.

(3) The calculated CO_2, CH_4, and N_2O annual emissions for each unit, expressed in metric tons of each pollutant emitted.

(4) A description of the method used to calculate the CO_2 emissions for each unit (e.g., reference section and equation number).

(5) If you use Equation Y-13 of this subpart, annual mass and carbon content of green coke fed to the unit, the annual mass and carbon content of marketable coke produced, and the annual mass of coke dust collected in dust collection systems.

(6) If you use a CEMS, the relevant information required under §98.36(e)(2)(vi) for the Tier 4 Calculation Methodology, the CO_2 annual emissions as measured by the CEMS and the annual process CO_2 emissions calculated according to §98.253(g)(1). Report the CO_2 annual emissions associated with fuel combustion under subpart C of this part (General Stationary Fuel Combustion Sources).

(7) Indicate whether you use a measured value, a unit-specific emission factor or a default for CH_4 emissions. If you use a unit-specific emission factor for CH_4, the unit-specific emission factor for CH_4, the units of measure for the unit-specific factor, the activity data for calculating emissions (e.g., if the emission factor is based on coke burn-off rate, the annual quantity of coke burned), and the basis for the factor.

(8) If you use a site-specific emission factor in Equation Y-10 of this subpart, the site-specific emission factor and the basis of the factor.

(j) For asphalt blowing operations, the owner or operator shall report:

(1) The unit ID number (if applicable).

(2) The quantity of asphalt blown (in Million bbl) at the facility in the reporting year.

(3) The type of control device used to reduce methane (and other organic) emissions from the unit.

(4) The calculated annual CO_2 and CH_4 emissions for each unit, expressed in metric tons of each pollutant emitted.

(5) If you use Equation Y-14 of this subpart, the CO_2 emission factor used and the basis for the value.

(6) If you use Equation Y-15 of this subpart, the CH_4 emission factor used and the basis for the value.

(7) If you use Equation Y-16 of this subpart, the carbon emission factor used and the basis for the value.

(8) If you use Equation Y-17 of this subpart, the CH_4 emission factor used and the basis for the value.

(k) For delayed coking units, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for all delayed coking units at the facility.

(2) A description of the method used to calculate the CH_4 emissions for each unit (e.g., reference section and equation number).

(3) The total number of delayed coking units at the facility, the total number of delayed coking drums at the facility, and for each coke drum or vessel: the dimensions, the typical gauge pressure of the coking drum when first vented to the atmosphere, typical void fraction, the typical drum outage (i.e. the unfilled distance from the top of the drum, in feet), and annual number of coke-cutting cycles.

(4) For each set of coking drums that are the same dimensions: the number of coking drums in the set, the height and diameter of the coke drums (in feet), the cumulative number of vessel openings for all delayed coking drums in the set, the typical venting pressure (in psig), void fraction (in cf gas/cf of vessel), and the mole fraction of methane in coking gas (in kg-mole CF_4/kg-mole gas, wet basis).

(5) The basis for the volumetric void fraction of the coke vessel prior to steaming and the basis for the mole fraction of methane in the coking gas.

(l) For process vents subject to §98.253(j), the owner or operator shall report:

(1) The vent ID number (if applicable).

(2) The unit or operation associated with the emissions.

(3) The type of control device used to reduce methane (and other organic) emissions from the unit, if applicable.

(4) The calculated annual CO_2, CH_4, and N_2O emissions for each vent, expressed in metric tons of each pollutant emitted.

(5) The annual volumetric flow discharged to the atmosphere (in scf), mole fraction of each GHG above the concentration threshold, and for intermittent vents, the number of venting events and the cumulative venting time.

(m) For uncontrolled blowdown systems, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for uncontrolled blowdown systems.

(2) ~~The total quantity (in Million bbl) of crude oil plus the quantity of intermediate products received from off-site that are processed at the facility in the reporting year.~~The information required for process vents in paragraph (l) of this section.

(3) ~~The methane emission factor used for uncontrolled blowdown systems and the basis for the value.~~

Reserved.

(n) For equipment leaks, the owner or operator shall report:

(1) The cumulative CH_4 emissions (in metric tons of each pollutant emitted) for all equipment leak sources.

(2) The method used to calculate the reported equipment leak emissions.

(3) The number of each type of emission source listed in Equation Y-21 of this subpart at the facility.

(o) For storage tanks, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for all storage tanks, except for those used to process unstabilized crude oil.

(2) The method used to calculate the reported storage tank emissions for storage tanks other than those processing unstabilized crude (AP-42, TANKS 4.09D, Equation Y-22 of this subpart, other).

(3) The total quantity (in MMbbl) of crude oil plus the quantity of intermediate products received from off-site that are processed at the facility in the reporting year.

(4) The cumulative CH_4 emissions (in metric tons of each pollutant emitted) for storage tanks used to process unstabilized crude oil.

(5) The method used to calculate the reported storage tank emissions for storage tanks processing unstabilized crude oil.

(6) The quantity of unstabilized crude oil received during the calendar year (in MMbbl), the average pressure differential (in psi), and the mole fraction of CH_4 in vent gas from the unstabilized crude oil storage tank, and the basis for the mole fraction.

(7) The tank-specific methane composition data and the gas generation rate data, if you did not use Equation Y-23.

(p) For loading operations, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for loading operations.

(2) The quantity and types of materials loaded by vessel type (barge, tanker, marine vessel, etc.) that have an equilibrium vapor-phase concentration of methane of 0.5 volume percent or greater, and the type of vessels in which the material is loaded.

(3) The type of control system used to reduce emissions from the loading of material with an equilibrium vapor-phase concentration of methane of 0.5 volume percent or greater, if any (submerged loading, vapor balancing, etc.).

(q) Name of each method listed in §98.254 or a description of manufacturer's recommended method used to determine a measured parameter.

§98.257 Records that must be retained.

(a) In addition to the records required by §98.3(g), you must retain the records of all parameters monitored under §98.255.

(b) For each process vent for which the concentration of CO_2, N_2O and CH_4 are determined to be below the thresholds in

§98.253(j), the owner or operator shall maintain records of the method used to determine the CO_2, N_2O, and CH_4 concentration and all supporting documentation necessary to demonstrate the thresholds in §98.253(j) are not exceeded during the reporting year.

§98.258 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Subpart AA—Pulp and Paper Manufacturing

§98.270 Definition of Source Category.

(a) The pulp and paper manufacturing source category consists of facilities that produce market pulp (i.e., stand-alone pulp facilities), manufacture pulp and paper (i.e., integrated facilities), produce paper products from purchased pulp, produce secondary fiber from recycled paper, convert paper into paperboard products (e.g., containers), or operate coating and laminating processes.

(b) The emission units for which GHG emissions must be reported are listed in paragraphs (b)(1) through (b)(5) of this section:

(1) Chemical recovery furnaces at kraft and soda mills (including recovery furnaces that burn spent pulping liquor produced by both the kraft and semichemical process).

(2) Chemical recovery combustion units at sulfite facilities.

(3) Chemical recovery combustion units at stand-alone semichemical facilities.

(4) Pulp mill lime kilns at kraft and soda facilities.

(5) Systems for adding makeup chemicals ($CaCO_3$, Na_2CO_3) in the chemical recovery areas of chemical pulp mills.

Subpart AA—Pulp and Paper Manufacturing

§98.271 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a pulp and paper manufacturing process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.272 GHGs to report.

You must report the emissions listed in paragraphs (a) through (f) of this section:[1]

(a) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each kraft or soda chemical recovery furnace.

(b) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each sulfite chemical recovery combustion unit.

(c) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each stand-alone semichemical chemical recovery combustion unit.

(d) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each kraft or soda pulp mill lime kiln.

(e) CO_2 emissions from addition of makeup chemicals ($CaCO_3$, Na_2CO_3) in the chemical recovery areas of chemical pulp mills.

(f) CO_2, CH_4, and N_2O combustion emissions from each stationary combustion unit. You must calculate and report these emissions under subpart C of this part (General

[1] WCI ERs previously included methodologies for calculating CH_4 and N_2O emissions from wastewater treatment plants at this source category. Coverage of these facilities will now be left to the discretion of the jurisdiction.

Stationary Fuel Combustion Sources) by following the requirements of subpart C.

§98.273 Calculating GHG emissions.

(a) For each chemical recovery furnace located at a kraft or soda facility, you must determine CO_2, biogenic CO_2, CH_4, and N_2O emissions using the procedures in paragraphs (a)(1) through (a)(3) of this section. CH_4 and N_2O emissions must be calculated as the sum of emissions from combustion of fossil fuels and combustion of biomass in spent liquor solids.

(1) Calculate fossil fuel-based CO_2 emissions from direct measurement of fossil fuels consumed and the methodology for stationary combustion sources specified by §98.33(a) (as modified by this Article) for the appropriate fuel type ~~default emissions factors according to the Tier 1 methodology for stationary combustion sources in §98.33(a)(1)~~.[2]

(2) Calculate fossil fuel-based CH_4 and N_2O emissions from direct measurement of fossil fuels consumed, default HHV, and default emissions factors and convert to metric tons of CO_2 equivalent according to the methodology for stationary combustion sources in §98.33(c).

[2] Although Subpart C generally allows the use of higher tiers, even when a lower tier is specified for a particular unit or fuel, section 98.273 could be read as *requiring* the use of Tier 1. WCI is seeking clarification of the correct interpretation of section 98.273 in order to assure that the proposed changes are consistent with harmonization.

(3) Calculate biogenic CO_2 emissions and emissions of CH_4 and N_2O from biomass using measured quantities of spent liquor solids fired, site-specific HHV, and default or site-specific emissions factors[3], according to Equation AA-1 of this section:

$$CO_2, CH_4, or\ N_2O\ from\ biomass = (0.907.18) * \text{Solids} * \text{HHV} * \text{EF} \quad \text{(Eq.AA-1)}$$

Where:

CO_2, CH_4, or N_2O, from Biomass	=	Biogenic CO_2 emissions or emissions of CH_4 or N_2O from spent liquor solids combustion (metric tons per year).
Solids	=	Mass of spent liquor solids combusted (short tons per year) determined according to §98.274(b).
HHV	=	Annual high heat value of the spent liquor solids (mmBtu per kilogram) determined according to 98.274(b).
EF	=	Default emission factor for CO_2, CH_4, or N_2O, from Table AA-1 of this subpart (kg CO_2, CH_4, or N_2O per mmBtu).
0.90718	=	Conversion factor from short tons to metric tons.

(b) For each chemical recovery combustion unit located at a sulfite or stand-alone semichemical facility, you must determine CO_2, CH_4, and N_2O emissions using the procedures in paragraphs (b)(1) through (b)(4) of this section:

(1) Calculate fossil CO_2 emissions from fossil fuels from direct measurement of fossil fuels consumed and the

methodology for stationary combustion sources specified by §98.33(a) (as modified by this Article) for the appropriate fuel type ~~default emissions factors according to the Tier 1 Calculation Methodology for stationary combustion sources in §98.33(a)(1)~~.

(2) Calculate CH_4 and N_2O emissions from fossil fuels from direct measurement of fossil fuels consumed, default HHV, and default emissions factors and convert to metric tons of CO_2 equivalent according to the methodology for stationary combustion sources in §98.33(c).

(3) Calculate biogenic CO_2 emissions using measured quantities of spent liquor solids fired and the carbon content of the spent liquor solids, according to Equation AA-2 of this section:

$$Biogenic\,CO_2 = \frac{44}{12} * \mathrm{Solids} * \mathrm{CC} * (0.90718) \qquad \text{(Eq. AA-2)}$$

Where:

Biogenic CO_2	=	Annual CO_2 mass emissions for spent liquor solids combustion (metric tons per year).
Solids	=	Mass of the spent liquor solids combusted (short tons per year) determined according to §98.274(b).
CC	=	Annual carbon content of the spent liquor solids, determined according to §98.274(b) (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.90718	=	Conversion from short tons to metric tons

(4) Calculate CH_4 and N_2O emissions from biomass using Equation AA-1 of this section and the default CH_4 and N_2O emissions factors for kraft facilities in Table AA-1 of this subpart and convert the CH_4 or N_2O emissions to metric tons of CO_2 equivalent by multiplying each annual CH_4 and N_2O emissions total by the appropriate global warming potential (GWP) factor from Table A-1 of subpart A of this part.

(c) For each pulp mill lime kiln located at a kraft or soda facility, you must determine CO_2, CH_4, and N_2O emissions using the procedures in paragraphs (c)(1) through (c)(3) of this section:

(1) Calculate CO_2 emissions from fossil fuels from direct measurement of fossil fuels consumed and the methodology for stationary combustion sources specified by §98.33(a) (as modified by this Article) for the appropriate fuel type. ~~and default HHV and default emissions factors, according to the Tier 1 Calculation Methodology for stationary combustion sources in §98.33(a)(1); use the default HHV listed in Table C-1 of subpart C and~~ Where the applicable method specified by § 98.33(a) allows the use of a default emission factor, use the default CO_2 emissions factors listed in Table AA-2 of this subpart.

(2) Calculate CH_4 and N_2O emissions from fossil fuel from direct measurement of fossil fuels consumed, default HHV, and default emissions factors and convert to metric tons of CO_2 equivalent according to the methodology for stationary combustion sources in §98.33(c); use the default HHV listed in Table C-1 of subpart C and the default CH_4 and N_2O emissions factors listed in Table AA-2 of this subpart.

(3) Biogenic CO_2 emissions from conversion of $CaCO_3$ to CaO are included in the biogenic CO_2 estimates calculated for the chemical recovery furnace in paragraph (a)(3) of this section.

(d) For makeup chemical use, you must calculate CO_2 emissions by using direct or indirect measurement of the quantity of chemicals added and ratios of the molecular weights of CO_2 and the makeup chemicals, according to Equation AA-3 of this section:

$$CO_2 = \left[M_{(CaCO_3)} * \frac{44}{100} + M_{(Na_2CO_3)} \frac{44}{105.99} \right] * 1000\, kg / metric\, ton \qquad \text{(Eq. AA-3)}$$

Where:

CO_2	=	CO_2 mass emissions from makeup chemicals (kilograms/yr).
M ($CaCO_3$)	=	Make-up quantity of $CaCO_3$ used for the reporting year (metric tons per year).
M ($NaCO_3$)	=	Make-up quantity of Na_2CO_3 used for the reporting year (metric tons per year).
44	=	Molecular weight of CO_2.
100	=	Molecular weight of $CaCO_3$.
105.99	=	Molecular weight of Na_2CO_3.

§98.274 Monitoring and QA/QC requirements.

(a) Each facility subject to this subpart must quality assure the GHG emissions data according to the applicable requirements in §98.34. All QA/QC data must be available for inspection upon request.

(b) Fuel properties needed to perform the calculations in Equations AA-1 and AA-2 of this subpart must be determined according to paragraphs (b)(1) through (b)(3) of this section.

(1) High heat values of black liquor must be determined no less than annually using T684 om–06 Gross Heating Value of Black Liquor, TAPPI (incorporated by reference, see §98.7). If measurements are performed more frequently than annually, then the high heat value used in Equation AA-1 of this subpart must be based on the average of the representative measurements made during the year.

(2) The annual mass of spent liquor solids must be determined using either of the methods specified in paragraph (b)(2)(i) or (b)(2)(ii).

(i) Measure the mass of spent liquor solids annually (or more frequently) using T-650 om–05 Solids Content of Black Liquor, TAPPI (incorporated by reference in §98.7). If measurements are performed more frequently than annually, then the mass of spent liquor solids used in

Equation AA-1 of this subpart must be based on the average of the representative measurements made during the year.

(ii) Determine the annual mass of spent liquor solids based on records of measurements made with an online measurement system that determines the mass of spent liquor solids fired in a chemical recovery furnace or chemical recovery combustion unit.

(3) Carbon analyses for spent pulping liquor must be determined no less than annually using ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7). If measurements using ASTM D5373-08 are performed more frequently than annually, then the spent pulping liquor carbon content used in Equation AA-2 of this subpart must be based on the average of the representative measurements made during the year.

(c) Each facility must keep records that include a detailed explanation of how company records of measurements are used to estimate GHG emissions. The owner or operator must also document the procedures used to ensure the accuracy of the measurements of fuel, spent liquor solids, and makeup chemical usage, including, but not limited to calibration of weighing equipment, fuel flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices must be recorded and the technical basis for these estimates must be provided. The procedures used to convert spent pulping liquor flow rates to units of mass (i.e., spent liquor solids firing rates) also must be documented.

(d) Records must be made available upon request for verification of the calculations and measurements.

§98.275 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required sample is not taken), a substitute data value for the missing parameter shall be used in the calculations, according to the requirements of paragraphs (a) through (c) of this section:

(a) There are no missing data procedures for measurements of heat content and carbon content of spent pulping liquor. A re-test must be performed if the data from any annual measurements are determined to be invalid.

(b) For missing measurements of the mass of spent liquor solids or spent pulping liquor flow rates, use the lesser value of either the maximum mass or fuel flow rate for the combustion unit, or the maximum mass or flow rate that the fuel meter can measure.

(c) For the use of makeup chemicals (carbonates), the substitute data value shall be the best available estimate of makeup chemical consumption, based on available data (e.g., past accounting records, production rates). The owner or operator shall document and keep records of the procedures used for all such estimates.

§98.276 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information in paragraphs (a) through (K) of this section as applicable:

(a) Annual emissions of CO_2, biogenic CO_2, CH_4, biogenic CH_4 N_2O, and biogenic N_2O (metric tons per year).

(b) Annual quantities fossil fuels by type used in chemical recovery furnaces and chemical recovery combustion units in short tons for solid fuels, gallons for liquid fuels and scf for gaseous fuels.

(c) Annual mass of the spent liquor solids combusted (short tons per year), and basis for determining the annual mass of the spent liquor solids combusted (whether based on T650 om-05 Solids Content of Black Liquor, TAPPI (incorporated by reference, see §98.7) or an online measurement system).

(d) The high heat value (HHV) of the spent liquor solids used in Equation AA-1 of this subpart (mmBtu per kilogram).

(e) The default emission factor for CO_2, CH_4, or N_2O, used in Equation AA-1 of this subpart (kg CO_2, CH_4, or N_2O per mmBtu).

(f) The carbon content (CC) of the spent liquor solids, used in Equation AA-2 of this subpart (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).

(g) Annual quantities of fossil fuels by type used in pulp mill lime kilns in short tons for solid fuels, gallons for liquid fuels and scf for gaseous fuels.

(h) Make-up quantity of $CaCO_3$ used for the reporting year (metric tons per year) used in Equation AA-3 of this subpart.

(i) Make-up quantity of Na_2CO_3 used for the reporting year (metric tons per year) used in Equation AA-3 of this subpart.

(j) Annual steam purchases(pounds of steam per year).

(k) Annual production of pulp and/or paper products produced (metric tons).

§98.277 Records that must be retained.

Subpart AA—Pulp and Paper Manufacturing

In addition to the information required by §98.3(g), you must retain the records in paragraphs (a) through (f) of this section.

(a) GHG emission estimates (including separate estimates of biogenic CO_2) for each emissions source listed under §98.270(b).

(b) Annual analyses of spent pulping liquor HHV for each chemical recovery furnace at kraft and soda facilities.

(c) Annual analyses of spent pulping liquor carbon content for each chemical recovery combustion unit at a sulfite or semichemical pulp facility.

(d) Annual quantity of spent liquor solids combusted in each chemical recovery furnace and chemical recovery combustion unit, and the basis for detemining the annual quantity of the spent liquor solids combusted (whether based on T650 om–05 Solids Content of Black Liquor, TAPPI (incorporated by reference, see §98.7) or an online measurement system). If an online measurement system is used, you must retain records of the calaulations used to determine the annual quantity of spent liquor solids combusted from the continuous measurements.

(e) Annual steam purchases.

(f) Annual quantities of makeup chemicals used.

Subpart AA—Pulp and Paper Manufacturing

§98.278 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Table AA-1 of Subpart AA—Kraft Pulping Liquor Emissions Factors for Biomass-Based CO_2, CH_4, and N_2O.

Wood Furnish	Biomass-Based Emissions Factors (kg/mmBtu HHV)		
	CO_2[a]	CH_4	N_2O
North American Softwood	94.4	0.030	0.005
North American Hardwood	93.7		
Bagasse	95.5		
Bamboo	93.7		
Straw	95.1		

[a] Includes emissions from both the recovery furnace and pulp mill lime kiln.

Table AA-2 of Subpart AA—Kraft Lime Kiln and Calciner Emissions Factors for Fossil Fuel-Based CO_2, CH_4, and N_2O

Fuel	Fossil Fuel-Based Emissions Factors (kg/mmBtu HHV)					
	Kraft Lime Kilns			Kraft Calciners		
	CO_2	CH_4	N_2O	CO_2	CH_4	N_2O
Residual Oil	76.7	0.0027	0	76.7	0.0027	0.0003
Distillate Oil	73.5			73.5		0.0004
Natural Gas	56.0			56.0		0.0001
Biogas	0			0		0.0001

Subpart CC—Soda Ash Manufacturing

§98.290 Definition of the source category.

A soda ash manufacturing facility is any facility with a manufacturing line that produces soda ash by one of the methods in paragraphs (a) through (c) of this section:

(a) Calcining trona.

(b) Calcining sodium sesquicarbonate.

(c) Using a liquid alkaline feedstock process that directly produces CO_2.

In the context of the soda ash manufacturing sector, “calcining” means the thermal/chemical conversion of the bicarbonate fraction of the feedstock to sodium carbonate.

§98.291 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a soda ash manufacturing process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.292 GHGs to report.

You must report:

(a) CO_2 process emissions from each soda ash manufacturing line combined.[1]

(b) CO_2 combustion emissions from each soda ash manufacturing line.

---

[1]Clarification – if CO_2 generated during calcination is recycled to carbonation towers, these calculated process emissions will be adjusted by the measured quantity of recycled CO_2 determined by the method identified in §98.293(d).

(c) CH_4 and N_2O combustion emissions from each soda ash manufacturing line. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(d) CO_2, CH_4, and N_2O emissions from each stationary combustion unit other than soda ash manufacturing lines. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

§98.293 Calculating GHG emissions.

You must calculate and report the annual process CO_2 emissions from each soda ash manufacturing line using the procedures specified in paragraph (a) or (b) of this section.

(a) For each soda ash manufacturing line that meets the conditions specified in §98.33(b)(4)(ii) or (b)(4)(iii), you must calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(b) For each soda ash manufacturing line that is not subject to the requirements in paragraph (a) of this section, calculate and report the process CO_2 emissions from the soda ash manufacturing line by using the procedure in either paragraphs (b)(1), (b)(2), or (b)(3) of this section; and the combustion CO_2 emissions using the procedure in paragraph (b)(4) of this section.

(1) Calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(2) Use either Equation CC-1 or Equation CC-2 of this section to calculate annual CO_2 process emissions from each manufacturing line that calcines trona to produce soda ash:

$$E_k = \sum_{n=1}^{12} [(IC_T)_n * (T_t)_n] * \frac{2000}{2205} * \frac{0.097}{1} \qquad \text{(Eq. CC-1)}$$

$$E_k = \sum_{n=1}^{12} [(IC_{sa})_n * (T_{sa})_n] * \frac{2000}{2205} * \frac{0.138}{1} \qquad \text{(Eq. CC-2)}$$

Where:

E_k = Annual CO_2 process emissions from each manufacturing line, k (metric tons).

$(IC_T)_n$ = Inorganic carbon content (percent by weight, expressed as a decimal fraction) in trona input, from the carbon analysis results for

		month n. This represents the ratio of trona to trona ore.
$(IC_{sa})_n$	=	Inorganic carbon content(percent by weight, expressed as a decimal fraction) in soda ash output, from the carbon analysis results for month n. This represents the purity of the soda ash produced.
$(T_t)_n$	=	Mass of trona input in month n (tons).
$(T_{sa})_n$	=	Mass of soda ash output in month n (tons).
2000/2205	=	Conversion factor to convert tons to metric tons.
0.097/1	=	Ratio of ton of CO_2 emitted for each ton of trona.
0.138/1	=	Ratio of ton of CO_2 emitted for each ton of soda ash produced.

(3) Site-specific emission factor method. Use Equations CC-3, CC-4, and CC-5 of this section to determine annual CO_2 process emissions from manufacturing lines that use the liquid alkaline feedstock process to produce soda ash. You must conduct an annual performance test and measure CO_2 emissions and flow rates at all process vents from the mine water stripper/evaporator for each manufacturing line and calculate CO_2 emissions as described in paragraphs (b)(3)(i) through (b)(3)(iv) of this section.

(i) During the performance test, you must measure the process vent flow from each process vent during the test and calculate the average rate for the test period in metric tons per hour.

(ii) Using the test data, you must calculate the hourly CO_2 emission rate using Equation CC-3 of this section:

$$ER_{CO2} = [(C_{co2} * 10000) * 2.59x10^{-9} * 44] * (Q * 60) * 4.53x10^{-4} \quad \text{(Eq. CC-3)}$$

Where:

ER_{CO2}	=	CO_2 mass emission rate (metric tons/hour).
C_{CO2}	=	Hourly CO_2 concentration (percent CO_2) as determined by §98.294(c).
10000	=	Parts per million per percent
2.59×10^{-9}	=	Conversion factor (pounds-mole/dscf/ppm).
44	=	Pounds per pound-mole of carbon dioxide.
Q	=	Stack gas volumetric flow rate per minute (dscfm).
60	=	Minutes per hour
4.53×10^{-4}	=	Conversion factor (metric tons/pound)

(iii) Using the test data, you must calculate a CO_2 emission factor for the process using Equation CC-4 of this section:

$$EF_{CO2} = \frac{ER_{CO2}}{(V_t * 4.53x10^{-4})} \quad \text{(Eq. CC-4)}$$

Where:

EF_{CO2}	=	CO_2 emission factor (metric tons CO_2/metric ton of process vent flow from mine water stripper/evaporator).
ER_{CO2}	=	CO_2 mass emission rate (metric tons/hour).
V_t	=	Process vent flow rate from mine water stripper/evaporator during annual performance test (pounds/hour).
4.53×10^{-4}	=	Conversion factor (metric tons/pound)

(iv) You must calculate annual CO_2 process emissions from each manufacturing line using Equation CC-5 of this section:

$$E_k = EF_{CO2} * (V_a * 0.453) * H \qquad \text{(Eq. CC-5)}$$

Where:

E_k	=	Annual CO_2 process emissions for each manufacturing line, k (metric tons).
EF_{CO2}	=	CO_2 emission factor (metric tons CO_2/metric ton of process vent flow from mine water stripper/evaporator).
V_a	=	Annual process vent flow rate from mine water stripper/evaporator (thousand pounds/hour).
H	=	Annual operating hours for the each manufacturing line.
0.453	=	Conversion factor (metric tons/thousand pounds).

(4) Calculate and report under subpart C of this part (General Stationary Fuel Combustion Sources) the combustion CO_2, CH_4, and N_2O emissions in the soda ash manufacturing line according to the applicable requirements in subpart C.

§98.294 Monitoring and QA/QC requirements.

Section 98.293 provides ~~three~~ four different procedures for emission calculations. The appropriate paragraphs (a) through (~~c~~d) of this section should be used for the procedure chosen.[2]

---

[2]For plants that recycle CO_2 generated during calcination to carbonation towers, WCI requested that CEMS be installed in the recycle loop to measure the quantity of recycled CO_2. As a result, an additional method was added to §98.293(d). The resulting measurement of the quantity of recycled CO_2 was also added to §98.296(a)(5) and §98.296(b)(12).

Subpart CC—Soda Ash Manufacturing

(a) If you determine your emissions using §98.293(b)(2) (Equation CC-1 of this subpart) you must:

(1) Determine the monthly inorganic carbon content of the trona from a weekly composite analysis for each soda ash manufacturing line, using a modified version of ASTM E359-00(Reapproved 2005)e1, Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate) (incorporated by reference, see §98.7). ASTM E359-00(Reapproved 2005)e1 is designed to measure the total alkalinity in soda ash not in trona. The modified method of ASTM E359-00 adjusts the regular ASTM method to expresse the results in terms of trona. Although ASTM E359-00(Reapproved 2005)e1 uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of trona input produced by each soda ash manufacturing line on a monthly basis using belt scales or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of trona consumed.

(b) If you calculate CO_2 process emissions based on soda ash production (§98.293(b)(2)Equation CC-2 of this subpart), you must:

(1) Determine the inorganic carbon content of the soda ash (i.e., soda ash purity) using ASTM E359-

00(Reapproved 2005)e1 Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate) (incorporated by reference, see §98.7). Although ASTM E359-00(Reapproved 2005)e1 uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of soda ash produced by each soda ash manufacturing line on a monthly basis using belt scales, by weighing the soda ash at the truck or rail loadout points of your facility, or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of soda ash produced.

(c) If you calculate CO_2 emissions using the site-specific emission factor method in §98.293(b)(3), you must:

(1) Conduct an annual performance test that is based on representative performance (i.e., performance based on normal operating conditions) of the affected process.

(2) Sample the stack gas and conduct three emissions test runs of 1 hour each.

(3) Conduct the stack test using EPA Method 3A at 40 CFR part 60, appendix A-2 to measure the CO_2 concentration, Method 2, 2A, 2C, 2D, or 2F at 40 CFR part 60, appendix A-1 or Method 26 at 40 CFR part 60, appendix A-2 to determine the stack gas volumetric flow rate. All QA/QC procedures

specified in the reference test methods and any associated performance specifications apply. For each test, the facility must prepare an emission factor determination report that must include the items in paragraphs (c)(3)(i) through (c)(3)(iii) of this section.

(i) Analysis of samples, determination of emissions, and raw data.

(ii) All information and data used to derive the emissions factor(s).

(iii) You must determine the average process vent flow rate from the mine water stripper/evaporater during each test and document how it was determined.

(4) You must also determine the the annual vent flow rate from the mine water stripper/evaporater from monthly information using the same plant instruments or procedures used for accounting purposes (i.e., volumetric flow meter).

(d) If you recycle CO_2 generated during calcination to carbonation towers, then you must install a CEMS in the recycle loop and measure this quantity of CO_2.

§98.295 Procedures for estimating missing data.

For the emission calculation methodologies in §98.293(b)(2)and (b)(3), a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., inorganic carbon content values, etc.).

Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in the paragraphs (a) through (d) of this section. You must document and keep records of the procedures used for all such missing value estimates.

(a) For each missing value of the weekly composite of inorganic carbon content of either soda ash or trona, the substitute data value shall be the arithmetic average of the quality-assured values of inorganic carbon contents from the week immediately preceding and the week immediately following the missing data incident. If no quality-assured data on inorganic carbon contents are available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon contents obtained after the missing data period.

(b) For each missing value of either the monthly soda ash production or the trona consumption, the substitute data value shall shall be the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes.

(c) For each missing value collected during the performance test (hourly CO_2 concentration, stack gas volumetric flow rate, or average process vent flow from mine water stripper/evaporator during performance test), you must repeat the annual performance test following the calculation and monitoring and QA/QC requirements under §§98.293(b)(3) and 98.294(c).

(d) For each missing value of the monthly process vent flow rate from mine water stripper/evaporator, the subsititute data value shall be the best available estimate(s) of the parameter(s), based on all available process data or the lesser of the maximum capacity of the system or the maximum rate the meter can measure.

§98.296 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information specified in paragraphs (a) or (b) of this section, as appropriate for each soda ash manufacturing facility.

(a) If a CEMS is used to measure CO_2 emissions, then you must report under this subpart the relevant information required under §98.36 and the following information in this paragraph (a):

(1) Annual consumption of trona or liquid alkaline feedstock for each manufacturing line (metric tons).

(2) Annual production of soda ash for each manufacturing line (tons).

(3) Annual production capacity of soda ash for each manufacturing line (tons).

(4) Identification number of each manufacturing line.

(5) Annual quantity of generated CO_2 recycled to carbonation towers (tons), if applicable.

(b) If a CEMS is not used to measure CO_2 emissions, then you must report the information listed in this paragraph (b):

(1) Identification number of each manufacturing line.

(2) Annual process CO_2 emissions from each soda ash manufacturing line (metric tons).

(3) Annual production of soda ash (tons).

(4) Annual production capacity of soda ash for each manufacturing line (tons).

(5) Monthly consumption of trona or liquid alkaline feedstock for each manufacturing line (tons).

(6) Monthly production of soda ash for each manufacturing line (metric tons).

(7) Inorganic carbon content factor of trona or soda ash (depending on use of Equations CC-1 or CC-2 of this subpart) as measured by the applicable method in §98.294(b) or (c) for each month (percent by weight expressed as a decimal fraction).

(8) Whether CO_2 emissions for each manufacturing line were calculated using a trona input method as described in Equation CC-1 of this subpart, a soda ash output method as described in Equation CC-2 of this subpart, or a site-specific emission factor method as described in Equations CC-3 through CC-5 of this subpart.

(9) Number of manufacturing lines located used to produce soda ash.

(10) If you produce soda ash using the liquid alkaline feedstock process and use the site-specific emission factor method (§98.293(b)(3)) to estimate emissions then you must report the following relevant information:

(i) Stack gas volumetric flow rate per minute (dscfm)

(ii) Hourly CO_2 concentration (percent CO_2)

(iii) CO_2 emission factor (metric tons CO_2/metric tons of process vent flow from mine water stripper/evaporator).

(iv) CO_2 mass emission rate (metric tons/hour).

(v) Average process vent flow from mine water stripper/evaporater during performance test (pounds/hour).

(vi) Annual process vent flow rate from mine stripper/evaporator (thousand pounds/hour).

(vii) Annual operating hours for each manufacturing line used to produce soda ash using liquid alkaline feedstock (hours).

(11) Number of times missing data procedures were used and for which parameter as specified in this paragraph (b)(11):

(i) Trona or soda ash (number of months).

(ii) Inorganic carbon contents of trona or soda ash (weeks).

(iii) Process vent flow rate from mine water stripper/evaporator (number of months).

(iv) Stack gas volumetric flow rate during performance test(number of times).

(v) Hourly CO_2 concentration (number of times).

(vi) Average vent process vent flow rate from mine stripper/evaporator during performance test (number of times).

(12) Annual quantity of generated CO_2 recycled to carbonation towers (tons), if applicable.

§98.297 Records that must be retained.

In addition to the records required by §98.3(g), you must retain the records specified in paragraphs (a) and (b) of this section for each soda ash manufacturing line.

Subpart CC—Soda Ash Manufacturing

(a) If a CEMS is used to measure CO_2 emissions, then you must retain under this subpart the records required for the Tier 4 Calculation Methodology specified in subpart C of this part and the information listed in this paragraph (a):

(1) Monthly production of soda ash (tons)

(2) Monthly consumption of trona or liquid alkaline feedstock (tons)

(3) Annual operating hours (hours).

(b) If a CEMS is not used to measure emissions, then you must retain records for the information listed in this paragraph (b):

(1) Records of all analyses and calculations conducted for determining all reported data as listed in §98.296(b).

(2) If using Equation CC-1 or CC-2 of this subpart, weekly inorganic carbon content factor of trona or soda ash, depending on method chosen, as measured by the applicable method in §98.294(b)(percent by weight expressed as a decimal fraction).

(3) Annual operating hours for each manufacturing line used to produce soda ash (hours).

(4) You must document the procedures used to ensure the accuracy of the monthly trona consumption or soda ash

prodcution measurements including, but not limited to, calibration of weighing equipment and other measurement devices. The estimated accuracy of measurements made with these devices must also be recorded, and the technical basis for these estimates must be provided.

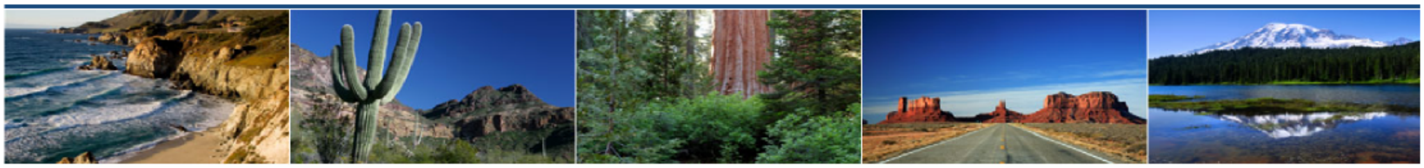
(5) If you produce soda ash using the liquid alkaline feedstock process and use the site-specific emission factor method to estimate emissions (§98.293(b)(3)) then you must also retain the following relevant information:

(i) Records of performance test results.

(ii) You must document the procedures used to ensure the accuracy of the annual average vent flow measurements including, but not limited to, calibration of flow rate meters and other measurement devices. The estimated accuracy of measurements made with these devices must also be recorded, and the technical basis for these estimates must be provided.

§98.298 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.



§WCI.8 REQUIREMENTS FOR VERIFICATION OF GREENHOUSE GAS EMISSIONS DATA REPORTS AND REQUIREMENTS APPLICABLE TO EMISSIONS DATA VERIFIERS (UPDATED FOR USE IN U.S. JURISDICTIONS TO CONFORM TO HARMONIZED ERS)

Note: The verification requirements laid out in this section strive for consistency with ISO 14064-3[1] requirements and set forth a high standard for verification that will ultimately support a WCI cap and trade program. Due to differences in rulemaking procedures between jurisdictions, Supplement 1 provides supplemental text that jurisdictions must incorporate into either the jurisdiction's prescriptive rule language, replacing more general procedural language in Section WCI.8, or into enforceable guidance documents. There are notes in WCI.8 that direct readers to appropriate text in Verification Supplement 1 when applicable.

It would be ideal for all jurisdictions to enforce the same requirements and have the same implementation processes for accreditation and verification to ensure that consistent accurate data exists throughout the WCI regional program. Reporters and verifiers with operations throughout the WCI region will benefit from a consistent approach and such an approach would facilitate administration of the verification requirements by a central body or designee.

(a) Applicability and Scope.

(1) Except as provided in WCI.8(a)(2) through (4) owners or operators [Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices] are required to obtain annual verification for a facility that emits 25,000 metric tons CO_2e or more per year in combined emissions from one or more of the source categories listed in ~~WCI.1~~section 98.2 in any calendar year starting on or after 2010.

(2) When the operation of a facility, fuel supplier, or electricity importer subject to the requirements of this section is changed such that the operator has reported less than 25,000 metric tons of CO_2e emissions for a calendar year, the operator shall obtain verification of annual emissions reports for the lesser of three subsequent calendar years or for those years remaining in the current compliance period. If CO_2e emissions of a facility, fuel supplier, or electricity importer subject to the requirements of this section

1 ISO (2006) ISO 14064-3: Greenhouse Gases-Part 3: Specification with guidance for the validation and verification of greenhouse gas assertions, March, 2006, International Organization for Standardization, Switzerland.

again exceed 25,000 metric tons in any calendar year the provisions of WCI.8(a)(1) apply.

(3) Carbon dioxide emissions from the combustion of biomass fuels shall be included in the determination regarding verification applicability, with the following exceptions:

(A) Until such time as [the jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, a maximum of 15,000 metric tons of carbon dioxide emissions from the combustion of pure solid biomass fuel may be excluded from calculation of GHG emissions for comparison to the 25,000 metric ton CO_2e per year verification threshold in paragraph (a) of this section.

(B) After such time as [the jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, the carbon dioxide emissions from the combustion of those fuels may be excluded from calculation of GHG emissions for determining whether the 25,000 metric tons CO_2e per year verification threshold in paragraph (a)(1) of this section has been met.

[Under Design Recommendation 1.3, carbon neutral biomass will be excluded from the cap-and-trade program. A WCI Partner jurisdiction, however, may, in its discretion, choose to require carbon dioxide emissions from the combustion of biomass fuel to be included in the determination of the verification threshold in order to obtain a complete inventory of the fuels being combusted in the jurisdiction.]

(4) Owners or operators may exclude carbon dioxide emissions from the combustion of biomass fuels that [jurisdiction] has deemed carbon neutral from the scope of verification.

[A WCI Partner jurisdiction may, in its discretion, choose to require carbon dioxide emissions from the combustion of biomass fuel to be included in the scope of verification.]

(5) Notwithstanding WCI.8(a)(2) and (3), any facility, fuel supplier or electricity importer subject to a cap-and-trade program for CO_2e emissions established by [the jurisdiction] shall obtain verification of reported annual emissions.

(b) Requirements for Annual Verification of Emissions Data Reports.

(1) Verification bodies shall conduct verification processes and design verification procedures to determine whether there is a reasonable level of assurance for each separate emissions data report every year of the verification cycle. The verification team shall find that there is a reasonable level of assurance for an emissions data report if the report

(A) contains no material misstatement; and

(B) conforms to the requirements of this article.

(2) The verification body must provide verification services in compliance with WCI.8.

(3) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification shall be subject to full verification requirements in the first year that verification is required for an emissions data report. Upon completion of a positive verification statement under full verification requirements, the facility owner or operator, fuel supplier, or electricity importer may be eligible for two years of less

intensive verification services as ~~described~~ defined in section WCI.8(x)~~9~~. This cycle may be repeated in subsequent three-year cycles; however, full verification requirements shall apply at least once every three years.

(4) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification will be required to obtain full verification services if any of the following apply:

(A) There has been a change in the verification body from the previous year; or

(B) A verification body issued an adverse verification statement for that facility's previous year's emissions data report.

(c) Accreditation Requirements for Verification Bodies.

(1) The accreditation requirements specified in this subsection shall apply to all verification bodies that wish to provide verification services under this rule.

(2) A verification body is qualified to conduct verification services for the WCI if

(A) it has demonstrated knowledge of the WCI reporting requirements; and

(B) it is accredited to ISO 14065 through a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum.

[Note the details of the WCI's specific accreditation process for verification bodies (which has yet to be developed) will be consistent with ISO 14065 through an accreditation program that will developed under ISO 17011 and will include demonstrated knowledge of the WCI reporting requirements. The WCI will explore additional accreditation requirements and/or other criteria for individual lead verifiers, general verifiers, and/or sector specialists.]

(3) Prior to January 1, 2013, accreditation by the California Air Resources Board under Title 17, California Code of Regulation, section 95132, may be substituted for the accreditation required under WCI.8(c)(2)(B).

(d) Requirements for Verification Services. The following verification services must be provided for each emissions data report.

(1) As part of the verification services, the verification team shall review documents submitted, assess risks of a material misstatement, develop a verification plan (that includes a sampling plan), evaluate the emissions data report against the verification requirements, and assess the materiality of errors, omissions and misstatements identified.

(2) The verification team shall request any information and documents needed for verification services. Such information shall include, but is not limited to original records and supporting data for the emissions data report.

(e) A verification team must include the following:

(1) a Lead Verifier;

(2) an Independent Peer Reviewer;

(3) any subcontractor elected to provide verification services under WCI.8(f).

(f) Subcontracting. The following requirements shall apply to any verification body that elects to subcontract verification services.

(1) The primary verification body must assume full legal responsibility for verification services performed by subcontracted verifiers or verification bodies.

(2) A verification body or verifier acting as a subcontractor to the primary verification body will not further subcontract that same work to another firm or individual.

(3) A verification body or verifier acting as a subcontractor is subject to all Conflict of Interest requirements in Section WCI.8(g).

(4) A verification body or verifier acting as a subcontractor must be identified by the primary verification body as part of the verification team.

(g) Conflict of Interest Requirements for Verification Bodies. The conflict of interest provisions of this section shall apply to the verification body, entities related to the verification body, and the verification team accredited according to the requirements of the WCI to perform verification services for the WCI program. Member for purposes of this section means any employee or subcontractor of the verification body or entities related to the verification body. Member also includes any individual with a majority equity share in the verification body or entities related to the verification body.

(1) Prior to a jurisdiction accepting a verification statement, and prior to a jurisdiction accepting the associated emissions report for consideration for approval, the AVA must determine that the verification body has a low potential for conflict of interest as described under WCI.8(g)(6). To inform this determination by the AVA, a self-evaluation of the potential for any conflict of interest that the verification body, entities related to the verification body, and members of the verification team, including subcontractors, may have with the owner or operator or their related entities for which verification services will be or have been provided shall be submitted to the AVA. This self-evaluation must include an evaluation of any threats to the verification body's independence including: [*note: a standardized Conflict of Interest Assessment form will be developed for the WCI*]

[To facilitate timely determinations of conflict-of-interest potential, and to reduce the risk of finding medium or high conflict-of-interest potential after verification services have been initiated, it is recommended that jurisdictions require that the self evaluations be submitted and evaluated by the AVA prior to the initiation of verification services. A jurisdiction may elect to allow verification services to commence prior to the determination of the conflict-of-interest potential by the AVA.]

(A) Threats created by the reporting operation offering inducements to the verification body, subcontractors or verification team members for a positive opinion;

(B) Threats created by members of the verification body, verification team members, subcontractors, or family of subcontractors or team members having a financial interest in the reporting operation or its operator;

(C) Threats created by members of the verification body reviewing work of the verification body, subcontractors, members of the verification team, or related companies, including but not limited to any situation where the body, subcontractors, team members or companies have provided services related to greenhouse gases;

(D) Threats created by members of the verification body, verification team members, or subcontractors having a close relationship with the reporting operation, such that they might become too sympathetic to the interests of the reporting operation; and

(E) Threats created by members of the verification body, verification team members, or subcontractors being deterred from acting objectively or exercising professional skepticism by threats, actual or perceived, from the reporting operation.

(2) The verification body shall deem the potential for conflict of interest to be low if

(A) No threats as listed in WCI.8(g)(1) exist, and

(B) Any non-verification services provided by the verification body to the owner or operator within the last three years are valued at less than five percent of the verification body's annual revenue in each of those years.

(3) The verification body shall deem the potential for conflict of interest to be high if threats as listed in WCI.8(g)(1)(A) or (E) exist.

[A jurisdiction may expand the list of high threats (i.e. un-mitigatable conflicts) with the items included in paragraph 2 of the Conflict of Interest section of Supplement 1 below.]

(4) The verification body shall deem the potential for a conflict of interest to be medium if the potential for a conflict of interest is not deemed to be either low or high as specified in sections WCI.8(g)(2)-(3).

(5) If a verification body deems the potential for conflict of interest to be medium and wishes to provide verification services for the owner or operator, then the verification body shall submit, in addition to the self-evaluation, a plan to avoid, neutralize, or mitigate the potential conflict of interest situation.

(6) Conflict of Interest Determinations. The AVA shall review the self-evaluation submitted by the verification body and determine the verification body's potential conflict of interest in performing verification services for the owner or operator.

[In addition to the AVA determination, a jurisdiction may elect to conduct audits of conflict of interest submissions for compliance verification and enforcement purposes.]

(A) The AVA shall notify the verification body in writing when the conflict of interest evaluation information submitted under section WCI.8(g)(1) is deemed complete. Within 45 days after deeming the evaluation information complete, the AVA shall determine the conflict-of-interest potential and shall notify the verification body or owner or operator if the potential conflict of interest is determined to be medium or high.

(B) If the AVA determines the verification body or any member of the verification team has any threats specified in section WCI.8(g)(1), the AVA shall find a high potential conflict of interest and verification services may not proceed.

(C) If the AVA determines that there is a low potential conflict of interest prior to the verification services being provided, verification services may proceed.

(D) If the AVA determines that the verification body and verification team have a medium potential for a conflict of interest, the AVA shall evaluate the conflict of interest mitigation plan and may request additional information from the applicant to complete the determination. In determining potential conflict of interest, the AVA may consider factors including, but not limited to, the nature of previous work performed, the current and past relationships between the verification body and its subcontractors with the owner or operator, and the cost of the verification services to be performed. The AVA will determine whether these factors when considered in combination with the mitigation plan demonstrate a low level of potential conflict of interest or a high level. If the AVA determines that there is a low potential conflict of interest prior to the verification services being initiated, verification services may proceed. If a high potential is determined prior to verification services being initiated, verification services may not proceed. If a high potential is determined after verification services have been initiated, the verification statement shall not be accepted..

(7) Monitoring Conflict of Interest Situations.

(A) After commencement of verification services, the verification body shall monitor and immediately make full disclosure in writing to the AVA regarding any potential for a conflict of interest situation that arises. This disclosure shall include a description of actions that the verification body has taken or proposes to take to avoid, neutralize, or mitigate the potential for a conflict of interest.

(B) The verification body shall monitor arrangements or relationships that may be present for a period of one year after the completion of verification services. During that period, within 30 calendar days of any change in arrangements or relationships with the owner or operator for which the verification body has provided verification services that may create a medium or high threat of conflict of interest, the verification body shall notify the AVA of the change and provide a description of the nature of the change. The AVA will make a conflict of interest determination under WCI.8(g)(6).

(C) The verification body shall report to the AVA any changes in its organizational structure, including mergers, acquisitions, or divestitures that may have created a medium or high threat of conflict of interest for one year after completion of verification services within 30 days and submit an evaluation of how the change(s) impacts the potential for conflict of interest.

(D) The AVA may invalidate a verification finding if a medium or high threat of a conflict of interest has arisen for the verification body or any member of the verification team and, in the case of a medium threat, the threat has not been adequately mitigated. In such a case, the owner or operator shall be provided 180 calendar days to have their emissions report verified by a different verification body.

(E) If the verification body or its subcontractor(s) are found to have violated the conflict of interest requirements of this section, the AVA may rescind its accreditation for any appropriate period of time . Additionally, the AVA may separately revoke its recognition of an accredited Verification Body under WCI.8(w). *[The WCI intends to develop more detailed accreditation requirements in the future.]*

(h) Notice of Verification Services. Prior to commencing verification services for a facility owner or operator, fuel supplier, and electricity importer, the verification body shall submit a notice of verification services to the AVA. Verification activities shall not proceed for 15 business days or until the verification body receives written approval to proceed from the AVA, whichever is earlier. If the AVA does not respond to the verification body within 15 business days, the verification body may begin to conduct verification activities.

[The NOVS form will be standardized across WCI and developed later.]

(i) Verification Plan.

(1) Accounting for requirements set by WCI.8, the verification plan shall document:

(A) the scope of the verification;

(B) the level of assurance;

(C) the verification standard;

(D) the verification criteria;

(E) the objectives of the verification;

(F) the timing of the verification, including site visits;

(G) the nature of the communications required;

(H) the resources required to conduct the verification, including the role of verification team members; and

(I) the nature, timing and extent of the verification procedures, including the sampling plan.

(2) The verification body shall retain the verification plan in paper, electronic, or other format for a period of not less than seven years following the submission of each verification statement.

(j) Site visits. In years for which full verification services are required under WCI.8(b)(3), at least one member of the verification team shall at a minimum make one onsite site visit to each facility or fuel supply location *[Note that exact location of fuel supplier site visits remains TBD]* for which an emissions data report is submitted. The verification team member(s) shall also conduct an onsite visit of the headquarters or other location of central data management, if different from the facility or fuel supply location, when the owner or operator is an electricity importer.

(k) Owners or operators shall make available to the verification team all information and documentation used to calculate and report emissions, electricity transactions, and other information required under this rule, as applicable.

(l) As applicable for electricity importers, the verification team shall review electricity transaction records, including receipts of power attributed to the Northwest or Southwest region as verifiable via North American Electric Reliability Corporation (NERC) E-Tags, settlements data, or other information as confirmation of the region of origin. [*Note that this procedure is subject to change pending WCI Electricity Committee review.*]

(m) Data Checks. To determine the reliability of the submitted emissions data report, the verification team shall use data checks as defined in WCI.~~9~~98(x). Verifiers will use their professional judgment in determining how many data checks are needed to provide a reasonable level of assurance.

(n) Emissions Data Report Modifications. If as a result of review by the verification team and prior to completion of a verification statement the owner or operator chooses to make improvements or corrections to the submitted emissions data report, a revised emissions data report must be submitted to [the jurisdiction] as specified by section WCI.8(q). The owner or operator shall maintain documentation to support any revisions made to the initial emissions data report. Documentation for all emissions data report submittals shall be retained by the operator for seven years pursuant to section ~~WCI.4~~ 98.3(g).

(o) Materiality and Conformance Assessment Criteria. The verifier shall determine if the annual emissions report is prepared in such a way that it satisfies WCI.8(b)(1).

(1) A verification team shall determine that an emission data report contains a material misstatement, if either of the following is true:

(A) Based on the verification team's own determination of the level of emissions subject to verification based on the sampling plan, the verification team concludes that total reported emissions are less than 95 percent accurate using the following equation:

$$PA = 100 - [(SOU/TRE) \cancel{*}\times 100)]$$

Where:

PA	=	Percent accuracy
SOU	=	The net result of summing overstatements and understatements resulting from errors, omissions and misreporting
TRE	=	Total reported emissions

(B) The individual or aggregate effect of one or more errors, omissions or misstatements identified in the course of verification make it probable that the judgment of a reasonable person regarding the total reported emissions would have been changed or influenced by the error, omission or misrepresentation.

(2) To assess conformance with this rule the verification team shall review the methods and factors used to develop the emissions data report for adherence to the requirements of this rule.

(3) The verification team shall keep a log of any issues identified in the course of verification activities that may affect determinations of material misstatement and nonconformance, and how those issues were resolved.

(p) Completion of verification services shall include:

(1) Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall prepare either a positive or adverse verification statement, for each emissions data report, based on its findings during the verification process. The verification body shall provide the verification statement(s) to the reporter and to the AVA [alternatively, this could be the reporter's responsibility to submit the statement to the AVA], according to the schedule specified in section WCI.2(b). Before each statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.

~~Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall complete a verification statement for each emissions data report, and provide that statement to the owner or operator and [the jurisdiction or other body] according to the schedule specified in section WCI.2(b). Before that statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.~~

~~The verification body shall provide either a positive or adverse verification statement to the reporter and to the AVA *[alternatively, this could be the reporter's responsibility to submit the statement to the AVA]* based on its findings during the verification process.~~

(2) The lead verifier in the verification team shall attest on the verification statement that the verification team has carried out all verification services as required by this rule, and the Independent Peer Reviewer shall attest to his or her independent review on behalf of the verification body and his or her concurrence with the verification findings. If the Independent Peer Reviewer does not determine that the verification team has carried out all verification services as required by the rule or if the Independent Peer Reviewer rejects the verification team's findings, then the verification body cannot issue a positive verification statement.

(3) The verification body shall provide to the owner or operator a detailed verification report. The verification report shall at minimum include the detailed comparison of the data checks with the submitted emissions data report, errors, omissions and misstatements identified during the course of the verification, any corrections made to the original annual emissions report as a result of the verification, and observations about the data management systems that are connected to the errors, omissions and misstatements identified, as well as any qualifying comments on findings during verification services. The detailed verification report shall be made available to [the jurisdiction] upon request.

(q) Prior to the verification body providing an adverse verification statement pursuant to WCI.8(p)(2), the owner or operator shall be provided at least 14 working days to modify the emissions data report to correct any material misstatement or nonconformance found by the verification team. The modified report and verification statement must be submitted to [the jurisdiction] before the applicable verification deadline, unless the operator makes a request to [the jurisidiction*]* as follows:

(1) If the owner or operator and the verification body cannot reach agreement on modifications to the emissions data report that result in a positive verification statement, the operator may petition the AVA to make a final decision as to the verifiability of the submitted emissions data report.

(2) If the AVA determines that the emissions data report does not meet the standards and requirements specified in this article, the owner or operator shall have the opportunity to submit within 60 calendar days of the date of this decision *[Note that this time frame may need to be changed pending details of cap-and-trade system design and needs.]* any emissions data report revisions that address the AVA's determination, for re-verification of the emissions data report. In re-verifying a revised emissions data report, the verification body and verification team shall be subject to the requirements in section WCI.8(q)-(s).

(3) Upon provision of the verification statement to [the jurisdiction], the emissions data report shall be considered final and no changes shall be made except as provided in section WCI.8(n) or (q). All verification requirements of this rule shall be considered complete upon provision of the verification statement.

(r) In addition to initiating WCI's dispute resolution process, the operator and verification body must inform the applicable accreditation body of the dispute.

(s) The AVA may make void the positive verification statement submitted by the verification body if:

(1) The AVA finds a high level of conflict of interest existed between a verification body and an owner or operator; or,

(2) An emissions data report that received a positive verification statement fails an audit by the AVA.

(t) Upon request by the AVA, the owner or operator shall provide the data used to generate an emissions data report, including all data available to a verification body. The AVA may also review the full verification report given by the verification body to the owner or operator. The full verification report shall be provided to the AVA upon request.

(u) Upon written notification by the AVA, the verification body shall make itself available for a verification services audit.

(v) Duration of verification services by one verification body. Facility owners or operators, fuel suppliers, or electricity importers subject to annual verification shall not use the same verification body for a period of more than six consecutive years. If a facility owner or operator, fuel supplier, or electricity importer is required or elects to contract with another verification body, they may contract verification services from the previous verification body only after not using the previous verification body for at least three years. If a verification body or verification team member has been providing verification services for an owner or operator in a greenhouse gas reporting or reductions program other than [the jurisdiction's] within the previous three years, those years of services will count towards the six consecutive year limit in this section.

(w) Revocation of Recognition. A jurisdiction may review, and for good cause, work to revoke or modify the accreditation status of a recognized verification body. If a recognized verification body is suspended in any other mandatory or voluntary GHG reporting or trading program, that verification body will not be allowed to provide any verification services until that suspension ends. If a recognized verification body has its accreditation revoked under any other mandatory or voluntary GHG reporting or trading program, that verification body will no longer be allowed to provide verification services under WCI.8 until it is reaccredited.

(x) Definitions. The following definitions shall apply to terms used in this section:

"Accreditation and Verification Authority" or "AVA" means [the jurisdiction] or any entity or entities to which [the jurisdiction] assigns any of the responsibilities for oversight and execution of the accreditation and verification program established in WCI.8.

"Adverse verification statement" means a verification statement rendered by a verification body stating that the verification body cannot conclude that there is a reasonable level of assurance for an emissions data report.

"Conflict of interest" means a situation in which, because of financial or other activities or relationships with other persons or organizations, a person or body is unable or potentially unable to render an impartial verification opinion of a potential client's greenhouse gas emissions, or the person or body's objectivity in performing verification services is or might be otherwise compromised.

"Data check" means an independent calculation or checking of data conducted by a verifier to recreate the emissions for a discreet source included in an emissions data report.

"Full verification" means all verification services as provided in section WCI.8(b).

"Less Intensive Verification" means the verification services provided in interim years between full verifications; less intensive verification only requires risk assessment and data checks on an owner or operator's emissions data report based on the most current sampling plan developed as part of the most current full verification services. This level of verification may only be used if the verifier can provide findings with a reasonable level of assurance.

"Material misstatement" means an error or omission, or a collection of errors or omissions, that results in a determination that a verification statement contains a material misstatement under WCI.8(o)(1)(A) or (B).

"Positive verification statement" means a verification statement rendered by a verification body stating that the verification body can say with reasonable assurance that the submitted emissions data report is free of material misstatement and that the emissions data report conforms to the requirements of this article.

"Verification" means a systematic, independent and documented process for the evaluation of an operator's emissions data report against the WCI's reporting procedures and methods for calculating and reporting GHG emissions.

"Verification body" means a firm accredited by the [Accreditation Body TBD] and recognized by the jurisdiction or its designee, that is able to render a verification statement and provide verification services for operators subject to reporting under this article.

“Verification cycle” means three years of verification activities. Each verification cycle must include at least one year of full verification, and may include two years of less intensive verification, if eligible.

“Verification statement” means the final written declaration rendered by a verification body attesting whether an operator’s emissions data report is free of material misstatement and whether the emissions data report conforms to the requirements of this article.

“Verification services” means services provided during verification as specified in WCI.8, including but not limited to reviewing an operator’s emissions data report, verifying its accuracy according to the standards specified in this article, assessing the operator’s compliance with this rule, and submitting a verification opinion to the *[jurisdiction or its agent]*.

“Verification team” means all of those working for a verification body, including all subcontractors, to provide verification services for an operator.

“Verifier” means an individual employed or contracted by an accredited verification body who has been deemed competent by the verification body to carry out verification services as specified in section WCI.8.

Verification Supplement 1

Note: the additional content in this Supplement must either be included in regulatory text in the appropriate subsections of WCI.8 or enforceable guidance documents by jurisdictions. The language in this section provides further explanation of items required in WCI.8 or alternative, more prescriptive language of those requirements.

Preliminary Activities and Verification Plan

The verification team shall discuss with the owner or operator the scope and objective of the verification services and obtain information from the owner or operator necessary to develop a verification plan. Such information shall include but is not limited to:

- Information to allow the verification team to develop a general understanding of facility or entity boundaries, operations, emissions sources, electricity transactions, as applicable;
- Information about the data management system used to track GHG emissions, electricity transactions, and other required measurement data as applicable;
- Information regarding the training or qualifications of personnel involved in developing the GHG emissions data report;
- Description of the specific methodologies used to quantify and report GHG emissions, electricity transactions, and other required data as applicable;
- Records of measured data related to emissions and operations for the prior and current period;
- Inventory of sources and their associated emissions for the reporting period, and
- Any prior verification reports, if applicable.

In developing the verification plan, the verifier shall:

- Gain an understanding of the organization and the process that emit greenhouse gases;
- Conduct a risk assessment to evaluate inherent, control and detection risk;
- Conduct preliminary analytical testing to identify anomalies in the data;
- Conduct a sensitivity analysis to assess the relative contribution of each source in the inventory to the reported annual emissions, and
- Consider any other relevant developments at the facility, in the regulations, or legal environment.

Sampling Plan

As part of the verification procedures, the verification team shall develop a sampling plan that, when combined with the other verification procedures, provides sufficient and appropriate evidence to allow the verifier to arrive at a conclusion. The sampling plan shall be designed to achieve the specified verification objective. The sample plan shall consider:

- Statistical versus non-statistical approaches
- Design of the sample, including the population characteristics
- Stratification (categorization of population into subgroups)
- Emission weighted selection
- Sample size

- Sample selection

As relevant information becomes available during the course of verification activities, the verification team must modify the sampling plan as necessary to address potential issues emerge of material misstatement or nonconformance with the requirements of this rule.

Data Checks

The verification team conducts data checks throughout the verification process and shall focus first on the largest and most uncertain estimates of emissions and electricity transactions.

- In establishing the verification plan, the verification team shall use professional judgment to determine the number of data checks required for the team to conclude with reasonable assurance whether the reported emissions and transactions are free of material misstatement and the emissions data report otherwise conforms to the requirements of this rule.
- The verification team shall choose emissions sources, and electricity transactions data as applicable, for data checks based on their relative sizes and risks of material misstatement as indicated in the verification plan;
- The verification team, through the conformance assessment, shall ensure that the appropriate methodologies and emission factors have been applied for the emissions sources and electricity transactions for sampled data covered under sections WCI.20 through WCI.XX;

Site Visits

During the site visit, the verification team member(s) shall conduct the following:

- Observe whether all sources at the site are represented in the emissions report as specified in sections WCI.20 to WCI.XX as applicable to the owner or operator.
- Assess whether the source inventory is identified, categorized, and reported appropriately. Collect evidence as to explanations for data anomalies identified in the verification plan.
- Understand the data trail used by the owner or operator to measure, quantify, and report greenhouse gas emissions and, when applicable, electricity transactions.
- Understand and evaluate the associated data controls used by the owner to ensure the completeness and accuracy of the data

Materiality Assessment

In assessing whether misstatements are material, the verification team shall determine whether the total reported emissions are at least 95 percent accurate using the following equation:

Percent accuracy = 100 **–** (sum of (errors, omissions, misreporting) * 100 / (total reported emissions))

To assess conformance with this rule the verification team shall review the methods and factors used to develop the emissions data report for adherence to the requirement of this rule. The verification team shall keep a record of any errors, omissions or misstatements identified in the course of verification activities that may affect determinations of material misstatement and nonconformance, and how those issues were resolved.

Conflict of Interest (*could replace more general procedural language in Section WCI.8*)

(1) Conflict of Interest Submittal Requirements for Accredited Verification Bodies.

(A) Before the start of any work related to providing verification services to an owner or operator, a verification body must first be authorized in writing by *the AVA* to provide verification services. To obtain authorization the verification body shall submit to *the AVA* a self-evaluation of the potential for any conflict of interest that the verification body, entities related to the verification body, and members of the verification team including, subcontractors may have with the owner or operator or their related entities for which it will perform verification services. For the purposes of this section, the term member refers to staff on the verification team, in the verification body and any subcontractors. The submittal shall include the following:

(i) Identification of whether the potential for conflict of interest is high, low, or medium based on factors specified in this section;

(ii) An organizational chart of the business structure of the verification body, including its related entities and brief description of the primary work done by the verification body and related entities;

(iii) iii. Identification of whether any member of the verification body, entities related to the verification body, or the verification team including subcontractors has previously provided verification services for the owner or operator or its related entities and, if so, the years in which such verification services were provided;

(iv) Identification of whether any member of the verification body, entities related to the verification body, or the verification team or including subcontractors has engaged in any non-verification services of any nature with the owner or operator or related entities either within or outside the WCI region during the previous three years. The verification body must also disclose any services listed under section (high COI list) it has provided to the owner or operator, regardless of when these services occurred. If non-verification services have previously been provided, the following information shall also be submitted:

(v) Identification of the nature and location of the work performed for the owner or operator and whether the work is similar to the type of work to be performed during verification, such as emissions inventory auditing, energy efficiency, renewable energy, or other work with implications for the operator's greenhouse gas emissions or the accounting of greenhouse gas emissions or electricity transactions;

(vi) The nature of past, present or future relationships the verification body, entities related to the verification body, and members of the verification team including subcontractors have with the owner or operator or related entity including:

- Instances when any member has performed or intends to perform work for the owner or operator;
- Identification of whether work is currently being performed for the owner or operator and, if so, the nature of the work;

- Whether any member has any contracts or other arrangements to perform work for the owner or operator or a related entity;
- Identify how much work was performed in each of the last three years, as a percentage of the verification body's total gross income for each of the last three years;
- Identify how much work related to greenhouse gases or electricity transactions was has performed for the owner or operator or related entities in each of the last three years, as a percentage of the verification body's income for each of the last three years;
- Identify how much work was performed by each subcontractor for the operator in each of the last three years, as a percentage of each subcontractor's total gross income for each of the last three years.

(vii) Explanation of how the amount and nature of work previously performed is such that any member of the verification team's credibility and lack of bias should not be under question.

(viii) A list of names of the verification team members that will perform verification services for the owner or operator and a description of any instances of personal or family relationships with management or employees of the owner or operator that potentially represent a conflict of interest; and,

(ix) Identification of any other circumstances or relevant information known to the verification body or owner or operator that could result in a conflict of interest, or any situation where the appearance of impartiality could undermine confidence in the verification body's ability to assess the reported emissions.

(2) The potential for a conflict of interest shall be deemed to be high where:

(A) The verification body and owner or operator share any management staff or board of directors membership, or any of the management staff of the owner or operator have been employed by the verification body, or vice versa, within the previous three years; or

(B) Within the previous three years, any member of the verification body, any entity related to the verification body, and the verification team has provided to the owner or operator any of the following non-verification services:

(i) Designing, developing, implementing, or maintaining an inventory or information or data management system for facility greenhouse gases, or, where applicable, electricity transactions;

(ii) Developing greenhouse gas emission factors or other greenhouse gas-related engineering analysis;

(iii) Designing energy efficiency, renewable power, or other projects which explicitly identify greenhouse gas reductions as a benefit;

(iv) Preparing or producing greenhouse gas-related manuals, handbooks, or procedures specifically for the reporting facility;

(v) Appraisal services of carbon or greenhouse gas liabilities or assets;

(vi) Brokering in, advising on, or assisting in any way in carbon or greenhouse gas-related markets;

(vii) Managing any health, environment or safety functions which explicitly identify greenhouse gas reductions as a benefit;

(viii) Bookkeeping or other services related to the accounting records or financial statements, unless those services limited to financial auditing;

(ix) Any service related to information systems, unless those systems will not be part of the verification process and excluding third-party auditor or registration services;

(x) Appraisal and valuation services, both tangible and intangible related to GHG emissions or reductions inventories;

(xi) Fairness opinions and contribution-in-kind reports in which the verification body has provided its opinion on the adequacy of consideration in a transaction, unless the resulting services shall not be part of the verification process;

(xii) Any actuarially oriented advisory service involving the determination of amounts recorded in financial statements and related accounts;

(xiii) Any internal audit service as provided under section (GHG plan) that has been outsourced by the operator that relates to the owner's or operator's internal accounting controls, financial systems or financial statements, unless no consulting or advice was provided as part of the audit;

(xiv) Acting as a broker-dealer (registered or unregistered), promoter or underwriter on behalf of the owner or operator;

(xv) Any legal services related to GHG emissions;

(xvi) Expert services to the owner or operator or his or her legal representative for the purpose of advocating his or her's interests in litigation or in a regulatory or administrative proceeding or investigation involving GHG emissions, unless providing factual testimony.

(C) The potential for a conflict of interest shall also be deemed to be high where any staff member of the verification body, entity related to the verification body, or the verification team has provided verification services for the owner or operator for six consecutive years or within three years of the termination of a previous GHG verification contract with the owner or operator. If a verification body or verification team member has been providing verification services for a [operator/owner] in a greenhouse gas reporting or reductions program other than WCI within the past three years, those years of services will count towards the six consecutive year limit in the WCI.

(D) The potential for a conflict of interest shall be deemed high where the Independent Peer Reviewer for the verification team has provided verification or non-verification services for the operator during the current reporting year.

(3) The potential for a conflict of interest shall be deemed to be low where no potential for a conflict of interest is found under section WCI.8(g) *[may need to be updated, depending upon final version of WCI.8)* and any non-verification services provided by all members of the verification body and the verification team to the owner or operator within the last three years are valued at less than five percent of the verification body's revenue.

****

WCI.8 OPTIONAL GUIDANCE

Note: This text is supporting material and not intended as part of the essential requirements.

Collection of Evidence

The verification body shall obtain sufficient and appropriate evidence to be able to draw reasonable conclusions on which to base the verification statement. The verification body obtains evidence by performing verification procedures. Verification procedures are classified as:

- **Computation (or Recalculation)** is the checking of mathematical accuracy of documents or records
- **Observation** of a process or procedure
- **Confirmation** is obtaining representations from a third party
- **Enquiry** is seeking information from a knowledgeable person
- **Inspection** of Records or Documents/Assets
- **Re-performance** is the verifiers independent execution of procedures or controls
- **Analysis** is the evaluation of information made by studying the plausible relationships among different types of data

Some or all of these techniques can be used to obtain sufficient and appropriate evidence. Site visits are used to obtain evidence that is readily available at that location.

Notice regarding *Electricity Imports, Exports and Leakage in the Eastern WCI Partners: Quebec, Ontario and Manitoba*

The WCI Partners note that, as with any detailed modeling analysis, specific results depend on the assumptions and the characteristics of the model. In particular, as noted by Navigant, while the assumptions around generation represent one of many scenarios, they cannot and do not entirely reflect current reality or the actual future. For example, the model includes new natural gas power plants in Quebec, while Quebec has made clear it has no intention to build new natural gas power plants, as described in the Quebec 2006-2015 Energy Strategy and the Hydro-Quebec Strategic Development Plan. Also, again as noted by Navigant, the model uses fixed demand and generation assets, which in reality would change in response to a cap and trade program.

The results of the study should be taken as indicative of trends and impacts of cap and trade and specifically the potential for leakage in the electricity sector, and do not constitute a forecast of generation or demand for the Partner jurisdictions. The release of this study by the Partner jurisdictions does not represent an endorsement of the specific projections on generation, demand, or trade of electricity.

This Report was prepared for WCI on terms specifically limiting the liability of Navigant Consulting, Inc. ("Navigant Consulting"). Navigant Consulting's conclusions are the results of the exercise of Navigant Consulting's reasonable professional judgment, based in part upon materials provided by WCI's Eastern partners and others.

Any third party reviewing or accessing this Report hereby agrees and acknowledges that (a) no use or distribution of this Report may be made without express prior written consent Navigant Consulting, (b) Navigant Consulting does not make any representations or warranties of any kind with respect to the accuracy or completeness of the information contained in this Report or any conclusions reached by Navigant Consulting as a result of this Report, and (c) any use which you or a third party makes of this Report, or any reliance on it, or decisions to be made based on it, are the responsibility of you or such third party. Navigant Consulting accepts no duty of care or liability of any kind whatsoever to you or any such third party, and all parties waive and release Navigant Consulting for all claims, liabilities and damages, if any, suffered as a result of decisions made, or not made, or actions taken, or not taken, based on this Report.

EXECUTIVE SUMMARY

This report summarizes the results of a study carried out by Navigant Consulting Inc. (NCI) on behalf of the Western Climate Initiative (WCI) from October 2009 – January 2010.

The intention of the study was to address the concern that reductions in fossil-fired generation within WCI Partner jurisdictions resulting from proposed WCI greenhouse gas regulation might be offset by increases in fossil-fired generation in non-WCI jurisdictions that would then be imported into WCI jurisdictions.

The study was designed to quantify the likely level of "leakage" – the ratio of emission increases in non-WCI jurisdictions to emission reductions in WCI Partner jurisdictions – at various levels of allowance costs and deemed emissions rates within the WCI. The study also considered the impact of other existing and proposed greenhouse gas regulations - RGGI (Regional Greenhouse Gas Initiative) and MGGRA (Midwestern Greenhouse Gas Reduction Accord) - to understand how these regulations could affect the potential for leakage.

The analysis required by the WCI was carried out by NCI using PROMOD IV, a commercial electricity market model, to simulate the hourly operation of the regions of the Canadian and US electricity system known as the 'Eastern Interconnect'. The Eastern Interconnect extends from eastern Canada to Florida to the U.S. Midwest and includes the three WCI partners – Manitoba, Ontario, Quebec – relevant for this study. The core of the study was a series of power system market simulations, for 2012 and 2020, with various levels of WCI allowance costs, import charges and regulatory assumptions for CO_2 emissions.

The starting point for the analysis was the definition of a 'Base Case' for 2012 and 2020 which represented a plausible evolution of the Eastern Interconnect – in terms of demand forecasts, fuel price assumptions, generation capacity, and environmental regulations – in the absence of WCI legislation.

Starting with this Base Case, a number of scenarios were defined to examine the effect on generation and emissions in the three Eastern WCI members – Manitoba, Ontario, Quebec – that might result as a consequence of imposing WCI CO_2 allowance charges, import ('First Jurisdictional Deliverer' or FJD) charges, and permitting "contract shuffling" (the ability to apply a zero 'import' charge to non-WCI generation that is sourced from non CO_2-emitting generation). In these scenarios, WCI CO_2 allowance prices ranged from $15 - $60/tonne, and import (FJD) charges were 500 kg/MWh or 1000 kg/MWh, which translated into $7.50 - $30/MWh[1] depending on the scenario. Some scenarios also considered the effect of additional

[1] The maximum FJD charge was $30/MWh, as the combination of $60/tonne CO_2 allowance charge and an FJD charge of 1000 kg/MWh was not in considered in any scenario.

greenhouse regulations, notably RGGI and MGGRA, in neighboring regions, and this involved defining allowance prices and FJD charges appropriate to those regions.

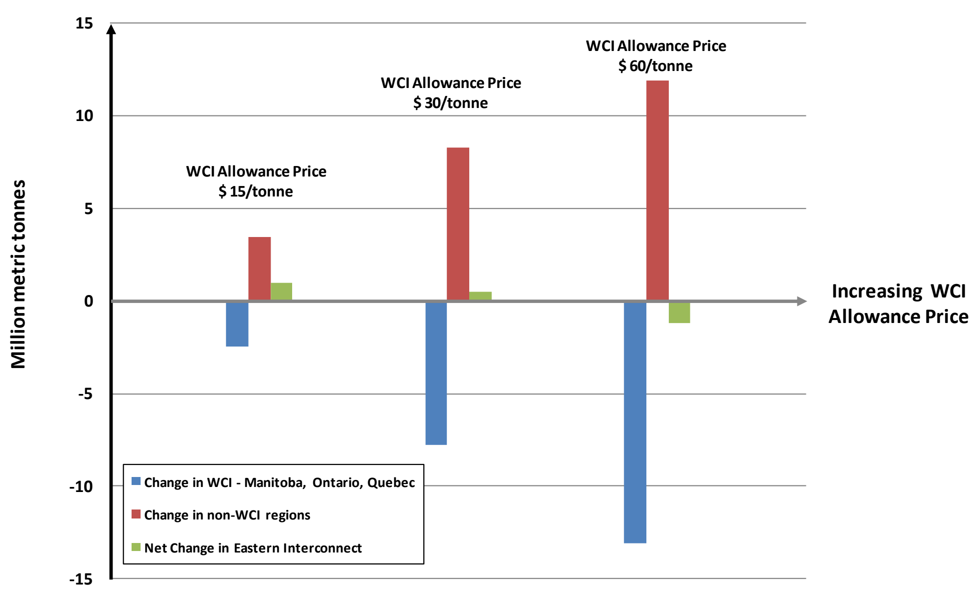
The modeling results showed a large (as much as 48%) decrease in the CO_2 emissions of the three WCI provinces as a result of introducing allowance prices. For scenarios with no corresponding regulation in MGGRA, the decrease in WCI emissions was offset by an increase in non-WCI emissions in every case, resulting in almost no net change in total emissions.

WCI emissions decrease because fossil generation (primarily from coal and gas plants in Ontario) falls when allowance prices are applied. This decrease in WCI generation leads to reduced exports from (or increased imports into) WCI. Non-WCI generation therefore needs to increase, and since only fossil generation has variable output, this means an increase in non-WCI fossil generation and CO_2 emissions. The small changes in total emissions that result are from replacing one type of generation (e.g., gas in Ontario) with another (e.g., coal in Ohio).

Import (FJD) charges reduce the attractiveness of importing power from non-WCI regions. The higher the FJD charge, the lower the imports into WCI, and the greater are the corresponding WCI generation and emissions. However, WCI generation and emissions are much less sensitive to the level of the FJD charge than they are to the WCI allowance price, and less sensitive to FJD charges in 2012 than in 2020.

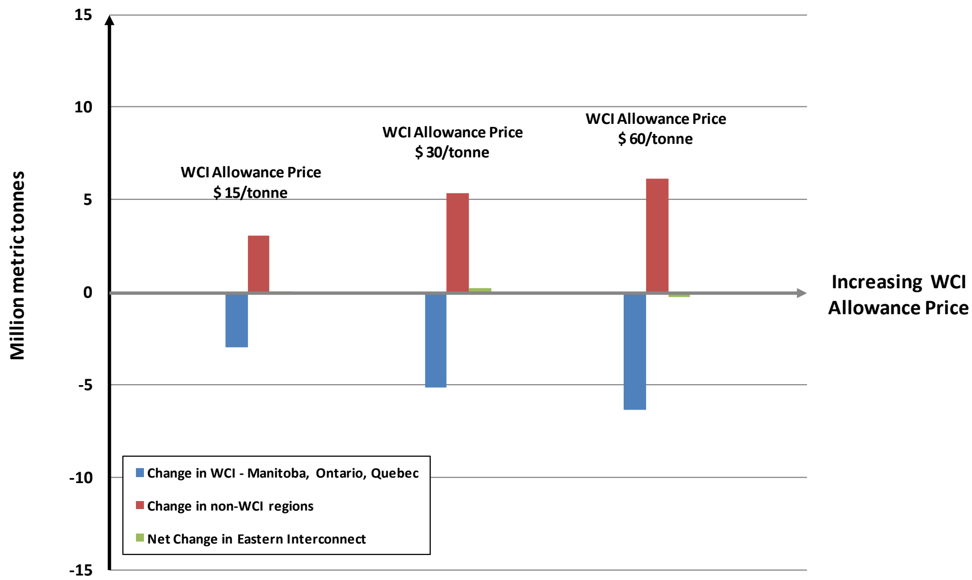
Figures ES-1 and ES-2 show the change in CO_2 emissions for 2012 and 2020 compared to the corresponding Base Case emissions. For clarity, the changes in CO_2 emissions indicated in these figures are averaged across the scenarios with the same WCI allowance prices but different FJD charges.

Figure ES-1: Changes in CO_2 Emissions in 2012 in Response to Allowance Costs



The results for 2020 and 2012 were similar, but the net changes in emissions in 2020 were generally lower across the scenarios. Much of the reduction in WCI emissions in 2012 comes from reductions in Ontario coal generation, as coal generation with a high carbon content is particularly affected by carbon charges. By 2020, all of Ontario's coal plants will have been shut down, making Ontario generation less sensitive to carbon charges.

Figure ES-2: Changes in CO_2 Emissions in 2020 in Response to Allowance Costs



Allowing "contract shuffling" led to a greater reduction in WCI generation and emissions, and a greater increase in non-WCI generation and emissions – i.e., more leakage. The scenarios with "contract shuffling" distinguished between imports from non CO_2-emitting sources and imports from CO_2-emitting sources, and applied a zero charge for imports from non CO_2-emitting sources. This reduced the impact of any given level of FJD charges compared to the simple scenarios where this distinction between imports from different sources was not made.

The scenarios that combined regulation in WCI with regulation in MGGRA and RGGI gave somewhat different results. Firstly, reductions in WCI generation and emissions were much smaller. This is because coordination of price allowances with RGGI and/or MGGRA reduces the incentive to import electricity from non-WCI jurisdictions (the main sources of these imports are RGGI and MGGRA).

The overall CO_2 emissions from the Eastern Interconnect were reduced when there was combined regulation across WCI, MGGRA and RGGI. This was because of a change in generation from coal to gas in MGGRA, and was not directly related to the WCI assumptions. It is a consequence of the effect of the additional allowance cost on the coal and gas MGGRA units.

NAVIGANT CONSULTING

This report for the Western Climate Initiative was prepared by staff from the Toronto and Washington D.C. offices of Navigant Consulting Inc. (NCI).

Navigant Consulting is a specialized independent consulting firm providing professional services to assist clients in identifying practical solutions to the challenges of uncertainty, risk and distress, and has over 1800 professionals in 30 cities.

The Energy Practice, hired by the WCI for this analysis, consists of more than 250 professionals and provides a full range of advisory services for energy sector clients, with particular expertise in clean energy, renewable generation and greenhouse gas issues.

The principal authors of the report were:

- Simon Carr, Director (Washington D.C.)
- Wesley Stevens, Associate Director (Toronto)
- Todd Williams, Director (Toronto)

1. INTRODUCTION

1.1 Background

This report summarizes the results of a study carried out by Navigant Consulting on behalf of the Western Climate Initiative (WCI) from October 2009 – January 2010.

The intention of the study was to address the concern that reductions in fossil-fired generation within WCI Partner jurisdictions resulting from proposed WCI greenhouse gas regulation might be offset by increases in fossil-fired generation in non-WCI jurisdictions that would then be imported into WCI jurisdictions.

The study was designed to quantify the likely level of "leakage" – the ratio of emission increases in non-WCI jurisdictions to emission reductions in WCI Partner jurisdictions – at various levels of allowance costs and deemed emissions rates within the WCI.

The study also considered the possible impact of other existing and proposed greenhouse gas regulations[2], notably RGGI (Regional Greenhouse Gas Initiative) and MGGRA (Midwestern Greenhouse Gas Reduction Accord), to understand how the existence of other greenhouse gas regulations could affect the potential for leakage.

The study, and the associated modeling of Canadian and U.S. electricity markets carried out by Navigant Consulting, was focused on the WCI members in Eastern Canada – Manitoba, Ontario and Quebec.

The report is structured as follows:

- **Introduction**, covering the background and objectives of the study
- **Modeling Methodology for WCI Study**, describing the PROMOD IV software and the demand, fuel price, generation and other assumptions used in the analysis
- **WCI Scenarios without Contract Shuffling**, which covers scenarios that do not involve contract shuffling or the effects of RGGI and MGGRA CO_2 regulation
- **WCI Scenarios with Contract Shuffling**, which covers the scenarios that involve contract shuffling and/or the effects of RGGI and MGGRA CO_2 regulation
- **Conclusions,** which summarizes Navigant's conclusions from the analysis of the various scenarios

[2] WCI – http://www.westernclimateinitiative.org/
MGGRA - http://www.midwesternaccord.org/
RGGI - http://www.rggi.org/home

- **Appendices**, which contain tables with more detailed results than shown in the body of the report

1.2 Scope of the Study

The Scope of Work defined by WCI stated:

"Under the Western Climate Initiative (WCI) Cap and Trade program, generators that emit greenhouse gases (GHG) in the eastern WCI Partner jurisdictions will need to acquire allowances or offsets in order to produce electricity. The cost of carbon for these generators becomes an additional marginal cost of production and will generally be added to the offer price of fossil-fired units in that jurisdiction. As the market clearing price rises, non-WCI fossil-fired generators that are not subject to the same emissions measures and requirements in nearby interconnected power markets may well find their units becoming more competitive. To discourage substitution of more carbon-intensive imports from non-WCI markets for WCI generation (an increase in emissions in uncapped areas known as leakage), the WCI market design includes emissions from electricity imports in the emissions of the WCI partners and holds the "First Jurisdictional Deliverer" (FJD) responsible for the emissions associated with imported electricity.

Efforts to regulate the emissions associated with imported electricity require the attribution of emissions on either a specified basis, using the emission rate of specified power plants, or an unspecified basis, using a default emission rate. The integrity of emission attribution may be undermined by a reallocation of generation resources on paper for the purposes of reducing compliance obligations. Importers of electricity generated by GHG-emitting sources in uncapped areas can use such a reallocation (sometimes called contract shuffling) to reduce GHG compliance obligations either by reporting the source as "unspecified" when the default rate is lower than the true emission rate, or by reporting the power as having originated at specified zero- or low-GHG plants. The existence of the Regional Greenhouse Gas Initiative (RGGI) and possible implementation of the Midwestern Greenhouse Gas Reduction Accord (MGGRA) may reduce the potential for both leakage and contract shuffling.

Objectives:

The purpose of this study is to simulate the impact of the proposed WCI caps in the three Eastern WCI Partners on power imports and exports, to estimate the GHG emission content of the power imports, and to estimate the potentials for leakage and contract shuffling. Results for both 2012 and 2020 are expected. The study should:
Estimate the quantity of electricity imported from non-WCI jurisdictions and the emissions associated with those imports in a business-as-usual (BAU) scenario without WCI.

Quantify the leakage potential by modeling the imposition of pure source-based cap and trade in WCI, with no attempt to account for emissions of imports, taking into account current and projected transmission constraints, RGGI, and MGGRA."

1.3 Overview of Navigant Consulting's Approach

The analysis required by the WCI was carried out by NCI using PROMOD IV, a commercial electricity market model, to simulate the hourly operation of the regions of the Canadian and US electricity system that is known as the 'Eastern Interconnect'. The Eastern Interconnect extends from eastern Canada to Florida to the U.S. Midwest and includes the three WCI partners – Manitoba, Ontario, Quebec – relevant for this study.

The core of the study was a series of power system market simulations, for 2012 and 2020, with various levels of WCI allowance costs[3], import charges[4] and regulatory assumptions for CO_2 emissions.

The starting point for the analysis was the definition of a 'Base Case' for 2012 and 2020 which represented a plausible evolution of the Eastern Interconnect – in terms of demand forecasts, fuel price assumptions, generation capacity, and environmental regulations – in the absence of WCI legislation. The assumptions for this Base Case were reviewed with the Eastern WCI partners in advance of the PROMOD market simulations.

Starting with this Base Case, a number of scenarios were defined to examine the effect on generation and emissions in the three Eastern WCI members – Manitoba, Ontario, Quebec – that might result as a consequence of imposing WCI CO_2 allowance charges, import ('First Jurisdictional Deliverer' or FJD) charges, and permitting contract shuffling. Some scenarios also considered the effect of additional greenhouse regulations, notably RGGI and MGGRA, in neighboring regions. The scenarios examined in the course of the study are outlined in detail in Chapters 3 and 4.

The analysis of the scenarios focused on the "deltas" – the differences between emissions, generation, imports in these scenarios - from the corresponding emissions, generation, and imports in the Base Case.

---

[3] The proposed WCI legislation would establish a 'cap and trade' system for CO_2 in the WCI jurisdictions. In modeling this with PROMOD, NCI assumed various levels of CO_2 allowance costs for emissions from CO_2-emitting plants in the WCI regions. This is analogous to modeling the CAIR SO_2 and NO_x regulation in PROMOD and is necessary because PROMOD (and similar models) do not usually simulate the emissions cap as such, except through the mechanism of allowance prices.

[4] Import charges are discussed in Chapter 2. Import charges are applied to electricity imports from non-WCI regions into WCI regions. In WCI terminology this is referred to as 'First Jurisdictional Deliverer' [FJD).

A key aspect of the analysis was that the definition of scenarios did not allow for changes in electricity demand, fuel prices, or the type of new generation that could result because of the imposition of allowance prices and import (FJD) charges:

- It is recognized that a significant part of the reduction in CO_2 emissions that would result from the introduction of WCI caps would probably come about through long-term changes in the generation mix or through price-induced conservation, rather than through short-term shifts in generation from existing and planned plants
- However, modeling such changes is very complex and it was agreed with the Eastern WCI partners that this was beyond the scope of the current project. In particular, the gas price was fixed for all scenarios, although in reality any CO_2 emission caps or cost allowances would change the demand for, and therefore the price of, natural gas

Power system simulation modeling can provide a great deal of insight into how WCI caps would affect electricity flows and generation in non-WCI jurisdictions, but it cannot capture all aspects. In particular, it is difficult for power system models to dynamically simulate contractual relationships that bypass the deemed emissions rates. PROMOD IV is capable of modeling specific detailed contracts, but it was agreed with WCI that this would not be feasible within the scope of this project.

In terms of PROMOD modeling, the commitment and dispatch of generation was based on minimizing the overall system cost, with plants 'bidding in 'at their marginal operating cost. The market modeling performed by PROMOD does not include any impacts on commitment and dispatch that would result from contractual arrangements, or from generators bidding into markets above or below marginal production cost.

The commitment and dispatch of generating plants does take into account the major transmission constraints that apply in the Eastern Interconnect, including those between WCI provinces and between the WCI provinces and the U.S.

1.4 Units

Unless otherwise indicated, in this report cost estimates are reported in real $US 2008. Emission allowance prices for WCI, MGGRA and RGGI are reported as $/tonne, i.e. metric units.

PROMOD uses imperial units – short tons – and the input data was adjusted were necessary to be consistent with the designated allowance costs in metric tons.

2. Modeling Methodology for WCI Study

2.1 PROMOD Software

PROMOD IV is a commercially-available software package[5] that simulates the hourly operation of electricity markets. It is widely used in the U.S. by a large number of utilities, energy consulting firms and ISOs including WECC, PJM and MISO.

PROMOD IV is typically used to forecast future electricity prices for various regions and unit revenues for various generators. It is often used to analyze the impact on prices of changes in the physical power system and changes in fuel prices.

PROMOD can also be used to study transmission planning and operations issues, including the effects of transmission line construction or enhancement, e.g., for siting studies.

PROMOD is supplied with three databases:

- WECC, the Western Electricity Coordinating Council, which covers the western U.S.
- ERCOT, the Electricity Reliability Council of Texas, which primarily covers Texas
- Eastern Interconnect, which is the electricity generation and transmission system that extends from Maine to Florida into the mid West. It includes Eastern Canada, ISO NE, NYISO, PJM, MISO markets and also regulated areas such as SPP, SERC and Florida in the southeastern U.S.

2.1.1 PROMOD IV Methodology

PROMOD IV is an optimization model that simulates the hourly operation of generation and transmission resources in market and non-market regions. For each hour, PROMOD commits and dispatches units in order of increasing generation cost until hourly demand is met, while taking into account unit operating constraints and transmission limits. The unit operating constraints represent system parameters such as planned and forced outages, unit minimum up and down times, ramp rates, and heat rate structures.

The transmission line limits and interface limits represent the operating restrictions that apply to the physical transmission system that links generators to demand.

PROMOD can be operated either as a zonal or a nodal model. As a nodal model, PROMOD contains a detailed representation of the transmission system in the form of a load flow and takes into account loss and congestion costs. As a nodal model, PROMOD can provide bus-

---

[5] Developed by Ventyx http://www.ventyx.com/about.asp

specific prices rather than the average zonal prices provided by PROMOD when run as a zonal model.

PROMOD capabilities include:

- Detailed and flexible unit commitment and dispatch modeling
- Chronological hourly modeling of loads and resource operation
- Individual transmission line modeling and modeling of operational transmission constraints [nodal model]
- Loss modeling, including marginal loss calculations [nodal model]
- Calculation of security constrained dispatch schedules [nodal model]

2.1.2 Locational Marginal Pricing – Nodal Simulation

When run as a nodal model, PROMOD IV contains an explicit load flow representation of the transmission system. This means that PROMOD can calculate locational marginal prices (LMPs) at each bus. Pricing mechanisms based on nodal prices are used in the PJM, ISO NE, NYISO, MISO and CAISO markets, and will be implemented in ERCOT in late 2010.

The LMP at a bus represents the value of supplying the next MW of load at a specific location, assuming that the system is being dispatched economically. Where there is no congestion, the LMPs at each bus are identical and equal to the cost of the most expensive generator that has been dispatched.

However, where there is transmission congestion, LMPs at different buses will differ. This difference in LMP prices directly reflects congestion and the cost of losses across the grid.

In addition to bus prices, PROMOD can provide load- or generation-weighted average LMPs across a region; this is analogous to the zonal average prices reported in zonal simulations.

2.1.3 Loss Modeling in PROMOD – Nodal Simulation

PROMOD IV can be run with a number of loss options:

- No losses
- Marginal losses
- Single pass losses

'No losses' assumes that losses are incorporated in the demand forecasts. It effectively assumes average losses across the system.

‘Marginal losses’ approximates the AC quadratic loss function through an iterative procedure, starting from a demand forecast that does not include losses. This option is computationally intensive and can significantly increase the run time for a PROMOD simulation.

‘Single pass losses’ is a linearized approximation to the quadratic loss calculation that is computationally much less intensive. In single pass losses, the demand forecast includes losses, but PROMOD uses the characteristics of the transmission system to apportion losses across the system and calculate LMPs with loss and congestion components.

In Navigant’s experience, the single pass loss calculation is the most appropriate choice for the majority of PROMOD nodal analyses.

2.1.4 PROMOD Setup for WCI Analysis

For the WCI analysis, PROMOD IV was operated as a nodal model with single pass losses. Although the run time for a nodal simulation is far greater than the run time for a zonal simulation, the requirements of the WCI analysis meant that a nodal analysis was required in order to accommodate certain specific requirements of the WCI analysis - particularly import (FJD) charges from generation in non-WCI regions serving load in WCI regions.

2.1.5 PROMOD Data Requirements

PROMOD IV is a data intensive model, and the Eastern Interconnect includes over 5000 existing units.

To run a PROMOD simulation, the user must provide, for any year that is to be studied:

- Expected annual peak demand, annual energy demand for each geographical region – 146 load areas - in the model
- Monthly fuel prices – coal, gas, oil, renewables such as biomass – for each unit
- Monthly emission allowance prices for each environmental regulation that is applicable
- Details of all existing generation, with their operating characteristics such as summer/winter capacity, heat rate, variable operating cost, emission rates, start costs etc
- Details of planned new generation and the relevant operating characteristics
- Expected monthly generation from renewable sources such as hydro, wind, solar, geothermal, biomass
- For a nodal analysis, load flows representing the transmission system linking generators to demand
- Transmission limits on individual lines (nodal simulations), and interface limits between regions

In creating a Base Case simulation for the WCI analysis, Navigant Consulting extensively modified the original Ventyx - supplied Eastern Interconnect database to include details of new transmission lines, new generators, revised demand forecasts, different fuel prices, and the WCI/MGGRA/RGGI regulatory structure.

2.2 WCI Analysis Requirements in PROMOD

The scope of the WCI analysis, as outlined above in Chapter 1, implied that PROMOD modeling would need to take into account the following requirements for the scenarios:

- The ability to selectively apply CO_2 emission cost adders to specific thermal units, based on their inclusion in particular regulatory schemes – notably WCI, MGGRA and RGGI
- Applying 'import' (FJD) charges to power sourced from generation in non-WCI regions that is serving load in WCI regions
- To investigate contract shuffling, the ability to apply a zero 'import' charge to non-WCI generation that is sourced from non CO_2-emitting generation[6]
- The ability to track electricity imports and exports into the WCI provinces

These requirements, and specifically import charges, required that PROMOD be operated as a nodal model. The only method of applying 'import' charges in PROMOD is through the PROMOD mechanism of 'pool-to-pool' charges, which is only available in PROMOD nodal modeling.

2.2.1 Simulation Years

The WCI analyses were conducted for two years, 2012 and 2020. For each year, PROMOD simulated the Eastern Interconnect for each hour in the year.

2.2.2 CO_2 Regulation and Emission Costs

Assigning particular units to regulatory groups, and applying emission costs to the units in those groups, is straightforward in PROMOD IV. This involves:

- Defining for the appropriate units an emission rate (by month) for the pollutant – for this analysis, CO_2
- Defining a monthly allowance price for CO_2 for the relevant regulation

[6] Contract shuffling presumes that (conceptually) the non CO_2-emitting generation in non-WCI regions is serving WCI load, and that the CO_2-emitting generation in non-WCI regions is serving non-WCI load. With that conceptual assignment, there is no import charge on power sourced from the non CO_2-emitting plants even though they are outside WCI regions

In the WCI analysis, the CO_2 regulations of interest were those proposed or implemented by WCI, MGGRA and RGGI. In PROMOD, CO_2-emitting units in the appropriate geographical areas were assigned to the appropriate regulation, and CO_2 allowance price series for WCI, MGGRA and RGGI were defined according to the individual scenario assumptions.

The criteria used to classify CO_2-emitting units as exempt or non-exempt in terms of the appropriate CO_2 regulation are listed in Table 1.

Table 1: CO_2 Regulations in WCI Analysis

Greenhouse Gas Regulation	Location of Generating Units	Criteria for Inclusion in Regulation	Notes
Eastern WCI[7]	Quebec Ontario Manitoba	Units/plants emitting more than 25,000 tons of CO_2 annually	Biomass units exempt
MGGRA	Iowa Illinois Kansas Manitoba Michigan Minnesota Wisconsin	Units producing more than 25,000 tons of CO_2 annually, and CO_2-emitting units >25 MW in size	Biomass units exempt To simplify modeling, units in Kansas were not included in MGGRA as they do not border the WCI provinces and FJD charges would not apply
RGGI	Connecticut Delaware Maine Maryland Massachusetts New Hampshire New Jersey New York Rhode Island Vermont	CO_2-emitting units > 25 MW in size	Biomass units exempt

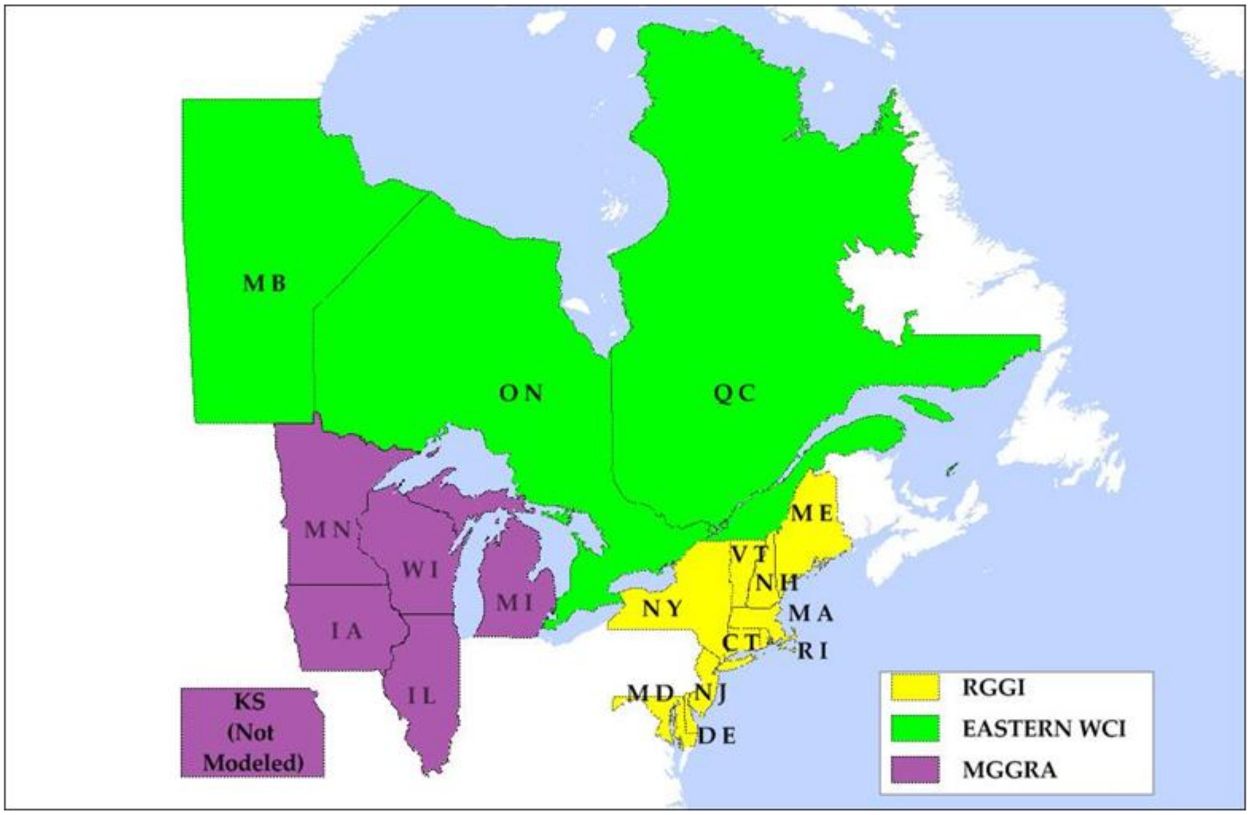
CO_2-emitting units in other regions – such as SERC, SPP, Florida – were not linked to any carbon regulation, because the WCI Base Case assumed no national U.S. carbon regulation.

[7] Western WCI members – not relevant for this study – are Arizona, British Columbia, California, Montana, New Mexico, Oregon, Utah, Washington

The CO_2 emission costs associated with RGGI, WCI or MGGRA regulation are additional to the SO_2 or NO_X emission costs associated with the CAIR SO_2 and NO_X regulations.

Figure 1 indicates the relationship between WCI, MGGRA and RGGI member province/states.

Figure 1: Eastern Interconnect Regions Surrounding WCI Footprint



2.2.3 Import (FJD) Charges in PROMOD

In the WCI analysis, import (FJD) charges are defined in terms of the assumed carbon intensity of the imports. In PROMOD, this is translated into an incremental[8] pool-to-pool tariff as shown in Table 2.

[8] The WCI Base Case has non-zero tariffs between pools in the Eastern Interconnect. These tariffs are defined in ISO schedules, based on FERC Order 888 - Open Access Transmission Tariffs. Typical tariffs are ~ $1-6/MWh, and thus much smaller than the import tariffs considered for the WCI scenarios, which are up to $60/MWh

For imports into the WCI region, the pool-to-pool tariffs were modified between the appropriate combinations of:

- Non-WCI regions: Saskatchewan and the Maritime provinces, ISO NE, NYISO, MGGRA, MRO
- WCI provinces: Manitoba, Ontario, Quebec

For the more complex scenarios, where WCI and MGGRA were considered under a common regulatory framework, the same principles were applied. In that case, there were no import charges between MGGRA and the WCI provinces, but there were import charges into MGGRA from MISO, MRO, and SPP.

Table 2: FJD Import Charges - Incremental Pool-to-Pool Transmission Tariff

FJD Charge	WCI CO_2 Allowance Price *$/tonne*	Incremental Transmission Tariff - Applied to Imports *$/MWh*
500 kg/MWh	0	0
	15	7.5
	30	15
	60	30
1000 kg/MWh	0	0
	15	15
	30	30
	60	60

Note

1 Allowance price and transmission tariff are $US real 2008

As regards RGGI, for scenarios where the WCI allowance prices and RGGI prices were not aligned (i.e., RGGI = $2.06/tonne), FJD charges were applied. For the scenarios where the WCI allowance price and the RGGI allowance prices were aligned, we presumed there would be no FJD charges.

Pool-to-pool tariffs are defined in PROMOD in both directions. So, for example, in a scenario where FJD charges are to be applied for imports into WCI provinces, the pool-to-pool tariffs from ISO NE into Quebec were increased according to the above table, but the pool-to-pool tariffs from Quebec to ISO NE were left unchanged. Similarly, the tariffs from NYISO into Quebec and Ontario were increased and those from Quebec and Ontario to NYISO were left unchanged.

FJD charges have to be implemented in terms of the import of electricity from non-WCI regions to WCI regions. They cannot be represented by increasing the cost of the generation as this also affects the cost of that unit as seen from non-WCI regions.

2.2.4 Contract Shuffling

Under WCI rules, non-fossil generation outside WCI can be exempt from import (FJD) charges if it is specified as no- or low-carbon. This can lead to "contract shuffling", as non-fossil generation is deemed to serve WCI load and fossil generation is deemed to serve local (non-WCI) load, with no change in total generation, fossil generation, flows, or emissions.

WCI rules regarding renewable attributes have not been finalized. For this analysis, it was assumed that renewables can "double-dip":

- Sell renewable attributes to U.S. states – count toward meeting Renewable Portfolio Standards AND
- Sell electricity to WCI provinces exempt from FJD charges

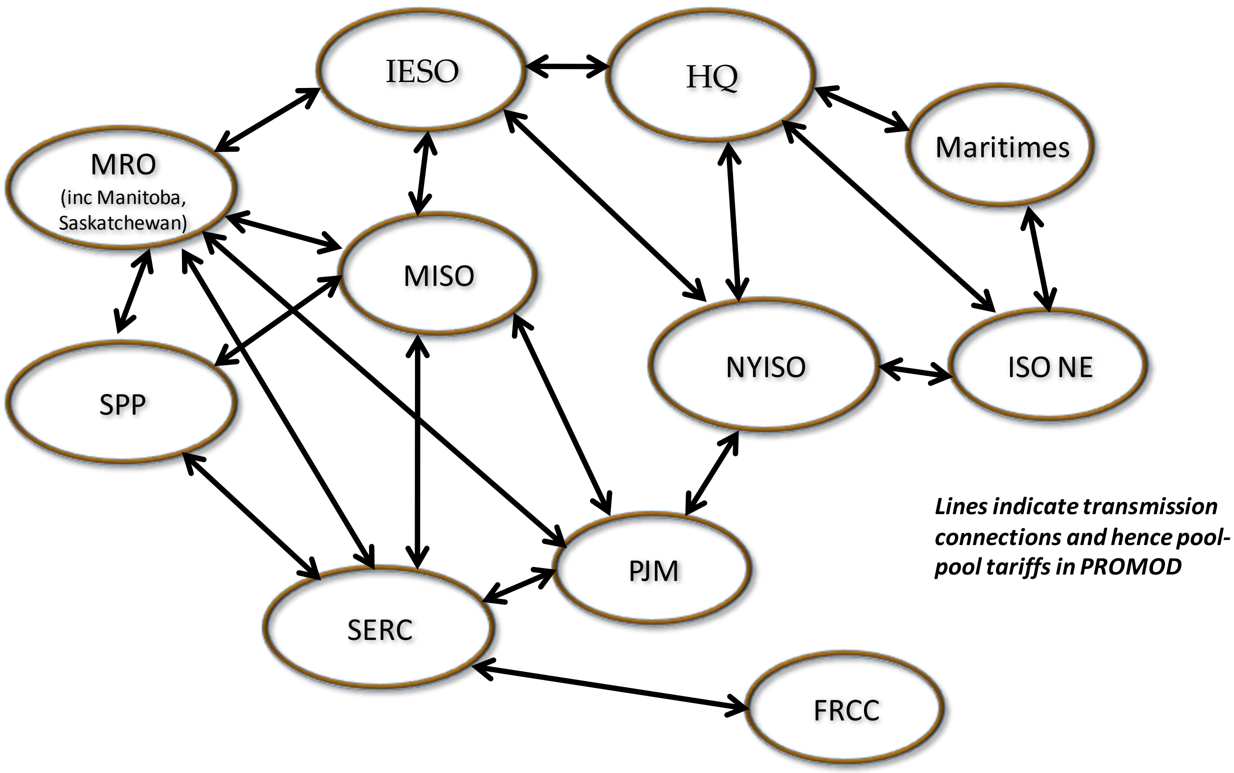
The impact of contract shuffling would be slightly less if renewable generation cannot double-dip, because most wind (but not nuclear or hydro) is tied to Renewable Portfolio Standards.

In PROMOD, in a region this can be represented by separating out the non-CO_2-emitting generation from the CO_2-emitting generation and placing this in a separate 'other' (non-fossil) pool, with a zero incremental transmission tariff for the pool with the non-CO_2-emitting generation. This requires a more complex pool structure which is described in Section 2.3.

2.3 Eastern Interconnect Pool Structure

The Eastern Interconnect Pool Structure, as usually represented, is shown in Figure 2. For the WCI analysis, this pool structure was modified to permit FJD charges and to allow contract shuffling.

Figure 2: Default Pool Representation in Eastern Interconnect



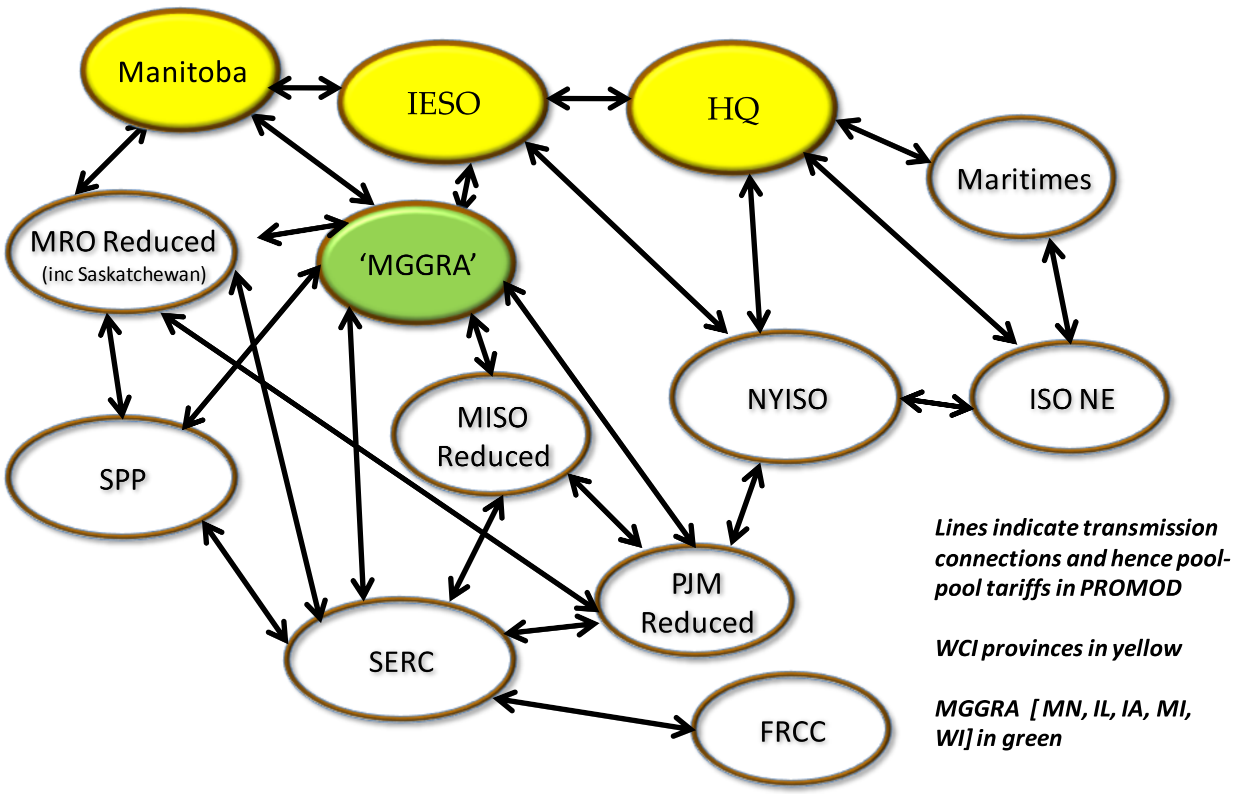
The changes to the pool structure for the WCI analysis were made in two steps.

For the 'simple scenarios' which did not involve contract shuffling, the existing pool structure in PROMOD was rearranged as shown in Figure 3.

- Manitoba was separated out from MRO
- Units in PJM, MISO and MRO that were located in Wisconsin, Minnesota, Michigan, Iowa and Illinois were removed from those pools and assigned to a new 'MGGRA'[9] pool

[9] For modeling simplicity, Kansas was not included as it is not geographically contiguous to the other MGGRA states. Also, Manitoba is in both MGGRA and WCI but was located in WCI for this study.

Figure 3: Modified Pool Representation in Eastern Interconnect - 'Simple' Scenarios



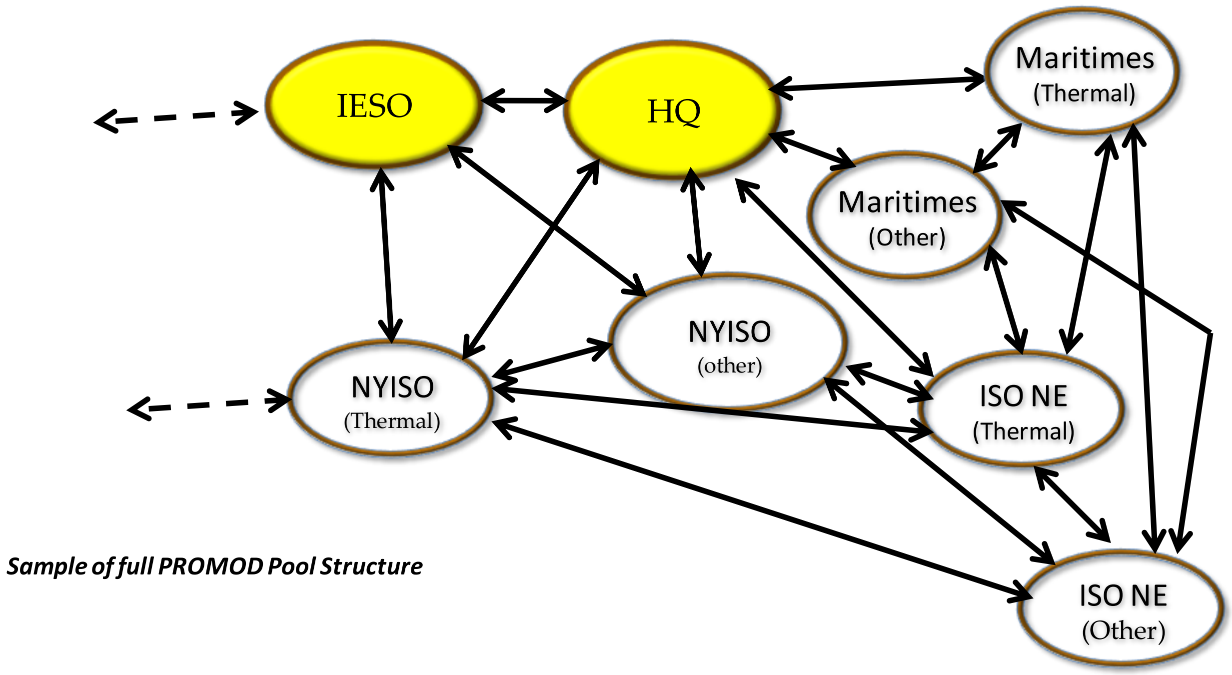
For the more complex scenarios, which involved contract shuffling, further modifications were needed, as shown in Figure 4, to allow import tariffs to apply only to power imported from non-WCI regions that was generated by CO_2-emitting units.

This was achieved by splitting each non-WCI pool – and MGGRA for some analyses – into a 'Fossil 'pool and an 'Other' pool. Thermal (except nuclear) units were located in the 'Fossil' pool, remaining units in the 'Other' pool. This is a conceptual split that does not affect the load distribution, physical location of plants, or transmission; there are minor effects on commitment and dispatch of units.

Splitting each non-WCI pool allows the incremental pool-to-pool tariff for a 'Fossil' pool to a WCI province to be set at the level appropriate for the scenario, and the incremental tariff for the corresponding 'Other' pool to be zero. This mimics contract shuffling in that particular non-CO_2 emitting renewable resources in non WCI regions are meeting WCI load, with no import charge.

This construction is only necessary for non-WCI pools that are contiguous to the WCI provinces, and similarly for the scenarios with consistent WCI-MGGRA CO_2 regulation.

Figure 4: Modified Pool Representation in Eastern Interconnect - 'Complex' Scenarios



The PROMOD modifications necessary to handle contract shuffling have a very significant effect on the simulation time, and this limited the number of complex scenarios that could be examined.

2.4 WCI Base Case Assumptions

The following sections summarize the key assumptions used in the WCI Base Case analysis. For the various WCI scenarios derived from the Base Case, fuel prices, demand forecasts and generation were unchanged in all scenarios.

WCI, RGGI and MGGRA CO_2 allowance prices and import (FJD) charges varied depending on the particular scenario, and these are described in Chapters 3 and 4.

2.4.1 WCI Demand Forecasts

Tables 3 - 4 summarize the 2010 – 2020 demand forecasts used for the WCI provinces in this study.

Table 3: Annual Peak Demand - Eastern WCI Provinces

Year	Manitoba *MW*	Quebec *MW*	Ontario *MW*
2010	4,487	36,547	23,779
2011	4,607	37,042	23,589
2012	4,715	37,402	23,426
2013	4,807	38,229	23,390
2014	4,852	38,574	23,342
2015	4,896	38,916	23,316
2016	4,941	39,218	23,250
2017	4,977	39,537	23,503
2018	5,030	40,087	23,604
2019	5,090	40,644	23,759
2020	5,150	41,209	23,781

Table 4: Annual Energy Demand - Eastern WCI Provinces

Year	Manitoba *GWh*	Quebec *GWh*	Ontario *GWh*
2010	24,937	186,923	143,634
2011	25,713	189,341	142,172
2012	26,362	193,894	141,814
2013	26,922	196,967	141,272
2014	27,241	198,806	140,642
2015	27,531	200,777	140,116
2016	27,827	203,163	140,769
2017	28,078	204,132	141,732
2018	28,418	206,663	142,718
2019	28,757	209,226	143,727
2020	29,095	211,820	144,760

2.4.2 WCI Fuel Prices

Tables 5 - 8 and Figures 5 – 6 summarize the 2010 – 2020 price forecasts for gas and oil for used for Eastern Canada in the WCI study. These forecasts are based on NCI's Fall 2009 fuel price forecast.

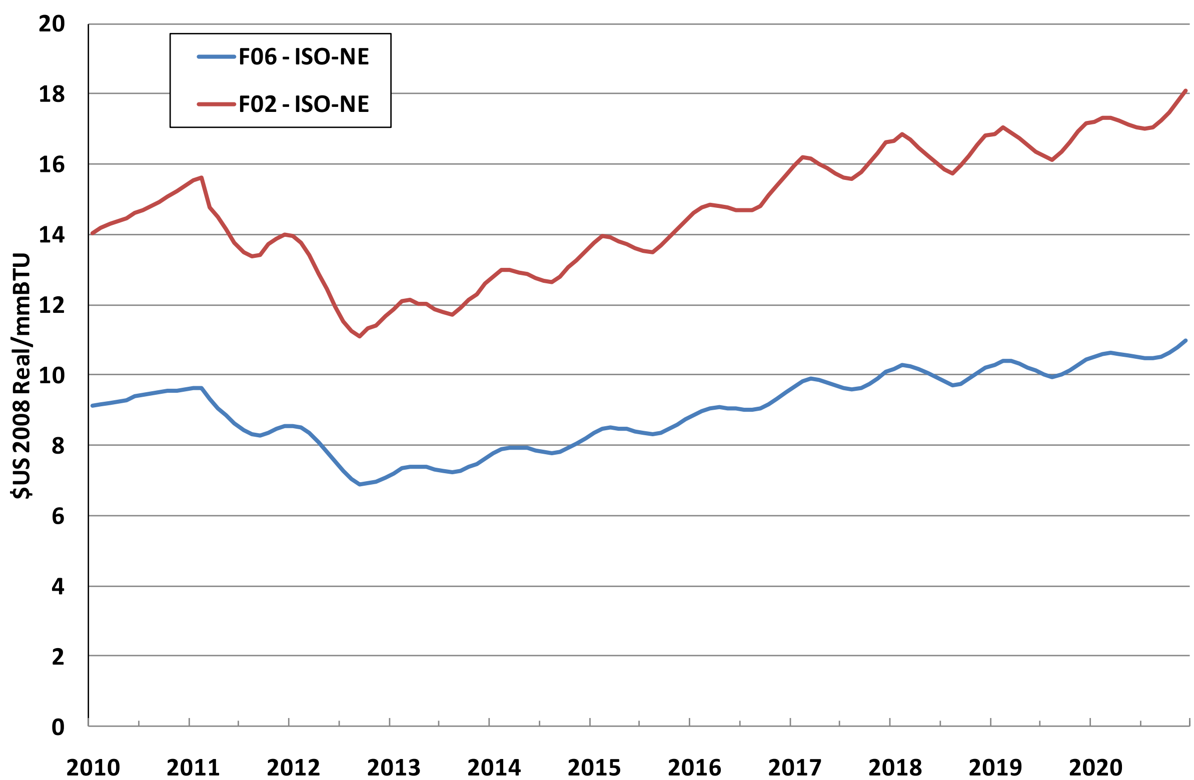
Figure 6: WCI Analysis - Monthly Oil Price Forecast



2.4.3 WCI Allowance Prices

In the WCI Base Case, the following environmental regulations[10] were assumed to be in place for units in the Eastern Interconnect:

- CAIR SO_2 and CAIR NO_X, both annual and seasonal
- RGGI CO_2
- The Base Case assumed no national U.S. carbon legislation
- The Base Case (and all other scenarios) assumed no national U.S. mercury legislation to replace CAMR

The allowance price values for CAIR SO_2 and NO_X reflect Ventyx - supplied PROMOD data, and the RGGI allowance prices are based on the September 2009 auction results.

Table 9: WCI Base Case Allowance Price Forecast

Year	CAIR SO_2 $/tonne[2,3]	CAIR Annual NO_X $/tonne[2,3]	CAIR Seasonal[1] NO_X $/tonne[2,3]	CAMR Hg $/tonne[2,3]	RGGI CO_2 $/tonne[2,3]	US National CO_2 $/tonne[2,3]
2010	79	661	165	0	2.29	0
2011	422	1,021	504	0	2.18	0
2012	764	1,380	843	0	2.06	0
2013	798	1,099	827	0	2.06	0
2014	854	789	812	0	2.06	0
2015	841	721	822	0	2.06	0
2016	780	711	770	0	2.06	0
2017	665	710	756	0	2.06	0
2018	607	680	767	0	2.06	0
2019	579	622	720	0	2.06	0
2020	556	601	750	0	2.06	0

Notes

1. CAIR Seasonal NO_X applies only in summer months (May - Sep)

2. In this table, PROMOD Allowance Prices are shown in metric units for consistency with scenario definitions, although data is in imperial units in PROMOD. 1 Metric Tonne = 1.102 Short Ton

3. Allowance prices are in $US 2008 Real

4.WCI analysis also had allowance prices for Ontario - $100/tonne SO_2, $300/tonne NO_X

---

[10] CAIR – Clean Air Interstate Rule

CAMR – Clean Air Mercury Rule

2.4.4 WCI Generation Assumptions

The generation assumed for Ontario, Quebec[11] and Manitoba is based on a Ventyx database for the Eastern Interconnect, updated to take into account unit changes, retirements and planned new developments. As part of this project, the details of existing generation were reviewed with the WCI partners. Planned new units were based on published data and a variety of previous planning studies for the various WCI provinces.

Throughout this report and in the tables following, "CC", "CT" and "ST" are conventional shorthand for combined cycle, combustion turbine and steam turbine respectively.

Table 10: Ontario Generating Capacity

Generation Type	Installed Capacity at Year End	
	2012 *MW*	**2020** *MW*
Wind	3,855	4,352
Hydro	7,925	8,720
Solar/Biomass	973	2,596
Nuclear	12,473	6,729
CC	7,019	7,674
CT Gas	794	1,669
ST Gas	2,110	1,060
ST Coal	3,785	0
Other	104	104
Total Ontario Generation	**39,038**	**32,905**

[11] In the WCI analysis, to reflect Hydro Quebec's intention to continue to export to the north-eastern U.S., NCI set up the Quebec hydro dispatch to generate more in the peak hours than is required to meet Quebec load. This encourages PROMOD to export power to the U.S. in those periods. As hydro generation is limited annually by inflows, this has the result that Quebec then needs additional power in off-peak periods to meet load, i.e. imports from Ontario. This can be seen in the Appendix in the tables that summarize flows at a provincial level.

Table 11: Quebec Generating Capacity

Generation Type	Installed Capacity at Year End	
	2012 **MW**	**2020** **MW**
Wind	1,565	5,339
Hydro	39,756	41,361
Solar/Biomass	277	897
Nuclear	675	675

Table 12: Manitoba Generating Capacity

Generation Type	Installed Capacity at Year End	
	2012 *MW*	**2020** *MW*
Wind	242	242
Hydro	5,304	5,991
Solar/Biomass	0	0
Nuclear	0	0
CC	0	0
CT Gas	274	274
ST Gas	140	140
ST Coal	97	0
Other	0	0
Total Manitoba Generation	**6,057**	**6,647**

2.4.5 Transmission Assumptions

The PROMOD simulations were run with load flows representing the transmission system in the Eastern Interconnect for 2012 and 2020 respectively. The load flows were based on the FERC 2007 release and were modified by Navigant Consulting to include various planned transmission enhancements in ISO NE, NYISO, PJM and in Eastern Canada.

Manitoba and Quebec are connected to various sections of the U.S. electricity system primarily by a number of asynchronous DC lines, and Ontario is similarly connected by AC lines. The results of the WCI analysis are affected by the import and export of electricity across these interfaces, and this creates the possibility for leakage, where U.S. generation and CO_2 emissions increase in response to WCI CO_2 regulation.

Also, Quebec and Manitoba have substantial hydro generation and generation in excess of demand. Hydro Quebec has indicated intentions to increase exports to the northeast US to reach ~15-20 TWh annually. This may be affected by the WCI CO_2 proposals if they lead to a reduction in thermal generation inside the WCI provinces.

Table 13 indicates the assumed interface capability between the WCI provinces and other sections of the Eastern Interconnect.

Table 13: Transmission Interfaces for Manitoba, Ontario, Quebec

Transmission Interfaces *WCI – non WCI Regions*	**Limit** *MW*
Quebec – New Brunswick	1,080
Quebec – ISO NE	1,670
Quebec – NYISO	1,625
Ontario – NYISO	1,825
Ontario – MISO	2,540
Manitoba – MISO	2,175

The Quebec – ISO NE interface does not include the expected increase that will result from development of the proposed 1200 MW NU/NSTAR DC line in 2015. This line was included in the 2020 simulations.

3. Initial WCI Scenarios Without Contract Shuffling

3.1 Scenario Definitions

The initial PROMOD simulations analyzed by Navigant Consulting were based on the Eastern Interconnect pool structure shown above in Figure 3, where a MGGRA pool was created and Manitoba was separated from MRO. Key aspects of this group of scenarios were:

- CO_2 regulation for generating units in the eastern WCI provinces – Quebec, Ontario, Manitoba
- No corresponding CO_2 regulation in MGGRA states
- RGGI regulation in NE US not aligned with WCI regulation in terms of CO_2 allowance price, but CO_2-emitting units in the 10 RGGI states were subject to an allowance cost of $2.06/tonne
- Non-WCI, non-RGGI generation was not subject to any CO_2 emission charges
- Import (FJD) charges applied to all imports into Quebec, Ontario, Manitoba from non-WCI provinces/states – no distinction made on basis of the carbon content of imported power
- As all imported power attracted the same FJD charge, contract shuffling was not possible

Within this common structure, a number of scenarios were run for 2012 and 2020 with different combinations of WCI allowance prices and import charges, as shown in Table 14.

Table 14: Allowance Prices and FJD Charges – Simple Scenarios

Scenario	Years	WCI CO_2 Allowance Price *$/tonne*	MGGRA CO_2 Allowance Price *$/tonne*	RGGI CO_2 Allowance Price *$/tonne*	FJD Charge *kg/MWh*	FJD Charge *$/MWh*
Scenario 1 *[Base Case]*	2012, 2020	0	0	2.06	0	0
Scenario 2	2012, 2020	30	0	2.06	0	0
Scenario 3	2012, 2020	30	0	2.06	500	15
Scenario 3a	2020	60	0	2.06	500	30
Scenario 4	2012, 2020	30	0	2.06	1000	30
Scenario 5	2012, 2020	15	0	2.06	0	0
Scenario 6	2012, 2020	15	0	2.06	500	7.5
Scenario 7	2012, 2020	15	0	2.06	1000	15
Scenario 8	2012, 2020	15	0	15	500	7.5

Notes

1. In this table, the RGGI allowance prices from the auction result - $US 1.87/short ton - has been converted to metric tonnes

2. In these scenarios the FJD charge applies to all imports from non-WCI regions regardless of the presumed type of generation

3.2 Scenario Results

3.2.1 WCI Generation, Emissions and Imports/Exports

Figures 7 - 8 show total WCI generation and emissions for these scenarios[12] in 2012.

With no import charge, both generation and emissions within WCI decline significantly as allowance prices increase from zero (Scenario 1), to $15/tonne (Scenario 5), to $30/tonne (Scenario 2). For a given WCI allowance price, WCI generation and emissions progressively increase as import charges increase, to $7.50/MWh (Scenario 6), $15/MWh (Scenarios 3 and 7) and $30/MWh (Scenario 4), though they remain well below the Base Case with no allowance price. From these results, it is clear that the WCI allowance price has a more significant effect than the FJD charge, and this remains true at the highest allowance prices investigated (Scenario 3a - $60/MWh).

[12] Tables corresponding to these figures, with WCI totals and breakdowns by province, are included in the Appendix

Figure 7: Eastern WCI Generation in 2012 – Simple Scenarios

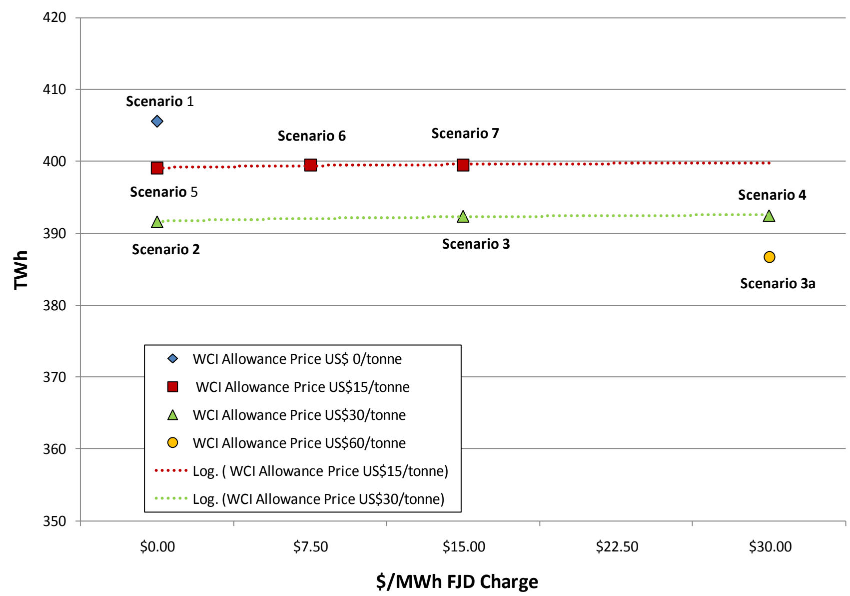

Figure 8: Eastern WCI CO_2 Emissions in 2012 – Simple Scenarios

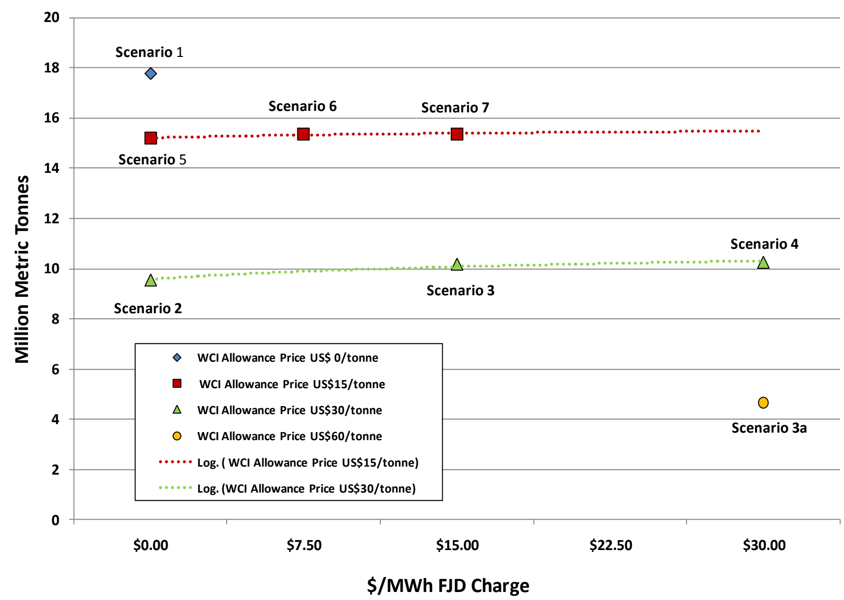
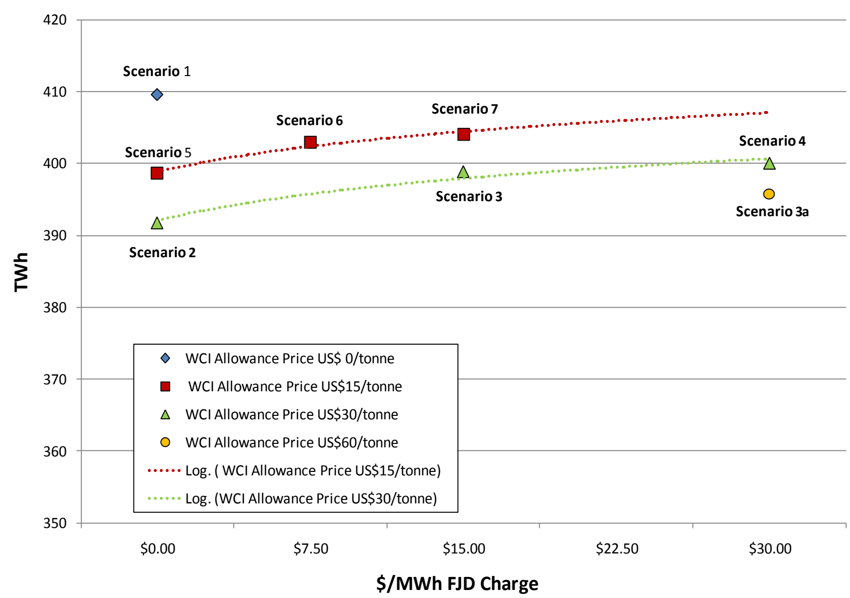


Figures 9 - 10 show generation and emissions for 2020. Base case WCI emissions are significantly lower in 2020 than in 2012 (14.8 instead of 17.8 million tonnes), primarily because Ontario coal plants will all have been shut down by then. The emission reductions are lower in absolute terms in most of the scenarios, but similar in percentage terms. For example, Scenario 2 shows a reduction of 8.2 million tonnes, or 54% of Base Case reductions, in 2012. In 2020, the reduction is only 7.1 million tonnes, but the percentage reduction (52%) is almost the same.

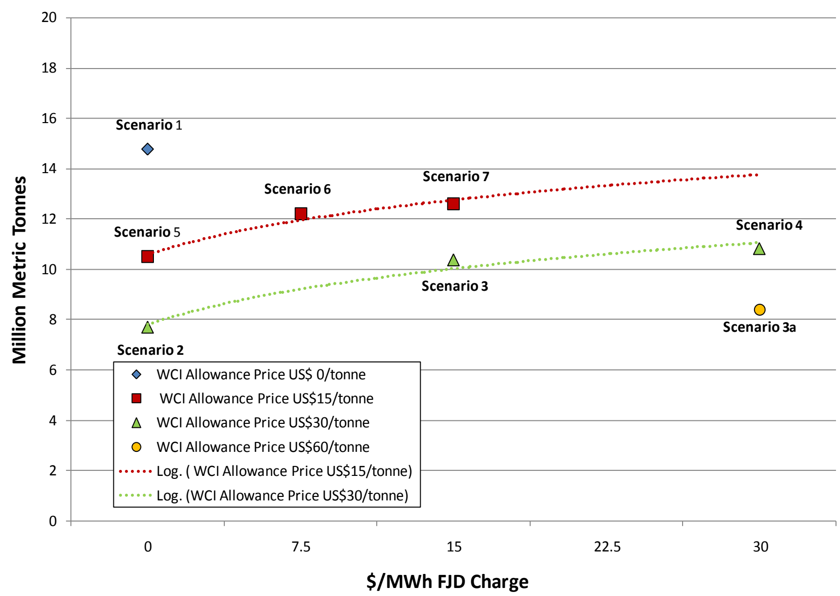
The reason for the decreases in WCI emissions shown in Figures 7 - 10 is that WCI fossil generation - gas and coal plants - is reduced as the WCI allowance cost increases. As the tables in the Appendix show, almost all of the decrease in emissions by the Eastern WCI provinces is due to changes in Ontario-based generation, rather than to changes in Manitoba or Quebec. This is to be expected since Ontario has the majority of the coal-fired generation in 2012[13], and most of the gas-fired generation in the Eastern WCI provinces in both 2012 and 2020.

Figure 9: Eastern WCI Generation in 2020 – Simple Scenarios



[13] Ontario fossil generation in 2020 is primarily gas as the Ontario coal plants are expected to be retired by the end of 2014

Figure 10: Eastern WCI CO_2 Emissions in 2020 – Simple Scenarios



These decreases in generation are offset by a decrease in net exports, as shown in Figures 11 - 12. Net exports from the WCI are substantially lowered by the imposition of a WCI CO_2 allowance price. The Appendix provides detailed tables of imports and exports by province. These show that in 2012, the reduction in net exports is primarily due to Ontario, which both imports more and exports less. In 2020, the reduction in net exports to non-WCI areas is due both to increases in imports into Ontario and decreases in exports out of Quebec. This reduction in Quebec's exports to non-WCI areas is offset by a change in net imports from Ontario (both less imports to, and more exports from, Quebec).

WCI Emissions are significantly more sensitive to FJD charges in 2020 than in 2012. This is because the WCI provinces are much more dependent on imports in 2020. In the 2012 Base Case, the WCI provinces export 50 TWh to non-WCI areas, and import only 8 TWh. In the 2020 Base Case, exports have fallen to 38 TWh and, more importantly for FJD charges, imports have doubled, to 16 TWh. The FJD charges therefore have a greater impact.

Figure 11: Eastern WCI CO_2 Net Exports in 2012 – Simple Scenarios

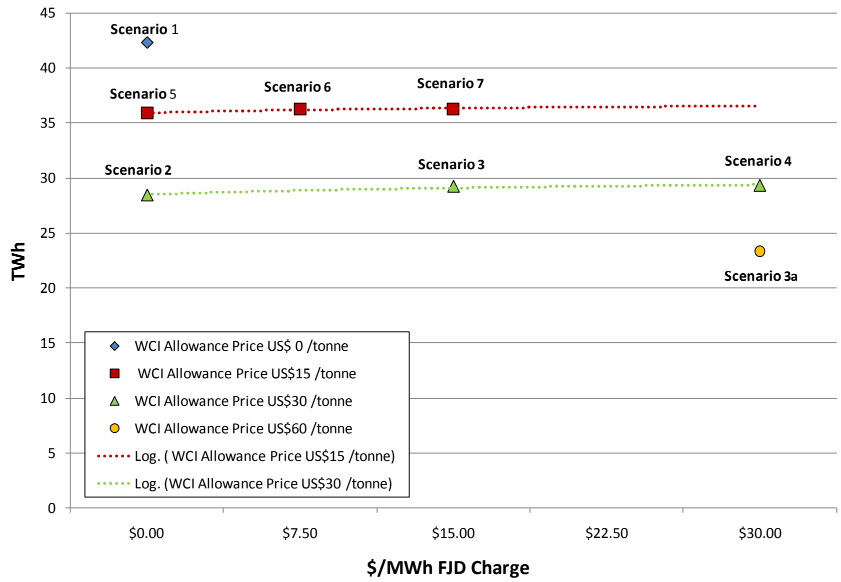


Figure 12: Eastern WCI CO_2 Net Exports in 2020 – Simple Scenarios

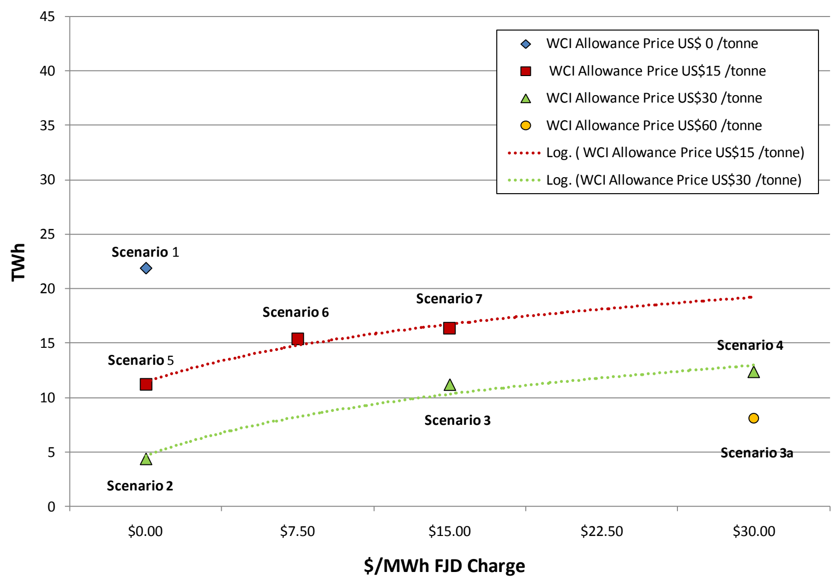

Tables 15 - 16 summarize the imports and exports into the Eastern WCI region – Manitoba, Ontario, Quebec – for the various scenarios.

Table 15: Summary of WCI Imports and Exports in 2012 – Simple Scenarios

Scenario	WCI Allowance Price	FJD Adder	RGGI Allowance Price	MGGRA Allowance Price	Imports Into WCI	Exports From WCI	Net Exports	Change in Net Exports	
	$/tonne	*$/MWh*	*$/tonne*	*$/tonne*	*TWh*	*TWh*	*TWh*	*TWh*	*%*

Scenario 6	15	7.5	2.06	0	18.8	34.2	15.4	-6.5	-30%
Scenario 7	15	15	2.06	0	18.3	34.7	16.4	-5.5	-25%
Scenario 8	15	7.5	15	0	17.5	37.0	19.5	-2.3	-11%

Figure 13 summarizes the net WCI exports for the base case and the scenarios with a WCI allowance price of $30/tonne. This shows that at a particular WCI allowance price level, as FJD charges increase, net WCI exports tend to return to the level of the Base Case. This is most noticeable in 2020, but also occurs in 2012.

Similar results can be seen for the scenarios with an allowance price of $15/tonne.

FJD charges can consequently provide a means of reducing leakage resulting from the imposition of WCI allowance charges.

Figure 13: Example of Effect of FJD charges on WCI Exports – Simple Scenarios

3.2.2 Changes in WCI Generation and Emissions

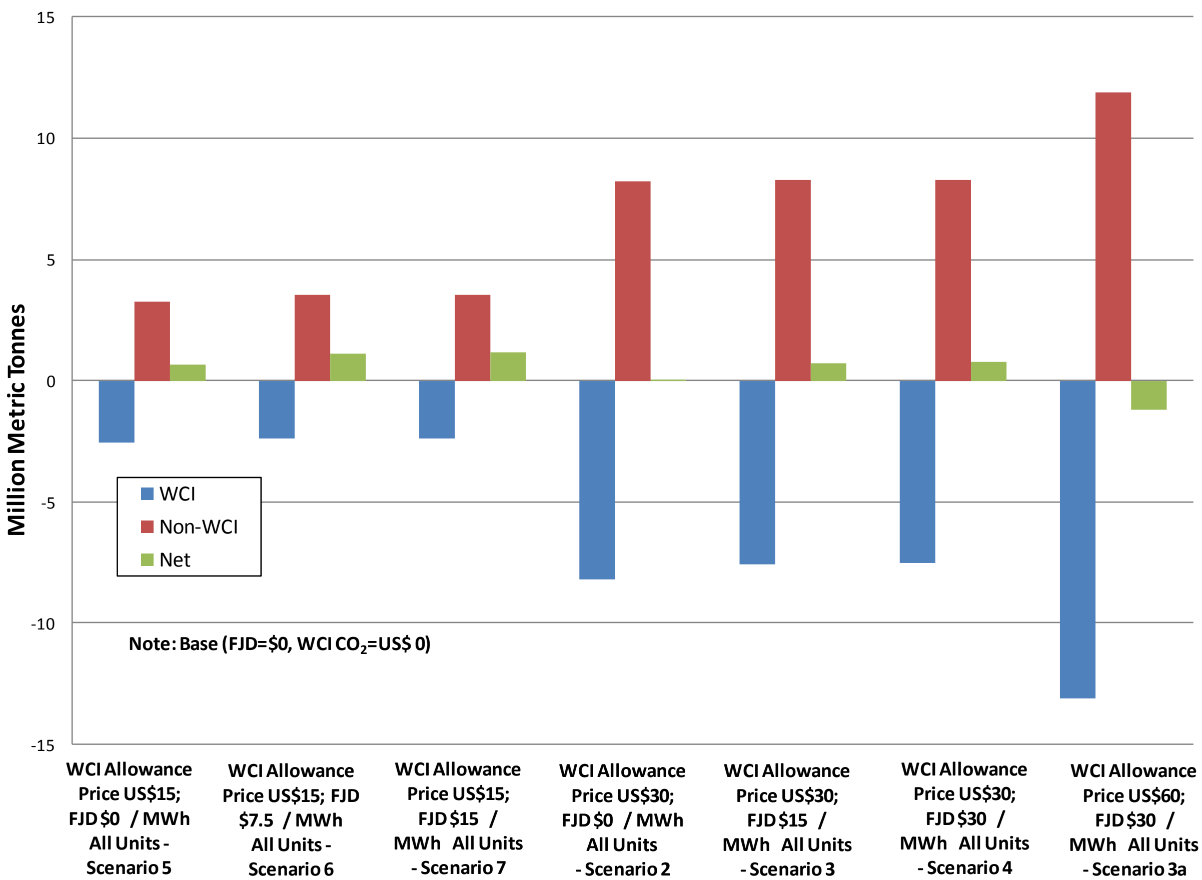
A decrease in net exports from WCI provinces means an increase in non-WCI generation, as total system demand is fixed. The annual output of all types of non-fossil generation – primarily hydro, wind – does not change and the reduction in exports from WCI is made up by increased non-WCI fossil generation, accompanied by an increase in CO_2 emissions. The net change in total emissions (WCI plus non-WCI) is very small, as shown in Figures 14 and 15 and Tables 17 and 18.

The overall result of introducing allowance prices - with or without import charges - in WCI, but not in the rest of the Eastern Interconnect, is in most cases a small increase in overall CO_2 emissions.

However, this is a consequence of assuming no change in demand and no change in the future generation mix in any of the scenarios. Since the annual output of total non-fossil generation is fixed, any reduction in fossil generation in one jurisdiction will be offset by an increase in fossil generation in another jurisdiction. To the extent that gas-fired generation in WCI is offset by coal-fired generation in non-WCI jurisdictions, total emissions will increase[14].

In reality, the introduction of allowance prices in WCI would increase prices and therefore reduce consumption. As well, higher prices for fossil-generation would lead to the development of more non-fossil generation, thus changing the future generation mix. As noted in the introduction, quantifying such the effects of such changes - in fossil generation at existing plants in WCI and non-WCI jurisdictions, in demand, and in capacity development - is a much more involved analysis, beyond the scope of this study.

Figure 14: Change in WCI, Non-WCI and Total CO_2 Emissions in 2012 – Simple Scenarios



[14] Differences in transmission losses may also have a small impact on generation and emissions. Note that an increase in non-WCI CO_2 is not inevitable – for example, the difference in generation could be made up by non-WCI gas fired capacity. The overall result depends on the availability and economics of coal generation vs. gas generation in the non-WCI regions.

Figure 15: Change in WCI, Non-WCI and Total CO_2 Emissions in 2020 – Simple Scenarios

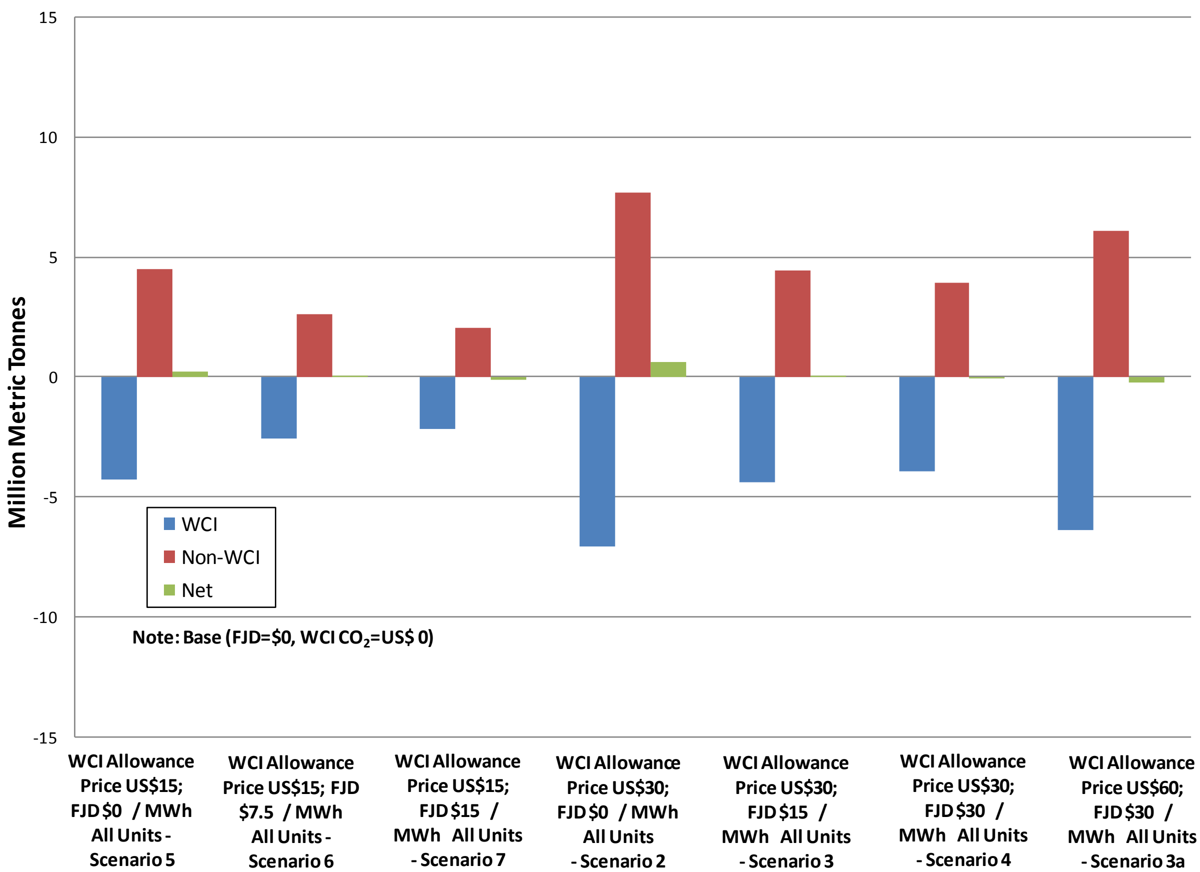


Table 17: Change in WCI, Non-WCI and Total CO_2 Emissions in 2012 – Simple Scenarios

3.2.3 Carbon Content of WCI Imports

As a final step in the analysis of the initial scenarios, the carbon content of non-WCI generation was estimated, as an indicator of an appropriate default level of import charges. This was done by dividing the increase in non-WCI emissions by the decrease in net exports, as shown in Table 19 and Figure 16. The results are clustered around 600 kg/MWh in 2012 and 400 kg/MWh in 2020. The difference is due to the fact that coal (which emits more CO_2 per MWh than gas) is on the margin less in 2020 than in 2012, so the decrease in WCI exports is offset by an increase in gas generation more often than coal generation.

Table 19: Average Carbon Content of Non-WCI Generation

	Change from 2012 Base Case			Change from 2020 Base Case		
Scenario	**Change in Non-WCI CO_2 Emissions** *Million Tonnes*	**Change in WCI Net Imports** *TWh*	**Average CO_2 Content of Import** *kg/MWh*	**Change in Non-WCI CO_2 Emissions** *Million Tonnes*	**Change in WCI Net Imports** *TWh*	**Average CO_2 Content of Import** *kg/MWh*
Scenario 1 *[Base Case]*	n/a	n/a	n/a	n/a	n/a	n/a

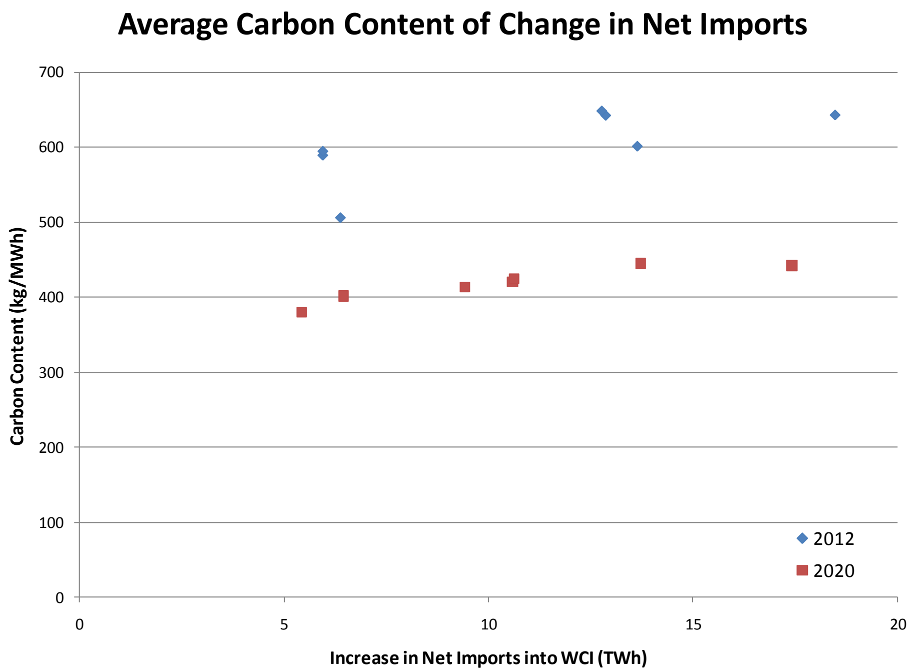
Notes

1 Scenario 8 has different RGGI allowance price from Base Case and CO_2 calculation is not appropriate

2 Average CO_2 content of imports = (change in non-WCI CO_2 emissions)/(Change in WCI imports)

Figure 16: Average Carbon Content of Non-WCI Generation



3.2.4 Changes in Generation and Emissions by Province

Tables 20 - 23 summarize the breakdown of generation and CO_2 emissions by province for the simple scenarios. In both 2012 and 2020, the changes in generation and emissions compared to the Base Case occur primarily in Ontario, primarily in response to the WCI allowance price. Changes in Quebec and Manitoba are limited as there is relative little thermal generation in those regions.

Overall emissions in 2020 are lower than those in 2012 because of the expected retirement of coal units in Ontario and Manitoba.

Table 20: Provincial Generation in 2012 – Simple Scenarios

Scenario	WCI Allowance Price	FJD Adder		Quebec Generation	Ontario Generation	Manitoba Generation	Total WCI Generation
	$/tonne	*kg/MWh*	*$/MWh*	*TWh*	*TWh*	*TWh*	*TWh*

Notes

1. Allowance price and FJD adder are $US 2008 Real

A more detailed breakdown by individual province is included in the Appendix.

3.3 Comparison of WCI Study with E3 Study

In March 2009, Energy and Environmental Economics ("E3") produced a report for the Electricity Sub-committee of the Western Climate Initiative titled "Electricity Leakage Analysis Summary Report" ("The E3 report"). The E3 report addressed many of the same questions as the current report, but for the Western WCI members, i.e., excluding Manitoba, Ontario and Quebec. However, the analysis is primarily qualitative. The main findings on the potential for leakage were that there is little potential for increased coal generation in neighboring jurisdictions, as the coal plants already have high capacity factors, but there is potential for increased generation from non-WCI gas plants. The current report takes a quantitative approach to this question, finding that the increase in non-WCI generation induced by WCI allowance prices will be a mix of coal and gas in 2012, and primarily gas in 2020.

The E3 report addressed the question of power plant investment incentives, considering whether WCI regulation of GHG emissions could create an incentive to build coal-fired plants in non-WCI areas. The approach was largely qualitative. The E3 report found the answer depends on WCI allowance prices, transmission costs and import charges (called "deemed emission rates" in the E3 report).

The current report does not address any issues related to power plant development in non-WCI regions.

4 WCI SCENARIOS WITH CONTRACT SHUFFLING

4.1 Scenario Definitions

The second set of PROMOD simulations analyzed by Navigant Consulting were based on the Eastern Interconnect pool structure shown earlier in Figure 4. Key aspects of this group of scenarios were:

- CO_2 regulation for generating units in the eastern WCI provinces – Quebec, Ontario, Manitoba – through the WCI CO_2 allowance cost as in the simple scenarios
- Some scenarios aligned CO_2 regulation in MGGRA states and RGGI regulation in NE US with WCI regulation in terms of a common CO_2 allowance price
- FJD charges applied to all flows into Quebec, Ontario, Manitoba from other provinces/states, but only applied to power sourced from CO_2-emitting plants
- For scenarios with aligned CO_2 regulation in WCI and MGGRA/RGGI, import (FJD) charges between WCI and MGGRA/RGGI were set to zero and import charges were applied for imports into MGGRA, but not into RGGI as that is existing legislation which currently does not include import charges
- These scenarios, with zero incremental transmission tariffs applied to imports from non-CO_2 emitting units outside the WCI (and MGGRA as appropriate), permit the examination of the effects of contract shuffling

For these more complex scenarios, because of the increased simulation time resulting from the more complex pool structure, the scenarios were run for 2020 only, as shown in Table 24.

Table 24: WCI Scenarios with Contract Shuffling

Scenario	Years	WCI Allowance Price	MGGRA Allowance Price	RGGI Allowance Price	FJD Charge	
		$/tonne	*$/tonne*	*$/tonne*	*kg/MWh*	*$/MWh*
Scenario 9 *[Base Case]*	2020	0	0	2.06	0	0
Scenario 10	2020	30	0	2.06	1000	30
Scenario 10a	2020	30	0	2.06	500	15
Scenario 12	2020	30	30	30	1000	30

Notes

1. RGGI allowance prices from the auction result - $1.87/short ton - have been converted to metric tonnes

2. Allowance prices and FJD charges are $US 2008 real

3. In these scenarios the FJD charge applies only to imports from carbon producing units

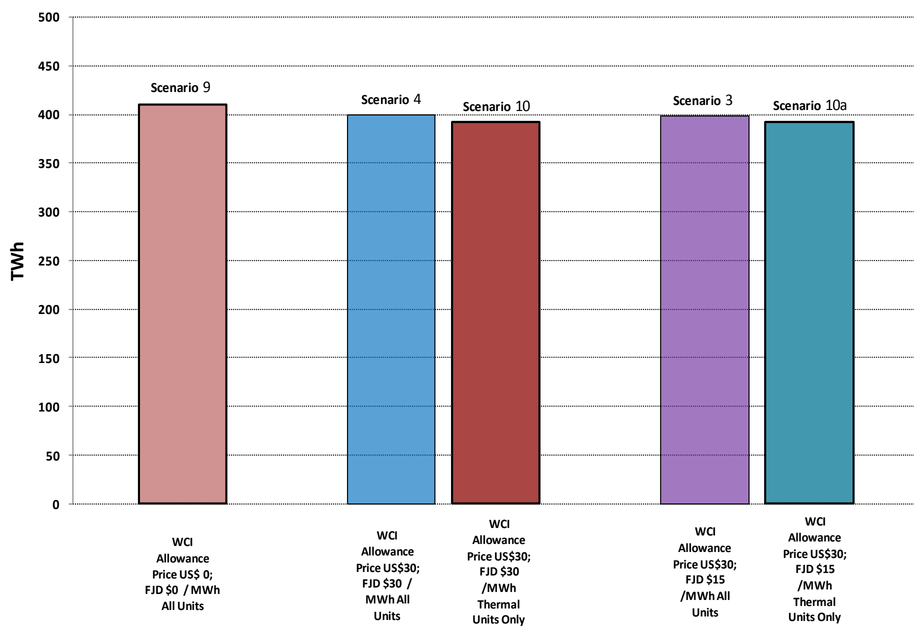
Scenario 9 represents the Base Case in the more complex pool structure. This was rerun to allow differences between scenarios to be evaluated without concerns arising from different pool structures.

4.2 Scenario Results

4.2.1 Changes in Generation and Emissions for Complex Scenarios

Figures 17 – 19 summarize the results from the PROMOD simulations for the more complex scenarios, where contract shuffling has been permitted. Although not run with the same pool structure as the simple scenarios, for reference the figures include comparable results from the earlier simple scenarios – no contract shuffling.

Figure 17: WCI Generation in 2020 – Complex Scenarios



Generally, permitting contract shuffling – with no import tariffs for imports sourced from non CO_2-emitting plants – leads to a reduction in WCI generation and in WCI emissions compared to the equivalent simulations where contract shuffling was not permitted. This is to be expected, as encouraging imports into the WCI from non CO_2-emitting sources requires additional thermal generation in non-WCI regions to meet load in those regions. The overall result, as shown in Figure 19, is an increase in total CO_2 emissions in the Eastern Interconnect, and the increase for scenarios with contract shuffling (Scenarios 10a, 10) is greater than that for the simple scenarios with no contract shuffling (Scenarios 3, 4). Effectively, allowing contract shuffling leads to an increase in leakage.

Figure 18: WCI CO_2 Emissions in 2020 – Complex Scenarios

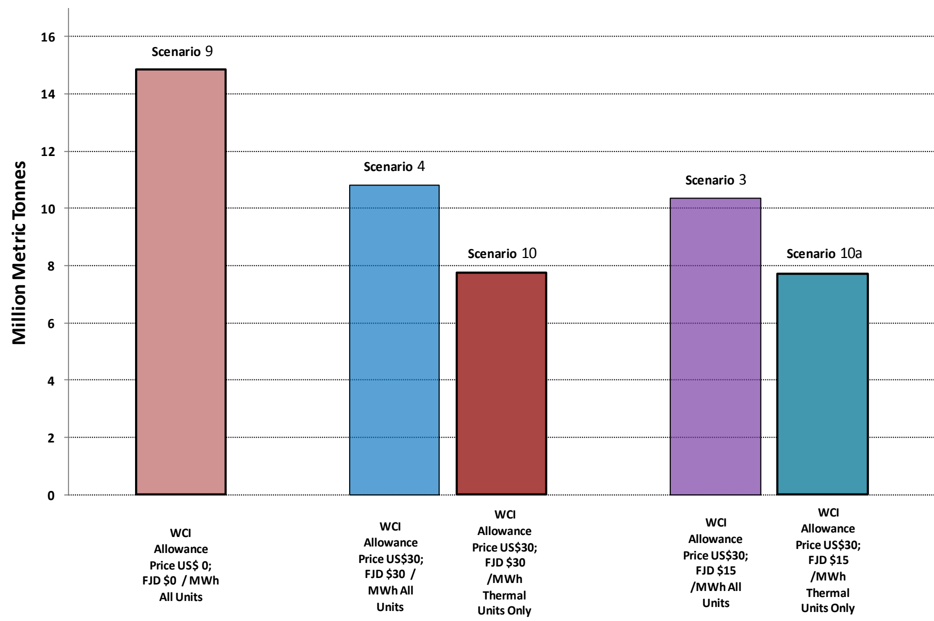


Figure 19: Change in WCI, Non-WCI and Total CO_2 Emissions in 2020– Complex Scenarios

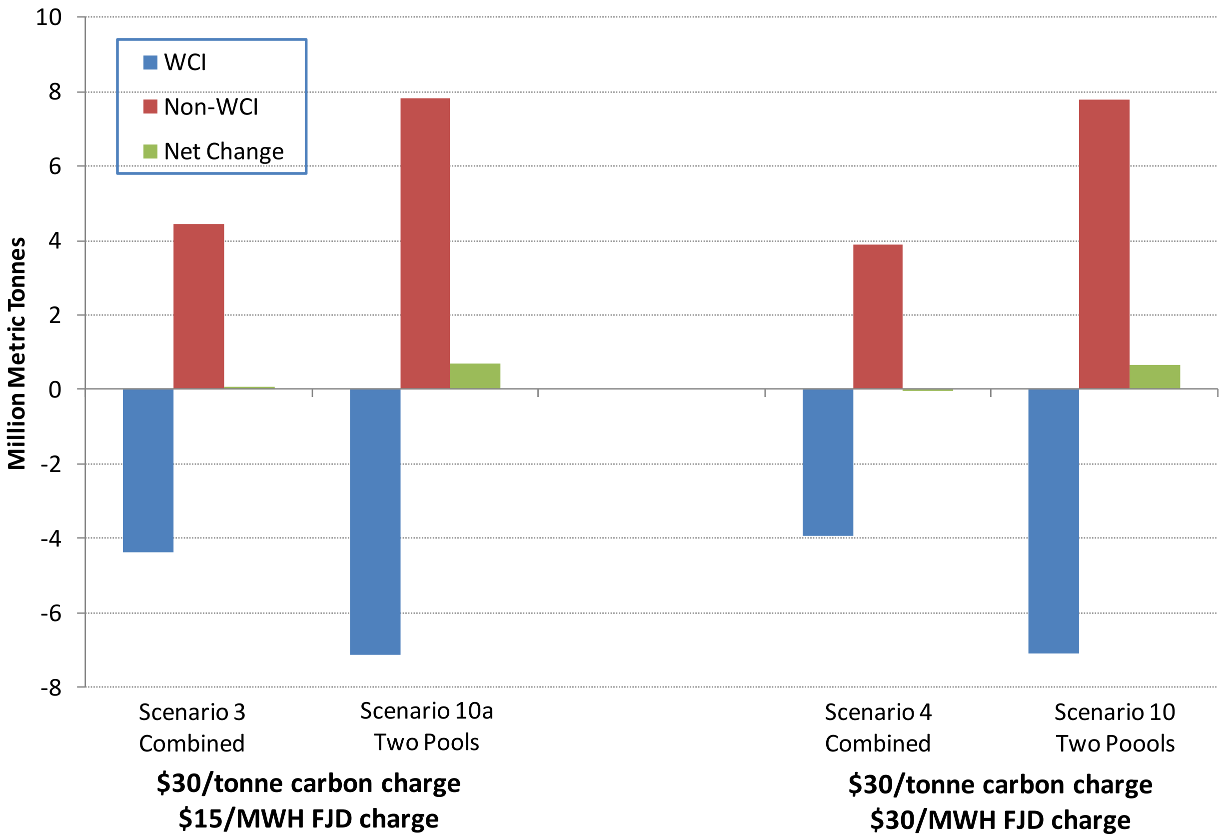


4.2.2 Changes in Generation and Emissions by Province

Tables 25 and 26 summarize the changes in WCI generation and emissions for the more complex scenarios. As with the simple scenarios, the presence of a WCI allowance price decreases WCI generation and emissions, with the exception of Scenario 12 which has a common regulatory framework and allowance price structure in WCI, MGGRA and RGGI. In that scenario, there is relatively little change to WCI generation and emissions even with a WCI CO_2 allowance price.

NAVIGANT CONSULTING

Table 25: Provincial Generation in 2020 – Complex Scenarios

Scenario	WCI Allowance Price	FJD Adder		Quebec Generation	Ontario Generation	Manitoba Generation	Total WCI Generation
	$/tonne	*kg/MWh*	*$/MWh*	*TWh*	*TWh*	*TWh*	*TWh*
Scenario 9 *[Base Case]*	0	0	0	232.2	140.9	36.7	409.8
Scenario 10	30	1000	30	229.6	125.6	36.7	391.9
Scenario 10a	30	500	15	229.6	125.6	36.7	391.9
Scenario 12	30	1000	30	231.7	137.4	36.7	405.7

Notes

1.Scenario 12 has MGGRA and RGGI CO_2 allowance prices of $30/tonne; Scenarios 10 and 10a have $0/tonne MGGRA CO_2 allowance price and $2.06/tonne RGGI CO_2 allowance prices

2.Allowance prices and FJD charges are $US 2008 real

Table 26: Provincial CO_2 Emissions in 2020 – Complex Scenarios

Scenario	WCI Allowance Price	FJD Adder		Quebec CO_2 Emissions	Ontario CO_2 Emissions	Manitoba CO_2 Emissions	Total WCI CO_2 Emissions
	$/tonne	*kg/MWh*	*$/MWh*	*Million tonnes*	*Million tonnes*	*Million tonnes*	*Million tonnes*
Scenario 9 *[Base Case]*	0	0	0	1.3	13.5	0.0	14.8
Scenario 10	30	1000	30	0.4	7.4	0.0	7.7
Scenario 10a	30	500	15	0.4	7.3	0.0	7.7
Scenario 12	30	1000	30	1.2	11.7	0.0	12.8

Notes

1.Scenario 12 has MGGRA and RGGI CO_2 allowance prices of $30/tonne; Scenarios 10 and 10a have $0/tonne MGGRA CO_2 allowance price and $2.06/tonne RGGI CO_2 allowance prices

2.Allowance prices and FJD charges are $US 2008 real

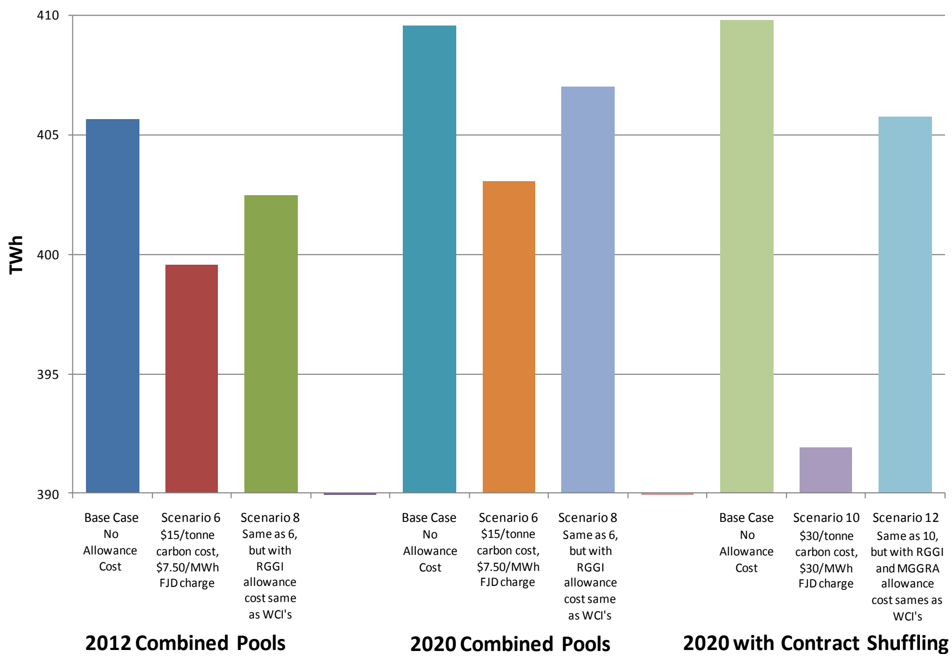
4.2.3 RGGI and MGGRA Scenarios

In several of the more complex scenarios, we also considered the effect on the WCI provinces of CO_2 regulation in MGGRA and RGGI.

In the base case, the ten RGGI states were assumed to have a low ($2.06/metric tonne) carbon price, and MGGRA (Illinois, Wisconsin, Minnesota, Iowa, Michigan) was assumed to have no carbon pricing. Both were subject to FJD charges where appropriate.

Several scenarios explored what would happen if eastern WCI, RGGI and/or MGGRA worked together to adopt similar carbon pricing regimes, and were therefore exempt from each other's FJD charges. For scenarios with the RGGI and MGGRA allowance prices aligned with the eastern WCI allowance prices, import (FJD) charges were applied to flows into WCI and MGGRA rather than just into WCI[15]. No FJD charge was applied to flows into RGGI. The results for these scenarios are shown in Figures 20 - 22.

Figure 20: WCI Generation in 2012 and 2020 – RGGI and MGGRA Scenarios



For both 2020 and 2012, Scenarios 8 and 12 – similar CO_2 allowance prices in MGGRA and RGGI as in WCI – led to higher levels of generation and CO_2 emissions in the WCI provinces, compared to Scenarios 6 and 10 where CO_2 prices were not aligned. There was still a reduction in generation and emissions compared to the Base Case with no allowance prices in the WCI or MGGRA, and a low allowance price in RGGI. This was true for scenarios with and without contract shuffling.

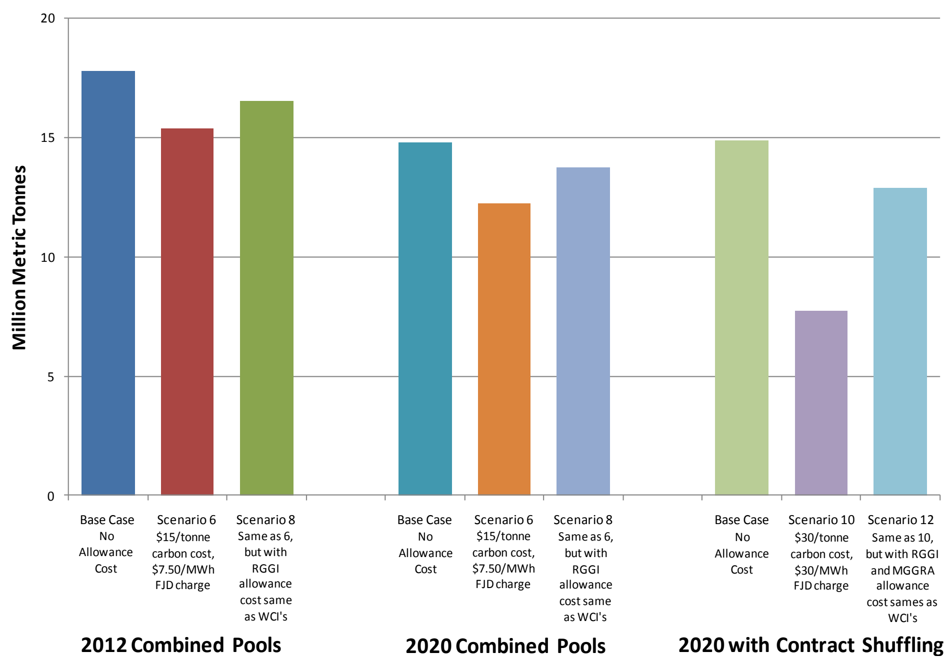
Figure 21 indicates the overall effect on total Eastern Interconnect CO_2 emissions. The combined regulatory effect leads to an overall reduction in total CO_2 emissions, from the substitution of gas for coal in non-WCI regions.

[15] No FJD charge was applied to flows into RGGI in this or any other scenario, as current RGGI regulations do not incorporate import charges into the RGGI region from non-RGGI regions

Effectively, the combination of consistent allowance prices in WCI, MGGRA and RGGI removes the economic justification for decreasing WCI thermal generation and consequently the reduction in WCI CO_2 emissions seen in other scenarios is much reduced. However, applying this level of CO_2 allowance prices to MGGRA and RGGI regions alters the economics of coal and gas plants in those regions, leading to greater gas-fired generation but overall lower CO_2 emissions[16].

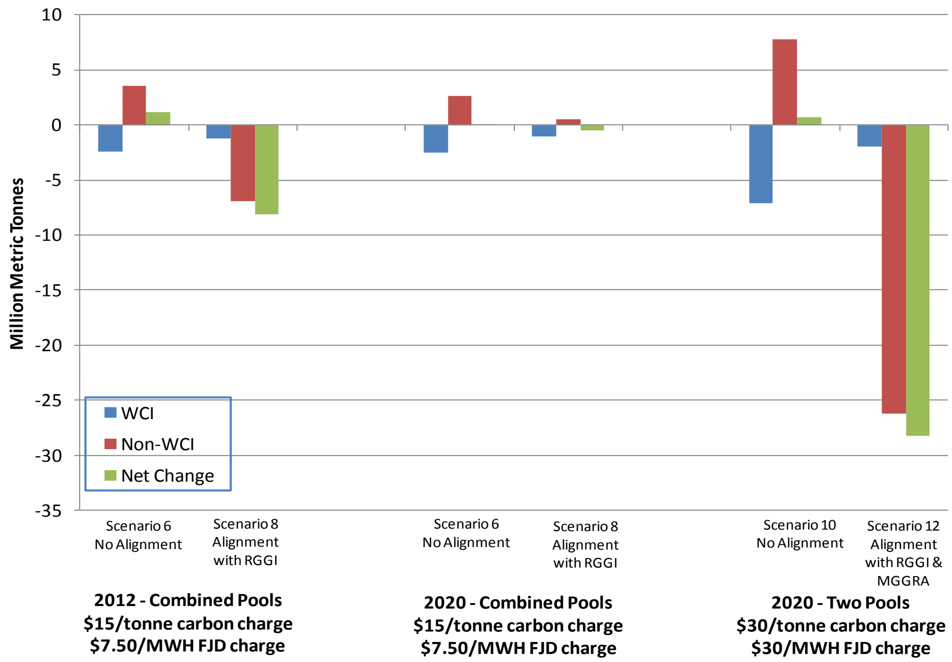
This is in contrast to the change in total emissions where there is no alignment of allowance prices and the overall effect is a slight increase in total CO_2 emissions across the Eastern Interconnect.

Figure 21: WCI CO_2 Emissions in 2012 and 2020 – RGGI and MGGRA Scenarios



[16] Although the CO_2 emissions are lower, the overall generation cost is higher than in the non-aligned case because there are CO2 emissions costs associated with substantially more thermal capacity.

Figure 22: Change in CO_2 Emissions in 2012 and 020 – RGGI and MGGRA Scenarios



4.3 Comparison of Current Study with E3 Report

The E3 report, discussed in Section 3.3 above, addressed the issue of contract shuffling by estimating the amount of hydro and gas capacity in non-WCI states in the WECC, and estimating the volume of CO_2 emissions that could be used for this purpose. This establishes a worst-case scenario. The current study addresses the contract shuffling issue in a much more detailed way, looking at system operation hour by hour and plant by plant.

The E3 report includes the possibility of contract shuffling by gas-fired plants, but assumes that plants selling into WCI pay import charges based on their actual emission rate. For example, if a gas plant's emission rate is 350 kg/MWh, and the import charges are based on a deemed emission rate of 500 kG/MWh, then the gas plant can be used in contract shuffling to avoid import charges equivalent to 150 kg/MWh. The analysis done in current study is much more complex, but some of the assumptions are simpler, as it would not be feasible to model more complex assumptions. In particular, the current study only considers contract shuffling by non-fossil generation, and it applies the same import charge to all generation in the fossil pool regardless of actual emission rates.

5 Conclusions

5.1 WCI Generation and Emissions

The modeling results showed a large (as much as 48%) decrease in the CO_2 emissions of the three WCI provinces as a result of introducing allowance prices. For scenarios with no similar CO_2 regulation in MGGRA and RGGI, the decrease in WCI emissions was offset by an increase in non-WCI emissions in every case, resulting in almost no net change in total emissions.

WCI emissions decrease because fossil generation (primarily in Ontario) falls when allowance prices are applied. This decrease in WCI generation leads to reduced exports from WCI. Non-WCI generation therefore needs to increase, and since only fossil generation has variable output, this means an increase in non-WCI fossil generation and CO_2 emissions. The impact of introducing WCI allowance prices in our analysis was consequently to shift fossil generation from the WCI provinces to non-WCI jurisdictions. The small changes in total emissions that result are from replacing one type of generation (e.g., gas in Ontario) with another (e.g., coal in Ohio).

In the scenarios, the majority changes in the pattern of WCI generation and CO_2 emissions occur in Ontario, the location of the majority of the WCI CO_2-emitting units.

The average carbon content of the increase in non-WCI generation is around 600 kg/MWh in 2012 and 400 kg/MWh in 2020. This is calculated as the increase in non-WCI emissions divided by the change in net imports (imports minus exports) into WCI. The reason for the change between 2012 and 2020 is that coal-fired generation is on the margin in non-WCI jurisdictions less often in 2020 than in 2012.

5.2 FJD Charges and Contract Shuffling

Import (FJD) charges reduce the attractiveness of importing power from non-WCI regions. Higher FJD charges lead to greater WCI generation and emissions, i.e. closer to those of the Base Case with no WCI regulation. However, WCI generation and emissions are much less sensitive to the level of the FJD charge than they are to the WCI allowance price.

The scenarios with “contract shuffling” distinguished between imports from non CO_2-emitting sources and imports from CO_2-emitting sources, and applied a zero charge for imports from non CO_2-emitting sources. This reduced the impact of any given level of FJD charges compared to the simple scenarios where this distinction between imports from different sources was not made.

5.3 Coordination with MGGRA and RGGI

The simulations that combined regulation in WCI with regulation in MGGRA and RGGI gave somewhat different results. The reductions in WCI generation and WCI CO_2 emissions that resulted from imposing allowance charges were much smaller when allowance prices were aligned across MGGRA, WCI and RGGI, compared to the scenarios with regulation in WCI only. This is because coordination of CO_2 allowances with RGGI and/or MGGRA reduces the incentive to import electricity from non-WCI jurisdictions, as the main sources of these imports are RGGI and MGGRA.

The overall CO_2 emissions from the Eastern Interconnect were reduced when there was combined regulation between WCI, MGGRA and RGGI (RGGI in terms of the RGGI allowance price). The analysis indicated this was because of a change in generation from coal to gas in MGGRA, and is not directly related to the WCI assumptions. It is a consequence of the effect of the additional allowance cost on the coal and gas MGGRA units, as discussed in Section 4.2.1.

5.4 CO_2 Leakage

The results of the WCI analysis indicated that CO_2 leakage - increases in non-WCI emissions - in all scenarios with WCI allowance prices where there was no regulatory coordination with MGGRA and RGGI. Import charges reduced the amount of leakage but did not completely eliminate this, and allowing contract shuffling increased leakage.

However, where WCI, MGGRA and RGGI have a consistent allowance price structure, there were in fact decreases in CO_2 emissions in WCI and in the non-WCI regions (i.e. no leakage). However this outcome is likely to be sensitive to the level of WCI allowance prices.

It should be noted that, given timing and budget constraints, the results presented in this report were based on a static modeling approach. In Navigant Consulting's analysis, demand, capacity, and the annual output of non-fossil plants (nuclear, hydro, wind, etc.) were kept constant. The only generation parameter that could change was the level of the output of different fossil generation facilities across the Eastern Interconnect. Consequently, a decrease in fossil generation in one area such as WCI must necessarily be offset by an increase in fossil generation in another, so that demand can be met.

In fact, imposing allowance prices in WCI would encourage consumers to reduce their usage because of higher prices, and would provide an incentive to build non-fossil capacity instead of fossil capacity, leading to a net reduction in CO_2 emissions. These dynamic impacts could not be captured in this study.

6 Appendices

6.1 Detailed Results for Simple Scenarios

Washington DC
20006

Table of Contents:

1 Background and Project Scope 4

2 Analytic Approach 4

3 Reference Case Inputs 7
3.1 Population and Economic Data 8
3.1.1 Economic Forecast 10
3.2 Energy Price Data 10
3.3 Historic Energy Consumption Data 11
3.4 Historic Emission Data 12
3.4.1 Emissions and Air Regulations 12
3.4.2 Emission Factors 13
3.5 Electricity Sector Data 13
3.5.1 Generation Data 13
3.5.2 Electricity Generation Capacity and Operation Data 14
3.5.3 Transmission Structure and Dispatch 16
3.5.4 Planned Capacity Changes 16
3.5.5 New Generation Characteristics 17
3.5.6 Industrial Generation and Co-generation 17
3.6 Transportation 18
3.7 Built Environment 19
3.8 Programs/Policies Incorporated in Reference Case 20
3.9 Alternate Reference Case 21

4 Complementary Policies 22

5 Sensitivity Analyses 24
5.1 Sensitivity Case: Half-Effectiveness of Complementary Policies 24
5.2 Sensitivity Case: Alternative Economic Forecast 24
5.3 Sensitivity Case: High Fuel Prices and Electricity Generation Costs 25
5.4 Sensitivity Case: 4% Annual Growth In Allowance Prices 25
5.5 Sensitivity Case: 12% Annual Growth In Allowance Prices 25

Appendix A: The ENERGY 2020 Model 26
Appendix B: Data Sources 37
Appendix C: Jurisdiction specific forecasts 39
Appendix D: Inter-Regional Transmission Capacity for WECC as modeled in ENERGY 2020 46
Appendix E: Data Sets Used in ENERGY 2020 51
Appendix F: Planned or Committed Coal Plants Post-2005 57
Appendix G: New Generation Performance and Cost Assumptions 58
Appendix H: Global Warming Potential 60
Appendix I: Renewable Portfolio Standards: Partner Jurisdictions and Rest of North America 61
Appendix J: Efficiency and Cost Data – Built Environment 76

Acronyms & Definitions

AEO	Annual Energy Outlook (published by EIA)
ARB	California Air Resources Board
BPA	Bonneville Power Administration
Btu	British Thermal Units
CAC	Criteria Air Contaminants (SO_x, NO_x, PM, etc.)
CFL	Compact Fluorescent Light bulb
CHP	Combined Heat and Power
CO_2e	Carbon Dioxide equivalent
GDP	Gross Domestic Product
GO	Gross Output
GWP	Global Warming Potential
DG	Distributed Generation
E3	Energy and Environmental Economics, Inc.
EIA	Energy Information Administration
EPACT	Energy Policy Act of 2005
ESCO	Energy Service Company
GHG	Greenhouse Gas
IECC	International Energy Conservation Code
IGCC	Integrated Gasification Combined Cycle
kW	Kilowatt
kWh	Kilowatt-hour
Mt	Megatonne
MW	Megawatt
MWe	Megawatt electric
Mt CO_2e	Megatonnes Carbon Dioxide Equivalent (also referred to as MTCE)
NOx	Nitrogen Oxides
OGCC	Oil/Gas Combined Cycle Turbine
OGCT	Oil/Gas Combustion Turbine
OGST	Oil/Gas Steam Turbine
PC	Pulverized Coal
REMI	Regional Economic Models, Inc.
RECS	Renewable Energy Certificates
Rest of US	Balance of systems in US
SO_x	Sulfur Oxides (including sulfur dioxide)
USEPA	United States Environmental Protection Agency
W	Watt
WCI	Western Climate Initiative
WECC	Western Electricity Coordinating Council

1 Background and Project Scope

The Western Climate Initiative (WCI) retained ICF International and its partner Systematic Solutions Inc. (SSI), to assist in modeling a cap-and-trade system for the western US and Canada. For 30 years, ICF has been known for its sophisticated models. Over that time, ICF has worked to build, enhance, and apply these tools for a variety of public and private sector clients to help answer complex questions on energy and environmental market issues. Over the same period, SSI has performed analysis to solve problems in all facets of the energy market, including electric and natural gas utilities, energy extracting industries, and the transportation sector. In addition, both firms have applied macroeconomic models in conjunction with their energy market modeling tools to address broader questions of economic impacts.

When this modeling was initiated, all eight WCI Partner jurisdictions were located within the Western Electricity Coordinating Council (WECC) region. In late 2008, ICF was authorized to expand the modeling effort to include all 11 of the current partners; including the provinces of Manitoba, Ontario and Québec. In order to properly represent the expanded geographic coverage of the WCI, the model was expanded to represent all of the US and Canada. In the process of building this expanded model, ICF took the opportunity to update some information in the model and address issues raised by the WCI Economic Modeling Team (EMT) and WCI stakeholders. The update also included revising the economic forecasts to include the effects of the economic recession.

This report describes the ENERGY 2020 model, assumptions in the analysis, and the input data and data sources.

2 Analytic Approach

This project uses ENERGY 2020 to model the business-as-usual outlook for the WCI Partner jurisdictions[1] as well as surrounding states and provinces and the impact of potential greenhouse gas (GHG) emissions reduction policies.

ENERGY 2020 is an integrated multi-region energy model that provides complete and detailed, all-fuel demand and supply sector simulations. These simulations can additionally include macroeconomic interactions to determine the benefits or costs to the local economy of new facilities or changing energy prices. The model can be used in regulated as well as deregulated and transitioning environments. GHG and criteria air contaminant pollution emissions and costs, including allowances and trading, are endogenously determined, thereby allowing assessment of environmental risk and co-benefit impacts.

The basic implementation of ENERGY 2020 for North America now contains a user-defined level of aggregation down to the 10 provincial and 50 state (and sub-state) level. ENERGY 2020 contains historical information on all generating units in the US and Canada. Data for Mexico can be incorporated as needed. ENERGY 2020 is parameterized with local data for each region/state/province as well as all the associated energy suppliers it simulates. Thus, it

[1] Arizona, California, Montana, New Mexico, Oregon, Utah, Washington, British Columbia, Manitoba, Ontario and Québec.

captures the unique characteristics (physical, institutional and cultural) that affect how people make choices and use energy. Collections of state and provincial models are currently validated from 1986 to the latest quarterly numbers.[2]

ENERGY 2020 can be linked to a detailed macroeconomic model to determine the economic impacts of energy/environmental policy and the energy and environmental impacts of national economic policy. For US regional and state level analyses, the REMI macroeconomic model is regularly linked to ENERGY 2020.[3] The Informetrica macroeconomic model is linked to ENERGY 2020 for Canadian national and provincial efforts.[4] The REMI and Informetrica macroeconomic models include inter-state/provincial, US and world trade flows, price and investment dynamics, and simulate the real-time impact of energy and environmental concerns on the economy and vice versa.

The structure of the model is well tested and has been used to simulate not only US and Canadian energy and environmental dynamics, but also those of several countries in South America, Western, Central, and Eastern Europe. These efforts include strategic and tactical analyses for both planning and energy industry restructuring/deregulation. In the 1990s, the US EPA made ENERGY 2020 available to interested states to analyze emissions, energy, and economic impacts of state-level climate change initiatives. Further, the model has been used successfully for deregulation analyses in all the US states and Canadian provinces. Many US and Canadian energy suppliers use the model for the analysis of combined electricity and gas deregulation dynamics.[5]

The default model simulates demand by three residential categories (single family, multi-family, and agriculture/rural), over 40 NAICS commercial and industrial categories[6], and three transportation services (passenger, freight, and off-road). There are approximately six end-uses per category and six technology/mode families per end-use.[7] Currently the technology families correspond to six fuels groups (oil, gas, coal, electric, solar and biomass) and 30 detailed fuel products. The transportation sector contain 45 modes including various type of automobile, truck, off-road, bus, train, plane, marine and alternative-fuel vehicles. More end-uses, technologies, and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical, locale-specific data. The load duration curves are dynamically built up from the individual end-uses to capture changing conditions under consumer choice and combined gas/electric programs.

Each energy demand sector includes cogeneration, self-generation, and distributed generation simulation, including mobile-generation, micro-turbines, and fuel-cells. Fuel-switching responses

[2] Energy supplier data comes from FERC and US DOE for the US and Statistics Canada. US and Canadian fuel and demand data come from the US Department of Energy and Natural Resources Canada, respectively. US and Canadian pollution data come from US EPA and Environment Canada, respectively.

[3] Regional Economic Models, Inc. www.remi.com

[4] Informetrica Limited www.informetrica.ca

[5] ENERGY 2020 is the only model known to have simulated and predicted the dynamics that occurred in the UK electric deregulation. These include gaming, market consolidation and re-regulation dynamics.

[6] NAICS is the North America Industrial Classification System which was developed jointly by the U.S., Canada, and Mexico to provide new comparability in statistics about business activity across North America.

[7] End-uses include Process Heat, Space Heating, Water Heating, Other Substitutable, Refrigeration, Lighting, Air Conditioning, Motors, and Other Non-Substitutable (Miscellaneous). Detailed modes include: small auto, large auto, light truck, medium-weight truck, heavy-weight truck, bus, freight train, commuter train, airplane, and marine. Each mode type can be characterized by gasoline, diesel, electric, ethanol, NG, propane, fuel-cell, or hybrid vehicles.

are rigorously determined. The technology families (which can be split, as an option, to portray specific technology dynamics) are aggregates that, within the model, change building shell, economic-process and device efficiency and capital costs as price or other information that the decision makers see, change. ENERGY 2020 utilizes the historical and forecast data developed for each technology family to parameterize and disaggregate the model.

The supply portion of the model includes endogenous detailed electric supply simulation of capacity expansion/construction, rates/prices, load shape variation due to weather, and changes in regulation.[8] The model dispatches plants according to the specified rules whether they are optimal or heuristic and simulates transmission constraints when determining dispatch.[9] A sophisticated dispatch routine selects critical hours along seasonal load duration curves as a way to provide a quick but accurate determination of system generation. Peak and base hydro usage is explicitly modeled to capture hydro-plant impacts on the electric system.

ENERGY 2020 supply sectors include electricity, oil, natural gas, refined petroleum products, ethanol, land-fill gas, and coal supply. Energy used in primary production and emissions associated with primary production and its distribution is included in the model. The supply sectors included in a particular implementation of ENERGY 2020 will depend on the characteristics of the area being simulated and the problem being addressed. If the full supply sector is not needed, then a simplified simulation determines delivered-product prices.

The ENERGY 2020 model includes pollution accounting for both combustion (by fuel, end-use, and sector) and non-combustion, and non-energy (by economic activity) for SO_2, NO_2, N_2O, CO, CO_2, CH_4, PMT, $PM_{2.5}$, PM_5, PM_{10}, VOC, CF_4, C_2F_6, SF_6, and HFC at the state and provincial level by economic sector. Other (gaseous, liquid, and solid) pollutants can be added as desired. Pollution does not need to be determined directly by coefficients but can recognize the accumulation of capital investments that result in pollution emission with usage. National and international allowance trading is also included. Plant dispatch can consider emission restrictions.

The model captures the feedback among energy consumers, energy suppliers, and the economy using Qualitative Choice Theory and co-integration.[10] For example, a change in price affects demand that then affects future supply and price. Increased economic activity increases demand; increased demand increases the investment in new supplies. The new investment affects the economy and energy prices. The energy prices also affect the economy.

Finally, the system includes confidence and validity testing software that places uncertainty bounds on simulation results, quantifies confidence intervals, and ranks the contributions to uncertainty in future conditions. This feature can be used to limit data efforts to information most important to the analysis.

---

[8] ENERGY 2020 does include a complete, but aggregate representation of the electric transmission system. Electric transmission data is provided by FERC, the Department of Energy, and the National Electric Reliability Council. The dispatch technologies in the basic model include: Oil/Gas Combustion turbine, Oil/Gas Combined Cycle, Oil/Gas Combined Cycle with CCS, Oil/Gas Steam Turbine, Coal Steam Turbine, Advanced Coal, Coal with CCS, Nuclear, Baseload Hydro, Peaking Hydro, Small Hydro, Wind, Solar, Wave, Geothermal, Fuel-cells, Flow-Battery Storage, Pumped Hydro, Biomass, Landfill Gas, Trash, and Biogas.

[9] A 110 node transmission system is used in the default model, but a full AC load-flow bus representation model has also been interfaced with ENERGY 2020.

[10] The model has used the work of Daniel McFadden and Clive Granger since its inception in the late 1970s.

In order to assess the potential impacts of proposed policy options, a b*usiness-as-usual* scenario is developed as a point of reference. This *Reference Case* represents a scenario that is viewed as a reasonable expectation of how the economy, energy use and emissions might develop over time.

Part of the nature of developing a Reference Case is the need to address inherently uncertain issues that can have significant impacts on future energy use and emissions. No forecast is going to be *right* or *accurate* in that no one can tell today how some of the key underlying issues may develop. Given the level of uncertainty involved in any projection of a possible future, caution should be used in applying a high level of precision to the modeling results. Understanding the Reference Case, however, can be extremely useful in providing an underlying structure against which to model proposed policies, and in determining directionality and cause and effect.

Numerous assumptions are required to perform an analysis of this type across a range of topic areas, including economic developments, fuel and electric markets, and regulatory structures. Projected outcomes are only as good as the input assumptions upon which they are based, with more rigorous assumptions leading to a more rigorous analysis. The inputs and assumptions described in this document were developed to provide as accurate a representation as possible of the activities and structures underlying energy use and GHG emissions in the WCI Partner jurisdictions.

3 Reference Case Inputs

ENERGY 2020 derives energy demands, such as the demand for electricity based on economic activity and device efficiency. The following sections provide a brief overview of the data inputs and assumptions as well as the sources of data used in the Reference Case. Actual data inputs for specific elements such as generating units, emission factors, etc., can be provided separately in Excel spreadsheets as required.

As a multi-sector analytical tool, ENERGY 2020 requires data and assumptions covering a broad range of economic sectors and their interactions. In most cases, the necessary data – both historical and projected – is available from the federal government (EIA, EPA, etc.). In past analyses, ENERGY 2020 has relied heavily on these federal sources to populate and calibrate the model. In developing the model for this project, a considerable amount of state-specific information was available and has been used wherever possible.

The following sections provide an overview of the data and assumptions that are required to perform the multi-sector analysis, and list the data sources used to populate ENERGY 2020.

Data inputs for ENERGY 2020 are required in five areas: [11]

1. Population and economic
2. Fuel prices
3. Energy use and consumption
4. Emissions and air regulations
5. Electricity generation capacity and operation

[11] "Data" here refers to both historical data and assumptions and projections of future inputs.

The sections below list the key data elements required in each of these areas, along with the sources that have been used to supply these data for other analyses. Appendix B lists a number of default data sources used by the model. The sections that follow provide a more specific description of the data used for this project including state-specific data used in place of national sources.

ENERGY 2020 requires both historical data and projections to calibrate and generate forward-looking projections. Various historical data will be used for the period 1985-2005 (the last year for which certain detailed sectoral and end-use are available). Projections for the period to be modeled (e.g. through 2030) will be gathered where possible to provide points of comparison and check the reasonableness of the projection.

The implementation of ENERGY 2020 for this project began with inclusion of the states and provinces within the Western Electricity Coordinating Council (WECC); specifically Arizona, California, Montana, New Mexico, Oregon, Utah, Washington, and British Columbia. Manitoba was initially not included in this modeling due to the complexity of extending the model beyond the WECC. Since that time, new partners have joined the WCI, including Ontario and Quebec. The current phase of the project expands the modeling to include all eleven current WCI Partner jurisdictions. In order to fully represent the interactions between these jurisdictions and their neighbouring states and provinces, the model has been expanded to represent all of the US and Canada.

3.1 *Population and Economic Data*

Demographic and economic data is required to generate demands for services. The historic data for the US states was obtained from the US Bureau of Economic Analysis (BEA). For the Canadian provinces, historic data is from Statistics Canada's CANSIM.

The following data sources were used to establish the reference case for the WCI policy modeling:

Description of Data/Input	**Sources**	**Detailed Reference**
Total population, historical and growth over time	US Census Bureau	*Historic (1985-2006):* Regional Economic Information System, Bureau of Economic Analysis, U.S. Department of Commerce http://www.bea.gov/regional/spi/default.cfm?satable=summary *California:* California population taken from: CEC *California Energy Demand 2008-2018 Staff Revised Forecast*
	Statistics Canada	Statistics Canada Table 051-0001 (based on census data)
	Future	For US - Future annual population growth rates are taken from Regional Forecasts from AEO then applied to the state historical population. Annual Energy Outlook 2007 (February 2007 release). http://www.eia.doe.gov/oiaf/aeo/supplement/suptab_1.xls through suptab_9.xls For Canada: projected based on Informetrica forecast.
Population by housing type	US Census Bureau	Population Estimates Program, Population Division

Description of Data/Input	Sources	Detailed Reference
(single-family, multi-family, etc.)	Statistics Canada	Household type, Structural Type of Dwelling and housing tenure for Private Households of Canada
Households by housing type (single-family, multi-family, etc.)	US Census Bureau	Household splits (data through 2001 then held constant): *Source: U.S. Census Bureau, Housing and Household Economic Statistics Division* Last Revised: *December 16, 2005* http://www.census.gov/hhes/www/housing/census/historic/units.html **Household size** US Census Bureau, Census 2000 - assumes household size is same for all housing types in state. **Number of households** Calculated based on population, household fraction, and household size.
	Statistics Canada	Household type, Structural Type of Dwelling and Housing Tenure for Private Households of Canada
	Future	Projected based on Informetrica forecast.
Personal income	US Bureau of Economic Analysis	*Historic (1985-2006)*: Bureau of Economic Analysis, 6/24/07 http://www.bea.gov/regional/spi/default.cfm?satable=summary *California*: Estimates provided by ARB (see Appendix C).
	Statistics Canada	Statistics Canada CANSIM table 384-0012
	Future	Apply changes in historic Personal Income to Total GRP ratio and apply to future to forecast out to 2030.

Project partners were provided with the default projections proposed for use in the modeling and invited to provide alternative jurisdiction-specific projections.

Several partners elected to accept the initial model projections, including:

- Montana
- Oregon
- Utah
- British Columbia
- California

It should be noted that the economic projection for California had been provided by the state based on work done as part of a prior project.

Some partners chose to provide jurisdiction-specific projections for some of the demographic and economic data, including:

- Arizona: personal income; population (state total); and gross output (from REMI)
- New Mexico: population
- Washington: population

For all other partners data from the sources listed in the tables above was used.

Population, housing and economic output projections provided by the partners are presented in Appendix C.

3.1.1 Economic Forecast

Economic conditions changed quite dramatically over the course of this project. ENERGY 2020 requires a detailed state and provincial level sector-by-sector forecast for the US and Canadian economy as a basis for modeling future economic activity and emissions. A projection for the US economy was obtained from Regional Economic Models, Inc. (REMI). For the Canadian economy, a long term projection prepared by Informetrica Ltd., was made available by the National Energy Board. Both of these projections pre-dated the economic downturn that started in late 2008. Given the speed with which the economy has changed, we found that economic forecasts with the level of detail required by the model were not yet available at the time when the Reference Case was being prepared.

In order to provide a more realistic representation of current economic expectations, ICF/SSI in consultation with the Economic Modeling Team (EMT) sought more recent projections that would reflect current expectations of the two economies. For the US, the projection of the Congressional Budget Office[12] was selected as providing a reasonable representation of a consensus view at that time. Recognizing the strong interaction between the two national economies, we sought projections for the Canadian economy which projected comparable US conditions to those presented in the CBO forecast. The Conference Board of Canada,[13] in its Winter 2009 Outlook, provides a forecast for both the Canadian and US economy. The depth and length of the US downturn presented in the Board's US outlook were reasonably aligned with the Congressional Budget Office's expectations. Unfortunately this projection did not have the level of detail required by the model. As a result, an earlier Conference Board of Canada forecast was used which implied a less severe US recession than the CBO forecast. This Canadian forecast therefore projected less of a downturn for Canada than the projection used for the U.S. These two forecasts were used to adjust the existing more detailed projections in order to reflect the effects of the economic downturn. In the case of the Conference Board projection, considerable sector detail was available to reflect differences in these impacts between provinces. Where jurisdiction specific projections had been provided by partners, these projections were also adjusted to reflect the changes in the broader economy.

3.2 *Energy Price Data*

Energy prices can play a significant role in end user decisions on equipment, capital and operating decisions. Fuel costs can be critical in determining the costs of electric dispatch, as well as input costs of some industrial processes and home heating. ENERGY2020 calculates future electric prices based in part on these fuel costs.

[12] Congress of the United States, Congressional Budget Office, The Budget and Economic Outlook: Fiscal Years 2009 to 2019, January 2009.
[13] ICF/SSI used the Conference Board's "Provincial Long Term Database" which provided the most recent available economic forecast available. The Board published a summary of its expectations for the Canadian economy in its "Canadian Outlook Executive Summary: Global Recession Weighs Heavily on Canada, Winter 2009".

Energy prices are largely determined by international markets, although domestic demand, such as electric sector demand for natural gas can influence prices. As a result, fuel prices are treated by the model as an exogenous input.

Historic energy price data are taken from US DOE State Energy Data and Statistics Canada. The model currently uses energy price forecast data for the US from the Energy Information Administration's 2009 Annual Energy Outlook Reference Case Price scenario for 2009 to 2030.[14] For Canada, the National Energy Board's price forecast is used[15].

Biomass Cost *(per MBtu in 2006$)*	
Residential	$11.53
Commercial	$10.09
Industrial	$10.06

Biomass prices in the model are based on research completed for a previous project, shown in the table below. Unlike other fuels, biomass prices are significantly influenced by local cost and supply issues.

Power prices are calculated endogenously by the model based on generation costs and dispatch. While, the model estimates retail electricity prices, actual consumer prices may differ as a result of political, regulatory or market influences. The model can be calibrated to actual prices, within reasonable parameters, for the historic period.

Given the time and resources available for the project, the model does not account for the different regulatory regimes among the partner jurisdictions with respect to electric price regulation (i.e., cost-of-service ratemaking vs. various forms of market-driven pricing). The intent of the modeling is rather to produce reasonable estimates of retail prices at the state or provincial level based on generation costs and historical mark-ups above generation costs.

3.3 *Historic Energy Consumption Data*

ENERGY 2020 models energy use at the end-use level within each economic sector based on the existing physical stock and the efficiency of that stock. The database of device efficiencies reflects both the average efficiency of energy use for current stocks and the efficiency/energy alternatives available to consumers at the margin. Technology and efficiency choices are modeled based on past experience with consumer choice rather than on a purely economic evaluation.

Historic energy use and consumption data used in the model is derived from the federal Energy Information Administration (EIA) State Energy Data (SEDS) database. Where state-specific data were available, these data was used to replace national data sources.

Default sectoral and end-use data as well as energy intensities are based on the Residential Energy Consumption Survey (RECS), Commercial Energy Consumption Survey (CECS) and Manufacturers Consumption Energy Survey (MECS).

[14] Energy Information Administration, Annual Energy Outlook 2008, Report #DOE/EIA-0383(2008), June 2008, http://www.eia.doe.gov/oiaf/aeo/

3.4 *Historic Emission Data*

3.4.1 Emissions and Air Regulations

Historic GHG emissions are based on the Canadian national inventory published by Environment Canada and the US GHG emissions inventory as published by the EPA.[16] ENERGY 2020 is calibrated using historic information on all of the major GHG emissions including:

- Carbon dioxide (CO_2),
- Nitrous oxide (N_2O),
- Methane (CH_4),
- Sulfur hexafluoride (SF_6),
- Hydrofluorocarbons (HFCs) and
- Perfluorocarbons (PFCs).

GHG emissions are presented in CO_2 equivalent (CO_2e) terms. The global warming potentials used to convert the different greenhouse gas emissions into CO_2e terms are provided in Appendix H.

[16] EPA website: http://www.epa.gov/climatechange/emissions/usinventoryreport.html

Input	Sources Used/Available
Emissions by sector, end-use, fuel & GHG	US EPA http://www.epa.gov/climatechange/emissions/usinventoryreport.html Environment Canada http://www.ec.gc.ca/pdb/ghg/inventory_e.cfm

3.4.2 Emission Factors

Emission factors for most fuels are based on values used by ICF in developing national and state inventories. For the transportation sector however, the emission factors for CH_4 and N_20 pollutants were adapted from the Canadian National Inventory Report.[17] ENERGY 2020 calculates GHG emissions at the point of combustion for most fuels. Upstream emissions from extraction and processing are captured as part of those respective economic sectors.

Emissions associated with the use of biomass as a fuel are deemed to be biogenic and therefore not contribute to global warming. As a result, the model assumes no GHG emissions are created from the use of biomass.

Emissions from ethanol and other biofuels represent an exception from a modeling perspective. In order to capture the emissions associated with their production and distribution, the model applies full cycle emission factors for these fuels. While the combustion of ethanol and biodiesel are not deemed to result in any anthropogenic emissions, the model uses an emission factor to recognize upstream emissions.

The full-cycle emission factors used in the model for each biofuels type are shown in the table below:[18]

Corn Ethanol	76 g CO_2e / MJ
Cellulosic Ethanol	14 gCO_2e / MJ
Biodiesel	30 gCO_2e / MJ

When these fuels are used in combination with other fuels, for example in a mix of gasoline and ethanol, the emissions associated with gasoline combustion are reported as part of total gasoline-related emissions.

3.5 *Electricity Sector Data*

3.5.1 Generation Data

The electricity sector differs from other sectors in the extent to which emissions associated with power use within the state may result from emissions outside the WCI region as power is imported from or exported to other areas.

[17] Environment Canada. National Inventory Report 1990-2005, Greenhouse Gas Sources and Sinks in Canada, April 2007. (Annex 12 Emission Factors)
[18] Alexander Farrell, UC Berkeley and Daniel Sperling, UC Davis, A Low-Carbon Fuel Standard for California Part 1: Technical Analysis May 29, 2007 Table 2-3 http://www.energy.ca.gov/low_carbon_fuel_standard/UC-1000-2007-002-PT1.PDF

ENERGY 2020 contains information on every generating unit in the state or province, as well as in neighboring jurisdictions which may supply power to the state. The model tracks and uses the following information for each generating unit:

- Historic Peak Capacity (MW);
- Historic generation levels (GWh);
- Type of fuel used;
- Heat rate;
- Historic annual fuel use (PJ);
- Emissions by pollutant type;
- O&M costs;
- Capacity factors;
- Emission rates;
- Outage rates;
- State or Province;
- Physical location (latitude and longitude);
- Ownership information;
- Plant type (Hydraulic, Coal, Combined Cycle Turbine, etc.)

The data on existing and committed generating units in the US was obtained from the National Electric Energy Data System (NEEDS) 2006 database and reconciled with a list of plants from BPA. The database of plants in Canada was developed based on the Canadian IPM®[19] module, modified and updated based on information from Statistics Canada, Environment Canada and the National Energy Board.

3.5.2 Electricity Generation Capacity and Operation Data

ENERGY 2020 is populated with data describing the type, operation and performance of every generating unit in the US and Canada. In order to improve model performance, some smaller units with common characteristics have been combined (i.e. wind units at the same site, or small hydraulic units). In addition to plant-level data, the table below includes other inputs necessary to describe the electric system, including transmission capability.

Input	Sources Used/Available
Plant type	Annual Electric Generator Report: EIA Form 860 (2006) Canadian IPM® Base Case 2004[20] Natural Resources Canada, Canada's Energy Outlook: Reference Case 2006[21] Supplemented by National Energy Board info.
Plant capacity	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Plant historical generation	EIA Form 906/920 (2001-2006) Total generation output by plant type for California from

[19] ICF's Integrated Planning Model®.
[20] http://www.ec.gc.ca/cleanair-airpur/caol/canus/IPM_TECHNICAL/ipm_technical_report/toc_e.cfm
[21] http://www.nrcan-rncan.gc.ca/com/resoress/publications/peo/peo-eng.php

Input	Sources Used/Available
	CEC Canada: as above
Plant fuel type	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Plant Heat Rate	EIA Form 906/920 (2001-2006) Canada: as above
Plant fuel consumption	EIA Form 906/920 (2001-2006)
Plant emissions by pollutant	EPA CAMD (2001-2006) Environment Canada
Plant costs (operation and maintenance, variable and fixed)	CA: E3 model data Canada: as above
Plant historical capacity factor	EIA Form 906/920 (2001-2006) Statistics Canada
Plant availability (outages)	Calculated using generation data Statistics Canada
Plant owner and location	Annual Electric Generator Report: EIA Form 860 (2006) Canada: as above
Planned capacity additions and retirements	Annual Electric Generator Report: EIA Form 860 California Public Utility Commission GHG Modeling process (E3) NRCan Energy Outlook
Transmission Capability	Canada: National Energy Board, *Canadian Electricity Trends and Issues (2001)* & *Canadian Electricity Exports and Imports (2001)*; National Resources Canada, *Electric Power in Canada 1998 – 1999*; NERC, *2004 Summer Assessment* & *2004 Winter Assessment: Reliability in the Bulk Electricity Supply in North America* Western US – Additional data provided by BPA and reports from the WECC (Approved 2006 Spring OTC Limits, March 16, 2006).

This data has been compared to generation data provided as part of modeling for the California Public Utilities Commission.[22]

The resulting list of generating units was matched to emission data from the EPA and Environment Canada in order to calculate emission rates. The resulting emission rates for the targeted GHG emissions were then reviewed for reasonableness based on plant type and capacity factors, etc.

Historic generation by plant type will be calibrated with historic generation data available from the EIA.

[22] www.ethree.com/cpuc_ghg_model.html

3.5.3 Transmission Structure and Dispatch

Power flows between neighboring US states are modeled within ENERGY 2020 based on existing transmission capabilities and interconnections as obtained from NERC reports.

Appendix D describes the inter-regional transmission capabilities between model regions (or nodes) as well as the maximum capacity limit of each transmission path used in the model. Interconnection capacities and transmission nodes used in the model were based on the IPM® Model 2006[23] updated to reflect changes in the region based on past work for past clients including the Bonneville Power Administration and review by the Economic Modeling Team.

Generation is dispatched at the node level for a set of sample hours in each season. Each node is economically dispatched, selecting lowest cost generation first with the resulting clearing price determining the generation price for that node as described in Appendix A. As part of the calculation the model can utilize resources from a neighboring node within the constraints of the transfer capacity between nodes. The transfer of energy between nodes is subject to a 1% loss to represent additional transmission losses.

3.5.4 Planned Capacity Changes

As part of the modeling process, ENERGY 2020 builds new capacity endogenously as needed to meet capacity and reserve requirements or to minimize the total cost of generation (e.g., in response to allowance prices). At any given time, however, plans may already be in place to build, re-furbish, upgrade or retire generation facilities. These plans must be incorporated into the model in order to reflect decisions and commitments that have already been made.

For this project, we reviewed information on generation projects planned in the Region, with particular emphasis on planned coal facilities. This list was then reviewed with the WCI Economic Modeling Team to determine which projects were felt to be most likely to proceed based on the current status. While it is not possible to determine which specific projects will proceed, for modeling purposes we have assumed that the units listed in Appendix F will be built during the modeled period.

ENERGY 2020 can determine the need for new generation based on a pre-determined reserve requirement. Normally, this determination is based on the highest level of demand for power and the available capacity at the time of that peak. Some types of generation, such as wind or some types of hydro-electric generation however, may not be available at the time of the peak. For modeling purposes the model assumes that only 15% of installed wind capacity is available at the time of the peak.

[23] Table 3.5 of section 3 of the documentation for the EPA Base Case 2006 (v3.0) posted on the EPA website: http://epa.gov/airmarkets/progsregs/epa-ipm/index.html#docs

3.5.5 New Generation Characteristics

The costs and characteristics of new generation are based on information developed as part of the GHG modeling process for the California Public Utility Commission[24] and are shown in Appendix G.

Carbon capture and storage (CCS) is not assumed to be available until after 2020. The performance and cost assumptions for new generating units equipped with CCS are shown in Appendix G. It should be noted that these costs represent capture costs only and do not include transportation or sequestration costs.

The model assumes that no new nuclear generation capacity will come online through 2020. Ontario nuclear units returning to service after scheduled refurbishment are not considered to be “new” capacity.

3.5.6 Industrial Generation and Co-generation

ENERGY 2020 models both utility generation, which supplies the power grid, and industrial generation which supplies a particular end user. Industrial generation is defined as power generation that is within the industrial end user’s facility and is not used to supply power to the grid. Industrial generation, as defined in ENERGY 2020, could also be referred to as self-generation or load displacement generation. Industrial generation may be supplied by any of the fuels listed below:

- Biomass
- Coal
- LPG
- Oil
- Solar
- Steam

Co-generation, or combined heat and power facilities, simultaneously generate electricity and supply a heat load. ENERGY 2020 recognizes that co-generation may occur either as industrial generation or as utility generation and may use any of a number of fuels.

- Within the power sector, these plants are treated as ‘must run’ units, meaning that they will always operate when available. Power from these units contributes to overall electricity supply. Heat from these units may be captured as part of a separate steam supply system, however, limited data is available regarding overall US steam demand.
- Within the industrial sector, co-generation capacity will run based on heating requirements. Heat produced from co-generation is used to meet industrial heat requirements based on a co-generation heat rate. Co-generated electricity is used to meet industrial power requirements, reducing net demand from the grid.

Where the heat contribution of co-generation is significant, the preferred modeling approach is to include these units in the industrial sector.

[24] www.ethree.com/cpuc_ghg_model.html

The databases used to represent electricity generation often include all significant generators, including both utility and industrial boilers and generators. By contrast, reported electricity consumption information tends to be based on metered electricity sales, and as such are net of self generation. Total electricity consumption and generation will generally be slightly higher than reported electricity sales. It is therefore important in calibrating the model with historic electricity consumption that existing generation used as industrial or self-generation be appropriately identified.

3.6 *Transportation*

ENERGY 2020 models passenger, freight and off road transportation separately, based on different underlying drivers. Transportation is assumed to be a derived demand based on levels of economic output (for freight) or personal income (for passenger). As the economic drivers (industrial gross output and personal income) grow, transportation demand increases. The amount of transportation required per unit of economic output changes over time based on historic trends.

Transportation requirements are developed for each geographic area in the model based on historic demands for transportation, consumer preferences, business requirements, and the cost for each mode of transportation. Consumers of transportation select among available modes within the model based on preferences and relative costs. Mode choices include bus, train, and various types of personal and freight vehicles. Consumers choose among modes based on consumer preferences and cost. The model uses average vehicle lifetimes to vintage the vehicle stock.

Personal vehicle choices are made in a similar manner. Consumers consider capital cost, fuel cost and efficiency as well as non-price factors in their purchase decision and seek to maximize perceived utility. Historically, non-price factors such as vehicle size, performance and appearance have dominated the choice decision with efficiency playing a relatively minor role. Costs are presented in the model in terms of the capital cost per mile traveled for different vehicle classes. Larger vehicles therefore have a higher associated capital cost as well as lower energy efficiency for the level of delivered service (miles traveled).

The transportation categories represented in the model are shown below.

E2020 Classifications				
Economic Categories	**Modes**	**Vehicle Classes** *(Personal Vehicles)*	**Fuel Types** *(Personal Vehicles)*	**Technology Types**
Passenger	Personal Vehicles	Light	Gasoline	Internal Combustion Engine
Freight	Motorcycle	Medium	Diesel	Hybrids
Off Road	Train	Heavy	Propane	Fuel Cell
	Plane		CNG	Plug-In Hybrid
	Marine		Electric	
			Ethanol	
			Hydrogen	

At present, plug-in hybrid and fuel cell options are not populated in the model. As more information on the costs and characteristics of these options becomes available these choices can be made available to transportation consumers.

Vehicle and modal efficiencies used in the model are based on the *Transportation Energy Data Book* (Edition 26, 2007)[25] published by the US Department of Energy's Oak Ridge National Laboratory. Specific data references are provided in the table below.

Input	Sources Used/Available
*All tables below are from **Transportation Energy Data Book** (Edition 26, 2007)[26] published by the US Department of Energy's Oak Ridge National Laboratory.*	
Average fuel economy	Tables 4.17 and 4.18
New Vehicle Efficiency	Tables 4.7 and 4.8
Scrap/Survival Rates	Tables 3.8, 3.9 and 3.10
Freight Truck Fuel Economy	Tables 5.1 and 5.2
Bus Efficiency	Table 2.13
Rail Efficiency – Passenger	Table 9.10 and 9.11
Rail Efficiency - Freight	Table 9.8
Marine – Freight	Table 9.5
Air Travel	Table 9.2

The model reflects the most recent changes in new passenger vehicle in CAFÉ standards, as embodied in the *Energy Independence and Security Act of 2007* (see section 4.8).

Off road transportation energy use in ENERGY 2020 is driven by activity in the Agriculture, Forestry and Construction sectors.

3.7 *Built Environment*

ENERGY2020 has been used to model energy for almost three decades. Much of the data on energy efficiency and costs was originally based on information provided by the Energy Information Administration's *Annual Report to Congress*[27] which was last published in 1980. Over the years, these data has been updated based on information gathered from clients as part of numerous projects. The resulting cost and efficiency data is used as default values in the model.

When a new model is built for a particular project, actual historic energy use is input to the model (generally from the EIA SEDS database) and allocated by sector based on census region data from the most recent energy surveys available from the EIA (e.g. Residential Energy Consumption Survey, Commercial Building Energy Consumption Survey, etc). Average and maximum device efficiencies are adjusted within the model over time in calibrating to this actual

[25] http://cta.ornl.gov/data/download26.shtml
[26] http://cta.ornl.gov/data/download26.shtml
[27] EIA, Annual Report to Congress, 1980: Volume 3. Energy Information Administration, USDOE, Report #: DOE/EIA-0173(80)/3.

energy use data. For the WCI project, ICF and SSI have subjected these data to an internal review and updated the values based on expert opinion and data from a variety of sources.

Appendix J presents the assumptions used in modeling the residential and commercial sectors, showing assumed levels of efficiency by period, maximum efficiency levels, initial and operating costs per mmBtu of energy use and device lifetimes for each end use for each fuel type. This data is used in the choice curves within the model.

Several of the jurisdictions involved in the WCI have had a long history of promoting energy efficiency and demand side management for electricity and natural gas energy use. As a result, average appliance and equipment efficiencies are expected to be higher than for the US and Canada as a whole. Where data permits, end-use data within the model has been adjusted to reflect current levels of efficiency and market saturations.

The Reference Case does not assume any increase in equipment or appliance efficiency other than the improvements due to the *Energy Independence and Security Act of 2007*, as noted in section 4.8.

3.8 *Programs/Policies Incorporated in Reference Case*

The *Energy Independence and Security Act of 2007* was passed into law in early January 2008. The following assumptions will be used to model the Act in the Reference Case:

- Renewable Fuels: The Act specifies a minimum volume of biofuels to be produced each year. For modeling purposes we have assumed that this volume of biofuels is produced and consumed in each year. The model assumes that each of the US states will use their pro-rata share of the available fuels.
- Residential Boilers and Furnace Fans: Savings estimates developed by the ACEEE for each state has been used to model this portion of the Act, using only the benefits realized by upgrades to the residential energy boilers, leaving out any energy benefits associated with reduced electricity consumption by furnace fans.
- Walk-In Coolers and Walk-In Freezers: Savings estimates developed by the ACEEE for each state has been used to model this portion of the Act.
- Electric Motor Efficiency Standards: The model will utilize the ACEEE savings projections, pro-rated to each states relative industrial electricity sales.
- External Power Supply Efficiency Standard: savings estimates developed by the ACEEE for each state have been used to model this portion of the Act.
- Energy Efficient Light Bulbs: The base assumptions are that general service lighting accounts for about 90% of residential lighting, 10% of commercial lighting and 5% of industrial lighting.
- Metal Halide Lamp Fixtures: The model assumes that 15% of commercial lighting and 60% of industrial lighting now use metal halide fixtures. For new installations the model assumes that 80% of this market would use pulse start ballasts.

On May 19, 2009, the Obama administration announced its intention to establish standards for vehicle GHG emissions and CAFÉ standards which would align with the GHG emission standards previously proposed by California. As a result, a national standard will be established which will require the fuel efficiency of new passenger cars and light trucks to reach an average fleet efficiency of 35.5 mpg by 2016. For modeling purposes we have assumed a fixed percentage increase in the efficiency of new vehicles each year starting in 2010 to reach the mandated level by 2016. Information relating to the cost of implementing this policy was based on estimates by the NHTSA[28]. We have assumed that fleet efficiency will continue to increase beyond 2016 but have included that increase in the complementary policies.

For the Canadian provinces, the model assumes that existing requirements for biofuels are met. Existing legislation requires that all gasoline sold in Canada contain 5% ethanol by 2012 and that all fuel oil and diesel contain 2% biofuels by 2010.[29]

The reference case includes Renewable Portfolio Standards for each US state as well as renewable energy targets established by Canadian provinces. Please refer to Appendix I for summaries of each jurisdiction's RPS.

3.9 Alternate Reference Case

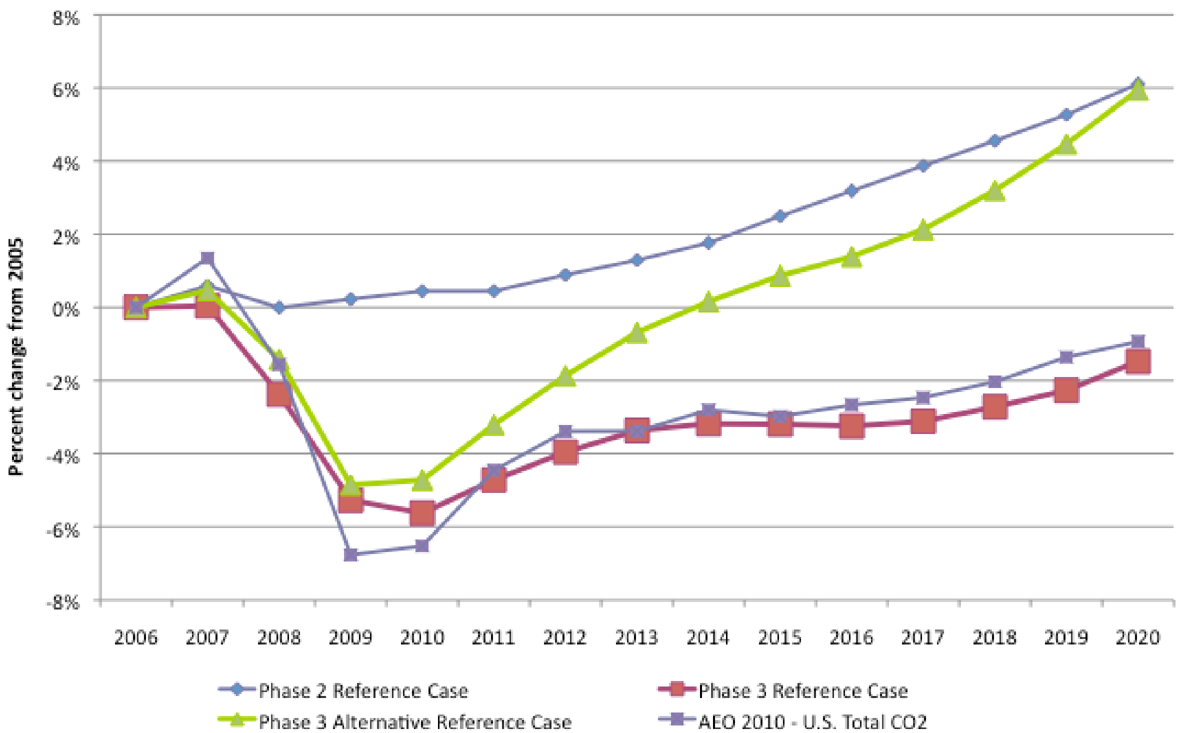
In testing the sensitivity of the analysis to different assumptions the EMT decided to model an "Alternate Reference Case." This Alternate case involved changing three assumptions in the main Reference Case:

1. That the economy would grow more rapidly; adding 0.5% per year growth starting in 2010.
2. That the biofuels mandate established by the US Energy Independence and Security Act (EISA) will not be fully met by 2020. Instead, the Alternate Reference assumes the level of biofuels reflected in the US Annual Energy Outlook (AEO) 2009.
3. Given uncertainties around the future price of oil and gas, the Alternate Reference assumes that prices follow a trajectory mid-way between the reference and low energy price scenario presented in the AEO 2009.

All of these 'alternate' assumptions have the effect of increasing the base level of GHG emissions relative to the base Reference Case. The comparison between the two cases is shown below.

[28] NHTSA, Corporate Average Fuel Economy Rulemaking, Document No. WP.29-145-13, June 2008, see also: NHTSA, Final Environmental Impact Statement, Corporate Average Fuel Economy Standards, Passenger Cars and Light Trucks, Model Years 2011 to 2015, October 2008.
[29] Renewable Fuels Strategy: ecoENERGY for Biofuels. Canada Gazette: http://canadagazette.gc.ca/partI/2006/20061230/html/notice-e.html#i3

Assumption	Base Reference Case	Alternative Reference run
Economic growth	Accounts for economic recession based on January 2009 Congressional Budget Office forecast	Faster economic growth to assess implications of a stronger than expected recovery
Fuel price forecast	AEO 2009 mid case	Average of AEO 2009 mid and low cases. Lower fuel prices results in more fuel consumption
Energy efficiency program impacts (used in complementary policy run)	Reduced demand for electricity and natural gas by 0.5% per year	Reduced demand for electricity and natural gas by 1.0% per year



4 Complementary Policies

It is expected that a number of programs to increase energy efficiency and reduce energy requirements will be introduced in conjunction with any cap-and-trade system implemented. These policies would complement the cap-and-trade system to assist in meeting GHG reduction goals. While it is expected that each partner will introduce its own particular set of policies to achieve these reductions, a *Complementary Policies* scenario was modeled that includes the following WCI-wide policies. These policies are in addition to any existing policies represented in the Reference Case or Alternate Reference. Some of these policies were modeled differently for the Reference Case and the Alternate Reference, as described below:

- **Vehicle Miles Traveled** – The combined effect of transportation and fuel programs recently put in place and being pursued is assumed to be equivalent to reducing vehicle miles traveled (VMT) by 2 percent from the reference case by 2020, beginning in 2008.

- **Energy Efficiency Programs** – The combined effect of energy efficiency programs recently put into place and being pursued (affecting the use electricity, natural gas, fuel oil and propane) are assumed to reduce energy use by *one-half of one percent in each year* below the reference forecast between 2012 and 2020. This change was introduced through increases to process and device efficiencies across the residential, commercial and industrial sectors. The costs of actual equipment upgrades associated with these efficiency gains are captured in the model. However, program and administration costs are not modeled by ENERGY 2020. The costs associated with implementing such a program could be funded through auction revenues. In the **Alternate Reference case**, which includes more robust economic growth, efficiency programs are assumed to reduce growth in energy use by *one percent each year* over the same period.

  - **Efficiency Improvement** - In order to translate this policy into modeling terms, ICF/SSI assumed that the increase in efficiency would be implemented across all sectors (residential, commercial and industrial) and all end uses. Through an iterative process, operating this policy on a stand-alone basis, we determined a level of efficiency gain for marginal devices for each year that would achieve the targeted reduction in energy use. The increase in efficiency was introduced into the model through a multiplier applied evenly across processes and devices.

  - **Economies of Scale** - An assumption was made that as more efficient devices were required, the cost of devices would benefit from economies of scale; shifting the cost curve for the efficiency improvement down.

    For modeling purposes the EMT directed that the economies of scale achieved as these technologies gain market share be limited to no more than 10% reduction in cost. In addition, the model will be constrained such that this reduction does not bring the cost of more efficient devices to a level below the cost for standard devices with current levels of efficiency.

  - **Retrofits** - No retrofits, or premature retirements of existing equipment, were assumed in the modeling. The efficiency improvements required to meet the policy target were assumed to take place at the margin. In ENERGY 2020 devices and processes are each continually replaced with assumed lifetimes of less than 20 years so at least 5% of the devices and processes are replaced each year.

  - **Process Efficiency Impacts on Device Investments** – Changes in process efficiency generally reflect changes in the level of energy service required (e.g. the amount of lighting reduced due to day-lighting or improved design or water heating needs reduced due to more efficient end-use devices). To the extent the process efficiency increases, this tends to lower the level of device investment required in these end uses; as lower lighting requirements are reflected in fewer new fixtures being required. For modeling purposes, we have assumed that 30% of the efficiency gains attained under the complementary policy will come from process efficiency gains, while 70% come from device efficiency gains.

- **Vehicle Efficiency Improvements** – The efficiency improvements included in the Reference Case (described above) result in new vehicle efficiency improvements until 2016. While no further improvements beyond that time are required under current law or regulation, the EMT has assumed that all WCI Partner jurisdictions will require continued improvements in vehicle efficiency through to 2020. The assumed improvement between 2016 and 2020 is based on emission reductions currently contemplated by the California ARB in its Scoping Plan.[30] This would increase the average efficiency of new cars and light trucks to 42.5 mpg by 2020.[31] The change in vehicle costs required to meet this standard are based on estimates by the California Air Resources Board.[32]

- **Ontario Coal Phase-out** – Assumes that Ontario phases out its coal-fired electricity generation by 2015, replacing it with hydro and wind power.

5 Sensitivity Analyses

The EMT ran several sensitivity cases to test the effects of different assumptions regarding the effectiveness of the complementary policies, economic forecasts, fuel prices and electricity generation costs, and growth rate of allowance prices.

5.1 *Sensitivity Case: Half-Effectiveness of Complementary Policies*

The purpose of this sensitivity case is to examine what happens if the energy efficiency and VMT programs achieve only half of their assumed emission reductions. Specifically, this case assumes that:

- The energy efficiency programs reduce the rate of growth in electricity and natural gas demand by only 0.25 percent per year, starting in 2012.
- Vehicle miles traveled decrease by only 1 percent from the reference case by 2020.
- The clean car standards are unchanged.
- The Ontario coal phase-out is unchanged.

5.2 *Sensitivity Case: Alternative Economic Forecast*

The purpose of this sensitivity case is to examine the implications of a different economic forecast than that assumed in the main policy case. The alternative economic forecast is described in a previous section.

[32] California Environmental Protection Agency, Air Resources Board, Regulations to Control Greenhouse Gas Emissions from Motor Vehicles, Final Statement of Reasons, August 4, 2005.

5.3 *Sensitivity Case: High Fuel Prices and Electricity Generation Costs*

The purpose of this sensitivity case is to examine the implications of energy prices being higher than assumed in the main policy case. There has been considerable stakeholder comment that the energy price forecast in the main policy case may be too low. Additionally, some stakeholders have commented that the power generation cost assumptions may be too low, indicating that recent increases in commodity prices have had an impact on these costs. This sensitivity case includes both increased energy prices and increased power generation costs as a set of conditions that could occur together in the future. In this case, energy prices are assumed to start at 2008 prices and increase in real terms by 50% by 2020, and capital and O&M costs for power generation are assumed to be 30% higher than in the main policy case. This case required its own reference and complementary policies runs.

5.4 *Sensitivity Case: 4% Annual Growth In Allowance Prices*

The purpose of this sensitivity case is to examine the implications of a slow-rising allowance price trajectory. This case uses a growth rate in the allowance price of 4 percent per year instead of 8 percent per year in the cases discussed above.

5.5 *Sensitivity Case: 12% Annual Growth In Allowance Prices*

The purpose of this sensitivity case is to examine the implications of a faster-rising allowance price trajectory. This case uses a growth rate in the allowance price of 12 percent per year instead of 8 percent per year in the cases discussed above.

Appendix A: The ENERGY 2020 Model

The Model – ENERGY 2020

ENERGY 2020 is an integrated multi-region, multi-sector energy analysis system that simulates the supply, price and demand for all fuels. It is a causal and descriptive model, which dynamically describes the behavior of both energy suppliers and consumers for all fuels and for all end-uses. It simulates the physical and economic flows of energy users and suppliers. It simulates how they make decisions and how those decisions causally translate to energy-use and emissions.

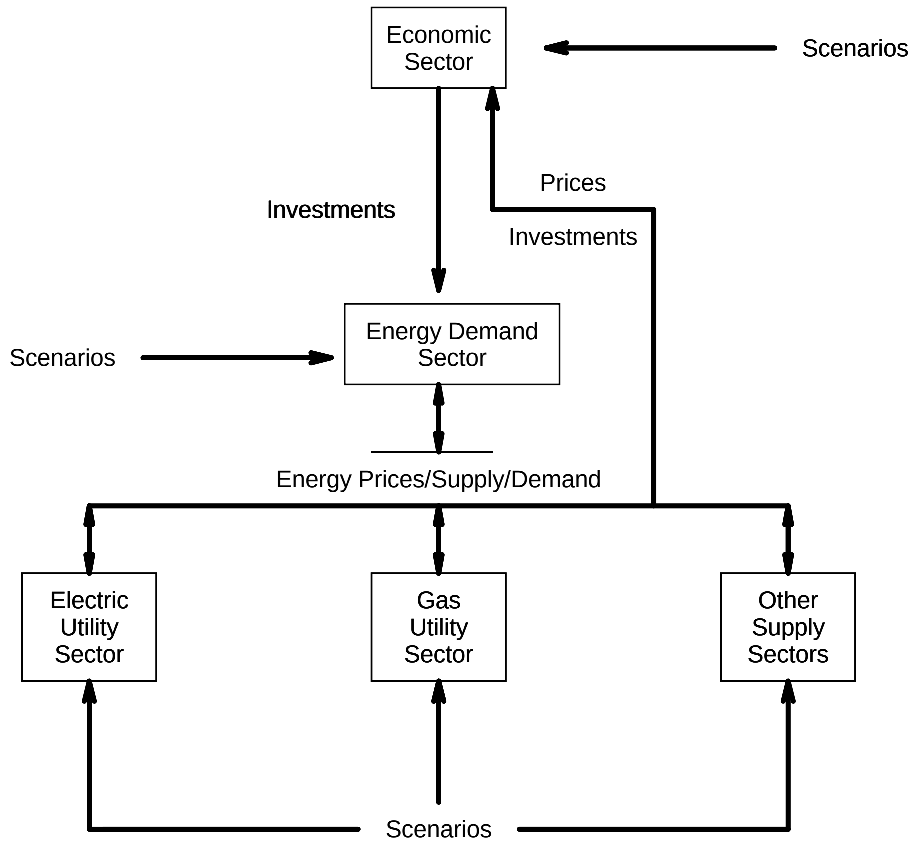
ENERGY 2020 is an outgrowth of the FOSSIL2/IDEAS model developed for the US Department of Energy (DOE) and used for all national energy policy since the Carter administration.[33] This early version of ENERGY 2020 was developed in 1978 at Dartmouth College for the DOE's Office of Policy Planning and Analysis.

Model Overview:

The basic structure of ENERGY 2020 is provided in Figure 1.1. Energy Demand sector interacts with the Energy Supply sector to determine equilibrium levels of demand and energy prices. Energy Demand is driven by the Economy sector, which in turn provides inputs to the Economy sector in terms of investments in energy using equipment and processes and energy prices. The model has a simplified Economy sector to capture the linkages between the energy system and the macro-economy. However, the model is best run with full integration with a macroeconomic model such as REMI. Given the modular nature of ENERGY 2020, additional sectors or modules from other, non-ENERGY 2020 related, models (macroeconomic, supply such as oil, gas, renewables etc.) can be incorporated directly into the ENERGY 2020 framework.

[33] *FOSSIL2 was the original version but was renamed to IDEAS a few years ago to reflect its evolutionary development since its original construction.*

Figure 1.1: ENERGY 2020 Overview



Energy Demand:

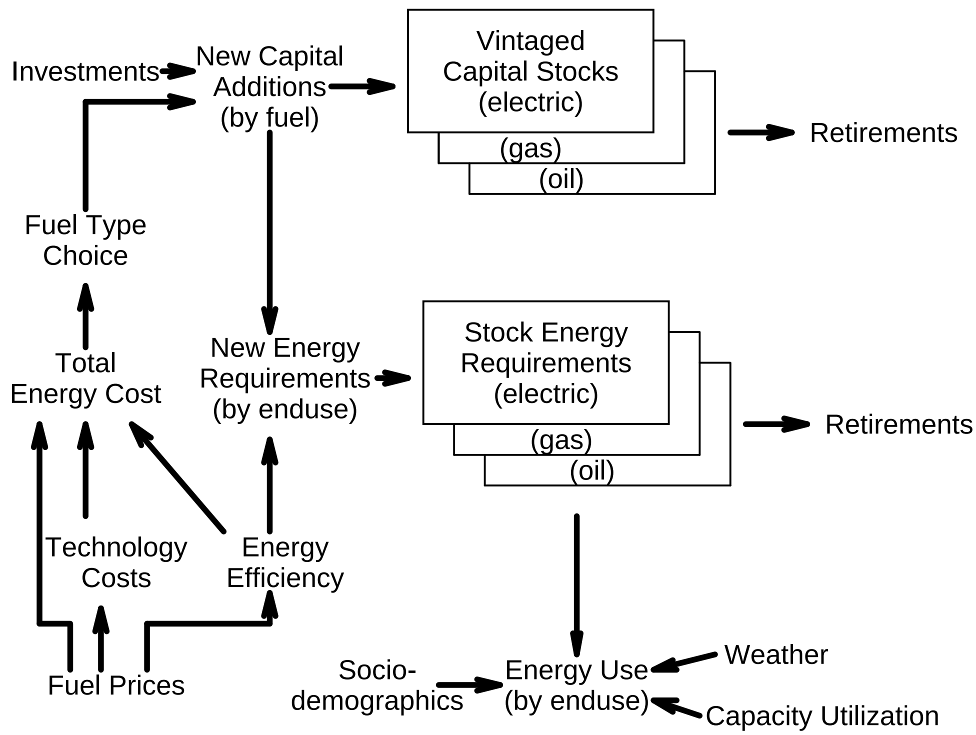
The demand sector of the model represents the geographic area by disaggregating the four economic sectors into subsectors based on energy services. As many or as few subsectors can be incorporated as required. Multiple technologies, multiple end-uses and multiple fuels are detailed. The level of detail that can be incorporated is of course subject to the data availability. The four economic sectors are:

- Residential sector which includes three classes, single family, multifamily and rural/agricultural with 8 end-uses including space heating, water heating, lighting, cooling, refrigeration, other substitutable, and other non-substitutable.
- Commercial sector which is aggregated into one class and end-uses including space heating, water heating, cooling, lighting, other substitutable, other non-substitutable.
- Industrial sector which includes 10 (23 for US) 2-digit SIC categories and is further broken down into process heat, motors, lighting, miscellaneous as the end uses.
- Transportation sector which includes several modes of transportation including automobile, truck, bus, train, plane, marine and electric vehicles. Also, each of the residential, commercial and industrial sectors has separate transportation demands.

For each of the end-uses, up to six fuels are modeled, for example, the residential space heating has the choice of a gas, oil, coal, electric, solar and biomass space heating technologies. Added end-uses, technologies and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical locale-specific data. The load duration curves are dynamically built up from the individual end-uses to capture changing condition under consumer choice and combined gas/electric programs.

A few basic concepts are crucial to an understanding of how the model simulates the energy system. These concepts including, the capital stock driver, the modeling of energy efficiency through trade-off curves, the fuel market share calculation, utilization multipliers and the cogeneration module are discussed below in abbreviated form. Figure 1.2 (Demand Overview) illustrates the demand sector interactions.

Figure 1.2: Demand Overview



Energy Demand as a Function of Capital Stock:

The model assumes that energy demand is a consequence of using capital stock in the production of output. For example, the industrial sector produces goods in factories, which require energy for production; the commercial sector requires buildings to provide services; and the residential sector needs housing to provide sustained labor services. The occupants of these buildings require energy for heating, cooling, and electromechanical (appliance) uses.

The amount of energy used in any end-use is based on the concept of energy efficiencies. For example, the energy efficiency of a house along with the conversion efficiency of the furnace determines how much energy the house uses to provide the desired warmth. The energy efficiency of the house is called the capital stock energy or process efficiency. This efficiency is primarily technological (e.g. insulation levels) but can also be associated with control or life-style changes (e.g. less household energy use because both spouses work outside the home.) The furnace efficiency is called the device or thermal efficiency. Thermal efficiency is associated with air conditioning, electromotive devices, furnaces and appliances.

The model simulates investment in energy using capital (buildings and equipment) from installation to retirement through three age classes or vintages. This capital represents embodied energy requirements that will result in a specified energy demand as the capital is utilized, until it is retired or modified.

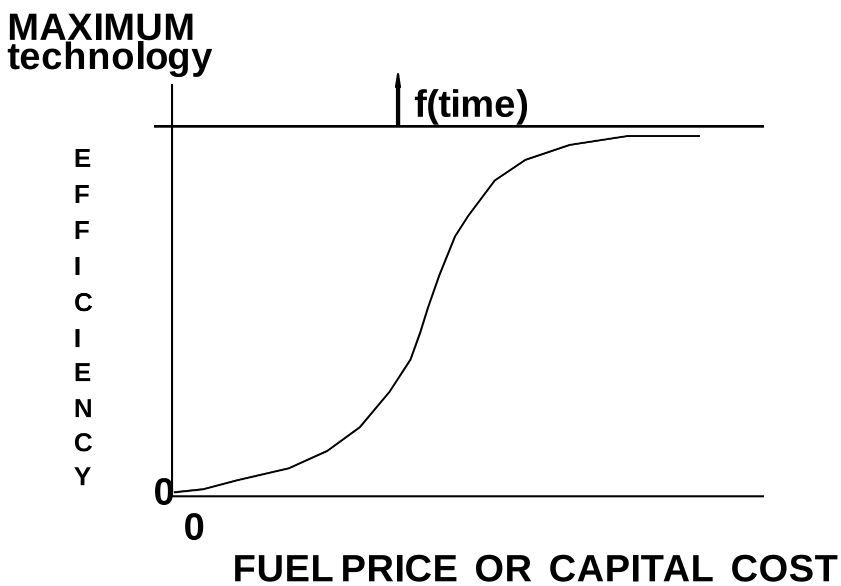
The size and efficiency of the capital stock, and hence energy demands, change over time as consumers make new investments and retire old equipment. Consumers determine which fuel and technology to use for new investments based on perceptions of cost and utility. Marginal trade-offs between changing fuel costs and efficiency determine the capital cost of the chosen technology. These trade-offs are dependent on perceived energy prices, capital costs, operating costs, risk, access to capital, regulations and other imperfect information.

The model formulates the energy demand equation causally. Rather than using price elasticities to determine how demand reacts to changes in price, the model explicitly identifies the multiple ways price changes influence the relative economics of alternative technologies and behaviors, which in turn determine consumers' demand. In this sense, price elasticities are outputs, not inputs, of the model. The model accurately recognizes that price responses vary over time, and depend upon factors such as the rate of investment, age and efficiency of the capital stock, and the relative prices of alternative technologies.

Device and Process Energy Efficiency:

The energy requirement embodied in the capital stock can be changed only by new investments, retirements, or by retrofitting. The efficiency with which the capital uses energy has a limit determined by technological or physical constraints. The trade-off between efficiency and other factors (such as capital costs) is depicted in Figure 1.3 (Efficiency/Capital Cost Trade-Off). The efficiency of the new capital purchased depends on the consumer's perception of this trade-off. For example, as fuel prices increase, the efficiency consumers choose for a new furnace is increased despite higher capital costs. The amount of the increase in efficiency depends on the perceived price increase and its relevance to the consumer's cash flow.

Figure 1.3: Efficiency/Capital Cost Trade-Off



The standard the model efficiency trade-off curves are called consumer-preference curves because they are estimated using cross-sectional (historical) data showing the decisions consumers made based on their perception of a choice's value. Many planners are now interested in measure-by-measure or least-cost curves which use engineering calculations and discount rates to show how consumers should respond to changing energy prices. Another analysis focuses on the technical/price differences in alternative technologies and the incentives needed to increase the market-share or market penetration of a specific technology. This perspective on the choice process uses market share curves. The model allows the user to select any of these three types of curves to represent the way consumers make their choices. Shared savings, rebate, subsidy programs, etc. can be tested using any of the curves.

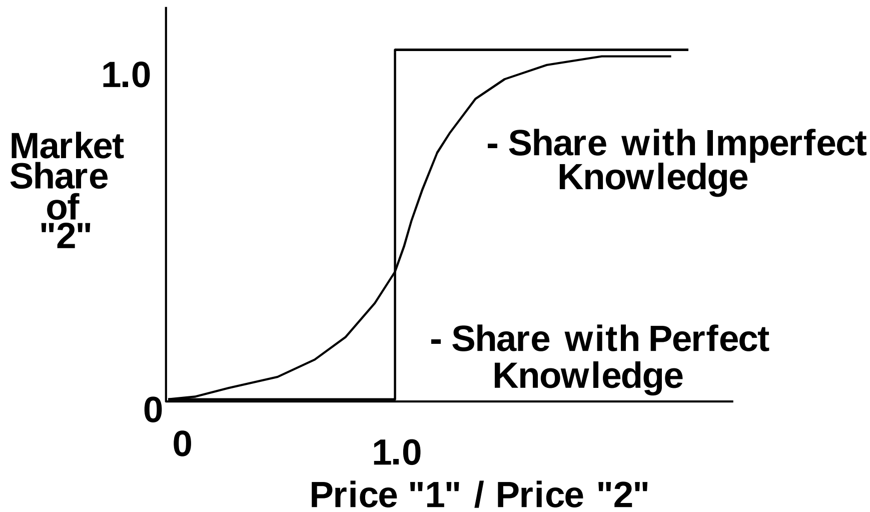
Cumulative investments determine the average embodied efficiency. The efficiency of new investments versus the average efficiency of existing equipment is one measure of the gap between realized and potential conservation savings.

The model uses saturation rates for devices to represent the amount of energy services necessary to produce a given level of output. Saturation rates may change over time to reflect changes in standard of living or technological improvements. For example, air conditioning has historically increased with rising disposable incomes. These rates can be specified exogenously or can be defined in relation to other variables within the model (such as disposable income).

The Market Share Calculation:

Not all investment funds are allocated to the least expensive energy option. Uncertainty, regional variations, and limited knowledge make the perceived price a distribution. The investments allocated to any technology are then proportional to the fraction of times one technology is perceived as less expensive (has a higher perceived value) than all others. This process is shown graphically in Figure 1.4 (Market Share Dynamics).

Figure 1.4: Market Share Dynamics



Short Term Budget Responses:

A short-term, temporary response to budget constraints is included in the model. Customers reduce usage of energy if they notice a significant increase in their energy bills. The customers' budgets are limited and energy use must be reduced to keep expenditures within those limits. These cutbacks are temporary behavioral reactions to changes in price, and will phase out as budgets adjust and efficiency improvements (true conservation) are implemented. This causes the initial response to changing prices to be more exaggerated than the long-term response, a phenomenon called "take-back" in studies of consumer behavior.

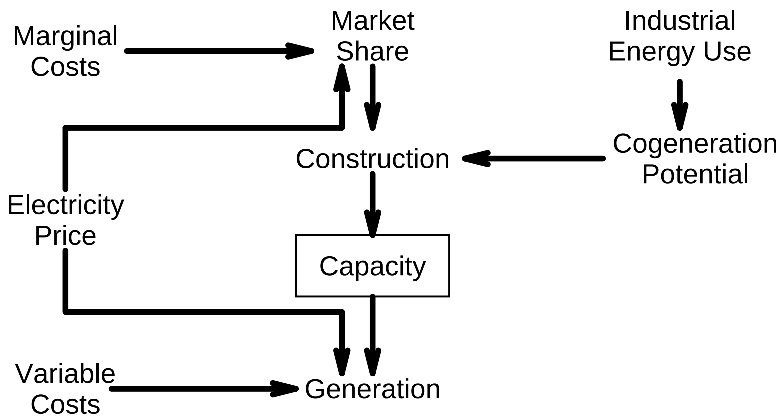
Accounting for Fungible Demand:

Some furnaces and processes can use multiple fuels. That is, they can switch almost instantaneously between, for example, gas and oil or coal and biomass as prices or the market dictates. Energy demand that is affected by this short-term fuel switching phenomena is called fungible demand. The model explicitly simulates this market share behavior.

Modeling Cogeneration:

Most energy users meet their electricity requirements through purchases from a utility. Some users (industrial and commercial) can, however, convert some of their own waste heat into usable electricity when economics warrant such action. Other users (residential and commercial) can purchase self-generation energy sources such as gas turbines, diesel-generators or fuel cells. Figure 1.5 shows a simplified overview of the cogeneration structure.

Figure 1.5: Cogeneration Concepts



In the model all energy used for heating is a candidate for cogeneration. The cost of cogeneration is the fixed capital cost of the investment plus the variable fuel costs (net of efficiency gains). This cogeneration cost is estimated for all technologies and compared to the price of electricity. The marginal market share for each cogeneration technology is based on this comparison.

Cogeneration is restricted to consumers who directly produce part of their own electricity requirement. Companies which generate power primarily for resale to the electric utility are considered independent power producers and are included in the electric supply model.

Energy Supply:

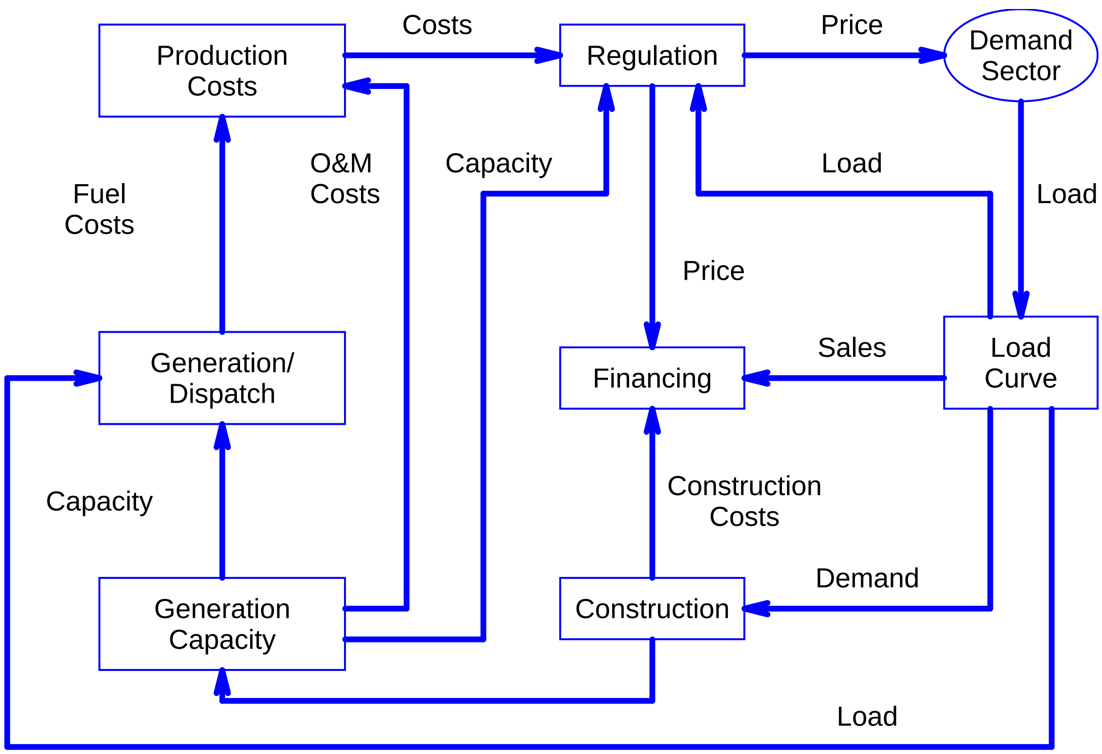
For electric and gas utilities (separate or combined), ENERGY 2020 internally and self-consistently simulates sales, load (by end-use, time-of-use, and class), production (across thirty-six dispatch types), demand-side management (by technology), forecasting, capacity expansion (new generation, independent power producers, purchases, and DSM), all important financial variables, and rates (by class, end-use, and time-of-use.)

The version currently used in this analysis only has the electricity utility sector (a full fledged natural gas utility sector for Canada is currently unavailable in the model, only a simplified natural gas supply function is used to calculate the supply price response).

With the inclusion of the electric utility sector, the generic supply model turns over the calculation of electricity prices to that sector. The model is capable of endogenously simulating the forecasting of capacity needs, as well as the planning, construction, operation and retirement of generating plants and transmission facilities. Each step is financed in the model by revenues, debt, and the sale of stock. The simulated utility, like its real world counterpart, pays taxes and generates a complete set of accounting books. In ENERGY 2020, the regulatory function is modeled as a part of the utility sector. The regulator sets the allowed rate of return, divides revenue responsibility among customer classes, approves rate base, revenues and expenses, and sets fuel adjustment charges.

The interactions in the electric utility sector are summarized in Figure 1.6

Figure 1.6: Electric Utility Structure Overview



Expansion Planning:

The utility sector endogenously forecasts future demand for electricity. From the forecast it projects the future capacity required meeting future demand by taking into account retirements and plants already under construction. Construction of additional capacity is initiated if future electricity requirements, including reserves, are forecast to exceed available capacity (using seasonal ratings).

If additional capacity is needed to meet forecasted needs, the basic capacity expansion module in ENERGY 2020 determines whether base or peaking capacity is required. The model determines the maximum number of hours that new peaking capacity can be economically operated, before it would be less expensive to construct and operate base load capacity instead. If the forecasted peaking capacity would operate more than that economic maximum, base loads units are initiated, otherwise peaking units are initiated. Any plant type including geothermal, wind, biomass and storage can be considered.

New plants, of a pre-specified minimum size, are initiated when the reserve margin would be violated if the plants were not built or if base load capacity is inadequate to serve base load energy needs at the end of the forecast period. The model does allow the minimum reserve margin to be temporarily violated at the peak if new base load capacity is scheduled to be available within the year. Peaking units are allowed to serve more than the maximum economical number of hours until base load capacity comes on-line.

Minimum plant size is exogenous. The mix of new base load plants (i.e. alternative coal technologies, hydro, or nuclear) is user-specified in the standard ENERGY 2020 configuration. The model also evaluates the financial implications of new construction, including total construction costs, cost schedules, and AFUDC/CWIP. The gross rate on AFUDC equals the weighted average cost of capital. The actual construction progress and financial impacts are simulated on a year by year basis.

ENERGY 2020 can also be configured to consider intermediate load units, firm purchases contracts, external sales, independent power producers, and demand-side options. These options can be optionally selected based on endogenous least-cost analysis or can be chosen by user-specified criteria to meet. A detailed automatic Integrated Resource Planning module that would endogenously choose (with user control) from DSM measures utility and non-utility generation and purchase alternatives using linear programming techniques is now being offered as an enhancement.

Financing:

The ENERGY 2020 utility finance sub-sector simulates the activities of a utility's finance department. It forecasts funding requirements and follows corporate policies for obtaining new funds. The model simulates borrowing and issuing of stock, and can repurchase stock or make investments if it has excess cash. Cash flows are explicitly modeled, as are any decision that affects them. Coverage ratios, intermediate- and long-term debt limits, capitalization, rates of return, new stock issues, bond financing, and short-term investments are endogenously calculated. The model keeps track of gross, net, and tax assets. It also calculates the depreciation values used for the income statement and tax obligations.

For this project, this element of the model is not used, and a simpler approach to estimating retail electricity prices is used.

Regulation:

The utility sector sets electricity prices according to regulatory requirements. The regulatory procedures use allowed rate-of-return and test year cost and demands to determine allowed revenues. Electricity prices are calculated from peak-demand fractions by allocation of costs. Any other allocation scheme can also be considered. The regulatory sub-sector of ENERGY 2020 automatically factors in a wide variety of regulatory policies and options. More importantly, the model can be readily modified to consider a wide spectrum of scenarios.

The regulatory process revolves around a test year, usually one year forward, when proposed rates will go into effect. The utility sector forecasts test year sales and peak demands by season and customer class, just as it does to determine capacity needs. These test year demand estimates are used to allocate responsibility for system peak, and therefore, generation capacity costs.

Fuel costs for the test year are estimated by dispatching the plants that will be available in the test year, using the dispatching routine explained below. Fuel costs and operating and maintenance costs are adjusted for expected inflation, and these costs are factored into the electricity rates using forecasted sales.

ENERGY 2020 calculates the utility rate-base according to a detailed conventional rate making formula. The model allows the user to adjust allowable costs, and has been used extensively to evaluate alternative rate-base scenarios for individual plants, including allowing return of, but no return on investment, and partial disallowment of construction and interest costs.

The ENERGY 2020 system also includes estimation of avoided costs, which determines when the utility may be required to purchase third party power. Environmental constraints, such as air pollution restrictions, can also be included in the model. If ENERGY 2020 is configured as a regional or state-wide system, municipal utilities, with their unique tax and rate structures, are incorporated. Similarly, regional or power pool interchange is also recognized by ENERGY 2020. As with the other sectors of ENERGY 2020, the regulatory subsector is flexible enough to accommodate any existing or hypothetical circumstance.

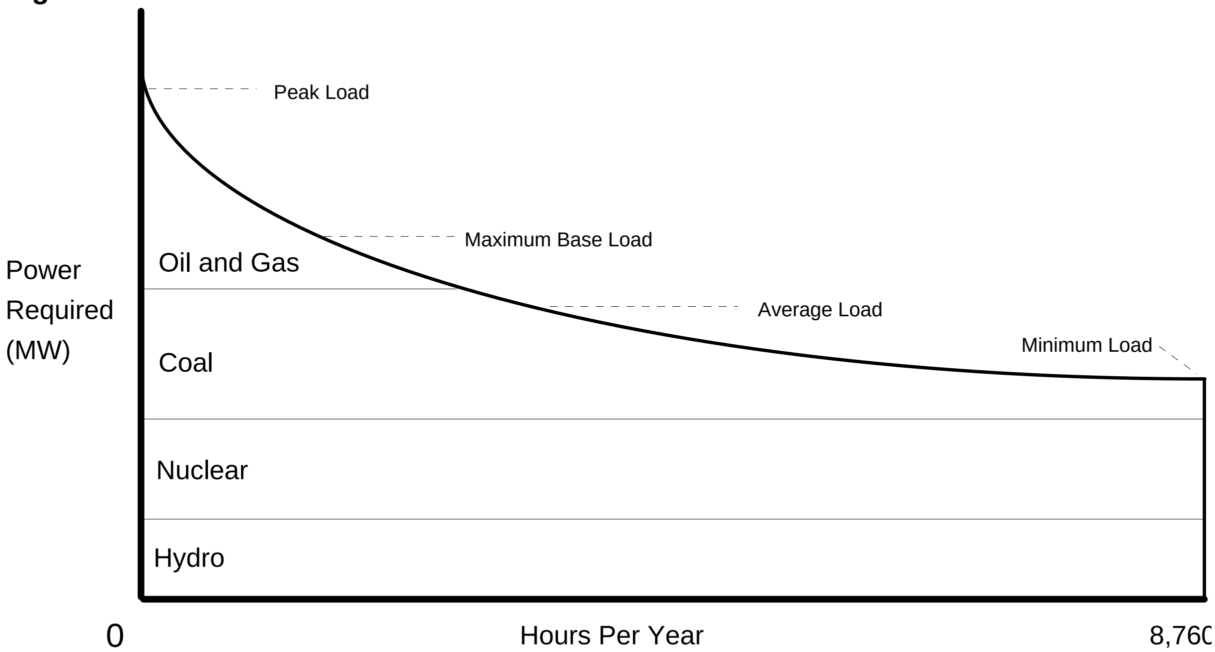
For this project, this element of the model is not used, and a simpler approach to estimating retail electricity prices is used.

Operations:

Each end-use in ENERGY 2020 has a related set of load shape factors. Typically, these factors define the relationship between peak, minimum and average load for each season. These factors when combined with the weather-adjusted energy demand by end-use and corrected for cogeneration, resale, and load management programs, form the basis of the approximated system load duration curve. Alternatively, unit hourly loads for each end-use for three days per month (average weekday, weekend and peak weekday) are used.

The standard ENERGY 2020 production subsector uses an advanced de-rating or chronological method to estimate the seasonal or hourly dispatch of plants. It purchases power externally when economic or necessary. Plant availability and generation for coal, nuclear, hydroelectric, oil and gas are currently considered, as well as pumped storage, firm purchases, interruptible load, and fuel switching and qualified facilities. Figure 1.7 also shows a typical plant dispatch schedule.

Figure 1.7: Generation from the Load Curve



The ENERGY 2020 system estimates conventional fuel costs based on the unit dispatch, heat rates, and fuel prices (from the supply sector.) Nuclear fuel costs are capitalized and depreciated throughout the re-fuelling cycle. Nuclear fuel expenses also include fuel disposal costs.

ENERGY 2020 explicitly models the costs of maintaining the transmission and distribution (T&D) system. New facility investments are scheduled and incurred endogenously. In addition, the user can specify the decision rules that dictate T&D expenditures. ENERGY 2020 also explicitly models both fixed and variable operation and maintenance costs, power pool interchanges, nuclear decommissioning costs, plant capital additions, plant cancellations, and general administration costs.

Model Applications:

The structure of the model is well tested and has been used to simulate not only US and the Canada energy and environmental dynamics but also those of several countries in Western, Central and Eastern Europe. Current efforts include strategic and tactical analyses for South America deregulation. Further, the model has been used successfully for deregulation analyses in over 50 energy suppliers and in all the US states and Canadian provinces. Several US and Canadian energy suppliers currently use the model for the analysis of combined electricity and gas deregulation dynamics.[34] The model contains confidence and validity packages that allow it to determine how to take maximal advantage of RTO rules. The ISO NE used the model to find gaps in its rules and to develop more efficient market conditions. The model was used for the CAPX/ISO to model to show, before the fact, many of the “games” played in the California market.

[34] *ENERGY 2020 is the only model known to have simulated and predicted the dynamics that occurred in the UK electric deregulation. These include gaming, market consolidation and re-regulation dynamics.*

Appendix B: Data Sources

The following describes the default data sources used in ENERGY 2020. Where these data has been replaced by jurisdiction-specific information, the jurisdiction-specific data is described in the main body of the document.

Historical Energy Prices and Demands

Historic energy prices and demands are from *State Energy Data*, Integrated Energy Statistics Divisions of the Office of Energy Markets and End Use, Energy Information Administration, USDOE. This document provides annual time series estimates of State-level energy consumption, prices, and expenditures by major economic sectors. In 2000, the *State Energy Data* replaced two former EIA reports: State Energy Data Report (SEDR) and State Energy Price and Expenditure Report (SEPER). Tables by major economic sector can be found at: http://www.eia.doe.gov/emeu/states/_states.html. New tables by energy source can be found at: http://www.eia.doe.gov/emeu/states/multi_states.html.

Future Energy Prices

To estimate future energy prices, we apply the forecasted price growth rates from the *Annual Energy Outlook (AEO*) *2008* to the prices from the last historical year (obtained from *State Energy Data*). The Annual Energy Outlook 2008 presents a forecast and analysis of US energy supply, demand, and prices through 2030.
http://www.eia.doe.gov/oiaf/aeo/supplement/index.html

Note that there is a gap between the most recently reported historical year of data and the first forecast year. We resolve this by including one year's worth of price data from the AEO of the previous year.

Future Energy Demands

Future energy demands are computed by the model, but the model can calibrate to future energy demands if desired. In this project, the model projections have been compared to other forecasts but have not been calibrated to any other forecast.

Device Energy Efficiency Standards

Device efficiency standards come mainly from the *Energy Policy Act of 1992*, with some efficiencies coming from other selected sources.
http://energy.navy.mil/publications/law_us/92epact/hr776toc.htm
This initial base of efficiency standards have been updated as new regulations have come into effect. Requirements in the ***Energy Independence and Security Act*** have also been included in the Reference Case.

Device Capital Cost, Efficiency, and Device Lifetimes; Cogeneration Capital Costs, Heat Rates and Parameters

These values were originally developed from the *Annual Report to Congress, 1980: Volume 3*. Energy Information Administration, USDOE, Report #: DOE/EIA-0173(80)/3. ICF and SSI have reviewed and updated these data which is used to provide the shape of choice curves within the model based on expert opinion and data from a variety of sources. The values used are presented in Appendix J.

End-Use Load Shapes
The end use load shapes were originally based on 1995 NEPOOL published reports. Load shapes for temperature sensitive loads are modified based on actual weather data for the state/region being modeled.

Industrial Energy Splits, Industrial End Use Splits and Commercial End-Use Splits
The energy that we obtain from *State Energy Data* is a total value that needs to be split among different industries and/or uses (end use demands, cogeneration demands, feedstock demands). We obtain the splits among industries and uses from the *Manufacturing Energy Consumption Survey*, Energy Information Administration, USDOE. The Manufacturing Energy Consumption Survey is conducted every five years and provides detailed data on energy consumption in the manufacturing sector. http://www.eia.doe.gov/emeu/mecs/contents.html

Residential Devices Saturations and Market Shares
Residential devices saturations and market shares are obtained from the *Residential Energy Consumption Survey*, Energy Information Administration, USDOE.
http://www.eia.doe.gov/emeu/recs/contents.html

Inflation Rate
Historical inflation rates are calculated from the consumer price index reported by the Bureau of Labor. Projections for inflation from 2004 through 2030 are calculated from the consumer price index projections of the *Annual Energy Outlook 2008*, Energy Information Administration, USDOE. http://www.eia.doe.gov/oiaf/aeo/index.html.

Fuel Choice Variance Factors, Return on Investment, and Maximum Process Efficiency Multiplier
The fuel choice variance factors, return on investment and maximum process efficiency multiplier variables come from projections obtained from the DEMAND81 energy model. Backus, George A. 1981. DEMAND81: National Energy Policy Model. Four Volumes. AFC 7-10. School of Industrial Engineering. Purdue University. West Lafayette, Indiana. These factors are updated as part of the calibration process.

Process Capital Costs
The data was developed from the US I/O Tables by REMI in $1987 and have been updated based on work with past clients.

Residential Energy Usage Per Appliance
The average usage per appliance was originally based on *NEPOOL April 1994 Forecast for Massachusetts*. The miscellaneous end use category is computed by adding the residential energy for all miscellaneous end uses and dividing by the number of households. Average use per appliance has been updated since that time based on input from various clients and is calibrated to actual energy use as part of the process of calibrating to actual energy use.

Number of Households
The number of households comes from the United States Census, US Census Bureau.
http://www.census.gov/main/www/cen2000.html.

Appendix E: Data Sets Used in ENERGY 2020

This Appendix describes the initial set definitions for ENERGY 2020 used for this project. The sets are the dimensions of the variables (sometimes called indexes) which delineate the scope and detail of the model. For example, the time frame set could be defined as a base year 1990 and every 5 years.

Time Frame

The initial historical year for calibration is 1990.
Current end year of the analysis is 2020, but analysis can be extended to 2030 or beyond.
The last historic year of data will be 2005.
All data sets include annual data for each year of history and the forecast.

For some data sets, the period covered by actual data will depend on available data (e.g., emissions).

Geographical Areas

Each area in the model will represent a state or a province (no sub-state break-outs).
The model will provide separate results for the eleven WCI Partner jurisdictions. The surrounding region (the rest of the WECC) and the rest of the US and Canada are also modeled.

The states and provinces included in the WCI region for modeling purposes include:

- Arizona
- New Mexico
- Washington
- Ontario
- California
- Oregon
- British Columbia
- Quebec
- Montana
- Utah
- Manitoba

Generating Units

The list of units is based on the NEEDS database for the US plus a similar database for the units in Canada. Within the Region and the rest of the US, some of the smaller plants may be aggregated by plant type in order to allow the expedite model operation. Under these assumptions regarding aggregation, this version of the model will include approximately 3,000 units/plants.

Electric Companies

Although ENERGY 2020 can model individual utilities or groups of utilities, for the WCI project the model assumes that each state has a single aggregate utility.

Sectors and Classes

The energy demand portion of the model will simulate residential, commercial, industrial, and transportation demands. There will be an electric sales class for each sector.

Emission Only Sectors

Several sectors generate emissions, but do not have full energy demand simulations in the model. These include solid waste, waste water, incineration, and land use. It may be possible to develop a full energy demand simulation for one or more of these.

Pollutants

The model currently has the capability to cover 15 pollutants, although the final set will depend on project requirements and available data. The GHG pollutants include Carbon Dioxide, Methane, Nitrous Oxide, Sulfur-Hexafluoride, Perfluorocarbon, and Hydrofluorocarbon. The criteria air pollutants include Sulfur Dioxide, Nitrogen Oxides, Total Particulate Matter, Volatile Organic Compounds, Carbon Monoxide, Particulate Matter $_{2.5}$, Particulate Matter $_{10}$, Mercury, and Ozone.

Fuels

There are currently two sets of fuels in the model. The largest category contains 33 fuels (shown below). The second category is the list of technologies which the energy demand sectors choose from. This smaller set contains only the basic types of fuels (Electricity, Natural Gas, Oil, LPG, Biomass, Solar). The aggregate category oil is later broken out into the different types of oil (LFO, HFO, petroleum coke, etc.).

Entire List of Fuels

- Asphalt
- Aviation Fuel
- Biomass
- Coal
- Coke
- Coke Oven Gas
- Diesel
- Electric
- Ethanol
- Geothermal
- Heavy Fuel Oil
- Hydro
- Hydrogen
- Kerosene
- Landfill Gases
- Light Fuel Oil
- LPG
- Lubricants
- Motor Gasoline
- Naphtha Specialties
- Natural Gas
- Nuclear
- Oil, Unspecified
- Other Non-Energy Products
- Petrochemical Feedstocks
- Petroleum Coke
- Solar
- Steam
- Still Gas
- Wave
- Wind
- Unknown 1
- Unknown 2

Electric Generation Plants Types

The electric generation plant types are used to hold the data for future generic plants which the model will construct endogenously. The list currently includes:

- Gas/Oil Peaking
- Gas/Oil Combined Cycle
- Gas/Oil Steam
- Coal
- Coal Advanced
- Coal with CCS
- Gas CC with CCS
- Nuclear
- Base Hydro
- Peak Hydro
- Other Generation
- Biomass
- Landfill Gas
- Wind
- Solar
- Fuel Cells
- Pumped Hydro
- Small Hydro
- Wave
- Geothermal
- Other Storage
- Biogas
- Trash

Residential Sectors

The residential sector is split into housing types:

- Single Family
- Multi-Family
- Other Residential

Commercial Sectors

- Transportation Services
- Pipelines
- Communication
- Electric Utilities
- Gas Utilities
- Water & Other Utilities
- Wholesale
- Retail
- FIRE
- Offices - Business Services
- Education
- Health & Social
- Food, Lodging, Recreation
- Government

Industrial Sectors

- Food & Tobacco
- Textiles
- Apparel
- Lumber
- Furniture
- Pulp & Paper Mills
- Converted Paper
- Printing
- Petrochemicals
- Industrial Gas
- Other Chemicals
- Fertilizers
- Petroleum Products
- Rubber
- Leather
- Cement
- Glass
- Lime & Gypsum
- Other Non-Metallic
- Iron & Steel
- Aluminum
- Other Nonferrous
- Fabricated Metals
- Machines
- Computers
- Electric Equipment
- Transport Equipment
- Other Manufacturing

- Iron Ore Mining
- Other Metal Mining
- Non-metal Mining
- Light Oil Mining
- Heavy Oil Mining
- Frontier Oil Mining
- Oil Sands In-Situ
- Oil Sands Mining
- Oil Sands Upgraders
- Gas Mining
- Coal Mining
- Construction
- Forestry
- Agriculture

Transportation Sectors

- Passenger
- Freight
- Off Road

Miscellaneous Sectors

- Misc. & Street Lighting
- Electric Resale
- Utility Electric Generation
- Industry Electric Generation
- Steam Generation
- Solid Waste
- Waste Water
- Incineration
- Land Use

Residential End-Uses

- Space Heating
- Water Heating
- Other Substitutable
- Refrigeration
- Lighting
- Air Conditioning
- Other Non-Substitutable

Commercial End-Uses

- Space Heating
- Water Heating
- Other Substitutable
- Refrigeration
- Lighting
- Air Conditioning
- Other Non-Substitutable

Industrial End-uses

- Process Heat
- Electric Motors
- Other Substitutable
- Miscellaneous

Transportation End-Uses

- Ground
- Air/Water

Residential, Commercial, and Industrial Technology Types

Each technology type has its own trade-off curve which determines the efficiency and the capital cost of the technology type. These curves allow the model to contain many different technologies within these broad types.

- Electric
- Gas
- Coal
- Oil
- Biomass
- Solar
- LPG
- Steam

Transportation Technology Types

Several technology types are provided for transportation, and each of these contains a trade-off curve which allows the model to simulate even more individual technologies.

- Plug-in Hybrids
- Light Gasoline
- Light Diesel
- Light Propane
- Light CNG
- Light Electric (Plug-in)
- Light Ethanol
- Light Hybrid Gasoline
- Light Hybrid Diesel
- Light Fuel Cell Gasoline
- Light Fuel Cell CNG
- Light Fuel Cell Hydrogen
- Medium Gasoline
- Medium Diesel
- Medium Propane
- Medium CNG
- Medium Ethanol
- Medium Hybrid Gasoline
- Medium Hybrid Diesel
- Medium Fuel Cell Gasoline
- Medium Fuel Cell CNG
- Medium Fuel Cell Hydrogen
- Heavy Gasoline
- Heavy Diesel
- Heavy Propane
- Heavy CNG
- Heavy Ethanol
- Heavy Hybrid Gasoline
- Heavy Hybrid Diesel
- Heavy Fuel Cell Gasoline
- Heavy Fuel Cell CNG
- Heavy Fuel Cell Hydrogen
- Motorcycle
- Bus Gasoline
- Bus Diesel
- Bus Propane
- Bus CNG
- Bus Fuel Cell Gasoline

- Bus Fuel Cell Hydrogen
- Bus Fuel Cell Ethanol
- Train
- Plane
- Marine
- Off Road

Prices

Delivered energy prices are presented for the following fuels:

- Residential Electricity
- Residential Natural Gas
- Residential Coal
- Residential Oil
- Residential Biomass
- Residential LPG
- Residential Steam
- Commercial Electricity
- Commercial Natural Gas
- Commercial Coal
- Commercial Oil
- Commercial Biomass
- Commercial LPG
- Commercial Steam
- Industrial Electricity
- Industrial Natural Gas
- Industrial Coal
- Industrial Oil
- Industrial Biomass
- Industrial LPG
- Industrial Steam
- Gasoline
- Diesel
- Aviation Fuel
- Transportation HFO
- Transportation Natural Gas
- Transportation LPG
- Electric Utility Residual Oil
- Electric Utility Distillate Oil
- Electric Utility Natural Gas
- Electric Utility Coal
- Electric Utility Nuclear
- Electric Utility Biomass
- Ethanol
- Hydrogen

Electric Load Segments

The model dispatches for 6 different hour types (high peak, low peak, high intermediate, low intermediate, high base load, low base load) for each of the four seasons.

Wind	$1,504	$1,815	$28	$34	0.92	1.11	27% - 40%	n/a
Coal ST	$1,901	$2,293	$26	$31	0.92	1.11	85%	8,844
Coal IGCC	$2,197	$2,651	$36	$43	0.92	1.11	85%	8,309
Coal IGCC with CCS	$3,144	$3,794	$42	$51	0.92	1.11	85%	9,713
Gas CCCT	$808	$975	$11	$13	0.92	1.11	90%	6,917
Gas CT	$619	$747	$11	$14	0.92	1.11	5%	10,807
Hydro - Large	$1,122	$2,031	$5	$11	0.41	0.78	15% - 65%	n/a
Nuclear	$3,066	$3,699	$63	$76	0.92	1.11	85%	10,400

Note: Variable O&M Costs do not include fuel costs. Range of costs is similar for several of the technologies.
Source: Energy and Environmental Economics, Inc., CPUC GHG Modeling - Generation Costs (Word document), 11/16/2007.www.ethree.com/cpuc_ghg_model.html

Appendix H: Global Warming Potential

ENERGY 2020 models emissions of each of the six greenhouse gases reported under the Kyoto protocol. These emissions are then translated into equivalent quantities of CO_2 emissions (CO_2e) based on the global warming potential of each of the gases.

The Global Warming Potential (GWP) values used in ENERGY 2020 are shown in the table below.

Greenhouse Gas	Global Warming Potential
Carbon Dioxide (CO_2)	1
Methane (CH_4)	21
Nitrous Oxide (N_2O)	310
Sulfur Hexafluoride (SF_6)	23,900
Perfluorocarbons (PFC)	7,000
Hydrofluorocarbons (HFC)	1,300

These values are consistent with the Global Warming Potential values used in the 1996 Second Assessment Report based on 100-year warming potential for the individual gases. In the case of HFCs and PFCs the GWP values used in the model are based on an estimated average GWP for these gases.

Appendix I: Renewable Portfolio Standards: Partner Jurisdictions and Rest of North America

State or Prov	Target	Policy
United States		
AZ	15% of generation from renewables by 2025	Regulated electric utilities must generate 15% of their energy from renewables by 2025. By 2012, at least 30% of the standard must be derived from distributed renewable energy (4.5% of total electricity sales by regulated utilities). RES specifies what technologies qualify (Solar Water Heat, Solar Space Heat, Solar Thermal Electric, Solar Thermal Process Heat, Photovoltaics, Landfill Gas, Wind, Biomass, Hydroelectric, Geothermal Electric, Geothermal Heat Pumps, CHP/Cogeneration, Solar Pool Heating (commercial only), Daylighting (non-residential only), Solar Space Cooling, Solar HVAC, Additional technologies upon approval, Anaerobic Digestion, Fuel Cells using Renewable Fuels) and allow for the addition of new technologies as they become feasible. Penalties for non-compliance. The new rules also require a growing percentage of the total resource portfolio to come from distributed generation.
CA	Major utilities 20% from renewable sources by 2010 on a retail sales basis	California's Investor-Owned Utility, Electric Service Providers, Small and Multi-Jurisdictional Utilities and Community Choice Aggregators to produce at least 20% of their electricity using renewable sources by 2010 based on renewable retail sales. Eligible technologies: Solar Thermal Electric, Photovoltaics, Landfill Gas, Wind, Biomass, Geothermal Electric, Municipal Solid Waste, Anaerobic Digestion, Small Hydroelectric, Tidal Energy, Wave Energy, Ocean Thermal, Biodiesel, and Fuel Cells using Renewable Fuels.

State or Prov	Target	Policy
MT	10% of generation load to be renewable by 2010; 15% by 2015	Each investor-owned and public utility should: Meet 20% of its load using renewable energy resources by 2020, increasing to 25% by 2025. The legislation contains a cost cap that encourages utilities to invest in renewable generation that is cost competitive with conventional generation. Eligible technologies: wind, solar, geothermal, existing hydroelectric projects, landfill or farm-based methane gas, wastewater-treatment gas, low-emission, nontoxic biomass, and fuel cells where hydrogen is produced with renewable fuels.
NM	10% of generation by 2011; 15% renewable by 2015; 20% by 2020	Applies to Investor-Owned Utility, Rural Electric Cooperative. IOUs: 15% power generation from renewable sources and 20% by 2020. RECs: 10% by 2020. This legislation expands on NM's current RPS requiring that 10% of the state's nergy come from such sources by 2011. IOUs must also meet: 20% of RPS from solar (4% of total sales); 20% of RPS from wind (i.e. 4% of total sales); 10% of RPS from geothermal and biomass (2% of total sales); 3% of RPS from distributed renewables (0.6% of total sales) by 2020. Eligible technologies: Solar Thermal Electric, Photovoltaics, Landfill Gas, Wind, Biomass, Hydroelectric, Geothermal Electric, Zero emission technology with substantial long-term production potential, Anaerobic Digestion, Fuel Cells using Renewable Fuels

State or Prov	Target	Policy
OR	25% of electric load must be renewable sources by 2025 (ramps up from 2015)	Largest utilities 25% of their electric load with new renewable energy sources by 2025. Interim targets of 5% by 2011; 15% by 2015; 20% by 2020; and 25% by 2025. Based on total retail sales volumes. Eligible technology: wind, solar, wave, geothermal, biomass, new hydro or efficiency upgrades to existing hydro facilities. Utilities are not required to comply with the standard if doing so will result in retail electricity price increases of more than 4%. If none of a utility's options for compliance are cost-effective, they can make an Alternative Compliance Payment (ACP) to help meet their renewable energy requirement. The level of the ACP will be determined by the PUC and will be set to provide adequate incentive for the utility company to generate qualifying renewable electricity instead of using an ACP payment to meet the RPS. The ACP will be placed into an account that can be used in the future to acquire renewable energy, invest in conservation or, for consumer-owned utilities, research and development.
UT	20% of sales by 2025 for Rocky Mountain Power and Co-ops or municipal electric utilities, if cost effective	The retail sales are adjusted by subtracting the non-carbon sources of energy (e.g. hydro, nuclear) and future carbon sequestration from the total retail sales. The 20% target would then apply to the carbon component of the utility's portfolio.Requires plans and reports concerning an electrical corporation's or municipal electric utility's progress in acquiring renewable energy.Requires the Utah Geological Survey to make rules concerning carbon capture and geological storage of captured carbon emissions.
WA	All new long term baseload facilities must meet 1,100 lbs CO_2/MWh starting July 2008	GHG performance standard for all new, long-term baseload electric power generation. Under the standard, all baseload generation for which utilities enter into long-term contracts must meet a greenhouse gas emissions standard of 1,100 pounds per MWh beginning in July 2008
WA	15% of production to be renewable by 2020 (small & low growth utilities exempt, so effectively 14%)	All utilities serving >25,000 people to produce 15% of their energy using renewable sources by 2020. Eligible technology: wind, solar, and tidal power as well as landfill-methane capture.

State or Prov	Target	Policy
CANADA		
PEI	15% by 2010	
Nfld	n/a	
NB	10% renewables by 2016	
NS	18.5% of electricity needs from renewables by 2013	
PQ	Produce 4,000 MW of electricity from wind by 2015	Additional hydro projects will begin operation by 2012, totalling 1,054 MW. The 1500Mw La Romaine facility will is projected to come on line in 2014.
ON	No coal-fired electricity generation in the province by 31 December 2014 Conserve 6,300 MW of electricity by 2025 (40% by 2010)50% increase in renewable energy capacity by 2015, including hydro; 15,700 MW by 2025 including up to 1,000 MW of renewable power to the grid by 2010	Regulation to phase out use of coal-fired generation enacted in 2007. Renewable power RFP being contracted for capacity and generation
MB	1,000 MW of wind power by 2016 Energy saving target of 842 MW of electricity by 2017	Most of Manitoba's power production is already from renewable sources. Target: 1,000 MW of wind power by 2016. The 1,000 MW will reduce GHGs by 3.5 Mt annually, and stimulate $2 billion in new investments. As a part of this, the province intends to add 300 MW of wind (starting construction in 2007-08). The 300 MW is in addition to the 99 MW St. Leon wind farm, which is already in operation.

State or Prov	Target	Policy
SK	Demand side management to reduce needs by 300 MW by 2017 New and replacement generation emissions-free or fully offset	By 2017, we commit to saving at least 300 megawatts of SaskPower's electricity generation through demand side management practices. Ensure all of SaskPower's new and replacement electricity generation facilities are either emissions-free or fully offset by emission credits
AB	By 2008, more than 12.5% of Alberta's total electricity generated will be generated from renewables	12.5% renewables, primarily wind and biomass
BC	Offset all O&G grid power emissions by 2016.	All existing natural gas and oil-fired generating facilities part of the integrated grid will need to completely offset their GHG emissions by 2016. All coal will need to use CCS, sequester or otherwise offset emissions, and all new O&G must not add to current levels of emissions50% of incremental electricity requirements to be met through conservation
BC	Maintain 90% clean sources - all new sources zero emissions.	Maintaining 90% clean power supply, including hydro. Note that no nuclear will be built in the province. Government will issue guidelines to define what sources qualify as clean or renewable and provide additional policy direction as required. In 2004, power generation accounted for only 3% of the total amount of GHG emitted.
NWT	n/a	Taltson River Hydro development (36 MW) set for construction and online by 2011 4 mini hydro possibilities
Yukon	n/a	$7M to install third turbine at Aishihik hydo plant planned to be in service between 2009 & 2012 (7 MW capacity)
Nunavut	n/a	n/a

Province or State	E2020 Description	RPS since 05/01/08	2020 RPS % Region Sales Target	State goal for renewable (% of sales)	Out of State Permitted	New Restrictions on generation location
IA	MAPP	no	0.2%	105 MW	Yes	Must own facilities located in the state or enter into long term contracts to purchase or wheel electricity from facilities located within the utility's service area
MN	MAPP	no	11.2%	Xcel Energy: 30% by 2020 All Others: 25% by 2025*	Yes	Allowed to use out of state generation - Local benefits. The commission shall take all reasonable actions within its statutory authority to ensure this section is implemented to maximize benefits to Minnesota citizens, balancing factors such as local ownership of or participation in energy production, development and ownership of eligible energy technology facilities by independent power producers, Minnesota utility ownership of eligible energy technology facilities, the costs of energy generation to satisfy the renewable standard, and the reliability of electric service to Minnesotans
ND	MAPP	no	0.7%	State Renewable Goal: 10% by 2015	%	"A portion or all of the renewable energy and recycled energy objective may be met by the purchase and retirement of renewable energy and recycled energy certificates representing credits from qualified sources and facilities as defined in section 49-02-26 and section 5 of this Act. Renewable energy and recycled energy certificates do not need to be acquired from an in-state facility."

Highlights of WCI Economic Analysis

The Partner jurisdictions of the Western Climate Initiative (WCI) have released an updated economic analysis confirming that its regional plan to reduce greenhouse emissions (GHG) is both environmentally achievable and economically positive.

Key Results of the WCI Economic Modeling Analysis

- The WCI Partner jurisdictions can meet their 2020 regional emissions reduction goal while realizing modest net cost savings.
- Policies implemented in conjunction with cap-and-trade, such as energy efficiency and clean car standards, have the potential to significantly reduce emissions and contain costs.
- Carbon allowance banking and offsets are important design elements for achieving emissions reductions and limiting costs.
- Higher-than-expected fuel prices would make it less costly to achieve the emissions reduction goal and would lower the allowance prices. Conversely, lower-than-expected fuel prices, coupled with a faster economic recovery, would raise the allowance price.

The economic analysis indicates that the WCI Partner jurisdictions can achieve the goal of reducing emissions to 15 percent below 2005 levels by 2020—and realize net cost savings of approximately US$100 billion between 2012 and 2020.

The report released today updates a 2008 economic analysis and incorporates new data reflecting the following:

- Expanded WCI membership (to include Manitoba, Québec, and Ontario)
- The 2008—2009 economic recession
- Various economic model improvements identified after extensive consultation with stakeholders

The updated economic analysis considered a range of scenarios with varying assumptions about future economic growth, fuel prices, and other factors. In each instance, the analysis showed that the WCI program would deliver net cost savings—even when the assumptions resulted in different carbon allowance prices. These findings are similar to the results of other recent economic analyses.

Western Climate Initiative

Updated Economic Analysis of the WCI Cap-and-Trade Program

WCI Stakeholder Call

July 13, 2010

Overview

- Highlights
- Changes since last analysis
- Results
- Next steps
- Stakeholder questions

Highlights

- The economic analysis demonstrates that the WCI program
  - can address climate change as a region and continue to grow the economy
  - can reduce dependence on imported oil
  - embodies policies that are affordable, gradual, and not disruptive to the Partners' economic growth

Highlights

- Transitioning from dirty energy to clean energy is a smart, affordable investment, with net economic benefits
- The cost savings are attributable to increased energy efficiency and reduced fuel consumption
- The WCI program will also stimulate investment and innovation in a green economy and produce clear environmental benefits, including cleaner air

Highlights

- The most expensive thing we can do is nothing. Examples include:
  - $36 billion in damage from sea-level in the San Francisco Bay area by 2050 ($100 billion state-wide by 2085)
  - $3 billion per year in CA agricultural crop losses by 2050
  - $1,250 per household per year in WA due to higher energy costs, health-related costs, and other factors by 2020

How the Model Works

- We used ENERGY 2020, an integrated North American economy, energy and emissions model. Major outputs include:
  - Emissions of GHGs and conventional air pollutants
  - Energy-related investments and expenditures on devices, processes, fuel, and operation and maintenance
  - Electric power sector results, including demand, generation, capacity, wholesale prices, LSE revenues and rates
  - Levels of energy efficiency and fuel use by type
- Using the model iteratively, we can determine the carbon price necessary to induce a 15% emission reduction

Changes Since Last Analysis

- Informed by stakeholder calls, meetings, written comments following September 2008 analysis
- Manitoba, Ontario, and Québec now included
- Economic forecast adjusted for recession
- Fuel price forecast updated
- Allowance banking and phasing of the cap are more appropriately simulated
- WCI offset limit more accurately simulated
- Offset supply and costs based on US EPA analysis

Changes Since Last Analysis

- Greater detail on electricity sector results included
- Energy efficiency policies assumed to reduce annual growth by 0.5% instead of 1.0% and now include program administration and O&M costs
- Phase I clean car standards included in reference case instead of cap-and-trade case
- Phase II clean car standards costs updated
- See Tables 1-2 and Figures 1-2 in report for a complete list of changes and further detail

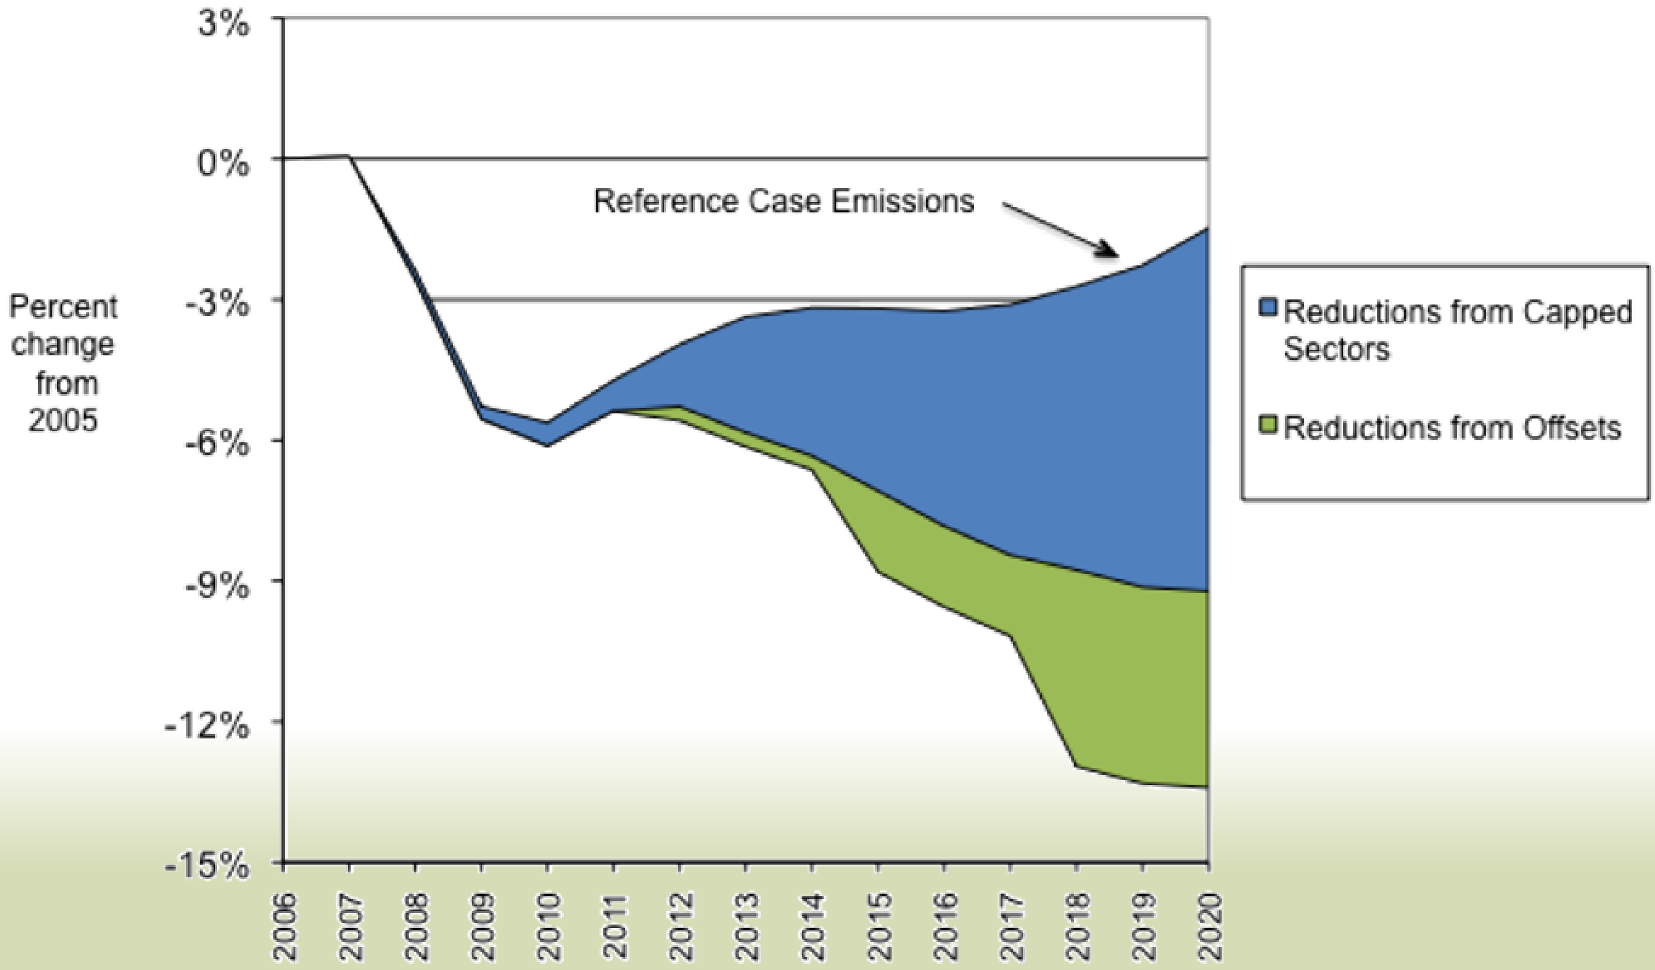
Results

- Results continue to show that WCI emissions reduction goal can be met with modest net cost savings
  - 15% below 2005 emissions levels by 2020
  - Savings of US$100 billion over the 2012-2020 period
- Policies implemented in conjunction with cap-and-trade help reduce emissions and limit costs

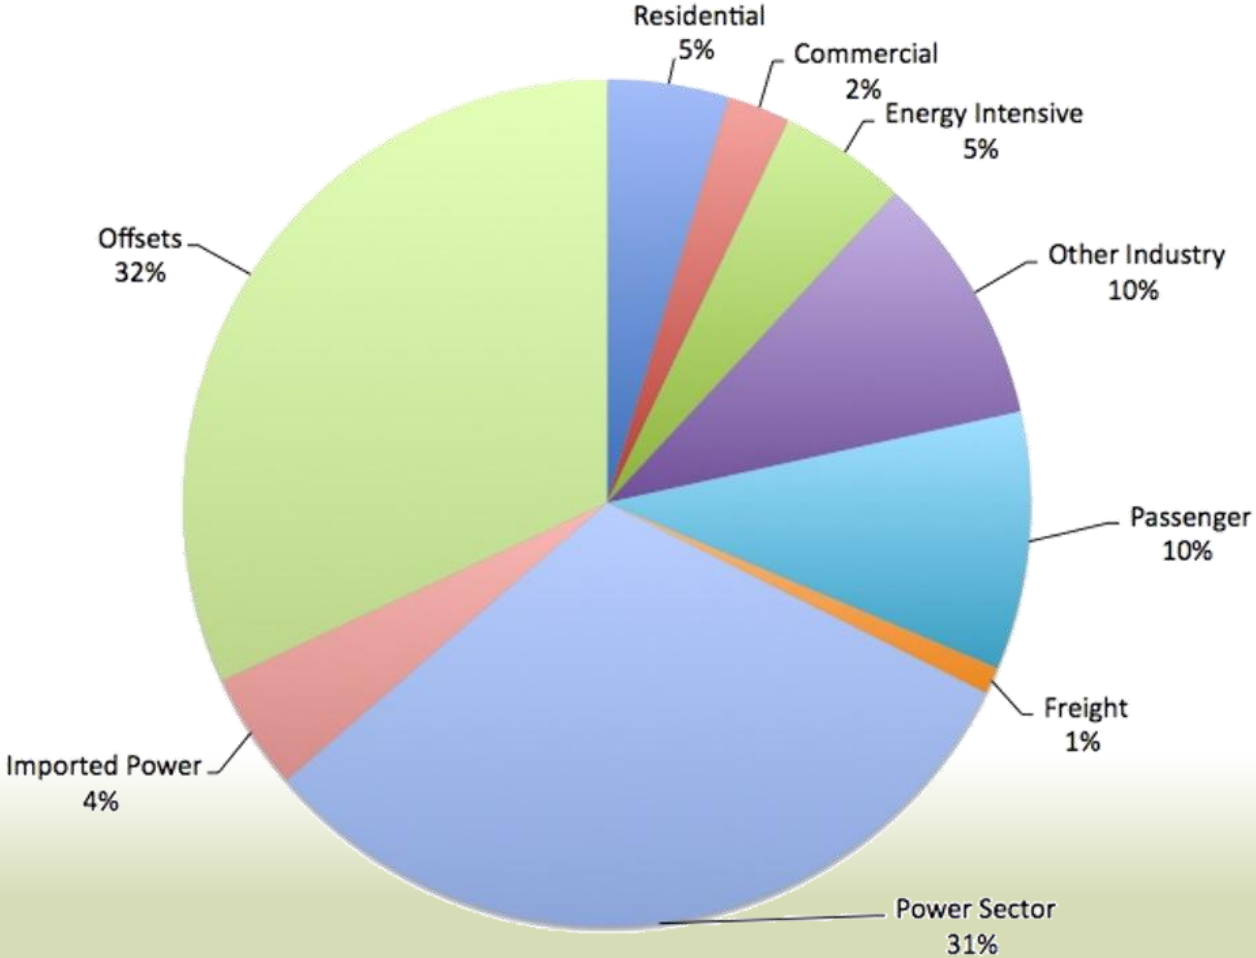
Results

- Allowance banking and carbon offsets are important design elements for achieving emissions reductions and limiting costs
- Varying assumptions about energy prices, economic growth, and the effectiveness of policies implemented in conjunction with a cap-and-trade program continues to demonstrate net cost savings, although their magnitude and the price of allowances vary across these scenarios

GHG Emissions Reductions Under the Cap
(Main Policy Case)



Source of Emissions Reductions Under the Cap
(Main Policy Case Relative to Reference Case, 2012-2020)



The WCI recommends offsets account for no more than 49% of emission reductions relative to emission levels in 2012 and 2015. The chart above, however, expresses reductions relative to the reference case. Hence, the offsets percentage appears smaller.

Cost Savings and Allowance Prices (Main Policy Case and Sensitivity Cases)

Economic Modeling Scenarios	Cost Savings 2012–2020 (2007 USD)	Emissions Allowance Price in 2020 (2007 USD)
Main Policy Case	US$102 billion	US$33 per metric ton
Sensitivity Cases		
Complementary policies only half as effective as in main case	At least US$38 billion	At least US$50 per metric ton
Faster economic growth and lower primary energy prices	At least US$202 billion	At least US$50 per metric ton
Higher energy prices and power plant construction costs	US$106 billion	US$13 per metric ton

Next Steps

- Continue developing comprehensive climate change policies informed by these results
- Incorporate results into state- and province-specific analyses
- While the WCI has completed economic modeling of its program design, it will continue accepting stakeholder comments for consideration during implementation of the cap and other policies

Western Climate Initiative

July 7, 2010

WCI Plan to Reduce Greenhouse Gas Emissions is Environmentally Achievable and Economically Positive

An updated economic analysis by the Western Climate Initiative Partner Jurisdictions underscores the benefits of a regional plan to mitigate climate change and spur investment in clean-energy technologies.

The Partner jurisdictions of the Western Climate Initiative (WCI) today released an updated economic analysis indicating that its regional plan to address climate change and help foster a clean-energy economy can significantly reduce greenhouse gas (GHG) emissions and achieve cost savings of approximately US$100 billion by 2020.

Working together, the seven U.S. states and four Canadian provinces that comprise the WCI have forged a comprehensive strategy to mitigate climate change that will spur investment in clean-energy technologies, create green jobs and reduce dependence on imported oil. When fully implemented, the plan will reduce GHG emissions to 15 percent below 2005 levels by 2020.

The WCI Partner jurisdictions are not alone in acting to address the challenge of climate change. The WCI is one of three regional initiatives in North America with action plans in place to reduce GHG emissions and accelerate the transition to a clean-energy economy. Although the WCI plan is not the first regional climate policy to be implemented, it is the most comprehensive and covers a broad range of economic sectors.

The report released, “Updated Economic Analysis of the WCI Regional Cap-and-Trade Program,” updates the 2008 WCI economic analysis by incorporating new data that reflects expanded WCI membership (the inclusion of Manitoba, Québec, and Ontario), the 2008—2009 economic recession, and various economic model improvements identified after extensive consultation with stakeholders.

The updated economic analysis indicates that the WCI Partner jurisdictions can achieve the goal of reducing emissions to 15 percent below 2005 levels by 2020, support continued economic growth, and realize net cost savings of approximately US$100 billion between 2012 and 2020. The cost savings are attributed to increased energy efficiency and reduced fuel consumption.

The plan will also stimulate investment and innovation in a green economy, spur the creation of green jobs within the WCI region, and result in a cleaner environment.

The estimated savings are modest (less than 0.2%) relative to the combined size of the WCI Partner jurisdiction economies, but they underscore that mitigation of GHG emissions and the move to a clean-energy economy can be achieved without negatively impacting the regional economy. This result is consistent with other recent state and federal analyses of climate mitigation programs.

The updated economic analysis evaluated a range of scenarios using varying assumptions about future economic growth, fuel prices and other factors. In each instance, the analysis showed that the WCI program would support robust economic growth and deliver net cost savings—even when the assumptions resulted in different carbon allowance prices.

Some of the WCI Partner jurisdictions will use the results of this economic analysis as the foundation for state- or province-specific analyses. The updated analysis will also inform ongoing WCI discussions on a comprehensive climate program that includes other emissions reduction strategies in addition to cap-and-trade.

While this report completes the economic modeling of the WCI design elements, the WCI Economic Modeling Team welcomes comments on the recent analysis. The WCI Partners will consider comments when devising an approach to implementing the cap-and-trade program and in continued work on other emission reductions strategies.

The report is available on the WCI website. The WCI Economic Modeling Team will hold a stakeholder conference call to present the analysis and results on Tuesday, July 13 from 10:00 am to 11:00 am PDT. To join the call dial 1-800-868-1837 and enter participant code 659537#. A PowerPoint presentation will be posted to the WCI website at the time of the call.

About the Western Climate Initiative

The Western Climate Initiative is a coalition of seven U.S. states and four Canadian provinces working together to identify, evaluate, and implement policies to mitigate climate change and spur investment in clean-energy technologies that create green jobs and reduce dependence on imported oil. The WCI regional approach is based on extensive economic analyses, stakeholder input, technical work, collaboration, and compromise. It reflects an understanding among the WCI Partner jurisdictions that a comprehensive solution to our economic, energy, and environmental challenges requires a coordinated regional strategy that respects the interests, needs, and circumstances of each jurisdiction.

Overview

This report summarizes the results of an economic analysis conducted by the Partner jurisdictions of the Western Climate Initiative (WCI). It updates the results of a 2008 economic analysis that informed the design of the WCI regional cap-and-trade program, which will reduce greenhouse gas (GHG) emissions contributing to climate change, spur development of new clean-energy jobs and technologies, and help achieve a strong economy.

The updated analysis incorporates new data reflecting expanded WCI membership, the economic downturn of 2008–2009, and various model improvements recommended by WCI Partner jurisdictions and stakeholders. Results of the updated analysis are consistent with the results of the 2008 report:

- The WCI GHG emissions reduction goal—a reduction of 15 percent from 2005 levels by 2020—can be achieved with a net savings of about US$100 billion between 2012 and 2020.
- Complementary policies such as standards for energy efficiency and clean cars are an important part of reducing emissions and containing costs.
- Offsets and allowance banking provisions in the cap-and-trade program are important features for containing costs.
- Savings to the economy may vary depending on such factors as future economic growth, fuel prices, and effectiveness of complementary policies.

The Western Climate Initiative

The Western Climate Initiative (WCI) is a coalition of seven U.S. states and four Canadian provinces working together to identify, evaluate, and implement policies to address climate change at a regional level.

Established in 2007, the WCI is a comprehensive effort to reduce GHG pollution, spur growth in new green technologies, help build a strong clean-energy economy, and reduce dependence on oil.

Through a regional cap-and-trade program and complementary policies, the WCI goal is to reduce emissions of the pollution that causes global warming to 15 percent below 2005 levels by 2020.

The WCI is one of three GHG initiatives in North America with action plans in place to achieve a transition to clean-energy economies. Others include the Regional Greenhouse Gas Initiative (RGGI) in the Northeastern and Mid-Atlantic states and the Midwestern Greenhouse Gas Reduction Accord in the midwestern United States.

A unique feature of the WCI is the consensus achieved among its 11 Partner jurisdictions in developing a GHG emissions reduction strategy that accommodates the diverse economies and interests of its members and takes into account lessons learned from existing programs.

The Imperative for Action

The WCI Partner Jurisdictions are motivated to act by four critical factors:

- The impacts of climate change already being experienced in the region
- The forecast of far more significant adverse climate change impacts if we do not act now
- The economic costs of inaction
- The economic opportunities associated with a green economy

Current climate change impacts include rising temperatures and changing precipitation patterns that are resulting in higher sea levels, longer droughts, increased flooding, more wildfires, and less water availability. Future impacts expected from unabated climate change include more extreme sea-level increases, longer heat waves, unhealthy air quality, more unpredictable water availability, and reduced biodiversity as invasions of non-native species increase and local habitat moves northward and to higher elevations. These impacts will affect a wide range of people, ecosystems, and economic sectors, including electricity generation, health care, agriculture, and tourism.

While the precise cost of inaction is uncertain, it is likely to far exceed the cost of undertaking well-conceived climate change mitigation activities. A number of Partner jurisdictions have evaluated the potential economic impact of climate change. An April 2010 report by the State of California's Climate Action Team, for example, forecast the

cost of coastal flooding associated with sea-level rise in the San Francisco Bay area at $36 billion by 2050 and nearly $100 billion for all of California by 2085.[1] The report also predicted severe consequences for California's agriculture industry, with reduced crop yields and lower crop quality resulting in losses estimated at $3 billion annually by 2050. Washington State's Department of Ecology released a 2009 report indicating that inaction could cost the average Washington household $1,250 per year by 2020 and more than double that amount by 2080, due to higher energy costs, increased health-related costs, and a variety of other factors.[2]

At the same time, WCI Partner jurisdictions are taking action to reduce these costs and are realizing the benefits associated with the transition to a clean-energy economy. In the U.S., the seven WCI Partner states comprise 20 percent of the U.S. economy, yet they garnered 60 percent of venture capital investments directed toward clean-technology businesses between 2006 and 2008. In 2007, the proportion of green businesses and green jobs in the economies of WCI Partner states was 20 percent higher than in the U.S. economy as a whole.[3] British Columbia's green businesses contributed C$15.3 billion to the provincial economy in 2008, and that number is expected to grow significantly in the next decade. Jobs tied directly or indirectly to B.C.'s green economy are also forecast to increase—from nearly 166,000 jobs in 2008 to more than 225,000 in 2020.[4]

In Ontario, environmental industries represent about 40 per cent of the Canadian environmental industry sector revenues.[5]

The WCI Cap-and-Trade Program

In September 2008, following 18 months of stakeholder consultation, analysis, and Partner deliberations, the WCI Partner jurisdictions released Design Recommendations for the WCI Regional Cap-and-Trade Program. Cap-and-trade has proven to be a successful means of reducing air pollution and is considered one of the most effective strategies to reduce GHG emissions. For example, the U.S. Acid Rain Program has reduced emissions 40 percent below 1990 levels—at a fraction of the cost originally estimated by the U.S. EPA.[6] Cap-and-trade programs place a market value on emissions reductions and provide incentives for emitters and investors to seek out the lowest-cost opportunities to reduce emissions, including energy efficiency and process improvements, greater use of renewable and lower-polluting fuels, and other clean-energy innovations.

As described in the *Design Recommendations* and subsequent policy documents released by the WCI Partners, each WCI Partner jurisdiction will have

[6] See www.edf.org/page.cfm?tagID=1085.

an emissions allowance budget consistent with its jurisdiction-specific emissions goal, along with the flexibility to decide how to allocate its allowance budget. For example, a Partner could give allowances to emitters operating within its jurisdiction, auction the allowances to willing buyers, or provide for some combination of the two.[7] Facilities that reduce their emissions below their allowance holdings can sell the excess allowances or "bank" them for use in a later compliance period. Selling excess allowances allows covered facilities to recoup some of their emissions reduction costs, while banking allowances will lessen the costs later, as the cap becomes more stringent.

In the initial compliance period, beginning in 2012, the program will cover emissions from electricity—including electricity generated outside the WCI Partner jurisdictions but used by them—industrial combustion at large sources, and industrial process emissions for which adequate quantification methods exist. In the second compliance period, beginning in 2015, the program will expand to include fuels combusted at industrial, residential, and commercial buildings that are not otherwise covered as emissions sources, as well as transportation fuels. The first compliance period will encompass about half of the economy-wide emissions in the WCI Partner jurisdictions. Starting with the second compliance period, the program will cover about 90 percent of GHG emissions in the WCI jurisdictions.

In crafting its cap-and-trade program, the WCI Partners carefully assessed the designs and performance of programs such as the U.S. Environmental Protection Agency's Acid Rain Program, the European Union's Emission Trading System, and the Regional Greenhouse Gas Initiative.

To ensure compliance with the overall cap, the cap-and-trade program includes a rigorous emissions reporting requirement, which will be followed consistently across participating jurisdictions. Each WCI Partner will require annual emissions reports (using equivalent measurement protocols and verified by a third party) from entities and facilities covered by the cap. This element of the program is consistent with well-designed cap-and-trade programs that have had compliance rates of more than 99 percent. At the end of each three-year compliance period, facilities and entities with covered emissions will be required to submit to their state or provincial government emissions allowances and offsets equal to the amount of GHGs they released or were responsible for during that compliance period. If the facility or entity does not have sufficient emissions allowances and offsets to cover its emissions, a requirement to submit three allowances will be assessed for each one that they are short, in addition to any penalties that may be applicable in the state or province where the violation occurred.

[7] An allowance is a tradable "permit," and one allowance is required to emit each metric ton of covered greenhouse gases, measured in carbon dioxide equivalents (CO_2e).

Economic Analysis

An important consideration in crafting the WCI Design Recommendations in 2008 was an economic modeling analysis (referred to here as Phase 2) of various cap-and-trade program design options. The Phase 2 analysis[8] showed that the WCI Partner jurisdictions could achieve the goal of reducing emissions to 15 percent below 2005 levels by 2020 and could realize a modest net cost savings through an increase in energy efficiency and reduced fuel consumption. These savings would be in addition to the benefits the region would accrue from a cleaner environment and spin-offs resulting from investment and innovation in a green economy.

A Phase 3 economic analysis was recently completed to account for expansion of the WCI (to include Manitoba, Québec, and Ontario) and the economic downturn of 2008–2009. It also reflects various model improvements identified by the WCI Economic Modeling Team (EMT) and stakeholders, including updated fuel price forecasts, assumptions about offset price and availability, algorithms for allowance banking, costs of implementing complementary policies, detail of model outputs for the electric power sector, and simulation of the WCI two-phase approach to capping emissions in 2012 and 2015.

The Economic Model: ENERGY 2020

The Phase 3 analysis was conducted by the WCI Economic Modeling Team—with support from its contractors, ICF International and Systematic Solutions, Inc. (SSI)—using ENERGY 2020, a well-established and well-tested multi-region, multi-sector energy model that can simulate energy demand, energy supply, energy costs, and GHG emissions under user-defined scenarios. The basic workings of the model have been described in multiple stakeholder conference calls, workshops, and reports.

The model simulates demand in more than 40 commercial and industrial categories, three transportation services (passenger, freight, and off-road), and three residential categories. There are approximately six end uses per category and six technology/mode families per end use. For all end uses and fuels, the model is parameterized based on historical, locale-specific data. Load duration curves for electricity demand are dynamically built up from individual end uses to capture changing conditions under consumer choice and combined gas/electric programs. Technology and efficiency choices are modeled based on past experience with consumer choice rather than on a purely economic evaluation.

Additional information about the ENERGY 2020 model can be found in the appendix to this report and in WCI's *Assumptions Book for ENERGY 2020* at www.westernclimateinitiative.org/component/remository/Economic-Modeling-Team-Documents/

[8] See www.westernclimateinitiative.org/component/remository/general/design-recommendations/Design-Recommendations-Appendix-B/.

In consultation with the EMT, ICF International and Systematic Solutions Inc. used ENERGY 2020 to run a main policy case along with several "sensitivity" cases. All cases estimate the costs (and cost savings) of meeting the regional GHG reduction goal, as well as an allowance (or carbon) price required to provide sufficient incentive for the emissions reductions. The main policy case simulates the design of the WCI cap-and-trade program and expectations of future economic growth, fuel prices, the use of offset credits, and complementary policies. Because these expectations affect the potential cost of the cap-and-trade program, several "sensitivity" cases were also run to estimate the range of costs under alternative future scenarios. Specifically, the EMT looked at complementary policies being only half as effective, a faster rate of economic growth (with lower fuel prices as well), higher fuel and electricity generation costs, and alternative carbon price escalation rates over the period of the cap (2012–2020).

Offsets

The WCI cap-and-trade program design recommendations include multiple features to provide flexibility and low-cost compliance options, including the limited use of offset credits. Offsets are reductions in GHG emissions from industries outside the capped sectors, such as forestry and agriculture. Offset credits may be issued for projects that sequester carbon dioxide from the air or reduce GHG emissions, as long as they meet rigorous criteria to ensure that emissions reductions are real, verifiable, surplus/additional, permanent, and enforceable. Offset credits may be purchased and traded like allowances and used along with allowances to meet a compliance obligation. The WCI program limits the use of offsets for compliance purposes to ensure that a majority of the required emissions reductions are achieved by the sources covered by the cap-and-trade program. Assumptions about the cost and availability of compliance-grade offsets in the future are important when modeling because the more available and cost-effective they are, the more the program's overall costs will be reduced.

Complementary Policies

The WCI Partner jurisdictions recognize that other policies, working in concert with a cap-and-trade program, will address market barriers that limit the use of cost-effective technologies and help achieve the regional GHG reduction goal. Complementary policies promote cost-effective emissions reductions that would not typically be responsive to the price signal created by the cap-and-trade program. They also reduce emissions in sectors not covered by the cap, prevent emissions shifting (or leaking) to sources outside the cap or the capped region, and encourage investments in low-carbon technologies.

Examples of complementary policies include energy efficiency targets and standards, emissions performance standards for electric power, renewable energy standards, renewable/low-carbon fuels standards, transportation planning, mass transit, government procurement policies, and direct government funding and investment in key technologies. These policies are identified in state and provincial climate action plans, and many have been implemented or are in the process of being implemented.

Assumptions about the effectiveness of complementary policies are important when modeling the costs of a cap-and-trade program. To meet the regional GHG reductions goal, any emissions reductions not achieved by complementary policies will have to be achieved through the cap-and-trade mechanism. The WCI Economic Modeling Team (EMT) made the following assumptions about complementary policies in its modeling:[9]

- **Ontario Coal Phase-Out.** Ontario will be phasing out coal-fired electricity generation between 2010 and 2014.[10]
- **Clean Car Standards.** The second phase of the California Clean Car Standards (Pavley II) will be implemented regionwide in 2017, with the effect of improving the efficiency of new passenger vehicles from 35.5 mpg in 2016 to 42.5 mpg by 2020.[11]
- **Energy Efficiency.** The combined effect of energy efficiency programs recently put in place and being pursued will reduce the growth rate of electricity and natural gas demand by 0.5% each year, starting in 2012.[12]

Summary of Economic Modeling Results

- The WCI can meet its 2020 regional emissions reduction goal with modest net cost savings.
- Complementary policies such as energy efficiency and clean car standards have the potential to significantly reduce emissions and contain costs. In this analysis, complementary policies result in negative costs, or cost savings.
- Banking and offsets are also important design elements for achieving emissions reductions and limiting costs.
- Higher-than-expected fuel prices would make it less costly to achieve the emissions goal, with lower allowance prices. Conversely, lower-than-expected fuel prices, coupled with a faster economic recovery, would raise the allowance price.

[9] The cost of obtaining the emissions reductions associated with these policies is included in the modeling results. A literature review of travel demand reduction programs showed a broad range of potential planning and development costs and savings, including potential infrastructure savings. This analysis excludes these potential costs and savings, and focuses solely on the impacts on vehicle use and fuel use.

[10] See news.ontario.ca/mei/en/2009/09/ontarios-coal-phase-out-plan.html.

[11] See arb.ca.gov/cc/ccms/ccms.htm.

[12] This is less than the 1.0% assumed in the Phase 2 analysis and is reasonable as a minimum expectation considering the efficiency provisions of the American Recovery and Reinvestment Act of 2009 in addition to complementary policies identified in state and provincial climate action plans. Studies by the California Energy Commission and the Northwest Power and Conservation Council suggest that a reduction of 1.0% is achievable with currently cost-effective measures.

- **Vehicle Miles Traveled (VMT).** The combined effect of transportation and fuel programs recently put in place and being pursued is equivalent to reducing the fore-casted travel demand so that VMT in 2020 is lower by 2%, starting in 2008.

Summary of Economic Modeling

The results of the WCI economic modeling suggest that the GHG emissions reduction goal for 2020 can be achieved with a cost savings of approximately US$100 billion in the region between 2012 and 2020. While significant, these savings are relatively modest (less than 0.2%) relative to the size of the overall economy of the 11 WCI Partner jurisdictions.

The cost savings result from the complementary policies, with the largest proportion of the savings attributable to a 2% reduction in the use of personal vehicles by 2020, and to a lesser extent by the energy efficiency investments that reduce the growth rate of electricity and natural gas consumption.[13] In practice, the cap-and-trade program is expected to facilitate and ensure the cost savings of complementary policies. That is, the *combination* of the price signal and market incentives associated with the cap-and-trade program *and* their effect on production and consumption choices would enable complementary policies to have their full emissions and cost-saving effects.

Economic Modeling Scenarios	Cost Savings 2012–2020 (2007 USD)	Emissions Allowance Price in 2020 (2007 USD)
Main Policy Case	US$102 billion	US$33 per metric ton
Sensitivity Cases		
Complementary policies only half as effective as in main case	At least US$38 billion	At least US$50 per metric ton
Faster economic growth and lower primary energy prices	At least US$202 billion	At least US$50 per metric ton
Higher energy prices and power plant construction costs	US$106 billion	US$13 per metric ton

[13] The net savings include the cost of administering and achieving the reduction in annual electricity and natural gas demand growth anticipated from complementary policies. The planning and development costs and benefits associated with reducing travel demand are not included in the analysis due to modeling and data limitations, although it is not clear that these costs and benefits would significantly affect the results.

To achieve the necessary emissions reductions under cap-and-trade, WCI modeling forecasts a carbon allowance price of US$33 in 2020. This is higher than the US$24 predicted in the WCI Phase 2 modeling but on par with government analyses of the WCI and other cap-and-trade proposals. (See Page 43 in the Appendix for details.)

In addition to the main policy case, three sensitivity runs were conducted with ENERGY 2020 to determine how cost savings might change if different assumptions about complementary policies and future economic growth and energy prices are made. As shown in the table above, the WCI program would continue to deliver net cost savings, although if future economic growth and energy prices deviate substantially from what is expected, allowance prices could range from US$13 to over US$50 to fully achieve the WCI emissions reduction goal.

Emissions Reductions

Total emissions from capped sectors in the reference case (a business-as-usual modeling scenario) are projected to be 7,999 million metric tons (Mt) of carbon dioxide equivalents from 2012 to 2020. To achieve a 15% reduction below 2005 emissions levels, WCI modeling forecasts a cumulative reduction of 719 Mt. Of this total, 235 Mt of reductions would be from offsets and 484 Mt would be achieved within the capped sectors. Figure 1 shows more specifically where WCI modeling forecasts that the 719 Mt of reductions will come from.

Figure 2 shows the projected trend in emissions reductions. Rather than reducing emissions in a straight line to 15% in 2020, sources in the WCI region are predicted to "over comply" with the cap in earlier years and "bank" the excess allowances for use in 2019 and 2020. In this way, the same

Figure 1. Source of Emissions Reductions Under the Cap, Main Policy Case Relative to the Reference Case, 2012–2020

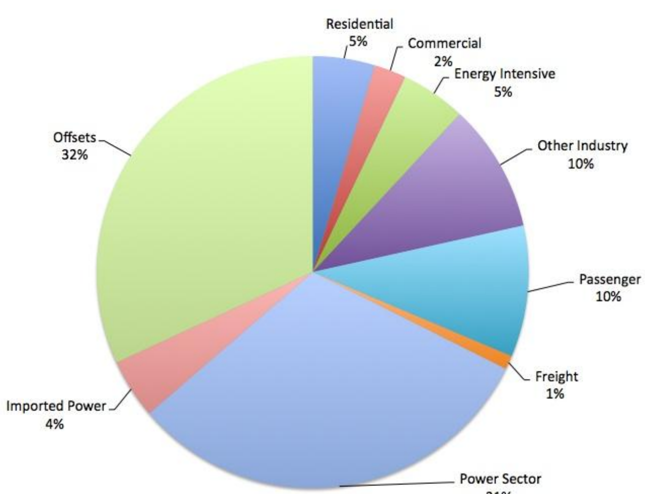

Figure 2. GHG Emissions Reductions Under the WCI Program

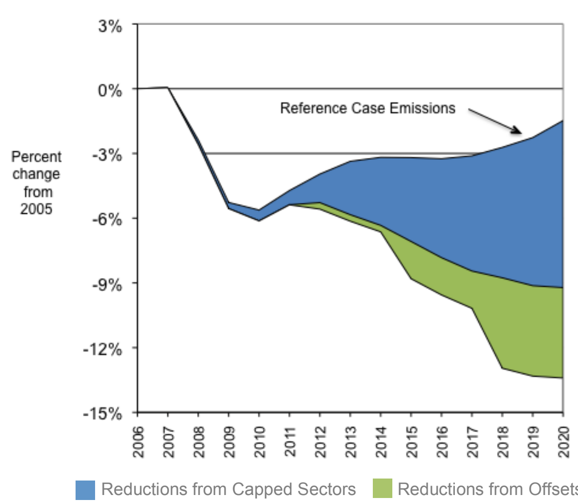

amount of emissions reductions is achieved, but sooner and with more flexibility at lower costs.

A Note About the Economic Analysis

Models are by necessity simplified representations of the real-world economy. They cannot predict the future, but they can shed light on important economic relationships, test the robustness of alternative policy architectures (e.g., against the uncertainty of future energy and commodity prices, technological development, etc.) and thereby help inform the design of a market-based climate change policy.[14] While ENERGY 2020 estimates the direct cost of energy use, it is not a macroeconomic model and does not estimate how direct costs (and cost savings) will translate into broader effects such as economic output, trade, employment, and government revenues. ENERGY 2020 results can be, and have been, used as inputs to macroeconomic models. But given the modest costs and savings predicted by ENERGY 2020 relative to the size of the WCI economy, such an analysis has not been conducted.

Other economic analyses, including macroeconomic analyses, however, have been conducted by individual WCI Partner jurisdictions. Some of these analyses are more detailed or are more specifically tailored to the programs and policies of the sponsoring jurisdiction. The WCI regional analysis does not replicate all aspects of these studies, nor is it a substitute.

Looking Ahead

The WCI Partner jurisdictions will be scheduling a conference call with stakeholders to review the analysis and results. Stakeholder comments are welcome and will be taken into consideration as WCI Partners continue implementing their GHG reduction policies. However, no further regional economic analysis or revisions to this report are planned by the WCI Partner jurisdictions.

The WCI Partner jurisdictions are also moving forward on several other fronts, including:

- Release of the *Detailed Program Design* in summer 2010, which will support the implementation of the cap-and-trade program by Partner jurisdictions.
- Development of policies and processes associated with the offset program.
- Establishment of carbon emissions allowance budgets for each Partner jurisdiction.
- Ongoing collaboration and development of complementary policies.
- Ongoing collaboration with other North American regional cap-and-trade programs.

Description of Analysis

This analysis was directed by the WCI Economic Modeling Team (EMT), with support from its contractors ICF International and Systematic Solutions, Inc. The EMT first analyzed the economic impacts of a WCI cap-and-trade program in 2008 using the ENERGY 2020 model designed and applied by its contractors. The EMT refers to this analysis as the Phase 2 analysis because it supplemented preliminary (Phase 1) work with population and economic forecasts provided by some WCI states for use in lieu of nationally available data. The results of the Phase 2 analysis informed the development of the *Design Recommendations for the WCI Regional Cap-and-Trade Program* and concluded that the program could achieve the WCI emissions reduction goal with a small cost savings, equal to about 0.2 percent of the region's gross domestic product.[15]

The analysis presented here (the Phase 3 analysis) updates the results of the Phase 2 analysis to account for new Partners within the WCI, the economic downturn of 2008-2009, and various model improvements identified by the EMT and WCI stakeholders. The differences between the Phase 2 and Phase 3 modeling are summarized in Tables 1 and 2 and in Figures 1 and 2.

The EMT modeling results are expressed as differences between "reference runs" and "cap-and-trade runs". Reference runs simulate energy use and emissions of the economy under a business-as-usual forecast. Cap-and-trade runs simulate the energy use and emissions of the economy after imposing a carbon price sufficient to reduce emissions to the level of the WCI regional goal.

It is important to note that this analysis does not model the costs of climate change, and therefore the benefits of cap-and-trade and complementary policies in terms of avoided costs, nor any co-benefits (such as reduced smog and resulting health improvements, for example).

Included in the cap-and-trade runs is a set of assumptions regarding the costs and energy use impacts of complementary policies under development by the WCI jurisdictions. Complementary polices are regulations and incentive programs that reduce energy use and greenhouse gas emissions, often at a net savings to the users of fuel. The costs of a cap-and-trade program depend on the effectiveness of complementary policies because any emission reductions not achieved by the complementary policies must be met through the cap-and-trade mechanism. The EMT therefore conducted "sensitivity runs" for the cap-and-trade program in which some of the major complementary policies were assumed to be only half as effective as in the cap-and-trade runs. The EMT also conducted sensitivity runs testing assumptions about the rate of economic growth, future fuel and electricity generation costs, and carbon (or allowance) price escalation rates over the period of the cap (2012-2020).

[15] The WCI's greenhouse gas emissions reduction goal is an aggregate reduction of 15% below 2005 levels by 2020.

Table 1: Differences Between Phase 2 and Phase 3 Modeling

Issue	Type	Phase 2	Phase 3	Comment
Jurisdictions included	Model capability	8 WCI Partners in the WECC	All 11 WCI Partners	Required substantial additions to the model, including specifications for the electric sector throughout U.S. and Canada
Program scope	Program definition	Compared broad scope throughout to narrow scope throughout	Represents program design with narrow scope (2012) followed by broad scope (2015)	Required model changes to be consistent with WCI Design Recommendations
Allowance budget	Program definition	Set in 2012 and linear decline through 2020	Set in 2012 for narrow scope. Set in 2015 for broad scope, with continued reduction in 2012 scope.	Setting the Phase 3 allowance budget in 2015 required assumptions regarding the rate of decline from 2012 to 2015
Electric sector outputs	Model capability	No detailed electric sector outputs	Added electric sector outputs to show investment costs and operating costs	Response to stakeholder request
Offset limit	Program definition	5% of cap	49% of emission reductions	Phase 3 limit is more strict and consistent with the WCI Design Recommendations
Offset supply	Assumption	Unlimited supply available at $20 per metric ton	Supply curve modeled using U.S. EPA analysis of domestic offset supply over time, adjusted to include Canadian supply	Phase 3 supply assumptions remain simplistic, but are an improvement over Phase 2. Offset prices start lower but can exceed $20 per metric ton.
Economic growth forecast	Assumption	Forecast did not include the recession. Used a single forecast.	Updated forecast to include the recession. Created an alternative forecast with extra growth post 2012	Figure 1: shows the Phase 2 and Phase 3 economic forecasts. The new forecast tends to decrease costs.

Issue	**Type**	**Phase 2**	**Phase 3**	**Comment**
Fuel price forecasts	Assumption	Annual Energy Outlook 2008 High Case as Reference Case	Reference run: Annual Energy Outlook 2009 Mid Case. Alternative Reference run: Average of AEO Mid and Low Cases High Price Case: AEO High Case	Figure 2 shows the Phase 2 and Phase 3 fuel price forecasts for crude oil. The higher fuel price forecast in the reference run leads to price driven efficiency improvements.
Policies included in the reference run	Assumption	US: EISA requirements Canada: CSA standards and "ecoENERGY" Renewable Fuels Strategy Partner: RPS requirements	All Phase 2 reference case policies plus the vehicle standards agreement through 2016 (modeled as Pavley 1)	By putting the Pavley 1 standards in the reference run, the emission reductions and cost savings are in the reference run and are not counted as part of the program
Costs of efficiency improvements in devices and processes	Assumption	Included declining costs due to economies of scale so that more efficient technologies cost less than standard technologies	Requires that more efficient devices and processes always cost more than standard technologies	This change in assumption increases the cost of improving efficiency. It is a conservative assumption (i.e., may overstate costs)
O&M costs	Assumption	Not estimated	Added for Phase 3 to capture non-fuel cost impacts on O&M associated improved efficiency	This change in assumption increases the costs of improving efficiency, resulting in a better estimate
Costs of reducing vehicle emissions beyond Pavley 1	Assumption	Not estimated	Added for Phase 3 to reflect incremental costs of additional efficiency improvements	This change in assumption increases the costs of improving efficiency, resulting in a better estimate
Complementary policies included	Program definition	Energy efficiency VMT reductions Vehicle standards	Energy efficiency VMT reductions Vehicle standards post 2016	The vehicle standards through 2016 are in the reference run

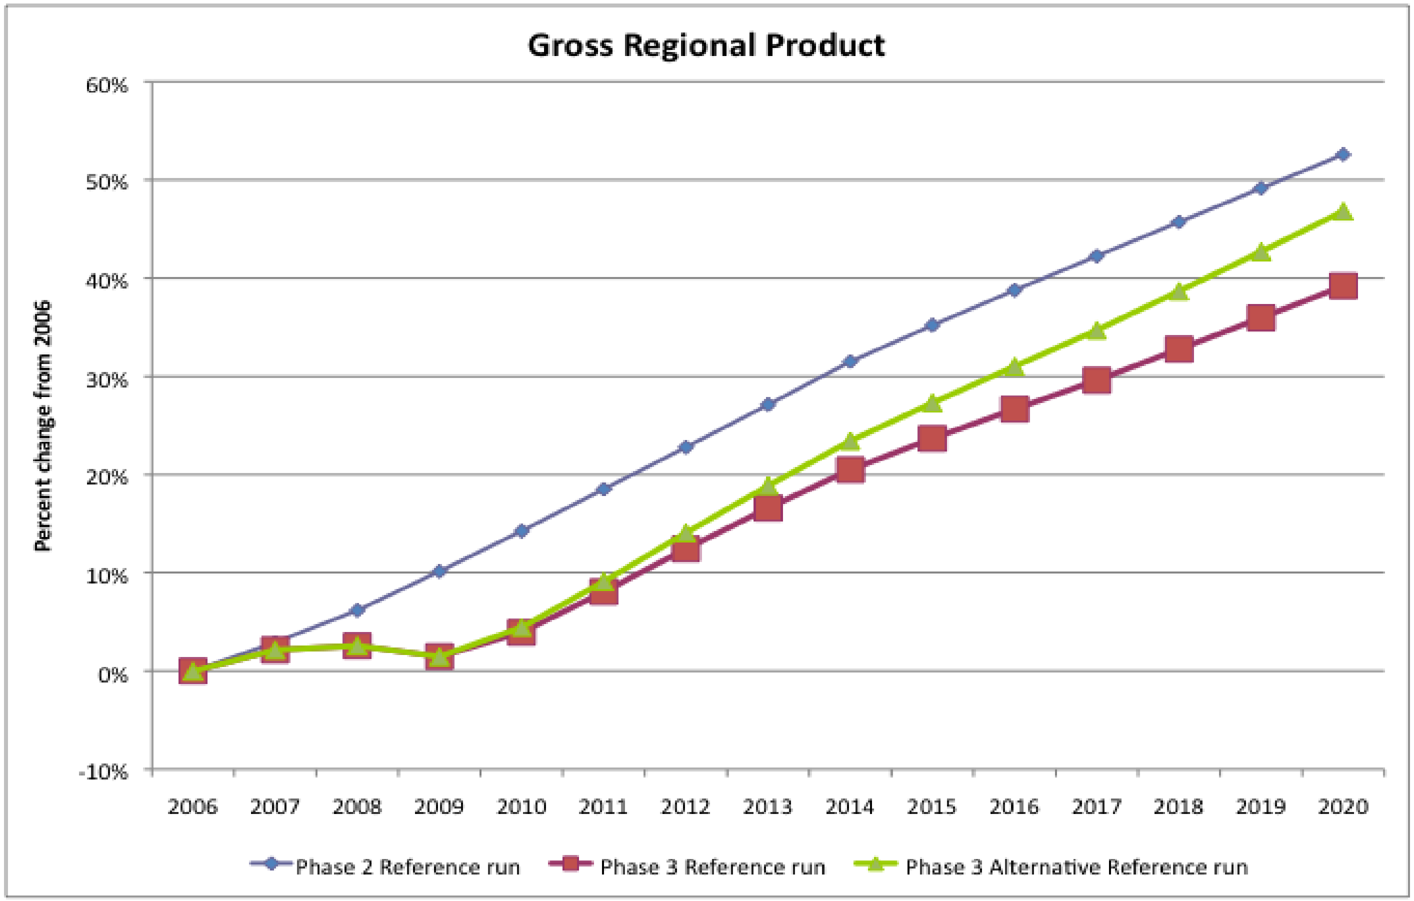
Issue	Type	Phase 2	Phase 3	Comment
Effect of energy efficiency programs	Assumption	Energy efficiency reduces rate of growth in electricity and natural gas demand by 1% each year	Energy efficiency reduces rate of growth in electricity and natural gas demand by 0.5% each year. (In the alternative economic forecast sensitivity case, 1% is assumed.)	The Phase 3 assumption regarding the effects of the EE programs makes it more costly to achieve the emissions target
Cost of administering energy efficiency programs	Assumption	Did not calculate program administration costs	Calculates program administration costs based on experience from existing electricity and natural gas programs	Phase 3 calculations add costs to the program
Banking algorithm	Model capability	Used a "rule of thumb" to approximate potential allowance banking behavior	Simulate economically rational banking behavior, namely increases in allowance prices over time that reflect the opportunity cost of banking allowances	An 8% annual increase in allowance price is assumed to reflect risk and time value of money. Sensitivity cases were analyzed using 4% and 12%.

Table 2: Summary of How Differences Between Phase 2 and Phase 3 Modeling Affect Cost Estimates

Phase 3 Aspects That Tend to Reduce Cost Estimates	Phase 3 Aspects That Tend to Increase Cost Estimates
Economic Forecast: Recession reduces emissions	Less gas-fired generation capacity build-out
Fuel Prices: 2009 forecast is higher	Phase I of the Clean Car Standards are placed in the reference run. All emission reductions (and cost savings) become part of the reference run and are not attributed to the WCI program.
	Costs for Phase II of the Clean Car Standards (2017 and beyond) were added, increasing costs
	The effect of energy efficiency programs is assumed to reduce electricity and natural gas growth by 0.5% instead of 1.0%, reducing the impact of efficiency programs increasing costs
	Costs for administering energy efficiency programs were added
	Devices exceeding energy efficiency standards are assumed to always have higher costs than standard devices, and their costs are not allowed to decrease by more than 10% over time
	Operation and maintenance costs were increased for more-efficient devices

Phase 2 and Phase 3 modeling differences that neither reduce nor increase cost estimates, or whose effects are uncertain, are not listed in this table.

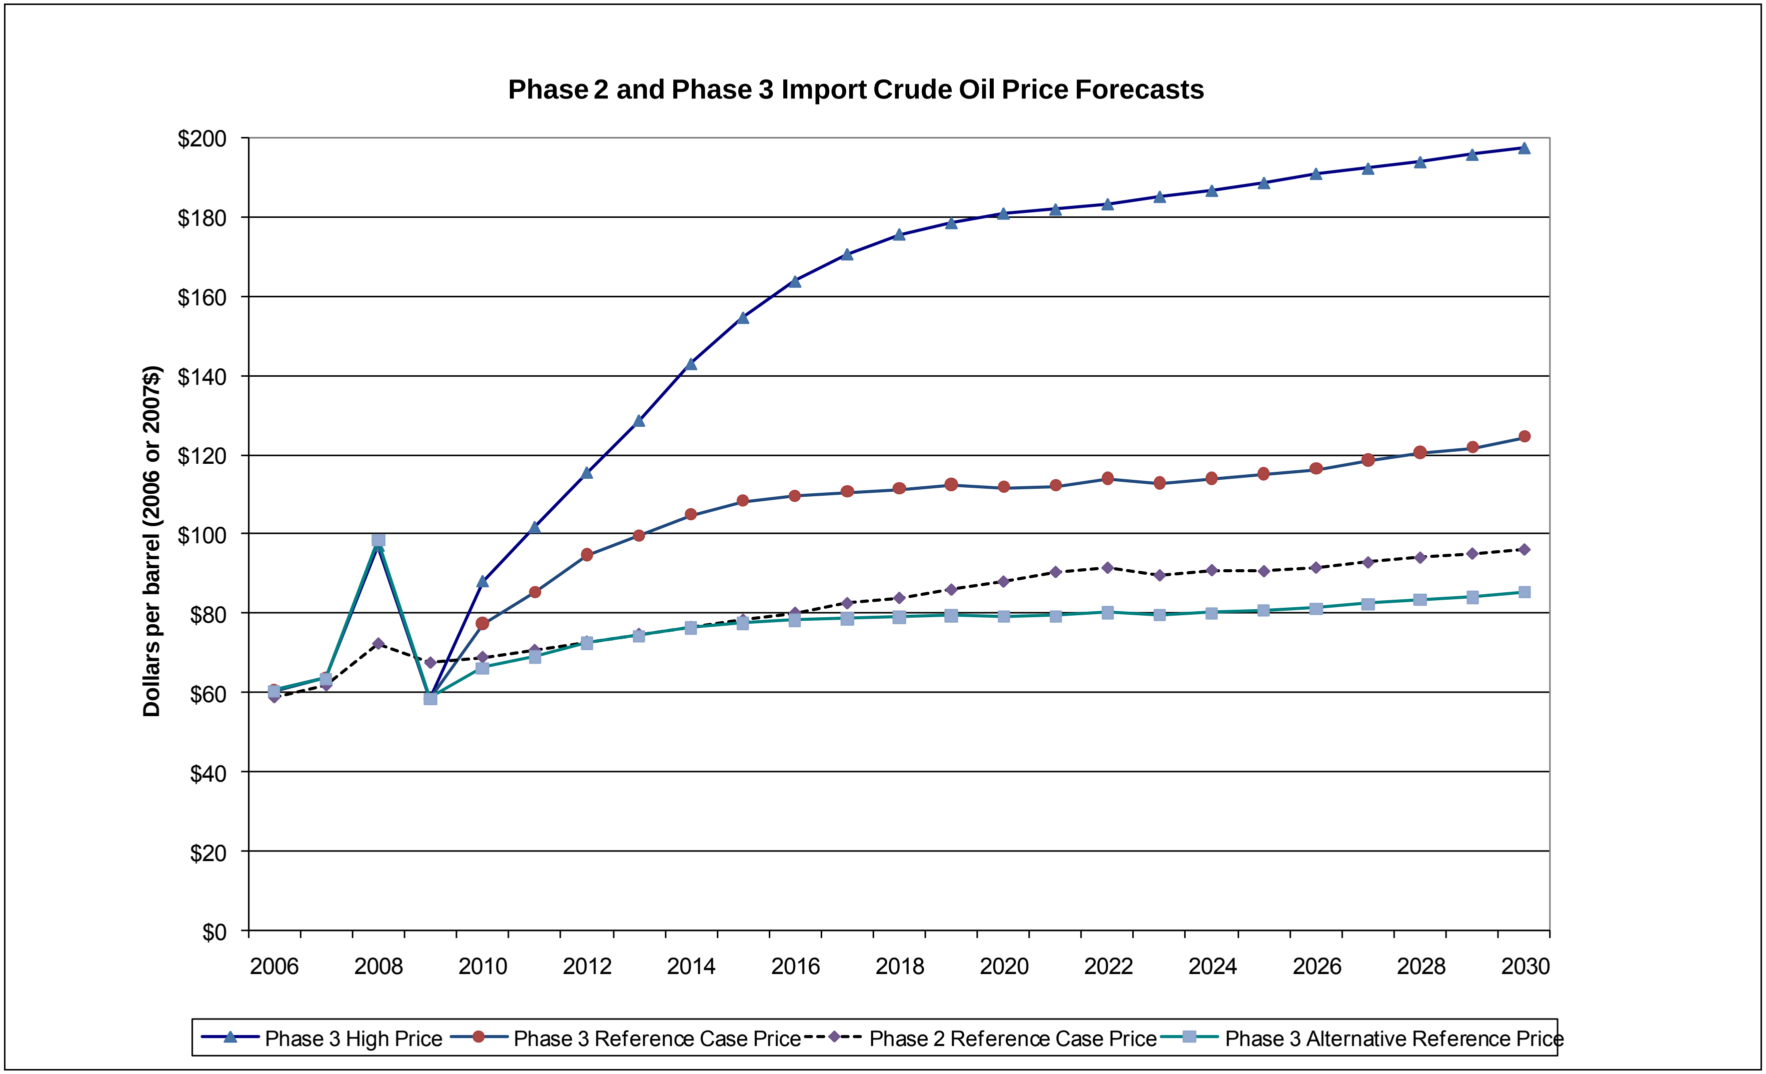
Figure 1: Economic Forecasts Used in Phase 2 and Phase 3 Modeling



Average annual growth rates from 2006 to 2020:

Phase 2 Reference run: 3.1% per year
Phase 3 Reference run: 2.4% per year
Phase 3 Alternative reference run: 2.8% per year

Figure 2: Fuel Price Forecasts Used in Phase 2 and Phase 3 Modeling



Results for all cap-and-trade and sensitivity runs include the change in emissions and net cost to covered sectors relative to the reference runs, as well as the 2020 allowance price required to achieve the WCI regional goal and the total market value of allowances over the 2012-2020 period. Additional details on the ENERGY 2020 model and the EMT's analytical approach can be found below and in the *Assumptions Book for Energy 2020* posted on the WCI website.[16]

Definitions

2012 is the first year of the first compliance period, and the starting year of the WCI cap-and-trade program.

2015 is the first year of the second compliance period, at which point additional sectors are subject to the cap.

2020 is the final year of the third compliance period, and the end year of the economic analysis.

Allowance budget means the number of allowances assumed to be issued throughout the region in a given year. In the WCI cap-and-trade program, one allowance is required to emit each metric ton of covered greenhouse gas emissions, expressed in carbon dioxide equivalents (CO_2e). For purposes of economic modeling, an allowance budget was determined for each year such that the WCI regional goal would be met in 2020 through a linear decline starting in 2012. The difference between the reference case emissions for covered sectors and the allowance budgets represents the total 9-year emission reduction that the main policy and sensitivity cases must achieve.

Allowance value means the allowance price in a given year multiplied by the allowance budget for that year.

Banking means that covered sources emit less than the allowance budget in one compliance period and bank the remaining allowances for use in a later compliance period. This banking allows covered sources to make cost-effective reductions earlier and lessen the costs later.

Compliance period means a three-year period at the end of which an emission source must hold a sufficient number of compliance instruments (allowances and offset credits) to account for its emissions during that period. The WCI compliance periods are 2012-2014, 2015-2017, and 2018-2020.

Compliance means that at the end of each compliance period emissions from all covered sectors, summed over each year since 2012, must be equal to or less than the allowance budgets issued since 2012, after accounting for offsets.

Covered sector means a sector of the economy whose emissions are covered by the cap-and-trade program in a given compliance period.

Uncovered sources are emission sources that are not included in the program scope in a given year.

[16] The posting on the WCI website is at: http://www.westernclimateinitiative.org/component/remository/Economic-Modeling-Team-Documents/

Narrow scope in the modeling means emissions from electric power generation within the WCI Partner jurisdictions, emissions from electric power generation outside the WCI Partner Jurisdictions for power imported into the WCI Partner Jurisdictions, and emissions from industrial fuel combustion and processes within the WCI Partner Jurisdictions.

Broad scope in the modeling means the narrow scope plus passenger and freight transport emissions and emissions from all remaining fossil fuel combustion, including residential, commercial, agriculture, and waste & wastewater. These emissions are covered in the second and third compliance periods. Not included in the broad scope are process emissions from agriculture, waste & wastewater, and high Global Warming Potential gases, such as refrigerants.

Reference run means an application of ENERGY 2020 to a business-as-usual scenario (i.e., absent any cap or other GHG abatement policies not already adopted).

Complementary policies run means an application of ENERGY 2020 in which complementary policies have been added to the reference conditions.

Cap-and-trade run means an application of ENERGY 2020 in which an allowance price has been imposed on the reference and complementary policies conditions. All of the cap-and-trade runs include complementary policies.

Case means a family of ENERGY 2020 runs consisting of a reference run, a complementary policies run, and a cap-and-trade run. Each case is characterized by assumptions on economic growth, energy/fuel prices, and effectiveness of complementary policies (full or half), generation cost, and allowance-price growth rate.

Abatement means the change in emissions in covered sectors due to complementary policies and the cap-and-trade policy. Specifically, it is the difference between the emissions in a cap-and-trade run and the emissions in the reference run. Reductions through offsets, therefore, are not included in this use of the term abatement.

Abatement cost means the resource cost to bring about abatement. In this analysis, proper quantification of total abatement costs requires that the value of allowances used in the electric power sector be subtracted from the abatement costs. This is required because electricity prices in the model were assumed to include the full market value of allowances in order to effectuate proper energy use decisions among end users in the residential, commercial, industrial, and transportation sectors. Because allowance values represent a financial transfer and not a resource (or abatement) cost, the allowance value is subtracted from the abatement cost so that it reflects the actual cost of reducing emissions.

Reduction means the difference between emissions in the reference run and the allowance budgets. Reductions define the threshold for compliance with the cap-and-trade program, whereas abatement refers to the decrease in emissions from covered sectors, which will be less than the reductions to the extent that offsets are used.

WCI regional goal (or target) is 15% below 2005 levels by 2020 of greenhouse gas (GHG) emissions for the entire regional economy.

WECC is the Western Electricity Coordinating Council.

Methodology and Assumptions

This section begins with two subsections describing the ENERGY 2020 model and the general modeling assumptions and input data. Following subsections describe how banking, offsets, and complementary policies are included in the modeling, as they are key factors in the design and cost-containment of the program. The final subsection describes the remaining assumptions pertinent to the main policy case and sensitivity cases.

ENERGY 2020

ENERGY 2020 was the model used in this analysis. A detailed description of ENERGY 2020 is available in the *Assumptions Book for Energy 2020* posted on the WCI website.[17] Additional documentation is available at the California Air Resources Board (ARB) website.[18] Below is a brief description of the model.

ENERGY 2020 is an integrated, multi-region energy model that provides all-fuel demand and supply sector simulations. The model simulates demand by three residential categories (single family, multi-family, and agriculture/rural), over 40 NAICS commercial and industrial categories,[19] and three transportation services (passenger, freight, and off-road). There are approximately six end-uses per category and six technology/mode families per end-use. End-uses include process heat, space heating, water heating, refrigeration, lighting, air conditioning, and motors. The technology families correspond to six fuels groups (oil, gas, coal, electric, solar and biomass) and 30 detailed fuel products. The transportation sector contains 45 modes, including various types of automobile, truck, off-road, bus, train, plane, marine and alternative-fuel vehicles. More end-uses, technologies, and modes can be added as data allow. For all end-uses and fuels, the model is parameterized based on historical, locale-specific data. The load duration curves for electricity demand are dynamically built up from the individual end-uses to capture changing conditions under consumer choice and combined gas/electric programs.

Each energy demand sector includes cogeneration, self-generation, and distributed generation simulation, including mobile-generation, micro-turbines, and fuel-cells. Fuel-switching responses are rigorously determined. The technology families (which can be split, as an option, to portray specific technology dynamics) are aggregates that, within the model, change building shell, economic-process and device efficiency and capital costs as price or other information that the decision makers see,

[19] NAICS is the North America Industrial Classification System which was developed jointly by the U.S., Canada, and Mexico to provide new comparability in statistics about business activity across North America.

change. ENERGY 2020 utilizes the historical and forecast data developed for each technology family to parameterize and disaggregate the model.

The supply portion of the model includes endogenous detailed electric supply simulation of capacity expansion/construction, rates/prices, load shape variation due to weather, a complete (but aggregate) representation of the electric transmission system, and changes in regulation. The model dispatches plants according to the specified rules whether they are optimal or heuristic and simulates transmission constraints when determining dispatch. A dispatch routine selects critical hours along seasonal load duration curves as a way to determine system generation. Peak and base hydro usage is explicitly modeled to capture hydro-plant impacts on the electric system.

In addition to modeling electricity supply, ENERGY 2020 can also model the supply of oil, natural gas, refined petroleum products, ethanol, land-fill gas, and coal. In the Phase 3 modeling, however, prices for these energy sources were provided exogenously to the model.

ENERGY 2020 includes pollution accounting for both combustion (by fuel, end-use, and sector) and non-combustion processes, and non-energy (by economic activity) for all GHGs that would be covered by the WCI cap-and-trade program, as well as conventional air pollutants at the state and provincial level by economic sector.

ENERGY 2020 can simulate the impacts of a wide variety of GHG mitigation policies, including regulations, demand reduction programs, taxes, and emission caps with trading. These capabilities were used in the reference runs (to reflect existing policies) and in cases involving complementary policies and the WCI cap-and-trade design. Details on specific policies included in the modeling appear in later sections and in the *Assumptions Book*.

ENERGY 2020 is not a macroeconomic model and does not predict the downstream effect of energy prices, costs, and cost savings on factors such as economic output, household income, trade and employment, although its outputs can and have been used in such assessments.

General Modeling Assumptions

This section presents an overview of the major assumptions used in the modeling. These assumptions are included in all modeling runs, except for the assumptions on economic growth, fuel prices, and electricity generation costs, which are altered in two of the sensitivity cases. The *Assumptions Book for ENERGY 2020* includes additional detail on the assumptions and model inputs, including links to data sources.

<u>Geographic Coverage</u>: The Phase 3 modeling covers the lower 48 states of the U.S. and all of Canada, which includes the 11 WCI Partners. By covering the entire electric grid in addition to the energy/emissions impacts in the 11-Partner region, the impacts of the WCI programs and policies on electricity generation in the non-WCI WECC states and provinces can be examined.

Sectors and Sources: The Phase 3 modeling includes energy use in all sectors, as well as most industrial process emissions. Landfill methane emissions and non-energy agriculture emissions are included in the total emissions estimates, but emission reductions are not estimated for these sources.[20] The analysis is based on gross emissions, so that forestry emissions and sinks are excluded.

WCI Population Forecast: A key driver in the ENERGY 2020 energy demand simulations is population forecast. Table 3 shows the population growth forecast used.

Table 3: Population Forecast for WCI Partners, Selected Years (Millions)

Jurisdiction	2006	2012	2015	2020
Arizona	6.2	7.4	7.9	8.8
British Columbia	4.3	4.6	4.8	5.1
California	37.4	40.1	41.5	44.1
Manitoba	1.2	1.2	1.2	1.2
Montana	0.9	1.0	1.1	1.2
New Mexico	2.0	2.6	2.7	2.8
Ontario	12.7	13.6	14.1	14.8
Oregon	3.7	4.0	4.1	4.4
Quebec	7.6	7.8	7.9	8.1
Utah	2.6	3.1	3.3	3.7
Washington	6.4	7.0	7.3	7.7
Total	**85.1**	**92.4**	**96.0**	**101.9**

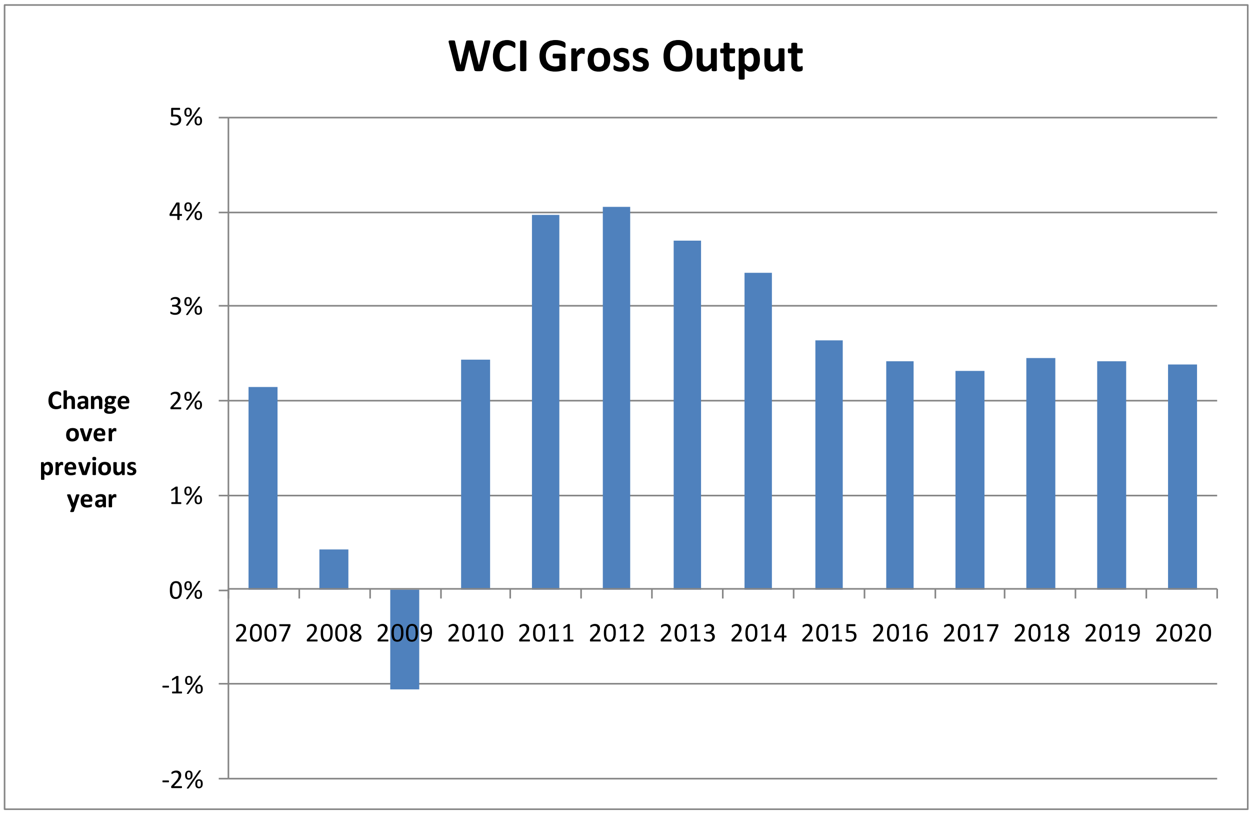
WCI Economic Growth Forecast: Another key driver in the ENERGY 2020 simulation of energy demand is sector-specific economic growth. Table 4 and Figure 3 show the gross economic output forecast for the WCI region.

Table 4: Regional Gross Economic Output Forecast for the WCI Region, Selected Years (Billion of 2007 US dollars)

2006	2009	2012	2015	2020	Avg. Annual Growth Rate 2006-2020
5,514	5,595	6,199	6,819	7,675	2.4%

[20] Examples of non-energy agriculture emissions are methane emissions from livestock and livestock manure management, and carbon and N_2O emissions from agricultural soils.

Figure 3: Regional Gross Economic Output Forecast for WCI Partners



Emission Abatement Options: The model simulates decisions by energy users for each end use, including: fuel choice; investment in end use efficiency (e.g., by purchasing devices that are more efficient than the minimum required by standards); and end-use utilization (how much the device is used). End-use specific choices are simulated as needed, such as mode choice for freight movement and passenger transportation. Choices are simulated based on costs (increased capital costs versus the value of fuel saved) as well as non-price attributes (convenience, acceptance of the technology). Past purchasing behavior is used to calibrate the non-price choice parameters for each end use.

Energy Independence and Security Act of 2007 (EISA): The reference runs, main policy case, and sensitivity cases include the requirements of the EISA, appliance and lighting energy efficiency standards, and the renewable fuels standard (RFS). These requirements are assumed to be implemented fully in the U.S. WCI Partner jurisdictions. For the Canadian provinces, lighting, equipment and appliance standards as defined by the Canadian Standards Association[21] as well as federal "ecoENERGY" Renewable Fuels Strategy.[22]

[21] http://www.oee.nrcan.gc.ca/regulations/home_page.cfm

[22] This strategy requires 5% average renewable content based on the gasoline pool that is produced or imported, starting in 2010, and 2% average renewable content in diesel fuel and heating oil (distillate) by 2012. The Canada Gazette indicates that the 2% renewable content in diesel fuel and heating oil is equivalent to 5% renewable content in on-road diesel use. (See http://canadagazette.gc.ca/partI/2006/20061230/html/notice-e.html#i3)

Clean Car Standards: All cases incorporate the Clean Car Standards through 2016, equivalent to California's Pavley I. In April, 2010, the U.S. federal government established standards for vehicle GHG emissions and CAFÉ standards which would align with the GHG emission standards previously proposed by California. (At the same time, the Canadian federal government also announced rules that would effectively align with those in the U.S.) As a result, a national standard was established which will require the fuel efficiency of new passenger cars and light trucks to reach an average fleet efficiency of 35.5 mpg by 2016. The Phase 3 modeling assumes a fixed percentage increase in the efficiency of new vehicles each year starting in 2010 to reach the mandated level by 2016. Information relating to the cost of implementing this policy was based on estimates by the NHTSA.[23] Efficiency improvements beyond 2016 (Pavely II) are included the complementary policies runs.

Renewable Portfolio Standards: All modeling runs incorporate the renewable portfolio standards (RPSs) currently in effect in the states and provinces. See Appendix I of the *Assumptions Book for ENERGY 2020* for details.

Fuel Prices: An important variable in the modeling is the forecast of fuel prices (oil, coal, natural gas, etc.). The model calculates electricity prices internally. Table 5 shows the AEO 2009 reference-case price forecast used in the modeling. State- and province-specific retail prices are derived in the model from the prices shown in this table.

Table 5: Fuel Price Forecast

	2006	2012	2015	2020
World Oil Price (2007 US$/barrel)	60.70	94.84	108.52	112.05
Natural Gas Wellhead Price (2007 US$/mmBtu)	6.91	6.75	6.90	7.43
Coal Prices (2007 US$/ton)	25.29	27.69	27.77	27.38

Source: EIA Annual Energy Outlook 2009 reference price series.

Technology Assumptions: To conduct the analysis, assumptions are required regarding the availability, cost, and use of a range of technologies through 2020. This analysis adopts assumptions, listed below, which overall are conservative in that they tend to increase the cost of achieving the WCI emissions goal. The WCI Partner jurisdictions recognize the promise of a variety of technologies as a means of reducing emissions, and they are promoting their development in some cases. However, their near-term commercial deployment remains uncertain. These assumptions are made for modeling purposes, and do not reflect WCI policy recommendations regarding the promise or use of these technologies.

- Coal Plants: Coal plants that are already planned and committed are assumed to be completed as planned and brought into service. No additional new coal plants are assumed to be built by 2020 in the WECC region beyond those already planned and committed. See Appendix F of the

[23] NHTSA, Corporate Average Fuel Economy Rulemaking, Document No. WP.29-145-13, June 2008, see also: NHTSA, Final Environmental Impact Statement, Corporate Average Fuel Economy Standards, Passenger Cars and Light Trucks, Model Years 2011 to 2015, October 2008.

Assumptions Book for ENERGY 2020 for a list of coal plants that are assumed to be planned and committed.

- Nuclear Plants: No new nuclear power plants are assumed to be built by 2020 in the WECC region.
- Carbon capture and storage: Carbon capture and storage is assumed for this analysis to not be feasible for electric power generation through 2020.
- Hydropower: No new hydropower capacity is assumed to be built in the WECC region through 2020.
- Plug-in hybrids: Electric vehicles, including plug-in hybrids, are assumed to be not available in significant numbers through 2020.
- Electricity Generation Costs: The Phase 3 modeling uses estimates of power generation capital costs, operating costs, and heat rates developed for a recent study by the California Public Utilities Commission, summarized in Table 6.

Table 6: Summary of Power Generation Cost Inputs

Technology	Total Capital Costs $/kW	Fixed O&M ($/kW-yr)	Variable O&M ($/MWh)	Capacity Factor	Nominal Heat Rate
Biogas	$2,623	107.5	0.01	85%	11,566
Biomass	$3,836	50.18	2.96	85%	15,509
Geothermal	$3,575	154.92	-	90%	-
Hydro - Small	$2,530	13.14	3.3	50%	-
Solar - Thermal	$2,840	49.63	-	40%	-
Wind	$1,983	28.51	-	37%	-
Coal ST	$2,671	25.91	4.32	85%	8,844
Coal IGCC	$3,087	36.36	2.75	85%	8,309
Coal IGCC with CCS	$5,127	42.82	4.18	85%	9,713
Gas CCCT	$878	11.04	2.4	90%	6,917
Gas CT	$794	11.4	3.36	5%	10,807
Hydro - Large	$2,530	13.14	3.3	50%	-
Nuclear	$4,999	63.88	0.47	85%	10,400
<5MW CHP	$1,952	11.04	2.4	40.5%	9,700
>5MW CHP	$1,259	11.04	2.4	85%	9,220

Allowance Banking

The EMT's methodology enables allowances to be banked when allowance prices are low and for banked allowances to be used when allowance prices are high. In its Phase 2 analysis, the EMT applied ENERGY 2020 in a mode that simulated a year-to-year clearing of the market for GHG allowances. In this mode, ENERGY 2020 applied the relevant annual emission cap and simulated emitters choosing among reduction options, offsets, and banking in response to a price for allowances. The model iterated until it found the market-clearing price for that year that met the emissions cap. This year-to-year mode required that the EMT specify a decision rule for emitters on when to bank allowances and when to withdraw them from the bank.

In its Phase 3 analysis, the EMT relied on a second approach, with stronger grounding in economic principles expected to guide banking by emitters. This approach assumes allowance prices in different years are linked by the discount rate of the allowance holders. In other words, holders of allowances recognize the time value of money so that when they bank an allowance in one time period (incurring the opportunity cost of not using it), they expect that it will have greater value in a future time period. Economic principles suggest that when banking is allowed under a cap-and-trade system, the allowance price will grow over time at a rate equal to the time value of money and investment risk.[24]

This approach was incorporated into the modeling by using ENERGY 2020 to evaluate vectors of allowance prices covering the period 2012-2020 (growing annually at a specified annual discount rate of 8%), rather than iterating a single year at a time and then moving on to the next year. Appropriate constraints were designed to reflect the limit on the use of offsets and the prohibition on borrowing of allowances.

The bank flow in any year is defined as follows:

Bank flow = Allowance budget – Capped sector emissions + Offsets used

The number of banked allowances in a given year is the sum of the annual bank flows from 2012 up to and including that year.

When a cap-and-trade system allows banking, the flexibility given to emitters means that a model can examine the ***cumulative*** cap over the relevant time period (along with allowed offsets), and iterate toward the price ***vector*** (i.e., price trajectory over the 2012-2020 period) that would result in meeting the cumulative cap. This approach assumes that emitters are likely to bank and use allowances in an economically rational manner and that the allowance price will rise over time to reflect the time value of money and investment risk.

[24] See, e.g., R. Newell et al, Managing Permit Markets to Stabilize Prices, Resources for the Future, June 2003, p.5 (http://www.rff.org/documents/RFF-DP-03-34.pdf), and P. Joskow, A.D. Ellerman et al, Emissions Trading Under the U.S. Acid Rain Program: Evaluation of Compliance Costs and Allowance Market Performance, Center for Energy and Environmental Policy Research, MIT (undated), p. 24, fn.38 (http://faculty-gsb.stanford.edu/wilson/archive/E542/classfiles/Joskow_napap.pdf).

Offsets

The modeling effort used an offset supply curve to calculate, for each year, the number of offsets available at the allowance price, as shown in Figure 4. The offset supply curve is based on a 2005 report by U.S. EPA.[25] Then the offset limit in the WCI program design is applied for each compliance period. According to Section 9.2 of the *Design Recommendations for the WCI Regional Cap-and-Trade Program*, the offset limit equals "49 percent of the total emissions reductions from 2012-2020."[26] The number of offsets actually used is the lesser of the offsets available from the offset supply curve and the offset limit.

Figure 4: Offset Supply Curves

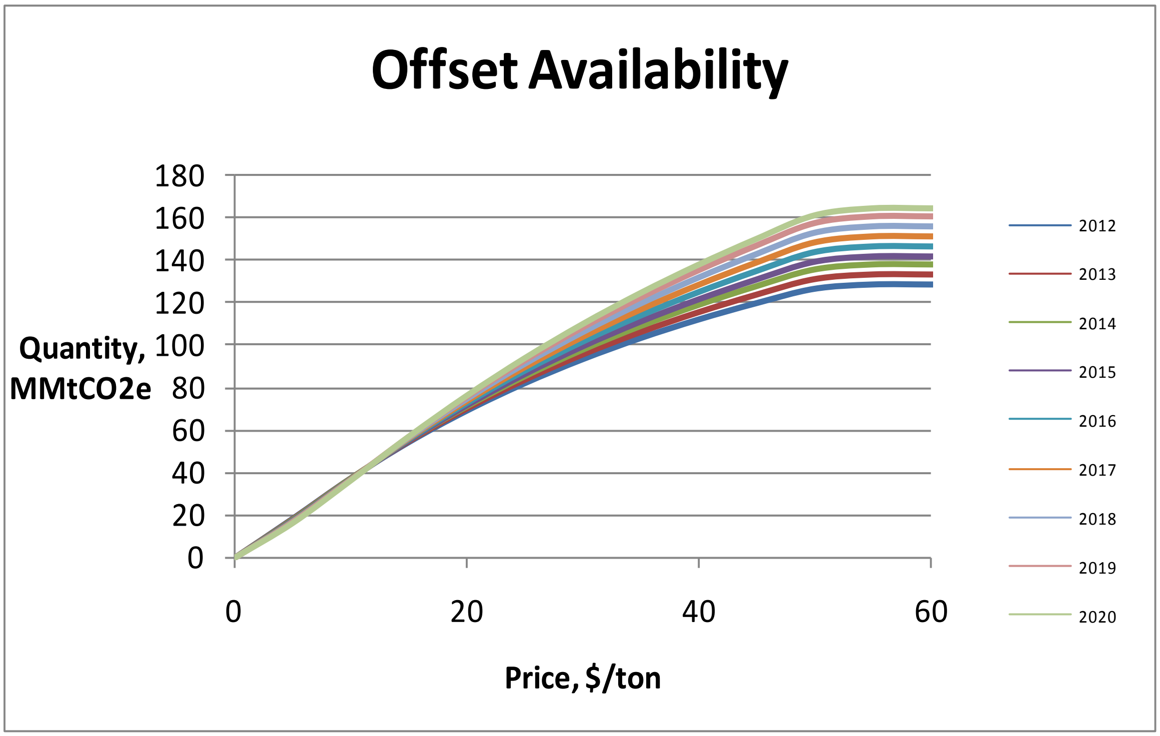

Table 7 shows the calculation of the offset limit for the main policy case. The "reduction calculation line" is equal to the 2012 narrow scope emissions of the complementary policies run, which is 464 Mt for the main policy case and discount rate sensitivity cases. For 2015 and beyond, the reduction calculation line also includes the other covered sector emissions for 2015, which is 464 + 597 = 1,061 Mt for the main policy case and discount rate sensitivity cases. The "total emission reductions" are the difference between the reduction calculation line and the allowance budget. The offset limit is 49 percent of the reductions.

[25] U.S. EPA, Greenhouse Gas Mitigation Potential in U.S. Forestry and Agriculture, 2005, http://www.epa.gov/sequestration/pdf/greenhousegas2005.pdf

[26] The emissions reductions in this case are relative to the 2012 emissions, not the reference case projections for 2012-2020.

Table 7: Calculation of Offset Limit, Main Policy Case and Discount Rate Sensitivity Cases

Year	Complementary policies run emissions, narrow scope (Mt)	Complementary policies run emissions, other covered sectors (Mt)	Reduction calculation line (Mt)	Allowance budget (Mt)	Reductions (Mt)	Offset limit (Mt)
2012	464		464	464	-	-
2013			464	456	8	4
2014			464	449	16	8
2015		597	464+597= 1,061	1,038	23	11
2016			1,061	1,017	44	22
2017			1,061	996	66	32
2018			1,061	975	87	42
2019			1,061	953	108	53
2020			1,061	932	129	63
Total						**235**

Complementary Policies

The following assumptions were made in the complementary policy run used in the main policy case and in three of the five sensitivity cases. The assumptions are somewhat different for the two sensitivity cases examining half effectiveness of complementary policies and high fuel price and electricity generation costs. These differences are explained in the Cases Analyzed section of this appendix.

Ontario Coal Phase-Out: Ontario will be phasing-out coal-fired electricity generation between 2010 and 2014.[27]

Clean Car Standards: This is equivalent to California's Pavley II. (Pavley I is included in the reference run.) This policy starts in 2017. By 2020, per-mile GHG emissions from new passenger vehicles decrease by 17 percent relative to new vehicle emissions in 2016.[28] ENERGY 2020 estimates the fuel savings and

[27] See news.ontario.ca/mei/en/2009/09/ontarios-coal-phase-out-plan.html.
[28] This is based on emission reductions contemplated in "California Air Resources Board, Climate Change Scoping Plan: a Framework for change, December 2008 Discussion Draft." Also see "California Air Resources Board, Comparison of Greenhouse Gas Reductions for the United States and Canada under U.S. CAFÉ Standards and California Air Resources Board Greenhouse Gas Regulations – An Enhanced Technical Assessment, 25 February 25, 2008."

changes to device investments and increases in operation and maintenance costs. Change in vehicle costs are based on estimates from the California Air Resources Board.[29]

Energy Efficiency: The combined effect of energy efficiency programs recently put in place and being pursued are assumed to reduce the rate of growth in electricity and natural gas demand by 0.5% each year starting in 2012.[30] ENERGY 2020 estimates the fuel savings and changes to device and process investments and operation and maintenance costs. The modeling also includes program administration cost, which is $0.6 billion per year by 2020.[31]

VMT Reduction: The combined effect of transportation and fuel programs recently put in place and being pursued is assumed to be equivalent to reducing travel demand so that vehicle miles traveled (VMT) are lower by 2 percent from the reference case by 2020, beginning in 2008. ENERGY 2020 estimates the fuel savings and decrease in device investment and operation and maintenance costs due to less wear and tear on the vehicles. ENERGY 2020 does not estimate the planning and development costs and savings associated with reducing travel demand. A brief literature review of travel demand programs and policies indicated a broad range of potential planning and development costs and savings, including potentially significant infrastructure savings. This analysis excludes these potential planning and development costs and savings, and focuses solely on the impacts on vehicle use and fuel use.

Other Cap-and-Trade Modeling Assumptions

This section describes assumptions regarding the cap, reductions, allowance prices, and compliance. These topics are relevant only to the cap-and-trade runs and not to the reference or complementary policies runs.

Allocation of Allowances: The model does not distinguish between freely allocated allowances and auctioned allowances. Rather, it determines the change in energy use and the costs associated with that change. These abatement costs are the same regardless of whether allowances are freely allocated or auctioned. The allocation method, instead, determines who benefits from the market value of the allowances.

Allowance Budgets: Recommendations to the WCI Partners on setting allowance budgets are under development by the WCI Cap Setting and Allowance Distribution (CSAD) Committee. However, for purposes of completing this economic modeling, the EMT had to make reasonable assumptions about the allowance budget and based these assumptions on the WCI Design Recommendations.

In the modeling, the cap for 2020 is assumed to be 15% below the 2006 model-estimated emissions, since this is the first year for which modeling results are available. Ideally, model-estimated emissions for 2005 would be available as the basis for the 2020 budget, but this is not expected to have a significant effect since U.S. and Canadian emissions, as reported by the federal governments, actually

[29] California Environmental Protection Agency, Air Resources Board, Regulations to Control Greenhouse Gas Emissions from Motor Vehicles, Final Statement of Reasons, August 4, 2005.
[30] For example, electricity sales for 2017 in the reference run are 1.2 percent higher than sales for 2016. In the complementary policies run, electricity sales for 2017 are 1.2% - 0.5% = 0.7% higher than sales in 2016.
[31] The EMT assumed administration costs of $6/MWh of electricity saved and $1/MMBtu of natural gas saved.

declined slightly between 2005 and 2006. Furthermore, all reductions necessary to meet the WCI economy-wide goal are assumed to come from sectors covered by the cap, which provides a slightly conservative estimate of the cost to the covered sectors. Thus:

2020 allowance budget = 0.85 x 2006 emissions[32] – 2020 emissions from uncovered sources

For modeling purposes, the 2012 allowance budget was set as the 2012 emissions from the narrow scope estimated in the complementary policies run. Emissions associated with imported power are included in the 2012 allowance budget. The trajectory for the first compliance period is based on the rate of reduction that would be required if the broad scope were in place in 2012. For modeling purposes, the 2015 allowance budget was set in two parts. The first part was the continued trajectory of the narrow scope emissions that started in 2012. The second part was the best estimate of the emissions covered for the first time in 2015. Emissions from these newly covered sources were estimated from the complementary policies run. The total allowance budget in 2015 is the sum of these two parts. The trajectory from 2015 to 2020 is a straight line, as defined in the *WCI Design Recommendations*.

Discount Rate: A real discount rate of 5% was used in annualizing costs and calculating net present values of cost streams. As noted above, the time value of money is also used to model allowance banking and use over time. The modeling used a rate of 8% to model banking, reflecting both the discount rate and investment risk specific to holding allowances. Sensitivity cases with values of 4% and 12% were also analyzed.

Compliance: As noted above, the goal of compliance is that the emissions in the capped sectors, summed over 2012-2020, equals the annual allowance budgets plus offsets, summed over 2012-2020. (Over-compliance in the first two compliance periods is acceptable. The banked allowances can be used in the final compliance period.) The emissions are a decreasing function of allowance price and offsets are an increasing function of the allowance price, up to the offset limit.

First Jurisdictional Deliverer: All cases incorporate a proxy to represent the first jurisdictional deliverer approach described in the *WCI Design Recommendations*. Consequently, emissions from electricity imported into the WCI Partner Jurisdictions from outside the WCI Partner jurisdictions are included in the analysis.

Cases Analyzed

This report presents six cases – that is, six families of model runs. Each family of runs consists of a reference run, a complementary policies run (that is, the complementary policies applied to the reference run), and cap-and-trade run (that is, an allowance price imposed on the complementary policies run). The cases are:

- Main policy case

[32] 2006 emissions include emissions associated with power imported from non-WCI jurisdictions.

- Sensitivity cases, which differ from the main policy case in the following ways:
    - Half-effectiveness of complementary policies (shares reference run with main policy case).
    - Alternative economic forecast, high economic growth, low energy prices (requires its own reference and complementary policies runs).
    - High fuel price and high electricity generation cost (requires its own reference and complementary policies runs).
    - Allowance price growth rate of 4% per year for cap-and-trade (shares reference run and complementary policies run with main policy case).
    - Allowance price growth rate of 12% per year for cap-and-trade (shares reference run and complementary policies run with main policy case).

The allowance price applies to the narrow scope sectors in 2012-2014 and to the broad scope sectors in 2015-2020. ENERGY 2020 determines the energy use changes and GHG emissions. The number of banked allowances is calculated from the emissions, the allowance budget, and number of offsets used.

Main Policy Case

This case simulates the effects of the WCI cap-and-trade program under the EMT's primary set of assumptions regarding future socio-economic conditions, complementary policies, and offset availability and costs. The following sensitivity cases allow the EMT to gauge the sensitivity of the main policy case results to changes in some of these key assumptions.

Sensitivity Case: Half-Effectiveness of Complementary Policies

The purpose of this sensitivity case is to examine what happens if the energy efficiency and VMT programs achieve only half of their assumed emission reductions. Specifically, this case assumes that:

- The energy efficiency programs reduce the rate of growth in electricity and natural gas demand by only 0.25 percent per year, starting in 2012.
- Vehicle miles traveled decrease by only 1 percent from the reference case by 2020.
- The clean car standards are unchanged.
- The Ontario coal phase-out is unchanged.

Sensitivity Case: Alternative Economic Forecast

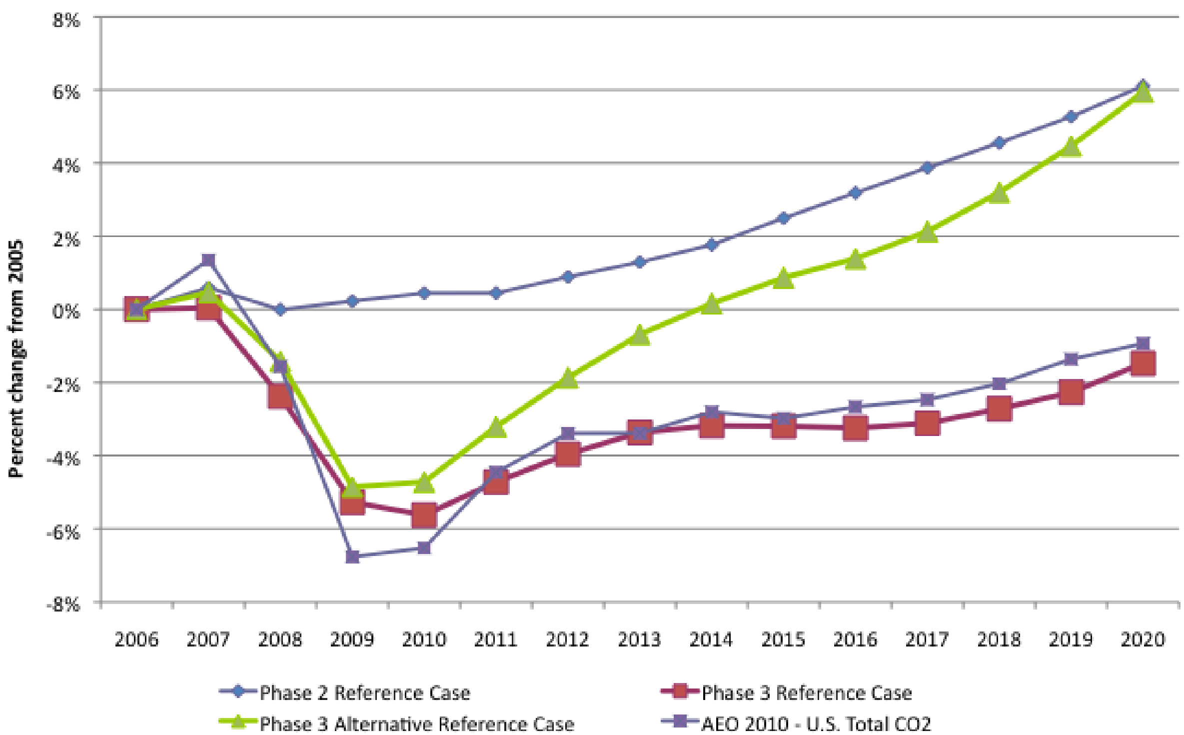
The purpose of this sensitivity case is to examine the implications of a different economic forecast than that assumed in the main policy case. The alternative economic forecast assumes a growth rate of 2.8 percent per year, about 0.5 percent per year higher than in the forecast used for the main policy case.

For energy prices, the alternative forecast uses the average of the AEO 2009 reference-price and low-price forecasts. This case also assumes that the EISA biofuels mandate will not be fully met by 2020. Instead, the case assumes the level of biofuels reflected in the AEO 2009. Each of these changes has the effect of increasing emissions in the reference case, and together, increase the challenge of meeting the WCI regional goal. Since the higher growth of the economy would also increase opportunities to become more energy efficient, an alternative complementary policies run was conducted for this sensitivity case in which the energy efficiency programs achieve a 1 percent per year decrease in the electricity and natural gas demand growth, starting in 2012. Table 8 and Figure 5 summarize the differences between the reference and alternative reference runs.

Table 8: Reference Run and Alternative Reference Run Assumptions

Assumption	Reference run	Alternative Reference run
Economic growth	Accounts for economic recession based on January 2009 Congressional Budget Office forecast	Faster economic growth to assess implications of a stronger than expected recovery
Fuel price forecast	AEO 2009 mid case	Average of AEO 2009 mid and low cases. Lower fuel prices results in more fuel consumption
Energy efficiency program impacts (used in complementary policy run)	Reduced demand for electricity and natural gas by 0.5% per year	Reduced demand for electricity and natural gas by 1.0% per year

Figure 5: Reference Run and Alternative Reference Run Emission Compared to the Latest National Forecast



Sensitivity Case: High Fuel Prices and Electricity Generation Costs

The purpose of this sensitivity case is to examine the implications of energy prices being higher than assumed in the main policy case. There has been considerable stakeholder comment that the energy price forecast in the main policy case may be too low. Additionally, some stakeholders have commented that the power generation cost assumptions may be too low, indicating that recent increases in commodity prices have had an impact on these costs. This sensitivity case includes both increased energy prices and increased power generation costs as a set of conditions that could occur together in the future. In this case, energy prices are assumed to start at 2008 prices and increase in real terms by 50% by 2020, and capital and O&M costs for power generation are assumed to be 30% higher than in the main policy case. This case required its own reference and complementary policies runs.

Sensitivity Case: 4% Annual Growth In Allowance Prices

The purpose of this sensitivity case is to examine the implications of a slow-rising allowance price trajectory. This case uses a growth rate in the allowance price of 4 percent per year instead of 8 percent per year in the cases discussed above.

Sensitivity Case: 12% Annual Growth In Allowance Prices

The purpose of this sensitivity case is to examine the implications of a faster-rising allowance price trajectory. This case uses a growth rate in the allowance price of 12 percent per year instead of 8 percent per year in the cases discussed above.

Results and Discussion

Emission Results for the Main Policy Case

Figure 6 shows the emission results of ENERGY 2020 for the main policy case. Offsets, complementary policies, and additional emission reductions caused by the cap are each important to achieving the WCI regional goal. Together, these emission reductions meet an allowance budget that decreases linearly to 15 percent below 2005 levels by 2020. Emission reductions in 2020 are predicted to be 13.4 percent below 2005 emissions due to over-compliance in earlier years and the use of banked allowances in 2019 and 2020.

Figure 6: Greenhouse Gas Emission Reductions Under the WCI Program, 2006-2020

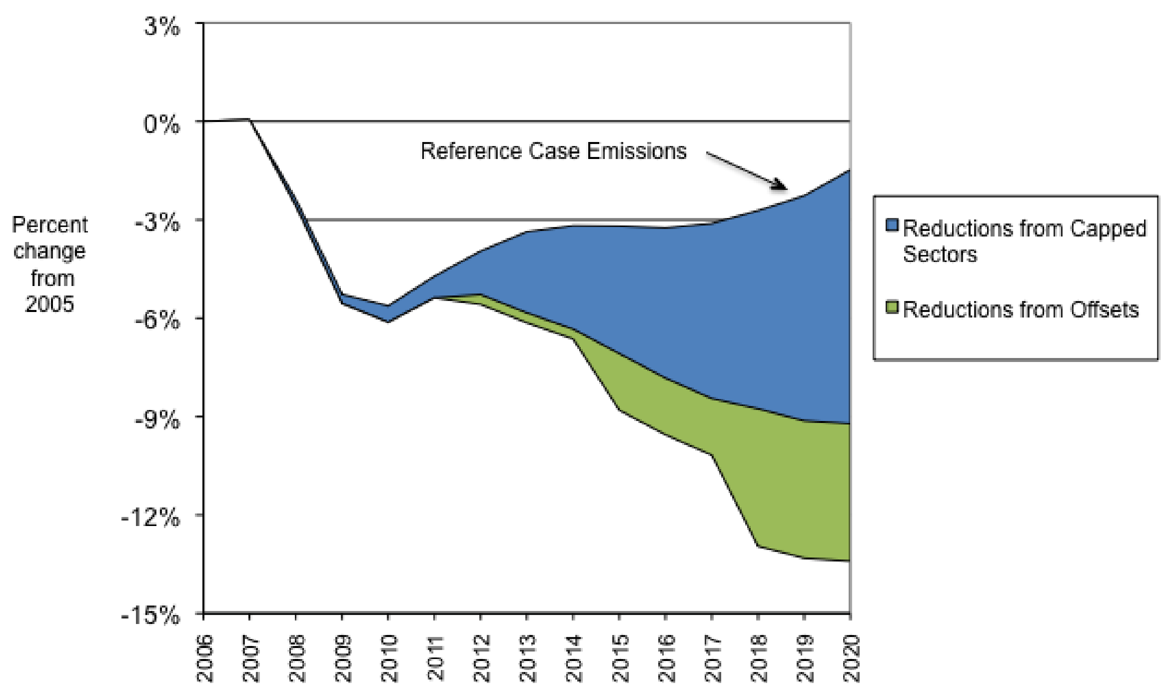


Figure 7 shows the relative amount that each type of reduction contributes to the total emissions reduced by the program over the period 2012-2020. Total emissions from capped sectors for this period in the reference run is 7,999 million metric tons (Mt) of carbon dioxide equivalents. The allowance budget described in Other Cap-and-Trade Modeling Assumptions would reduce emissions by 719 Mt over the 2012-2020 period. The contribution of each sector to this reduction is shown in Figure 8.

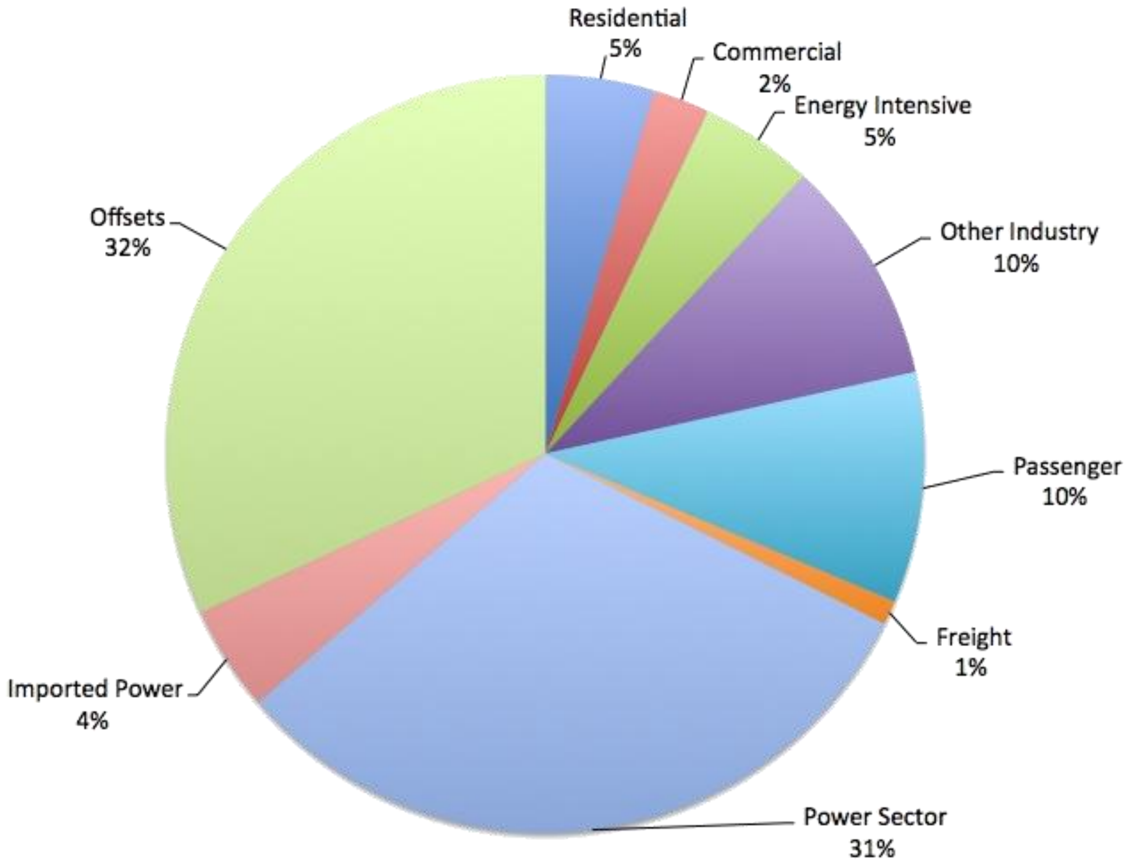
Figure 7: Source of Emission Reductions Under the Cap, Main Policy Case Relative to the Reference Case, 2012-2020



Economic Results for the Main Policy Case and Sensitivity Cases

Table 9 summarizes the results for the six cap-and-trade cases. The main policy case achieves the WCI regional goal at an allowance price of $33 in 2020. The net cost over the period analyzed (abatement cost plus offset cost) is -$102 billion, which represents a net cost savings. The sensitivity cases indicate that reducing the effectiveness of complementary polices by half, or assuming a rapid economic recovery and low energy prices, raise allowance prices to over $50, but still produce a net cost savings.[33] The sensitivity cases also suggest allowance prices would be much lower than the main policy case if energy prices and electricity production costs in the reference case are higher than expected.

Table 10 provides detailed cost estimates for the main policy case by sector and cost type, summed over the years 2012-2020. Negative costs (i.e., savings) are shown in parentheses. The cost savings result from the complementary policies. The largest single savings are attributable to the passenger transportation sector. In particular, the reduction in VMT reduces expenditures on fuel and on other vehicle costs. Figure 8 shows the fuel cost savings, other costs, and total costs for all sectors for the main policy case. The total savings of $102 billion, however, is modest relative to the size of the WCI

[33] Modeling runs were not performed for allowance prices over $50. This price, however, achieved 94% of the emission reductions required by the cap for both sensitivity cases.

economy (less than 0.2 percent of the combined economies of the 11 WCI Partner jurisdictions). The total market value of all allowances distributed in the main policy case is $188 billion.

Table 9: Summary of Economic Results for Main Policy and Sensitivity Cases (savings in parentheses)

Case Description	Abatement by covered sectors, 2012-2020 (Mt CO2e)	Reduction from offsets, 2012-2020 (Mt CO2e)	Abatement cost,* 2012-2020 (2007 $B)	Offset cost, 2012-2020 (2007 $B)	Allowance price in 2020 that achieves compliance (2007 $)	Allowance value 2012-2020 (2007 $B)
Main policy case	484	235	(105)	3	33	188
Sensitivity Cases						
Half the VMT reduction and energy efficiency improvements	483	243	< (38)	3	> 50	> 285
Faster economic growth & lower primary energy prices**	816	291	< (202)	4	> 50	> 287
Higher energy prices and power plant construction costs	420	208	(106)	2	13	72
4% annual allowance price escalation	484	235	(105)	3	28	179
12% annual allowance price escalation	484	235	(106)	3	39	200

* Abatement cost includes approximately $3B for energy efficiency program administration.
** This case assumes greater economic growth will create more opportunities to improve energy efficiency and therefore reduce the annual growth rates by 1% per year instead of 0.5% per year.

Table 10: Economic Results for the Main Policy Case by Sector and Cost Type, 2007 Million US$ Summed Over 2012-2020 (savings in parentheses)

Sector	Fuel	Device	Process	O&M	Total

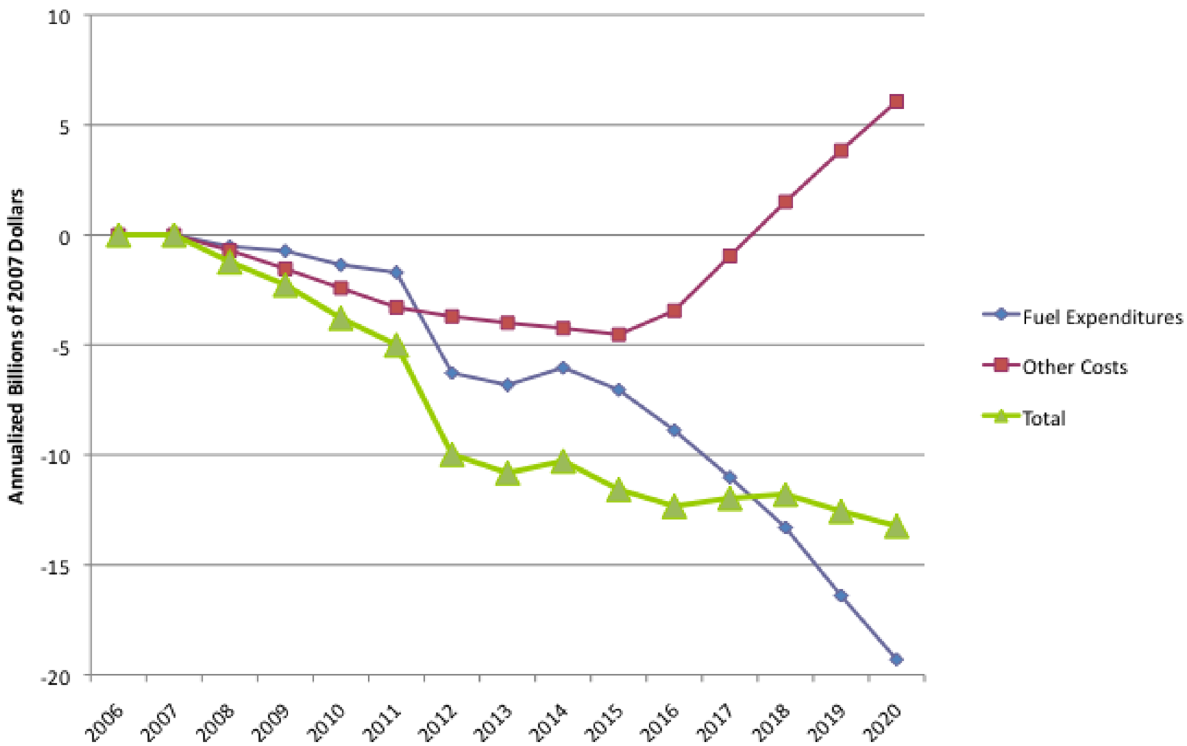
Waste & Wastewater	0	0	0	0	0
Total**	(95,070)	(20,580)	670	7,230	(107,750)

* Energy Intensive Industry is a subtotal of the seven energy-intensive sectors listed beneath it.
** Does not include offset costs or complementary policies administrative costs, which are estimated and reported separately.

Figure 8: Economic Results for the Main Policy Case by Year, 2007 Billion US$



The half-effectiveness of complementary policies case achieves compliance for an allowance price trajectory that has a higher price than $50 in 2020. (The modeling effort did not include any runs higher than $50.)

The alternative economic forecast case also achieves compliance for an allowance price above $50 in 2020. The potential for savings, however, is higher in this case than any other (at least $198 billion). This is because the faster economic growth was assumed to create more opportunities to improve energy efficiency. Hence, complementary policies were assumed to reduce the growth rate of electricity and natural gas demand by 1 percent in each year. Nonetheless, the faster economic growth and lower fuel prices leads to greater emissions in the reference run and a greater need for emission reductions in the cap-and-trade run, requiring an allowance price greater than $50 to achieve the WCI regional goal.

The high energy price and electricity generation cost sensitivity case achieves compliance at a lower allowance price of $13. The allowance price is so low that the WCI offset limit is not reached because offset prices begin to exceed the allowance price. The cost savings potential is larger than the main policy case because the low allowance price preserves a greater portion of the savings from the complementary policies.

The final two sensitivity cases imply that the precise slope of the price trajectory (discount rate) assumed by the EMT has little effect on the economic results.

To put the results of Table 9 into some context, the 2020 allowance prices estimated in other studies are provided below. These studies differed from the EMT's analysis and from each other in their geographic scope, emission targets, time period, use of offsets, and type of computational model used.

- WCI 2008, $24 in 2020.[34]
- California Scoping Plan, $10 in 2020.[35]
- Updated Analysis of California's Scoping Plan, $21.[36]
- U.S. EPA analysis of Waxman-Markey (ACES), $20 in 2020.[37]
- Congressional Budget Office analysis of Waxman-Markey, $28 in 2020.[38]
- Energy Information Agency analysis of Waxman-Markey, $32 in 2020.[39]
- U.S. EPA analysis of Kerry-Lieberman (APA), $24 in 2020.[40]

Finally, Figure 9 shows the abatement curve for the main policy case. The curve suggests that reducing emissions from three percent below the reference case to four percent below the reference case, and from five to eight percent below the reference case, can be achieved through modest escalation of allowance prices. In the four to five percent range, however, the cost of abatement alternatives rises faster as greater emission reductions are sought within this range.

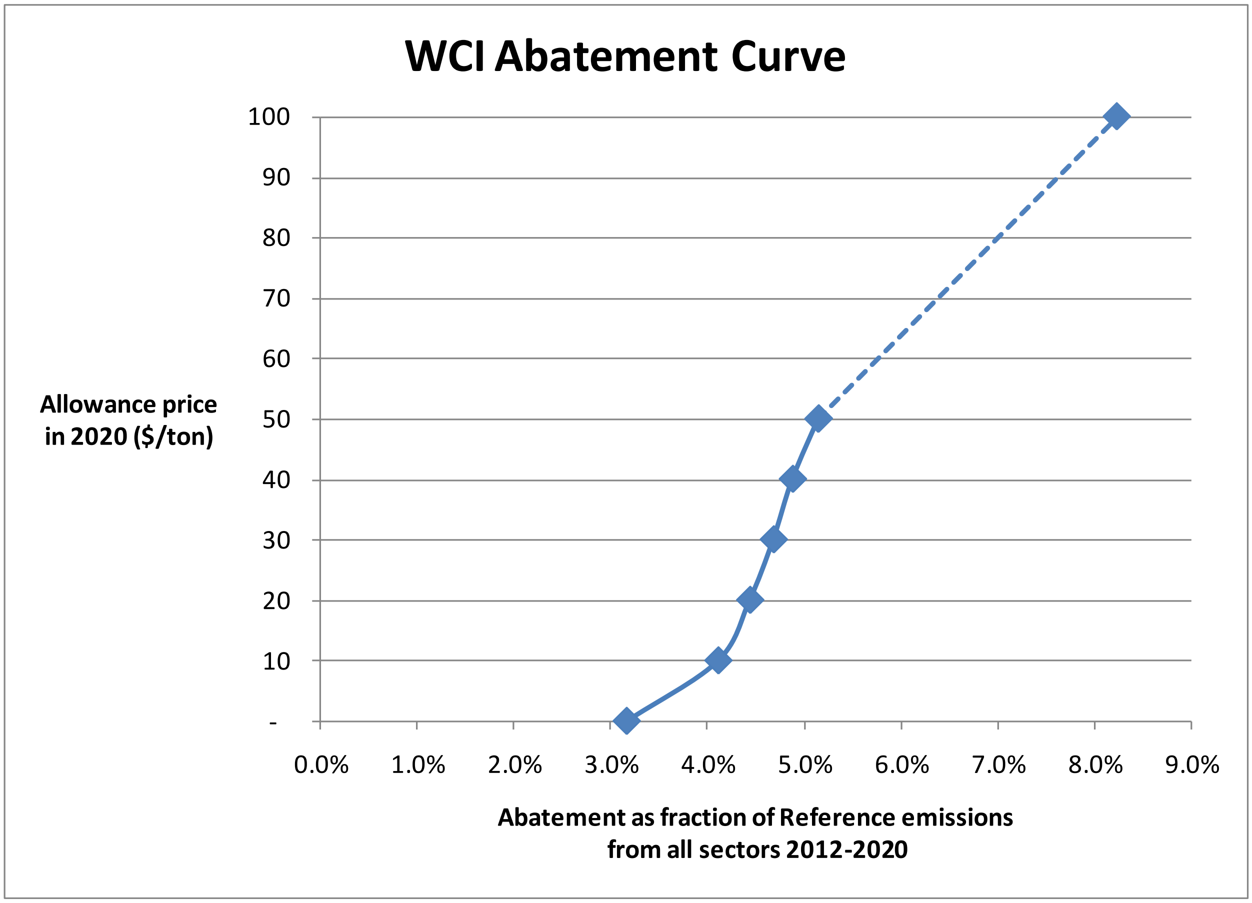
Figure 9: Abatement for the Main Policy Case



Conclusions

- The WCI emissions reduction goal for 2020 can be achieved with a net cost savings of approximately $100 billion in the WCI region over the 2012-2020 period. While significant, these savings are modest (less than 0.2 percent) relative to the economic size of the 11 WCI Partner jurisdictions.

- The allowance price predicted in 2020 to achieve the regional emission reduction goal in the main policy case is $33, which is higher than the $24 predicted in the Phase 2 modeling but comparable to the results of other independent studies.

- Complementary policies have the potential to significantly reduce emissions and contain costs. In this analysis, they produce negative costs, or cost savings. Complementary policies provide net savings because the reduction in fuel and other expenditures is greater in magnitude than the cost of the emission reductions. If complementary policies have roughly half the effect that the EMT assumed in the main policy case, then an allowance price of over $50 would be required to achieve the WCI regional goal.

- Higher-than-expected fuel prices would make it less costly to achieve the emissions goal, with lower allowance prices. Conversely, lower-than-expected fuel prices, coupled with a faster economic recovery, would raise the allowance price.

- Banking and offsets are important design elements to achieve emissions reductions and limit costs. Although no sensitivity cases were conducted to test the EMT's assumptions about offsets, it appears that none of the cases analyzed here would achieve the regional goal at an allowance price below $50 if not for the availability and price of offsets assumed in this report.

Detailed Results for the Reference Run and Main Policy Case

Description of Outputs

Table 11 through Table 16 present detailed results for the reference run used in the main policy case. Table 17 through Table 23 present detailed results for a representative cap-and-trade case. All dollars shown are 2007 dollars. These tables present annual results for selected years: 2006 (the first year modeled); 2012 (when the narrow scope begins); 2015 (when the broad scope begins); 2020 (the final year modeled). Another column shows the average annual growth rate for 2006-2020. For the cap-and-trade cases, the final column compares the 2020 value with the 2020 value from the reference run. Below are brief explanations of the model results shown in the tables.

Greenhouse Gas (GHG) Emissions: GHG emissions are presented in millions of metric tons of carbon dioxide equivalent (Mt CO_2e). Emissions for the 11 WCI Partner jurisdictions included in the analysis are presented by major sector.

Total Energy Use: Total energy use is reported by fuel type in units of TBtu/year.

Electric Sector: Outputs for the electric sector include:

- Generation capacity in units of megawatts (MW) by generation type. Note that estimated generation capacity grows due to capacity additions, but capacity retirement is not calculated. Consequently, generation capacity does not decline in the model outputs.

- Generation output in units of gigawatt-hours per year (GWh/year) by generation type.

- Electricity sales in units of GWh/year, including electricity imports into the eight WCI Partner jurisdictions in the WECC.

- Generating utility costs in $M/year, as requested by stakeholders.

Transportation Sector: Outputs for the transportation sector include VMT for passenger and freight vehicles, as well as miles traveled per passenger. The fleet average efficiency and marginal efficiency (for new vehicles) are reported for four vehicle types in miles per gallon. The average vehicle market share and marginal vehicle market share are reported for passenger vehicles.

Fuel Prices: Fuel prices are reported for electricity, natural gas, coal, fuel oil, LPG, gasoline, and diesel in 2007 dollars per million Btu (2007 $/mmBtu). The prices include the forecasted energy prices (presented in Table 5 above for the reference run) as well as the costs of delivering the fuels to market, but not fuel taxes. The prices reported for the cap-and-trade policy cases also include the allowance price, reflecting the appropriate carbon content of the fuel.

Fuel Expenditures: Fuel expenditures are reported by major sector. Estimates of fuel expenditures do not include the value of the allowances, although they do take into account the increase in the price of electricity driven by the allowance price.

Costs and Savings: For the cap-and-trade cases, costs and savings are reported in millions of 2007 dollars per year ($M/Yr). Total costs are reported by major sector, which are the sum of changes in fuel expenditures, changes in investment costs, and changes in O&M. Investment costs increase as more efficient devices, buildings, and processes are purchased in response to the limit on GHG emissions. The investment costs are annualized using a 5% real discount rate over the life of the equipment. The annualized costs are counted each year over the life of the equipment. The estimates of total costs include both the change in fuel expenditures and the change in investment costs. As shown in the tables below, the fuel expenditure savings typically offset most or all of the increased investment costs. The sub-total does not include the adjustments for program administration of the complementary policies or the allowance value of the power sector. These adjustments are added to get the total cost.

Reference Run

A reference run represents a business-as-usual scenario through 2020 (i.e., absent any cap or other GHG abatement policies not already adopted). Table 11 through Table 16 show model outputs for the reference run used in the main policy case. This reference run was also used in the half effectiveness complementary policies sensitivity case and the discount rate sensitivity cases. Alternative reference runs were used to assess the other two sensitivity cases, but these outputs are not included in this report.

Guidance for Developing
WCI Partner Jurisdiction Allowance Budgets

July 8, 2010

Table of Contents

1 Purpose And Summary ... 1

2 Methodology For Calculating Preliminary Allowance Budgets ... 6

2.1 Preliminary Allowance Budget For 2012 ... 6
2.2 Preliminary Allowance Budgets For 2013 And 2014 ... 7
2.3 Preliminary Allowance Budget For 2015 ... 7
2.4 Preliminary Allowance Budgets For 2016 Through 2020 ... 8
2.5 Preliminary Allowance Budgets For Partner Jurisdictions Whose Caps Begin After 2012 ... 8

3 Process For Reviewing, Finalizing, And Adjusting Allowance Budgets ... 8

3.1 Establishing Annual Budgets In 2010 ... 8
3.2 Finalizing Annual Budgets Prior To The Start Of The First Compliance Period ... 10
3.3 Adjusting Annual Budgets Prior To The Start Of The Second And Third Compliance Periods ... 11
3.4 Establishing And Adjusting Budgets When A Jurisdiction Enters The Cap-And-Trade Program After 2012 ... 12

4 Early Reduction Allowances ... 12

1 Purpose And Summary

The purpose of this document is to provide recommended guidance to WCI Partner jurisdictions for calculating, establishing, and reviewing annual allowance budgets, the sum of which is the regional cap.[1] The *Design Recommendations for the WCI regional Cap-and-Trade Program* describe conceptually how these budgets should be developed.[2] Recognizing, however, that further technical analysis and regional coordination would be needed to develop the budgets properly and consistently across jurisdictions, the *WCI 2009-10 Work Plan* established the Cap Setting and Allowance Distribution (CSAD) Committee and charged the Committee with, among other things, proposing a methodology and/or guidelines for establishing and periodically reviewing Partner allowance budgets.[3]

The WCI Partner jurisdictions believe there is great value in developing a budget-setting process in advance of when budgets must be established and with public knowledge of how the process will be conducted. For this reason, the CSAD Committee released the draft of this guidance well ahead of when allowance budgets must be established, recognizing that changes to the method or process described within this guidance may be necessary in response to federal developments, state and provincial implementation schedules, availability and results of mandatory reporting data, and updated emission inventories and forecasts. While these factors will continue to influence the budget setting process, this document incorporates improvements identified to date by WCI stakeholders and Partner jurisdictions.[4]

The objectives of this guidance are to:

- Describe the responsibilities of WCI Partner jurisdictions and the CSAD Committee in the process of developing allowance budgets;
- Promote consistency across WCI Partner jurisdictions in establishing allowance budgets;
- Provide transparency to the budget-setting process such that WCI Partner jurisdictions and the public can be confident that budgets were determined fairly and using the best available data; and
- Establish a timeframe for the budget-setting process to work in concert with the development of jurisdictional regulations and the emergence of an allowance market.

---

[1] In British Columbia, the emissions from transportation and residential, commercial, and industrial fuels will be covered by a carbon tax in lieu of a cap. The carbon tax will be integrated with the cap-and-trade program such that reductions incented by the tax, in combination with the cap on industrial sources, will achieve BC's GHG reduction goal.

[2] See http://www.westernclimateinitiative.org/the-wci-cap-and-trade-program/design-recommendations

[3] See http://www.westernclimateinitiative.org/component/remository/general/workplans/, CSAD Tasks 2.2 – 2.4.

[4] Written comments received from WCI stakeholders are posted at http://www.westernclimateinitiative.org/public-comments/document/15.

The guidance is organized into three major sections, as follows:

Section 1

- Summarizes the recommended major activities and outcomes in developing and reviewing allowance budgets (Table 1);
- Recommends how preliminary budgets should be calculated (Figure 1); and
- Provides a hypothetical illustration of a WCI Partner jurisdiction allowance budget (Figure 2).

Section 2

- Provides recommendations on how each WCI Partner jurisdiction should calculate preliminary allowance budgets.

Section 3

- Recommends a process to establish allowance budgets from the preliminary budgets;
- Recommends a process to finalize Partner budgets prior to the start each compliance period; and
- Recommends a process to establish budgets for WCI Partner jurisdictions joining the cap-and-trade program after 2012.

Section 4

- Summarizes the role of early reduction allowances (ERAs).

The guidance recognizes the major factors in, and recommends the procedures for, developing a Partner jurisdiction's allowance budgets. Although developed in a regionally-coordinated manner through these guidelines, each Partner jurisdiction will determine and adopt its own budget. Each Partner jurisdiction will also determine how allowances within its budget will be distributed (e.g., to address competitiveness and leakage issues). The guidance does not seek to resolve all outstanding technical issues or policy decisions likely to have an effect on a jurisdiction's allowance budgets, such as the best estimate of capped-source emissions in 2012 and 2015, but identifies where such data and policy decisions would be incorporated into the calculation of allowance budgets and provides a roadmap for coordinating regional efforts over the course of the program.

Finally, there is a role for those Partner jurisdictions implementing the WCI's cap-and-trade program in the process of developing, reviewing, and finalizing allowance budgets. Since the process would extend over several years, it is possible this role may be filled by the CSAD Committee or another regional committee/forum (e.g., a regional administrative organization).

Table 1. Summary Of Budget Development And Review Process.

	Activity	Completion	Outcome*	Purpose
Section 2	• CSAD contractor develops regionally-consistent forecasts of emissions from covered sources.	Q2 2010	Emission forecasts	Support determination of a best estimate of emissions from covered sources the year they enter program.
	• Each Partner calculates a preliminary allowance budget. (See Figure 1.)	Q3 2010	Preliminary budgets	Form a consistent starting point to develop budgets that meet Partner and regional goals.
Section 3.1	• Partners provide preliminary budgets and supporting information to CSAD. • CSAD conducts a first review of budgets/info for consistency. • Partners may revise budgets after considering CSAD review.	Q3 2010	Established budgets	Basis for developing jurisdictional rules. Provide early market signal. Support any pre-2012 auctioning.
	• CSAD conducts a second review of budgets/info for consistency. • Partner jurisdictions establish budgets, including any potential adjustments to address electricity generated in one Partner jurisdiction but consumed in another.	Q4 2010		
Section 3.2	• Partners inform CSAD of any changes to established budgets. • CSAD reviews any changes and emissions reporting data. • Partner jurisdictions finalize budgets.	Q4 2011	Final budgets	Account for final program rules and available emissions and market data. Increase allowance market certainty, enable full distribution of allowances.
Section 3.3	• Similar to 2011 process, but include assessment of the program's progress.	Q3 2014	Revised final budgets	Account for new data, program changes, and program performance.
	• Same as 2014 process, but incorrect or inaccurate emissions/forecast data not expected to be a factor by this time.	Q3 2017	Revised final budgets	Account for new data, program changes, and program performance.

* Each outcome will be made publicly available.

Figure 1. Calculation Of A Preliminary Allowance Budget.

2012 = 2012 emissions forecast for Phase I sources (including emissions associated with electricity imports), determined with CSAD contract support to account for:

- Population growth*
- Economic growth*
- Mandatory emissions reductions (including those from complementary policies)*

\+ 2012 forecast adjustments, determined by Partner jurisdictions to account for:

- Voluntary emissions reductions (including those from complementary policies)*
- Shut-down sources
- New sources

"Best Estimate"

2013 = 2012 preliminary budget - ROD_1

2014 = 2013 preliminary budget - ROD_1

2015 = 2014 preliminary budget - ROD_1 + 2015 best estimate of Phase II sources

2016 = 2015 preliminary budget - ROD_2

2017 = 2016 preliminary budget - ROD_2

2018 = 2017 preliminary budget - ROD_2

2019 = 2018 preliminary budget - ROD_2

2020 = 2019 preliminary budget - ROD_2

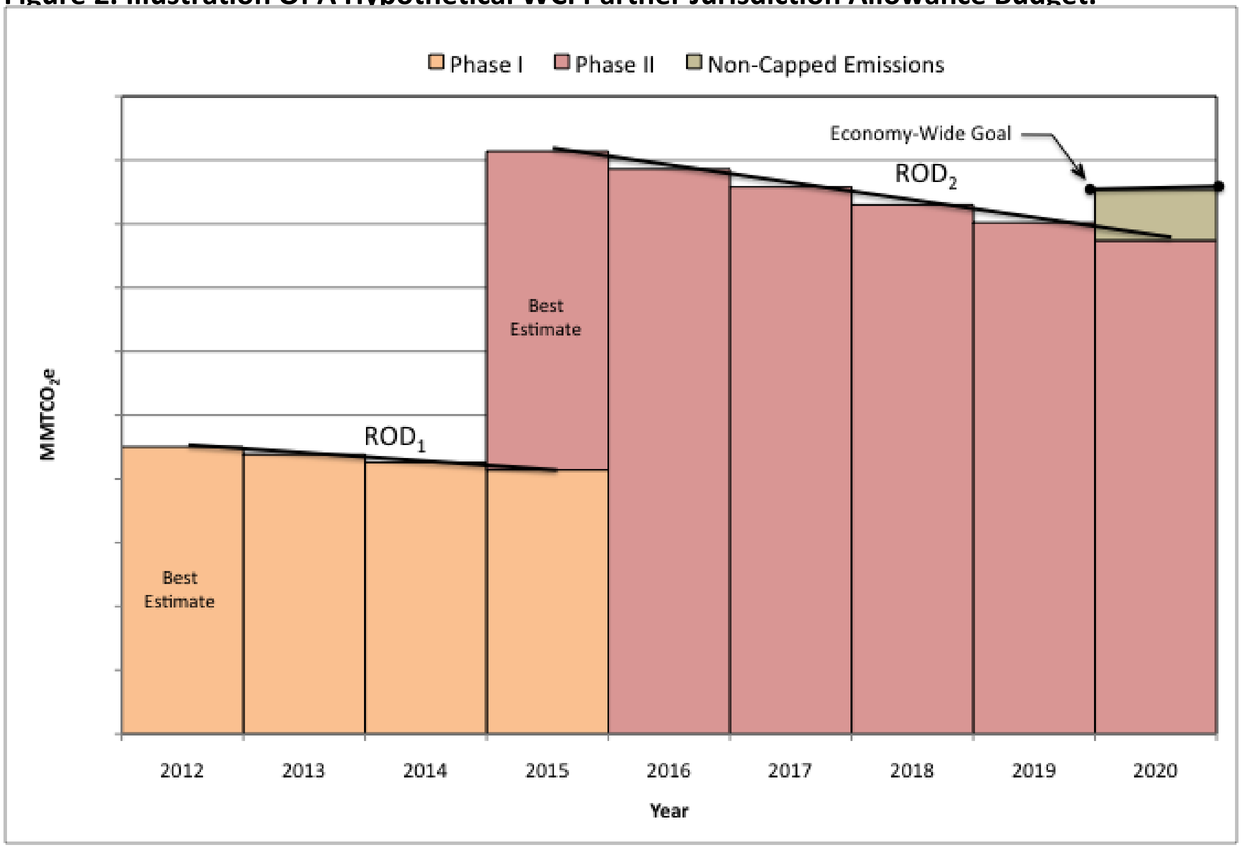
---

* These factors are also used to determine the 2015 best estimate for Phase II sources.

ROD_1 = Rate of decline (i.e., annual decline in allowance budgets) during Phase I, expressed in $MMTCO_2e$

ROD_2 = Rate of decline during Phase II

Figure 2. Illustration Of A Hypothetical WCI Partner Jurisdiction Allowance Budget.



2 Methodology For Calculating Preliminary Allowance Budgets

2.1 Preliminary Allowance Budget For 2012

1. The Partner jurisdiction will calculate its 2012 preliminary allowance budget as the best estimate of expected emissions for sources covered in the cap-and-trade program in the Partner's jurisdiction in 2012, accounting for population growth, economic growth (including new and shut-down sources), and voluntary and mandatory emission reductions through 2012. The best estimate will be an outcome of each Partner's application of the forecast methods recommended by the CSAD Committee and is shown as the first colored bar in Figure 2. Alternatively, the Partner jurisdiction may base its best estimate on its own emissions forecast if it considers the method to be more accurate for its jurisdiction than the regional method recommended by the Committee. For the purpose of determining the best estimate of 2012 emissions:

    a. New sources are sources which are not included in the Partner jurisdiction's emission inventory but are expected to be emitting covered GHGs prior to January 1, 2013. The Partner jurisdiction will estimate, using any methods developed by the Committee to promote consistency, covered emissions from new sources and include these emissions in its 2012 best estimate.

    b. Shut-down sources are sources which are included in the Partner jurisdiction's emission inventory but are expected to be permanently shut down prior to January 1, 2012. The Partner jurisdiction will remove covered emissions from shut-down sources from its 2012 best estimate.

    c. Voluntary emission reductions are the emissions avoided in 2012 as a result of consumers or sources taking action which reduces GHG emissions and is not required by law or regulation. Such action must occur prior to 2012 and should have permanent emission benefits (e.g., persisting until 2020).[5]

[5] Actions first taken in 2012 can not necessarily be considered voluntary when Phase I producers are subject to the cap and when consumers face the cap's consequent price increase.

2.2 Preliminary Allowance Budgets For 2013 And 2014

1. The Partner jurisdiction will determine an annual decline of allowance budgets for the first phase of the cap-and-trade program (ROD_1). ROD_1 shall be expressed in units of million metric tons of CO_2 equivalents ($MMTCO_2e$) and shall be greater than zero.[6]

2. The Partner jurisdiction will calculate its 2013 preliminary allowance budget as the 2012 preliminary allowance budget minus ROD_1.

3. The Partner jurisdiction will calculate its 2014 preliminary allowance budget as the 2013 preliminary allowance budget minus ROD_1.

2.3 Preliminary Allowance Budget For 2015

1. The Partner jurisdiction will calculate its 2015 preliminary allowance budget as the sum of the 2014 preliminary allowance budget minus ROD_1 plus the 2015 best estimate of expected emissions for sources first covered in the cap-and-trade program in the Partner's jurisdiction in 2015, accounting for population growth, economic growth, and voluntary and mandatory emission reductions. The best estimate of 2015 emissions will be an outcome of each Partner's application of the forecast methods recommended by the CSAD Committee and is shown as the top half of the 2015 bar in Figure 2. Alternatively, the Partner jurisdiction may base its best estimate on its own emissions forecast if it considers the method to be more accurate for its jurisdiction than the regional method recommended by the Committee. For the purpose of determining the best estimate of 2015 emissions:

    a. Voluntary emission reductions are the emissions avoided in 2015 as a result of consumers or sources taking action which reduces GHG emissions and is not required by law or regulation. Such action must occur prior to 2015 and should have permanent emission benefits (e.g., persisting until 2020).

---

[6] The purpose of ROD_1 (and ROD_2 below) is to ensure, as stated in the Design Recommendations, that the trajectory for each WCI Partner jurisdiction's annual allowance budget for covered sectors will be a straight line from the year of initial coverage to 2020. This is the only way to ensure for planning purposes that the 2020 reduction goal is met. However, the actual annual trajectories of jurisdictional emissions and allowance distribution to specific sources will not necessarily follow a straight line reduction trajectory. For instance, any given Partner jurisdiction's emission reduction trajectory will depend on regional trading and the use of offsets by covered sources. In addition, the three-year compliance periods will allow covered sources to reduce emissions at various rates across the three-year period.

2.4 Preliminary Allowance Budgets For 2016 Through 2020

1. The Partner jurisdiction will determine a rate of decline for the second phase of the cap-and-trade program (ROD_2). ROD_2 shall be expressed in units of $MMTCO_2e$ per year and shall be greater than zero. ROD_2, in conjunction with any reductions in non-covered emissions in the Partner's jurisdiction, shall be sufficient to achieve the Partner jurisdiction's 2020 economy-wide goal.[7]

2. The Partner jurisdiction will calculate its preliminary allowance budgets for 2016 through 2020 by subtracting its ROD_2 from the prior year's preliminary allowance budget, starting with 2016 and continuing to 2020.

2.5 Preliminary Allowance Budgets For Partner Jurisdictions Whose Caps Begin After 2012

1. A Partner jurisdiction whose cap begins after 2012 will determine its preliminary annual allowance budget as described in Sections 2.1 through 2.4, with the exception that the Partner's first-year budget may be based on the best estimate of emissions for that year.

3 Process For Reviewing, Finalizing, And Adjusting Allowance Budgets

3.1 Establishing Annual Budgets In 2010

The purpose of this process is to compile and harmonize preliminary allowance budgets as much as possible for Partner consideration, revision, and agreement. The outcome of this process will be "established budgets" for each Partner jurisdiction in the summer of 2010.

The established budgets are intended to (a) provide a basis for each Partner jurisdiction in developing its regulations implementing the regional cap-and-trade program and (b) provide an early indication of the supply of allowances in the regional marketplace. Although established budgets may be revised when finalized prior to the start of the first compliance period (see Section 3.2), the limited and specific conditions under which such revisions would occur should preserve the value of established budgets as an early market signal.

---

[7] ROD_2 may equal ROD_1 if the sectors capped in the second phase of the program are the same as those in the first.

1. Using a template common to all the WCI Partner jurisdictions, each Partner jurisdiction will provide the following to the CSAD Committee to facilitate the collection and comparison of the Partner data:

    a. A preliminary allowance budget for each year in the period 2012-2020.
    b. A ROD for each phase of the cap-and-trade program.
    c. An explanation of how the RODs were determined.
    d. A presumptive ROD_1, determined as the product of:
        i. the ROD resulting from a straight-line reduction from the 2012 best estimate of Phase I and Phase II source emissions to the 2020 preliminary budget, and
        ii. the ratio of the best estimate of Phase I source emissions to the best estimate of Phase I and II source emissions in 2012.
    e. A best estimate of economy-wide emissions in 2005 and 2020, assuming emissions from capped sources in 2020 are equivalent to the preliminary budget for 2020.[8]

2. The Committee will compile and review the jurisdictional preliminary budgets with respect to maintaining a regionally-consistent approach to achieving the regional goal.

3. After considering the Committee's review, the Partner jurisdiction may revise its preliminary budget.

4. The Committee will re-compile and review the jurisdictional preliminary budgets, including any budgets revised per the paragraph above, with respect to maintaining a regionally-consistent approach to achieving the regional goal.

5. After considering the Committee's review, the Partner jurisdiction will collaborate with other Partner jurisdictions in developing established budgets for each Partner jurisdiction. The established budget should include any potential adjustments which are part of an equitable solution to electricity generated in one Partner jurisdiction but consumed in another.

---

[8] In British Columbia, the emissions from transportation and residential, commercial, and industrial fuels will be covered by a carbon tax in lieu of a cap. The carbon tax will be integrated with the cap-and-trade program, and the information provided by BC to the Committee will demonstrate how reductions incented by the tax, in combination with the cap on industrial sources, will achieve its GHG reduction goal.

3.2 Finalizing Annual Budgets Prior To The Start Of The First Compliance Period

The purpose of this process is to adjust, where necessary and according to Section 7.4 of the *Design Recommendations*, the established budgets from 2010. The outcome of this process will be a "final budget" for each Partner jurisdiction in autumn of 2011.[9]

1. The Partner jurisdiction will notify the Committee of any potential changes to its established budgets resulting from each of the following conditions:

    a. Changes in jurisdictions participating in the cap-and-trade program.
    b. Changes in scope or threshold of the WCI regional program design.
    c. Differences in scope or threshold between the jurisdiction's final regulations and the sources included in the 2012 and 2015 best estimates.
    d. Incorrect or inaccurate data that were used to determine the established budgets of 2010, including emissions from new and permanently shut down sources not identified in Section 2.1.
    e. Emissions data that were not available in 2010, such as those that may become available as a result of new mandatory reporting rules.

2. The Committee will review proposed changes to the established budgets and any supporting information with respect to maintaining a regionally-consistent approach to achieving the regional goal. The review will include collecting mandatory reporting data for capped sources in each Partner jurisdiction and comparing them to the 2012 and 2015 best estimates of Phase I and Phase II sources and Partner allowance budgets. Mandatory reporting data collected in 2011 will be especially important for finalizing budgets where the emissions data available in 2010 are uncertain or unavailable.

3. After considering the Committee's review, the Partner jurisdiction will collaborate with other Partner jurisdictions in finalizing budgets for each Partner jurisdiction.

4. The Partner representative will seek the appropriate approvals from its respective jurisdictional authorities for the final budgets discussed with other Partners.

[9] This date would allow time for submittal and review of the mandatory reporting data collected according to the WCI essential requirements, which would first be submitted to the Partner jurisdictions by April 1, 2011 and verified by September 1, 2011.

3.3 Adjusting Annual Budgets Prior To The Start Of The Second And Third Compliance Periods

The purpose of this process is to adjust, where necessary and according to Section 7.4 of the *Design Recommendations*, the budgets for Phase II of the program finalized in 2011. The potential outcome of this process would be a "revised final budget" for one or more Partner jurisdiction in the summers of 2014 and 2017.[10]

1. The Partner jurisdiction will notify the Committee of any potential adjustments to its final budgets resulting from each of the following conditions:

    a. Changes in jurisdictions participating in the cap-and-trade program.
    b. Changes in scope or threshold of the WCI regional program design.
    c. Changes in scope or threshold of the jurisdiction's regulations.
    d. Incorrect or inaccurate data that were used to determine the final budgets of 2011. This condition shall not apply after the start of the second compliance period.[11]

2. The Committee will review any proposed adjustments to the final budgets and any supporting information with respect to maintaining a regionally-consistent approach to achieving the regional goal. The review will include mandatory reporting data for capped sources in each Partner jurisdiction and potentially other data to assess the progress of the regional cap-and-trade program.

3. After considering the Committee's review, the Partner jurisdiction will collaborate with other Partner jurisdictions in any budget adjustments.

4. The Partner representative will seek the appropriate approvals from its respective jurisdictional authorities for any budget adjustments discussed with other Partners.

[10] Adjustments for Phase II budgets can occur earlier in the year than adjustments for Phase I budgets because verified data may be submitted earlier than September 1 for reporting years 2012 and later and because more mandatory data will be available in 2014 and 2017 than in 2011.

[11] By the time of the second compliance period, any inaccuracies should be revealed by the mandatory reporting data .

3.4 Establishing And Adjusting Budgets When A Jurisdiction Enters The Cap-And-Trade Program After 2012

1. Date Of Entry. A Partner jurisdiction may enter the regional cap-and-trade program on January 1 of any year agreed to by the entering jurisdiction and jurisdictions currently in the program.

2. The annual allowance budgets for the entering jurisdiction will be determined as follows:

   a. The entering jurisdiction will calculate preliminary annual allowance budgets as described in Section 2.5.
   b. The entering jurisdiction will provide to the other Partner jurisdictions at least six months prior to the date of entry all the applicable information described in Section 3.1.1.
   c. The Partner jurisdictions will collaborate on the development of the entering jurisdiction's budgets, particularly with respect to maintaining a regionally-consistent approach to achieving the regional goal.
   d. The Partner representative for the entering jurisdiction will seek the appropriate approvals from its respective jurisdictional authorities to adopt the budgets discussed with other Partners.

3. Any jurisdiction currently in the cap-and-trade program that has included allowances within its budgets to account for emissions associated with electricity imports from the entering jurisdiction will collaborate, bilaterally, with the entering jurisdiction on an equitable solution to avoid double allocating allowances for the same set of emissions.

4 Early Reduction Allowances

Guidelines for issuing ERAs are provided in separate documentation. The issuance of ERAs does not affect the budgets developed above in Sections 2 and 3.

Western Climate Initiative

Status Update on Market Oversight Recommendations

July 22, 2010

The WCI Partner jurisdictions are committed to strong market oversight and vigilant market monitoring. This update gives a short description of the status of WCI's market oversight recommendations.

The Partner jurisdictions have engaged stakeholders and employed expert advisers to identify and evaluate market oversight options. The WCI Partner jurisdictions released three reports: a white paper (November 2009); draft recommendations (April 2010); and a report on holdings limits (May 2010). The Partner jurisdictions solicited stakeholder feedback on each of these products, and have incorporated the feedback into their decisions. Through this process, the Partner jurisdictions identified twelve policy decisions to make for market oversight. The final recommendation or status of each of these twelve is described below:

1. Whether to treat compliance instrument derivatives as commodity derivatives for market oversight purposes.

A paramount question for WCI jurisdictions is whether oversight of markets for compliance instruments should primarily be similar to or different from oversight of other markets; and if the former, which markets to use as models. In other environmental cap-and-trade programs, compliance instruments have been considered to be sufficiently like commodities to be regulated by the same agencies and under the same framework. Following this model would allow the jurisdictions to rapidly bring existing rules and resources to bear on carbon markets. The Partners recommend that compliance instrument derivatives should be treated as commodity derivatives for market oversight purposes.

The Partners are committed to working with commodity derivatives regulators to ensure that oversight of compliance instrument markets is robust and fully integrated.

2. Whether to require the reporting of over-the-counter derivative contracts to a central repository.

Over-the-counter (OTC) derivatives markets may be comparable in size to or larger than exchange-traded derivatives markets, but in contrast to exchange contracts, OTC contracts are not typically reported to regulators. The Partners have considered a requirement that OTC derivatives based on compliance instruments be reported to a central repository. Financial reform proposals have included various approaches to reporting and regulation of OTC derivative contracts. Whether the Partner jurisdictions would recommend reporting of compliance instrument OTC derivatives, which would diverge from current framework for commodities derivatives regulation, may depend on the form and enactment of changes to that framework. Consequently, the Partners will closely watch this critical issue in monitoring the progress of financial reform.

3. Whether allowances and offsets should be treated differently.

Allowances and offset certificates are created by different processes and, because of the limit on the number of offset certificates that may be used for compliance, will be used differently. Consequently, the Partners have considered whether these differences imply a difference in the oversight of the respective markets. For the eleven other policy decisions identified in this section, the Partners recommend that allowances and offset certificates be treated identically.

4. Establishing a jurisdictional relationship with market participants.

The Partners recommend that a market participant's having an account in the tracking system or ownership interest in a compliance instrument can be used to establish a jurisdictional relationship with that participant. This does not exclude the use of other ways, e.g., physical presence, to establish a jurisdictional relationship.

5. Whether to limit market participation to compliance entities.

Limiting who could participate in cash and derivatives markets would be practically challenging and would reduce liquidity. It is doubtful that such limits would have any benefits in reducing the risks of manipulation. The Partners recommend that market participation should not be limited to compliance entities.

6. Whether to require registration of intermediaries as market professionals.

In securities and derivatives markets, many types of intermediaries (for example, brokers and advisers) are required to register as market professionals, which identifies them to regulators, screens them for fitness, and credentials them for other market participants, to ensure proficiency, financial viability, and good business conduct. The Partners recommend that intermediaries be required to register as market professionals. The jurisdictions may develop a list of acceptable registrations.

7. Whether to limit the number of compliance instruments an entity could hold.

An entity that controls a large fraction of the available instruments could have the ability to move prices through its behavior. Even the perception that an entity could exercise "market power" in this way can have an impact on other market participants. One approach to limiting this type of market power is to limit the number of compliance instruments one entity can hold. The Partners commissioned and released a consultant's report on such "holdings limits" and will continue to work to develop an appropriate recommendation that incorporates stakeholder input.

8. Whether to allow over-the-counter cash market transactions.

Cash transactions (for immediate delivery of allowances or offset certificates) could take place on a variety of venues with different characteristics. Some venues offer more transparency to the public and to market participants than others. Limiting the type of venues on which cash transactions could occur would enhance transparency, but if participants would prefer other venues, could lead to fewer trades overall. The Partner jurisdictions will not restrict market participants from using over-the-counter trades. Recognizing that venues like exchanges may enhance public price discovery and increase transparency, the Partner jurisdictions will work to encourage and facilitate exchange trading through the design of the WCI program and tracking system.

9. Whether to require the reporting of beneficial ownership.

"Beneficial ownership" is when one person holds property or another interest on behalf or for the benefit of another person. Knowing the actual identity of the beneficial owner is important for determining concentration of ownership in order to effectively monitor the markets. The Partners recommend that account holders be required to report the beneficial owners of each account, and their respective proportionate interest in the account. Account holders and those with ownership interest in compliance instruments must also disclose corporate affiliations (e.g., holding companies) when affiliates have compliance accounts or ownership interest in compliance instruments.

10. What information should be required for compliance instrument transfer.

To monitor the market and allow the tracking system to be a record of ownership, the Partners recommend requiring the following information be submitted to the tracking system to transfer compliance instruments between accounts:

- The identifying number of the account of origin;
- The name of the account representative authorizing the transfer from the account of origin;
- The identifying number of the receiving account;
- The name of the account representative authorizing the transfer to the receiving account;
- The serial numbers of the compliance instruments transferred;
- The price for each type of instrument.

The Partners will consider accommodating exchanges or others that may wish to "net" transactions and provide net reports, and not requiring price information for transfers between corporate affiliates.

11. What account and transfer information should be disclosed to the public.

The Partners are committed to transparency, but recognize that public release of some information can promote rather than inhibit market manipulation. The Partners recommend the following information be made public:

- The names, affiliations, and location (state or province in the US or Canada, or country if outside) of account holders, account authorized representatives, and beneficial owners of compliance instruments;
- The number of compliance instruments in each compliance account, but not each general account;
- The volume and price of transactions, when necessary aggregated to prevent the identification of parties to transactions.

12. How to perform market monitoring.

The Partners are committed to vigilant monitoring of compliance instrument markets, including coordinated efforts across jurisdictions. A description of jurisdiction and agency collaboration on monitoring is being developed.

1 Executive Summary

This paper is the third paper issued by the WCI Offsets Committee as part of its efforts to offer design recommendations for the WCI offset system to the WCI Partner jurisdictions. This paper describes the final recommendations for the WCI offset definition and essential criteria. As such, it follows up on two previous papers—the first of which was an options paper for the definition and criteria and the second of which offered draft recommendations.

The first paper, entitled *Offset Definition (Task 1.1) and Eligibility Criteria (Task 1.2) White Paper*[1] ("the Criteria White Paper") was released in July 2009 and presented options for defining an offset and the criteria essential to generating an offset within the cap-and-trade program implemented by the WCI Partner jurisdictions. The release of the first paper was followed by a period of gathering stakeholder input through stakeholder conference calls and written comments from stakeholders.[2] The WCI Offsets Committee then prepared the second paper, the *Offset System Essential Elements Draft Recommendations Paper* (the "Criteria Draft Recommendations Paper"), based on the first options paper, stakeholder feedback, and input from WCI Partners. Following the release of that second paper in April 2010, stakeholders provided feedback via two conference calls and through written comments. This final recommendations paper presents final recommendations for the offset definition and essential criteria, based on draft recommendations, consideration of stakeholder feedback received, and further discussion with WCI Partners

A fair number of the final recommendations are unchanged from the draft recommendations or received only minor clarifying revisions. The most significant changes from the draft to final recommendations regard the additionality criterion. For ease of reference, all of the final recommendations in this paper are copied in Table 1.0 below.

Table 1.0 Final Recommendations

Section	Criteria	Final Recommendations
3.1	Offset Definition	An offset certificate is a type of compliance instrument that is awarded by the program authority in a participating partner jurisdiction under the Partner jurisdiction's cap-and-trade program to the sponsor of a GHG emissions offset project, subject to all applicable limitations contained in the program design summary and recommendations included in this paper. An offset certificate represents a reduction or removal of one metric ton of carbon dioxide equivalent (tCO_2e). The reduction or removal must meet the recommended essential criteria for reductions and removals to be real, additional, permanent, and verifiable. Reductions and removals must also be clearly owned, adhere to recommended protocols, and result from a project located in a qualifying geographic area.
3.2.1	Offset Ownership	An offset project proponent must have legal ownership of the greenhouse gas emission reduction or removal resulting from the offset project. The offset project proponent will be responsible for all statements and information provided to the WCI Partner Jurisdiction issuing the offset certificate during the creation of the offset certificate and verification of the reduction or removal. The WCI Partners should establish a registry of offset certificates issued and make the registry publicly available.
3.2.2	Use of Approved Protocols	A WCI Partner jurisdiction will issue offset certificates for compliance with its cap-and-trade program only from projects which employ protocols that have been recommended through the WCI protocol review process ("WCI offset protocols").
3.2.3	Geographic Limits	A WCI Partner jurisdiction may issue offset certificates for projects located within its own jurisdiction as well as jurisdictions outside the WCI Partner Jurisdictions within North America. A WCI Partner jurisdiction will accept offset certificates issued by other WCI Partner jurisdictions. As described in section 9.8 of WCI's design document, WCI Partner jurisdictions may also accept offset certificates from outside North America.
4.1	Real	An offset certificate represents a reduction or removal of one metric ton of CO_2e that results from a clearly identified action or decision. A WCI offset project's reduction or removal is quantified using accurate and conservative methodologies that appropriately account for all relevant greenhouse gas sources and sinks and leakage risks. WCI offset projects result in emissions reductions or removals that take place at sources controlled by the project proponent.

Section	Criteria	Final Recommendations
4.2.1	Quantification, Uncertainty, and Accuracy	**Quantification:** WCI Partner jurisdictions shall ensure that net emission reductions or removals are capable of being measured or modeled in a reliable and repeatable manner that includes all relevant sources and sinks. Quantification methodologies for GHG emissions or emission reductions shall: • Be appropriate to the GHG source or sink • Be current at the time of quantification • Consider local conditions, whenever applicable • Account for uncertainty – be calculated in a manner that yields accurate and reproducible results • When uncertainty is above the defined threshold, apply the principle of conservativeness to GHG During quantification procedures, project proponents shall convert each type of GHG to metric tons of CO2e. In addition, WCI offset protocols shall use uniform quantification methods whenever feasible. **Uncertainty and accuracy:** Quantification methodologies and measurement techniques shall set standards for acceptable statistical precision and be based on the best available science. They shall also reduce bias, except for promoting conservative estimates. When uncertainty remains high in quantifying the amount of a greenhouse gas emission reduction or removal, the principle of conservativeness shall be applied. **Principle of conservativeness:** Where uncertainties are above the defined threshold, offset quantification methods should use more conservative quantification parameters, assumptions, and measurement techniques that minimize the risk of overestimating emission reductions and removals credited for a given project. The principle should be employed when significant uncertainties arise to ensure a higher level of confidence that all calculated reductions are real.

Section	Criteria	Final Recommendations
4.2.2	Leakage	To address activity-shifting and market leakage, WCI Partner jurisdictions will require assessments of whether functional equivalence has been maintained within projects and require that WCI offset protocols include methods for leakage assessments. WCI offset protocols will evaluate functional equivalence for each project. WCI offset protocols will also require an assessment of potential leakage associated with each project type. In general, WCI Partner jurisdictions prefer the following methods to review leakage risk: • A quantitative assessment of leakage will be performed whenever possible. • When a quantitative assessment is not feasible, a qualitative risk assessment will determine whether the risk of systematic leakage is significant or not. • WCI offset protocols will include a threshold to identify significant leakage. If leakage is found to be above the threshold, the WCI offset protocol quantification methodology will include a factor to account for leakage.

Section	Criteria	Final Recommendations
5.1	Additional	Offset certificates will be awarded only for the portion of greenhouse gas emission reductions or removals that would not have happened under a baseline scenario. The WCI Partner jurisdictions intend for additionality to be established in a manner that will require offset projects to be evaluated against a baseline that reflects conservative assumptions that are consistent across all WCI Partner jurisdictions. These assumptions will be described in the procedures for setting a baseline in WCI offset protocols. Modeling or other methods of developing the baseline shall use assumptions, methodologies, and values which assure that GHG reductions or removals from a project are not over-estimated (consistent with the principle of conservativeness in 4.2.1). When possible, the baseline shall be set using a sector-specific or activity-specific performance standard which is set in WCI offset protocols based on a regional assessment of project performance or common practice. WCI Partners intend that all baselines will reflect the most stringent regulatory and legal requirements of any WCI Partner jurisdiction (those requirements leading to the most conservative calculation of emission reductions). When a baseline based on the most stringent regulatory requirement is not practical because of regional differences, the WCI Partners may recommend a protocol using an alternative method. When it is not possible to set a baseline using a performance standard, a project-specific baseline may be used. Then the baseline will be set to reflect all binding agreements, regulatory requirements and legal requirements applicable to the project and also to ensure that the project is beyond business as usual.

Section	Criteria	Final Recommendations
5.2.1	Eligibility Date	Offsets may be awarded only for projects that are initially commenced on or after January 1, 2007, the start of the year in which the original WCI Memorandum of Understanding (MOU) beginning the development of the cap-and-trade program by Partner Jurisdictions was signed. Offset certificates may be awarded for all GHG reductions or removals occurring on or after January 1, 2007. An offset project proponent must apply to register its project with a WCI Partner Jurisdiction within one year of project commencement. Projects that commenced prior to finalization of the applicable WCI offset protocol must apply within one year of that protocol's finalization.
5.2.2	Crediting Period	The crediting period for non-sequestration WCI offset projects will be 10 years. At the end of a crediting period a project proponent may renew a project subject to the current WCI offset protocol for that project type. Renewal of a project at the end of a crediting period will include a reevaluation of a project's additionality and reevaluation of how the reductions are quantified and verified. Thus, the baseline scenario will be reevaluated at each renewal. The crediting period for sequestration projects will be specified by the applicable WCI offset protocol. However, any individual crediting period may not exceed 25 years before a renewal, and the total crediting period including all renewals may not exceed 100 years for sequestration projects. The applicable WCI offset protocol will also lay out the requirements for project renewal. At a minimum, the project must reevaluate quantification and monitoring methods based on the current WCI offset protocol. If possible, projects will also need to reassess project additionality and baselines in order to renew the project.

Section	Criteria	Final Recommendations
6.1	Permanent	With respect to offset project activities, permanence means either that reductions or removals are not reversible or that, if reductions or removals are reversed, the provisions outlined in the remainder of this recommendation must be met. Sequestration projects must be designed so that the net atmospheric effect of their greenhouse gas removal is comparable to the atmospheric effect achieved by non-sequestration projects. The atmospheric effect will be based on the current international standard established by the UNFCCC, which is currently 100 years. This international standard may be updated from time to time, and the WCI Partner jurisdictions will adopt the new international standard if/when it is updated. If an emission reduction is reversed after offset certificates are issued, the project developer must either replace the certificates representing reversed reductions with other compliance units from within the system or return certificates that were issued to the project. The number of certificates required to be replaced or returned will, at a minimum, be the difference between the atmospheric benefit the sequestration project until it was reversed and the total sequestration for which certificates were issued. Applicable approaches to assuring permanence for a project type will be included in the appropriate WCI offset protocol. In conformance with the applicable WCI offset protocols, project proponents shall follow or establish effective (i) monitoring systems, (ii) risk mitigation approaches, and (iii) contingency plans which address how, in the event of a reversal that is the result of proponent intention or negligence, any affected offset certificates will be replaced. The contingency plan shall include specific mechanisms that are exercisable at the time a reversal is identified whether or not the proponent is solvent, exists in its original form, and/or has ownership of or responsibility for the project. WCI Partner jurisdictions will establish mechanisms to address reversals that are not the result of proponent intention or negligence and where proponents' contingency measures prove inadequate.

Section	Criteria	Final Recommendations
7.1	Verifiable	With respect to offset project activities, verifiable means that a GHG reduction or removal, or assertion thereof, is well documented and transparent such that it lends itself to an objective review by a qualified verifier. Verifiers for WCI offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner jurisdiction in which the project is registered.
7.2.1	Validation	With regards to WCI offsets, validation is a required review by an accredited independent third party or the WCI Partner jurisdiction to assess the likely result of reductions or sequestration from a proposed project that would use a WCI offset protocol.
7.2.2	Enforceable	Each Partner jurisdiction will, to the extent permissible by law, put in place sufficient compliance/enforcement mechanisms and detail for the jurisdiction to compel compliance with its requirements and with WCI offset protocols.
7.2.3	Material	Material misstatement means that errors, omissions or an aggregation of both in the reported GHG reductions or assertion exceeds a +5% threshold. For a WCI offset, the verifier must be able to state with reasonable assurance the total reported reductions or removals are free of material misstatement.
8.1	Transparency	Partner Jurisdictions' offset systems will provide transparency such that sufficient and appropriate protocol, project and certificate information is disclosed in a timely manner to allow offset system participants and the general public to make decisions with reasonable confidence.
8.2	Co-Benefits	WCI Partners recognize the environmental, social, economic and health benefits that may arise from an offset project and the offset system will focus on those benefits directly related to mitigating climate change. A WCI offset project is required only to result in a greenhouse gas emission reduction or removal.
8.3	Assessment of Environmental or Social Impacts	WCI offset projects must meet all applicable local environmental regulations and be in compliance with all applicable laws in the jurisdiction where the project is located. If environmental or socioeconomic assessments of the proposed project have been done, the project's registration application should reference this work and include a summary of the findings. WCI offset protocols for specific offset project types may require analysis of environmental and socioeconomic impacts beyond what the local jurisdiction would otherwise require and may require additional mitigation of potential negative impacts.

2 Purpose and Background

The purpose of the WCI Offset Committee is to make recommendations to the WCI Partner jurisdictions on the design and operation of the offset system as part of the WCI cap-and-trade program. In particular, this paper includes the Offsets Committee's final recommendations for criteria that reductions must meet in order to demonstrate that reductions from offset projects are sufficiently rigorous to meet compliance obligations within the regional cap-and-trade program. The WCI's September 2008 Design Recommendations document specified that the criteria ensure offsets result in a GHG reduction or removal that is real, additional, permanent, and verifiable.[3] The design of the offsets system must also ensure that the quantification of the GHG reduction or removal is accurate and not double-counted. According to the WCI's design principles, reductions from offsets must also be enforceable by the WCI Partner jurisdictions.

This final recommendations paper is the third and final stage in developing a clear definition of a WCI greenhouse gas (GHG) offset and the detailed eligibility criteria for GHG offset projects used for compliance purposes as identified in the WCI 2009/10 Workplan released in February 2009. On July 24, 2009 the WCI Offsets Committee released the *Offset Definition (Task 1.1) and Eligibility Criteria (Task 1.2) White Paper* ("the Criteria White Paper") describing options for defining a WCI GHG offset and the WCI essential offset criteria (real, additional, verifiable, and permanent), as well as other principles and technical considerations that are important for the offset system. On July 30, 2009 and August 27, 2009, the WCI Offset Committee held stakeholder webinars to discuss the released white paper. Stakeholders also submitted written comments via the WCI website by the August 21, 2009 deadline. On April 12, 2010 the WCI Offsets Committee released the *Draft Recommendations Offset Definition (Task 1.1) and Eligibility Criteria (Task 1.2) White Paper* ("the Criteria Draft Recommendations Paper") providing draft recommendations for defining a WCI offset and the essential offset criteria. On April 22, 2010 and May 5, 2010, the WCI Offset Committee held stakeholder conference calls to discuss the draft recommendations. Stakeholders also submitted written comments via the WCI website by the May 12, 2010 deadline.

The purpose of this final recommendation paper is to establish the final decision by the WCI Partner jurisdictions on the definition of a WCI offset and essential criteria. This paper provides the following for each criterion (or consideration):

- a final recommendation

[3] WCI Design Recommendations for the WCI Regional Cap-and-Trade Program: September 23, 2008; revised March 13, 2009. p. 10 Available at: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F21252.pdf.

- a summary of stakeholder comments received on the draft recommendation
- a discussion of the final criteria recommendation

These final recommendations provide the basis for further work by the WCI Offsets Committee. The *Process Draft Recommendations Paper* will present the requirements for the registration, validation, monitoring, quantification, reporting, verification, certification, and issuance of offsets. Task 3, the review and development of WCI offset protocols has used these recommendations as the basis for the offset protocol evaluation. It will also provide a basis for Task 2's review of offsets and allowances from outside the WCI jurisdictions as they will have to determine the extent to which the criteria and supporting criteria are appropriate to offsets from other systems. For example, this paper includes a recommendation for the appropriate length of crediting periods in the WCI. The recommendation in this paper does not imply that the offsets from another system that uses crediting periods of a different length would be ineligible to meet WCI compliance obligations.

Like in the *Criteria Draft Recommendations Paper*, this paper frequently employs the term "WCI offset" and "WCI offset project." This paper uses those terms to describe an offset certificate issued by a WCI Partner Jurisdiction and the projects which are the basis for offset certificates issued by WCI Partner Jurisdictions.

3 Definition of an Offset

This section offers the final recommendations for the WCI offset definition and three key considerations in how WCI offsets are created which are referenced in the offset definition.

3.1 Offset

As noted in the *Criteria Draft Recommendations Paper*, the biggest consideration for the WCI Offsets Committee was how broad or prescriptive the offset definition should be. The final recommendation text for the offset definition revises the draft recommendation, with the new text intended for clarity only.

3.1.1 Final recommendation

An offset certificate is a type of compliance instrument that is awarded by the program authority in a participating partner jurisdiction under the Partner jurisdiction's cap–and-trade program to the sponsor of a GHG emissions offset project, subject to all applicable limitations contained in the program design summary and recommendations included in this paper An offset certificate represents a reduction or removal of one metric ton of carbon dioxide equivalent (tCO_2e). The reduction or removal must meet the recommended essential criteria for reductions and removals to be real, additional, permanent, and verifiable. Reductions and removals must also be clearly owned, adhere to recommended protocols, and result from a project located in a qualifying geographic area.

3.1.2 Summary of stakeholder input

Stakeholders' comments generally focused on aspects of the offset certificate after issuance, including comments that the definition should specify that offsets certificates once issued are not revocable, that offset certificates are bankable and tradable, and that the definition should be more specific that an emission elsewhere is being offset and that offsets are not property rights. One comment emphasized that "avoided" emissions be included in the definition.

3.1.3 Discussion of final recommendation

The Offsets Committee intended that the definition should be broad and refer to the main criteria while leaving the detail to be described within each criterion. Offsets are described in the Detailed Program Design as compliance instruments, which are bankable and tradable. With regard to offsets not constituting a property right, each jurisdiction will need to specify how offsets fit within their respective legal structures and will take this comment into consideration as they write the program regulations. The Committee did not include "avoided" emissions in the definition, as the term often implies that no real reduction took place, which conflicts with the criterion "real" and is inconsistent with the ISO.

3.2 Other considerations

This section includes the final recommendations for three issues referenced in the offset definition.

3.2.1 Ownership issues

The *Criteria Draft Recommendations Paper* included a description on the importance of clearly established ownership to the well functioning of an offset system. The final recommendation text regarding ownership is <u>unchanged</u> from the draft recommendation.

3.2.1.1 Final recommendation

An offset project proponent must have legal ownership of the greenhouse gas emission reduction or removal resulting from the offset project. The offset project proponent will be responsible for all statements and information provided to the WCI Partner Jurisdiction issuing the offset certificate during the creation of the offset certificate and verification of the reduction or removal. The WCI Partners should establish a registry of offset certificates issued and make the registry publicly available.

3.2.1.2 Summary of stakeholder input

Several stakeholder comments raised the concern that the draft recommendation was restrictive in a manner that could constrain the financial arrangements that are part of an offset project. Otherwise, the comments were generally supportive of the draft recommendation, and one other comment noted that additional guidance would be needed beyond this definition for implementation.

3.2.1.3 Discussion of final recommendation

The intent is to establish that each project has a proponent who has a superior legal claim to the reductions and that the proponent will bear the responsibility for meeting the process requirements during the offset project's operation. Beyond that, this recommendation is not restrictive in trying to define or restrict who the project proponent may be. The recommendation also still includes a sentence affirming the importance of a registry in tracking the ownership of issued offset certificates.

3.2.2 Use of approved protocols

As noted in the *Criteria Draft Recommendations Paper*, the WCI Partners are beginning a process to recommend protocols that meet the essential criteria. Aside from two minor clarifying edits, the final recommendation text regarding use of approved protocols is <u>unchanged</u> from the draft recommendation.

3.2.2.1 Final recommendation

A WCI Partner jurisdiction will issue offset certificates for compliance with its cap-and-trade program only from projects which employ protocols that have been recommended through the WCI protocol review process ("WCI offset protocols").

3.2.2.2 Summary of stakeholder input

Several stakeholder comments recommended project types they would like the WCI Partner Jurisdictions to more actively pursue (e.g., coal mine methane). Some comments also requested clarification about how offsets that have been issued by other offset systems would be treated by the WCI Partner jurisdictions. Other comments suggested that more detail was needed to explain how the WCI offset protocol recommendation process would work.

3.2.2.3 Discussion of final recommendation

The WCI offset protocols are intended to be adopted through each jurisdiction's legal processes, resulting in a harmonized set of protocols across the WCI. Since the comments generally discussed which protocols should be approved for use in the WCI region or how offsets generated in other systems would be treated by WCI Partner jurisdictions, the Committee directs stakeholders to its ongoing Task 3 and upcoming Task 2 work for additional information in response to the stakeholder concerns outlined in response to this supporting criterion.

3.2.3 Geographic limits

The *Criteria Draft Recommendations Paper* acknowledged that WCI's previous Design Recommendations document had implications for offsets in regards to geographic limits which should be included in the Essential Elements recommendations. Aside from a minor clarifying edit, the final recommendation text regarding geographic limits is unchanged from the draft recommendation.

3.2.3.1 Final recommendation

A WCI Partner jurisdiction may issue offset certificates for projects located within its own jurisdiction as well as jurisdictions outside WCI Partner Jurisdictions within North America.
A WCI Partner jurisdiction will accept offset certificates issued by other WCI Partner jurisdictions. As described in section 9.8 of WCI's design document, WCI Partner jurisdictions may also accept offset certificates from outside North America.

3.2.3.2 Summary of stakeholder input

Several comments suggested that the geographic limit should be even more restrictive, in particular, limiting offsets to only projects located in WCI Partner jurisdictions. Other comments suggested the geographic limit recommendation was too restrictive, lacking a rationale for why cost-effective projects on one side of a border would be ineligible while similar or even less cost-effective projects on the other side of the border would be eligible.

3.2.3.3 Discussion of final recommendation

This final recommendation continues to affirm the relevant recommendation from the WCI's Design Recommendations document published September 23, 2008. The WCI Partner jurisdictions have found a reasonable balance between emission reductions at covered sources and stimulating emission reductions beyond those sources and outside the WCI region. Agreements (e.g., MOU's) may need to be executed to facilitate projects outside WCI Partner jurisdictions.

4 Defining the Real criterion

This section provides the final recommendations for the Real criterion and its supporting criteria.

4.1 Real

The *Criteria Draft Recommendations Paper* explained that offset reductions or removals are real in order to ensure the integrity of the cap-and-trade system. Aside from a minor clarifying edit, the final recommendation text regarding the Real criterion is unchanged from the draft recommendation.

4.1.1 Final recommendation

An offset certificate represents a reduction or removal of one metric ton of CO_2e that results from a clearly identified action or decision. A WCI offset project's reduction or removal is quantified using accurate and conservative methodologies that appropriately account for all relevant greenhouse gas sources and sinks and leakage risks. WCI offset projects result in emissions reductions or removals that take place at sources controlled by the project proponent.

4.1.2 Summary of stakeholder input

Some stakeholder comments addressing the real criterion were generally supportive of the draft recommendation. Other comments suggested that the draft recommendation was too restrictive in disallowing the crediting of reductions that occur at sources not controlled by the project developers.

4.1.3 Discussion of final recommendation

Stakeholders expressed general support for the draft recommendation. A fuller explanation for the draft recommendation can be found in the *Criteria Draft Recommendations Paper*. The Committee acknowledges the somewhat controversial decision to restrict projects to those with reductions occurring at sources controlled by the project developers. Within the WCI region, this is justified by double-counting concerns. For other parts of the United States and Canada, the policy decision against crediting reductions which would be capped in the WCI region applies.[4]

The Offsets Committee also discussed whether to amend the draft recommendation for the real criterion with text explicitly addressing whether the WCI's definition for real prevents forward crediting of anticipated reductions or removals. The Committee decided that such text was not necessary as part of this recommendation given that the verifiable criterion presumes reductions or removals have already been realized in order to be verified. The WCI Partner jurisdictions will not issue offset certificates for anticipated reductions.

[4] See section 9.7 (page 11) of the WCI Design Recommendations (September 2008).

4.2 Supporting criteria

This section provides the final recommendations for the supporting criteria related to the Real criterion.

4.2.1 Quantification, uncertainty, and accuracy

The *Criteria Draft Recommendations Paper* provided the WCI Offset Committee's efforts to balance the natural tension between conservative and accurate estimates of emission reductions. The final recommendation text regarding quantification, uncertainty, and accuracy is unchanged from the draft recommendation.

4.2.1.1 Final recommendation

Quantification: WCI Partner jurisdictions shall ensure that net emission reductions or removals are capable of being measured or modeled in a reliable and repeatable manner that includes all relevant sources and sinks. Quantification methodologies for GHG emissions or emission reductions shall:

- Be appropriate to the GHG source or sink
- Be current at the time of quantification
- Consider local conditions, whenever applicable
- Account for uncertainty – be calculated in a manner that yields accurate and reproducible results
- When uncertainty is above the defined threshold, apply the principle of conservativeness to GHG

During quantification procedures, project proponents shall convert each type of GHG to metric tons of CO2e. In addition, WCI offset protocols shall use uniform quantification methods whenever feasible.

Uncertainty and accuracy: Quantification methodologies and measurement techniques shall set standards for acceptable statistical precision and be based on the best available science. They shall also reduce bias, except for promoting conservative estimates. When uncertainty remains high in quantifying the amount of a greenhouse gas emission reduction or removal, the principle of conservativeness shall be applied.

Principle of conservativeness: Where uncertainties are above the defined threshold, offset quantification methods should use more conservative quantification parameters, assumptions, and measurement techniques that minimize the risk of overestimating emission reductions and removals credited for a given project. The principle should be employed when significant uncertainties arise to ensure a higher level of confidence that all calculated reductions are real.

4.2.1.2 Summary of stakeholder input

Stakeholder feedback on quantification was diverse. Comments called for using a panel of experts to evaluate current science and quantification methods, approving projects only where there is a high level of confidence that reductions have occurred, developing procedures for reevaluating quantification methodologies and publication of changes in advance, and providing suggested language to explain the principle of conservativeness.

4.2.1.3 Discussion of final recommendation

After evaluating the diverse stakeholder feedback, the Offsets Committee has decided to leave the draft recommendation unaltered. Stakeholders may find a fuller explanation for the draft recommendation in the *Criteria Draft Recommendation Paper*. The Committee concluded that stakeholder comments for this draft recommendation generally provided very apt suggestions for the successful implementation of the WCI offsets system but generally did not suggest how the text itself may be changed. The notable exception to this is the stakeholder suggestion for additional language explaining the principle of conservativeness. The Committee notes for stakeholders that its definition for a principle of conservativeness would be as follows: erring on the side of caution while balancing accuracy standards with the need for cost-effective offset projects. The Committee was not comfortable, however, with including that text in the recommendation itself.

4.2.2 Leakage

As noted in the *Criteria Draft Recommendations Paper*, evaluating leakage is important to maintaining that quantified emissions reductions are real. The final recommendation text regarding leakage is unchanged from the draft recommendation.

4.2.2.1 Final recommendation

To address activity-shifting and market leakage, WCI Partner jurisdictions will require assessments of whether functional equivalence has been maintained within projects and require that protocols include methods for leakage assessments. WCI offset protocols will evaluate functional equivalence for each project. WCI offset protocols will also require an assessment of potential leakage associated with each project type. In general, WCI jurisdictions prefer the following methods to review leakage risk:

- A quantitative assessment of leakage will be performed whenever possible.
- When a quantitative assessment is not feasible, a qualitative risk assessment will determine whether the risk of systematic leakage is significant or not.
- WCI offset protocols will include a threshold to identify significant leakage. If leakage is found to be above the threshold, the WCI offset protocol quantification methodology will include a factor to account for leakage.

4.2.2.2 Summary of stakeholder input

Most stakeholder comments supported the assessment of leakage when clear guidelines, policies, or procedures are included in WCI offset protocols. Others requested guidance or further discussion on how to determine market (external) leakage as well as functional equivalence.

4.2.2.3 Discussion of final recommendation

After reviewing stakeholder comments, the Offsets Committee has the left the draft recommendation regarding leakage unchanged. In recognition of the comment requesting additional guidance, the Committee does offer some further discussion on the topics. Further guidance for evaluating leakage will be contained within each WCI offset protocol.

Projects must determine if a significant risk of leakage exists in accordance with WCI offset protocol methods and offset criteria. If the determination results in 'no risk of leakage' in specific cases, the WCI offset protocol may waive a leakage assessment. If the leakage assessment finds a significant risk above a pre-determined threshold, the WCI offset protocol may require a project to mitigate the risk by using a factor to account for leakage when determining the level of GHG emissions or removals.

To ensure a meaningful comparison can be made between the project and baseline case, the baseline must be 'functionally equivalent' to the project. Functional equivalence assesses whether a project is reducing emissions simply by reducing the production of a good or service – instead of providing the same level of production with fewer total GHG emissions. In other words, the baseline must be able to deliver the same types and levels of products or services as the project. An example of functional equivalence would be a biomass and natural gas fired boiler – if both deliver the same quantity and quality of heat, they are functionally equivalent.

The WCI offset protocol used as the basis for a GHG project plan should provide a justified baseline assessment for the particular project type in question. The end result must be the selection of a conservative baseline scenario that is unlikely to overestimate the level of GHG emissions (or underestimate the level of GHG removals) under the business as usual case. In cases where multiple potential baselines appear equally likely to occur even after application of a detailed barriers test or other selection process, the baseline that would result in the lower emission reductions for the project should be selected.

5 Defining the Additional criterion

This section provides the final recommendations for the Additional criterion and its supporting criteria.

5.1 Additionality and Baseline

The final recommendation <u>differs</u> from the draft recommendation based on stakeholder comments and further discussion by the Offsets Committee considering stakeholder feedback.

5.1.1 Final recommendation

Offset certificates will be awarded only for the portion of greenhouse gas emission reductions or removals that would not have happened under a baseline scenario.

The WCI Partner jurisdictions intend for additionality to be established in a manner that will require offset projects to be evaluated against a baseline that reflects conservative assumptions that are consistent across all WCI Partner jurisdictions. These assumptions will be described in the procedures for setting a baseline in WCI offset protocols. Modeling or other methods of developing the baseline shall use assumptions, methodologies, and values which assure that GHG reductions or removals from a project are not over-estimated (consistent with the principle of conservativeness in 4.2.1).

When possible, the baseline shall be set using a sector-specific or activity-specific performance standard which is set in WCI offset protocols based on a regional assessment of project performance or common practice. WCI Partners intend that all baselines will reflect the most stringent regulatory and legal requirements of any WCI Partner jurisdiction (those requirements leading to the most conservative calculation of emission reductions). When a baseline based on the most stringent regulatory requirement is not practical because of regional differences, the WCI Partners may recommend a protocol using an alternative method.

When it is not possible to set a baseline using a performance standard, a project-specific baseline may be used. Then the baseline will be set to reflect all binding agreements, regulatory requirements and legal requirements applicable to the project and also to ensure that the project is beyond business as usual.

5.1.2 Summary of stakeholder input

Stakeholders generally supported the recommended preference for a performance-standard baseline. It was suggested that the definition should clarify that the WCI's intent that additional reductions and removals would not have otherwise occurred in the absence of the offset project. Several comments expressed concern that exclusive reliance on a baseline method will allow eligibility for some non-additional projects and suggested that a common practice or barrier test accompany the performance standard.

While there was some support for using a regional regulatory baseline, many commenting stakeholders were concerned that setting a baseline at the most stringent regulatory requirement would unduly limit offset supply and could be difficult to apply in some sectors (e.g., forestry). From their point of view, projects which the WCI Partner jurisdictions should view as additional would be deemed to be non-additional. Those concerned suggested that the WCI apply this on a case-by-case basis or remove this part of the draft recommendation completely.

5.1.3 Discussion of final recommendation

Given the depth of the comments on additionality, the Offsets Committee gave the recommendation a fairly extensive makeover. Given the extent of the changes, the discussion below does not focus so much on changes from the draft recommendation but on discussing the final recommendation itself.

The recommended definition of additionality and baseline is consistent with the International Standards Organization's (ISO) 14064-2 standard by defining what is additional as emission reductions or removals beyond any reductions or removals achieved under a baseline scenario. Under this definition offset projects can generate offsets for early adoption of activities that will be required in the future by a current or expected regulation until the requirement takes effect. However, new regulations or requirements that were not implemented or expected during project registration or renewal will not affect project additionality until the end of the current crediting period.

Each WCI offset protocol must lay out the methodologies that a project proponent shall use to determine additionality and model the baseline scenario. The WCI Partners prefer protocols that take a sector-specific or activity-specific performance standard approach to determining additionality. In this method, the baseline is set as the performance standard or the minimum actions required by law, whichever is higher.

In setting baselines it is the intent of WCI Partners that the performance standard will be set to reflect the most stringent regulatory or legal requirements in any WCI Partner jurisdictions. This will result in the most conservative assessment of offset reductions, helping to ensure the integrity of the WCI offset system. Setting a performance standard based on the most stringent regulation in any WCI jurisdiction will 'level the playing field' among WCI Partner jurisdictions and remove any incentive to weaken or solely maintain environmental protections in order to qualify more offset projects. For some project types it will be difficult to apply this standard based on regional differences. In these protocols, the WCI Partners may address regional differences using alternative methods.

When a performance standard approach is not the best alternative for a certain project type or it will take a number of years to develop a reasonable performance standard, the WCI Partners may recommend protocols that use alternative methods as long as they meet the criteria for determining additionality and baseline. When an alternative method is used, the baseline will reflect the chosen standard and the regulatory and legal requirements applicable in the jurisdiction where the project is located. Methods such as a common practice test, investment test, barrier analysis, or other tests of financial additionality can be used to determine whether a project is beyond business as usual.

The WCI Partners intend to use baselines that exceed this minimum by favoring performance standards since performance standards generally set higher baselines and are thus more conservative. Performance standards are designed to capture common practice or business-as-usual investment activity such that there is high confidence that the reductions or removals of greenhouse gas emissions by offset projects exceed those already occurring – especially when what is already occurring exceeds regulatory requirements.

The WCI Partners are retaining the option of using proportional additionality as the means to develop performance standards for sequestration projects in agriculture and forestry. Proportional additionality models sector activity in aggregate across either a WCI jurisdiction or the WCI region as a whole– the level of project activity that would occur absent the offset programs of WCI Partner Jurisdictions (i.e., baseline activity) and the level of aggregate project activity that is induced in response to the WCI offset program. The portion of a projects emissions reductions or sequestration over the sectoral baseline is considered additional. Over time as practices become more common projects receive a small portion of offset credit for these actions.

The WCI Partners' draft recommendation for additionality and baseline sets an overall standard but at the same time provides flexibility by deferring to the WCI offset protocols the specific methods used to achieve the standard. For example, WCI offset protocols may include additionality tests for project types that do not lend themselves to a performance standard approach. In this way, WCI offset protocols for project types that otherwise would be excluded can still be included in Partner Jurisdictions' offset programs. The WCI Offset Committee generally concurs with the prevailing view of commenting stakeholders concerned about using investment, funding or financial barriers tests in determining additionality. Thus, Partner Jurisdictions will not require them on a system-wide level, although they could be required by a WCI offset protocol where they are deemed appropriate for a given project type.

5.2 Supporting criteria

This section provides the final recommendations for the supporting criteria related to the Additional criterion.

5.2.1 Eligibility date

The offset project eligibility start date establishes a date such that only projects commenced after that date are eligible to generate offset certificates. The final recommendation differs from the draft recommendation based on stakeholder comments and further discussion by the Offsets Committee considering stakeholder feedback.

5.2.1.1 Final recommendation

Offsets may be awarded only for projects that are initially commenced on or after January 1, 2007, the start of the year in which the original WCI Memorandum of Understanding (MOU) beginning the development of the cap-and-trade program by Partner Jurisdictions was signed. Offset certificates may be awarded for all GHG reductions or removals occurring on or after January 1, 2007.

An offset project proponent must apply to register its project with a WCI Partner Jurisdiction within one year of project commencement. Projects that commenced prior to finalization of the applicable WCI offset protocol must apply within one year of that protocol's finalization.

5.2.1.2 Summary of stakeholder input

Most written comments addressed the project eligibility date. Many supported an eligibility date earlier than that proposed in the draft recommendation (September 23, 2008) while some other stakeholders suggested a later project start date, or at least a later date before which reductions could be credited with offset certificates. Overall, stakeholders suggested a number of alternative project eligibility dates ranging from January 1, 2001 to January 1, 2012.

5.2.1.3 Discussion of final recommendation

This recommendation establishes a project eligibility start date of January 1, 2007. This is based on the date when the WCI was established. The Offsets Committee believes that projects initiated before the formation of the WCI cannot readily claim they were developed based on incentives from the WCI cap-and-trade program. The MOU establishing the WCI was signed by the governors of five U.S. states on February 26, 2007. The WCI Partners have chosen to make the eligibility start date the beginning of the year in which the WCI was created.

5.2.2 Crediting period

As noted in the Criteria Draft Recommendations Paper, a crediting period determines how long an approved offset project is eligible to generate offset certificates. The final recommendation differs from the draft recommendation based on stakeholder comments and further discussion by the Offsets Committee considering stakeholder feedback.

5.2.2.1 Final recommendation

The crediting period for non-sequestration WCI offset projects will be 10 years. At the end of a crediting period a project proponent may renew a project subject to the current WCI offset protocol for that project type. Renewal of a project at the end of a crediting period will include a reevaluation of a project's additionality and reevaluation of how the reductions are quantified and verified. Thus, the baseline scenario will be reevaluated at each renewal.

The crediting period for sequestration projects will be specified by the applicable WCI offset protocol. However, any individual crediting period may not exceed 25 years before a renewal, and the total crediting period including all renewals may not exceed 100 years for sequestration projects. The applicable WCI offset protocol will also lay out the requirements for project renewal. At a minimum, the project must reevaluate quantification and monitoring methods based on the current WCI offset protocol. If possible, projects will also need to reassess project additionality and baselines in order to renew the project.

5.2.2.2 Summary of stakeholder input

Stakeholders offered a number of comments concerning the length of a crediting period and the number of crediting period renewals for which each project should be eligible. There was support from stakeholders for both extending and shortening the recommended crediting period for both sequestration and non-sequestration projects. Stakeholders also suggested not limiting the number of crediting period renewals for projects that continue to generate real, additional, and verifiable reductions.

5.2.2.3 Discussion of final recommendation

During a crediting period a project will generate certificates based on the methods laid out in the applicable WCI offset protocol at the time a project is registered. A project will continue to generate certificates throughout the crediting period assuming it reduces or sequesters more greenhouse gases beyond the baseline established at the time project registration. Changes in regulations or the WCI offset protocol itself will not affect a project during its current crediting period, unless the project developer chooses to use the updated protocol instead of the protocol version in place at the time of project registration.

Crediting period length remains unchanged from the draft recommendation. However, the final recommendation lifts the limit on the number of renewals for non-sequestration projects. For project renewal, non-sequestration projects will undergo a full reevaluation of all criteria based on the current WCI offset protocol for that project type.

Sequestration project will be able to renew a crediting period such that the total crediting period for any project does not exceed 100 years. A WCI offset protocol will lay out the criteria a project must meet in order to qualify for renewal. At a minimum the project proponent will need to modifying quantification and monitoring methods and plans to reflect the current practices laid out in the most recent WCI offset protocol for that project type. For project types where it is possible to reassess additionality, the project will need to undergo a full reevaluation of baselines to ensure it continues to meet the criteria for additionality. For project types such as afforestation where it is impossible to reassess the project baseline, projects will still be eligible for crediting period renewal assuming they continue to sequester carbon.

6 Defining the Permanent criterion

This section provides the final recommendation for the Permanent criterion.

6.1 Permanent

As noted in the *Criteria Draft Recommendations Paper*, permanence is an issue which needs to be addressed in projects which involve a risk of reversal, most notably geologic and terrestrial sequestration of carbon (i.e., carbon that is stored in biomass and soil). The final recommendation text revises the draft recommendation.

6.1.1 Final recommendation

With respect to offset project activities, permanence means either that reductions or removals are not reversible or that, if reductions or removals are reversible, the provisions outlined in the remainder of this recommendation must be met.

Sequestration projects must be designed so that the net atmospheric effect of their greenhouse gas removal is comparable to the atmospheric effect achieved by non-sequestration projects. The atmospheric effect will be based on the current international standard established by the UNFCCC, which is currently 100 years. This international standard may be updated from time to time, and the WCI Partner jurisdictions will adopt the new international standard if/when it is updated.

If an emission reduction is reversed after offset certificates are issued, the project developer must either replace the certificates representing reversed reductions with other compliance units from within the system or return certificates that were issued to the project. The number of certificates required to be replaced or returned will, at a minimum, be the difference between the atmospheric benefit the sequestration project until it was reversed and the total sequestration for which certificates were issued. Applicable approaches to assuring permanence for a project type will be included in the appropriate WCI offset protocol.

In conformance with the applicable WCI offset protocols, project proponents shall follow or establish effective (i) monitoring systems, (ii) risk mitigation approaches, and (iii) contingency plans which address how, in the event of a reversal that is the result of proponent intention or negligence, any affected offset certificates will be replaced. The contingency plan shall include specific mechanisms that are exercisable at the time a reversal is identified whether or not the proponent is solvent, exists in its original form, and/or has ownership of or responsibility for the project.

WCI Partner jurisdictions will establish mechanisms to address reversals that are not the result of proponent intention or negligence and where proponents' contingency measures prove inadequate.

6.1.2 Summary of stakeholder input

Stakeholder groups offered valuable feedback on the permanent criterion. There was consensus that the environmental integrity of the offsets system needs to be ensured. There was also broad agreement that various measures including buffer pools, pro-rating, discounting and replacement could be employed in order to maintain the atmospheric benefit of projects. Stakeholders expressed concern over the 100-year standard for assessing permanence, and at least one stakeholder suggested creating temporary or short-term credits. Stakeholders also expressed support for an approach where the buyer of offsets is not held liable for reversals, with some stakeholders suggesting that punitive penalties be applied for intentional reversals.

6.1.3 Discussion of final recommendation

The final recommendation for the permanent criterion remains largely unchanged from the draft recommendation. Following review of stakeholder feedback regarding permanence and further discussion among themselves, the WCI Partners revised the permanence recommendation to clarify when reversals will necessitate the replacement of issued offset certificates. This recommendation provides the system-level requirements, with additional detail to be provided in the WCI offset protocols.

Some stakeholder comments suggested measures for assessing permanence (e.g., use of conservation easement). Under the final recommendation, such measures will be evaluated at the protocol level. The WCI Offsets Committee understands the concern over the appropriateness of a 100-year standard and has included provisions for the possible reevaluation of the standard. The WCI Partners also discussed the possibility of temporary crediting, but experience with this approach to date suggests that it may not sufficiently incentivize the desired sequestration activities.

7 Defining the Verifiable criterion

This section provides the final recommendation for defining the Verifiable criterion and three supporting criteria.

7.1 Verifiable

As noted in the *Criteria Draft Recommendations Paper*, the biggest question related to the term verifiable is who will objectively review the GHG assertion or reduction and making a finding whether the GHG assertion or reduction is accurate. The final recommendation text is unchanged from the draft recommendation.

7.1.1 Final recommendation

With respect to offset project activities, verifiable means that a GHG reduction or removal, or assertion thereof, is well documented and transparent such that it lends itself to an objective review by a qualified verifier. Verifiers for WCI offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner jurisdiction in which the project is registered.

7.1.2 Summary of stakeholder input

Several stakeholders offered written comments on this criterion. Stakeholder suggestions included that the WCI should enable a public comment process as part of the verification process and that accreditation requirements should be harmonized across the WCI region. There were recommendations to prohibit verifiers from having a financial stake in the offsets projects they verify.

7.1.3 Discussion of final recommendation

The Offsets Committee regards the stakeholder comments as providing helpful guidance for the WCI Partner jurisdictions to implement an effective verification program for WCI offsets. From these comments, the Committee did not find a reason to modify the draft recommendation. Many of the stakeholder comments on the draft recommendation were related to offsets process (e.g., accreditation of verifiers) and will be addressed in the *Process Draft Recommendations Paper*. The Offsets Committee also wishes to stress its view that emission reductions and removals being verifiable prevents so-called forward crediting of offset certificates until after the reductions have been realized and verified.

7.2 Supporting Criteria

This section includes final recommendations for three supporting criteria related to the verifiable criterion.

7.2.1 Validation

As noted in the *Criteria Draft Recommendations Paper*, the key questions regarding validation were whether validation would be required and who would perform the validation. The final recommendation differs from the draft recommendation. The changes are not so much because of stakeholder comment but a result of further consideration by the Offsets Committee as it drafted the *Process Draft Recommendations Paper*.

7.2.1.1 Final recommendation

With regards to WCI offsets, validation is a required review by an accredited independent third party or the WCI Partner jurisdiction to assess the likely result of reductions or sequestration from a proposed project that would use a WCI offset protocol.

7.2.1.2 Summary of stakeholder input

Stakeholders offered a mixed view on validation. Some stakeholders commented that a validation step is absolutely necessary, while others suggested that validation should not be required at all. Some suggested that third-party validation should not be required.

7.2.1.3 Discussion of final recommendation

After further discussion, the Offsets Committee has concluded that validation is necessary in the offsets process. Project details must be evaluated at some point, and the Committee's recommendation is to require validation prior to project registration. The final recommendation retains for each WCI Partner jurisdiction the flexibility to have validation performed either by an accredited third party auditor or by itself.

7.2.2 Enforceable

Enforceability is key to ensuring that offset project developers comply with the WCI offset protocols and offset system requirements. The final recommendation text is unchanged from the draft recommendation.

7.2.2.1 Final recommendation

Each Partner jurisdiction will, to the extent permissible by law, put in place sufficient compliance/enforcement mechanisms and detail for the jurisdiction to compel compliance with its requirements and with WCI offset protocols.

7.2.2.2 Summary of stakeholder input

Stakeholders generally commented enforcement requirements and penalties should be consistent across all WCI Partner jurisdictions. A couple written comments suggested more detail should be provided.

7.2.2.3 Discussion of final recommendation

The *Criteria Draft Recommendations Paper* offered the Offsets' Committee reasoning for the above recommendation. After reviewing the stakeholder comments, the Offsets Committee did not identify any reason to change the recommendable regarding the enforceable criterion. The Committee does appreciate stakeholder comments for more detail on the enforcement process in regards to WCI offsets, and this detail will be provided in a future deliverable from the Offsets Committee.

7.2.3 Material

As explained in the *Criteria Draft Recommendations Paper*, the term "materiality" refers to a threshold beyond which differences in reported emissions/reductions are deemed unacceptable. The final recommendation <u>revises</u> the draft recommendation.

7.2.3.1 Final recommendation

Material misstatement means that errors, omissions or an aggregation of both in the reported GHG reductions or assertion exceeds a +5% threshold. For a WCI offset, the verifier must be able to state with reasonable assurance the total reported reductions or removals are free of material misstatement.

7.2.3.2 Summary of stakeholder input

There were few written comments offering comments specific to the Materiality supporting criterion. One suggestion from stakeholders was to define material misstatement as errors or emissions resulting in significant overestimates (e.g., +5% only, not ±5%) since underestimates of emission reductions do not harm environmental integrity of the overall program. Another suggestion from stakeholders was to apply a different threshold for small projects as their errors could exceed materiality thresholds despite affecting only a small number of tons.

7.2.3.3 Discussion of final recommendation

The level of the ±5% threshold in the draft recommendation was consistent with the materiality threshold for emitters with mandatory reporting obligations in the WCI jurisdictions (as described in the Essential Reporting Requirements document). Following suggestion from stakeholder comment, the WCI Offsets Committee has modified its previous reasoning about not deviating the threshold from that used for mandatory reporting. Because of the uncertainty inherent with most offsets, it may be appropriate to apply the threshold only to overestimated reductions and not to underestimated reductions. The Offsets Committee considered the stakeholder suggestion about a different threshold for smaller projects but concluded based on current information to recommend the same threshold to all projects regardless of size—consistent with the same threshold being applied to all emitters under mandatory reporting regardless of their size.

8 Other considerations

This section includes final recommendations for three considerations that were of importance to the Offsets Committee for this paper but did not otherwise fit well under the discussions of the offset definition or essential criteria.

8.1 Transparency

The final recommendation text for transparency is unchanged from the draft recommendation, aside from a minor clarifying edit.

8.1.1 Final recommendation

Partner Jurisidictions' offset systems will provide transparency such that sufficient and appropriate protocol, project and certificate information is disclosed in a timely manner to allow offset system participants and the general public to make decisions with reasonable confidence.

8.1.2 Summary of stakeholder input

Several stakeholders provided written comment on transparency, and each tended to focus on a different aspect of a transparent offset system, including (a) concern whether system requirements would not sufficiently respect the privacy of small family farms involved in generating offsets, (b) the importance of registries making standardized information available, and (c) the importance of timely public disclosure of offset documents allowing for public comments on proposed projects.

8.1.3 Discussion of final recommendation

Unaltered, this recommendation maintains the important role of transparency in the WCI offsets system. As discussed in the Criteria Draft Recommendations Paper, details regarding transparency will be provided via subsequent deliverables from the Offsets Committee, including the *Process Draft Recommendations Paper* (Task 1.3) and other deliverables from Task 1.5.

8.2 Co-benefits

The final recommendation text regarding co-benefits is unchanged from the draft recommendation.

8.2.1 Final recommendation

WCI Partners recognize the environmental, social, economic and health benefits that may arise from an offset project and the offset system will focus on those benefits directly related to mitigating climate change. A WCI offset project is required only to result in a greenhouse gas emission reduction or removal.

8.2.2 Summary of stakeholder input

Written stakeholder comments generally supported the draft recommendation, although that support was not unanimous. Some comments also suggested that priority or advantage should be given to offsets with positive co-benefits or that the WCI's registration and reporting processes for offsets require a report on any co-benefits.

8.2.3 Discussion of final recommendation

While stakeholders are not unanimous in supporting this recommendation, the Offsets Committee believe it has made the appropriate recommendation and leaves the draft recommendation unchanged. With this recommendation, the WCI Partner jurisdictions keep the focus of the offsets program on GHG emissions reductions and removals—the reason behind establishing the WCI regional cap-and-trade program—but they also remain neutral on how co-benefits associated with an offset project may be treated or claimed by policies or programs other than the greenhouse gas cap-and-trade program (as noted and explained in the *Criteria Draft Recommendations Paper*).

8.3 Assessment of Environmental or Social Impacts

The final recommendation text regarding assessment of environmental or social impacts is unchanged from the draft recommendation.

8.3.1 Final recommendation

WCI offset projects must meet all applicable local environmental regulations and be in compliance with all applicable laws in the jurisdiction where the project is located. If environmental or socioeconomic assessments of the proposed project have been done, the project's registration application should reference this work and include a summary of the findings. WCI offset protocols for specific offset project types may require analysis of environmental and socioeconomic impacts beyond what the local jurisdiction would otherwise require and may require additional mitigation of potential negative impacts.

8.3.2 Summary of stakeholder input

Several stakeholders provided written comment on this draft recommendation with none explicitly supporting the draft recommendation. A few comments indicated that the draft recommendation was not strong enough in what would be required, while other comments suggested that the draft recommended requirements were too strong and could inhibit the development of offsets.

8.3.3 Discussion of final recommendation

While stakeholders did not explicitly support the draft recommendation regarding co-impacts, the divide between stakeholders who think the recommendation is either too lax or too stringent indicates to the Offsets Committee that they have struck a reasonable balance to address concerns over potential negative co-impacts from the implementation of offset projects. The Offsets Committee anticipates that more specific detail on co-impacts will become available as WCI offset protocols are completed.

9 Conclusion

This paper has presented the final recommendations for defining a WCI offset and its essential criteria, as well as other supporting criteria and considerations. These recommendations will inform the ongoing work of the Offsets Committee. As these are final recommendations, the Offsets Committee is not seeking further stakeholder feedback on these recommendations, but the Offsets Committee does thank stakeholders for their patience and feedback through multiple stages. Table 9.0 below updates stakeholders on planned deliverables from the Offset Committee's Essential Elements (Task 1) work.

Table 9.0 Offsets Committee Task 1 Workplan

Task 1 Subtasks	Subtask Description	Deliverables (Dates)
1.1	Define a WCI GHG offset	Options Paper—June 2009 Draft Recommendations—April 2010 Final Recommendations—July 2010
1.2	Develop detailed eligibility criteria for GHG offset projects for compliance purposes under the cap-and-trade system	Options Paper—June 2009 Draft Recommendations—April 2010 Final Recommendations—July 2010
1.3	Develop detailed requirements for the registration, validation, monitoring, quantification, reporting, verification, certification, and issuance of offsets	Draft Recommendations—August 2010 Final Recommendations—TBD
1.4	Recommend aspects of regulation and enforcement related to offsets that should be included in the cap-and-trade essential elements	TBD
1.5	Recommend functions of the regional administrative body and tracking system related to the offset system	TBD

Western Climate Initiative

Guidance to Partners for Distributing Early Reduction Allowances

June 22, 2010

1. Introduction/Purpose

According to the September 23, 2008 *Design Recommendations for the WCI Regional Cap-and-Trade Program*, Early Reduction Allowances (ERAs) may be awarded for reductions by covered facilities between January 1, 2008 and January 1, 2012. As proposed in the Design Recommendations, ERAs would be issued in addition to a WCI jurisdiction's allowance budget. Therefore, those reductions must be voluntary, additional, real, verifiable, permanent, and enforceable in order to preserve the integrity of the WCI cap-and-trade program. Issuance of ERAs for eligible reductions is itself voluntary, and not required by WCI partner jurisdiction. ERAs are fungible compliance units, in the same way as allowances.

There are two approaches for identifying ERA eligible projects:

1) Under the program authority review, a WCI partner may use existing emissions information to identify potentially eligible projects and request those projects to submit emissions information in order to assess and verify their eligibility. The program authority review enables Partner jurisdictions that already have much of the data required under the application process (second approach below) to minimize their administrative burden by not requiring an application process. Projects awarded ERAs under the program authority review must still meet all requirements set forth in this document with the exception of the application process (section 4.2).

Or

2) A WCI partner jurisdiction may institute a process where emission sources apply for ERA consideration. Once the application is made for an emissions source, and verification provided, the WCI Partner Jurisdiction will decide whether to approve the application and award ERAs for the early reduction, or reject the application.

Under both approaches, the burden of proving that a project qualifies for ERAs is the responsibility of the source or facility claiming the reduction. A Partner jurisdiction may require the verification of the information provided be carried out by a government agency or may require it be done by an accredited third party verifier.

This guidance document presents the requirements and methodologies for the issuance and distributions of ERAs under both approaches.

2. Greenhouse Gases Covered

For the purpose of the Early Reduction Allowance (ERA) program, the Committee recommends covering all the GHGs covered in the GHG cap and trade program. That includes: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), hydrofluorocarbons (HFCs), nitrogen trifluoride (NF_3), and perfluorocarbons (PFCs).

3. Common Requirements for Awarding Early Reduction Allowances

This section presents the common requirements that Partners recommend to include in their Early Reduction Allowance provisions.

Eligibility

To be eligible to receive ERAs, a project must involve permanent emissions reductions at a source subject to the greenhouse gas emissions requirements of the Partner jurisdiction's cap-and-trade program (covered source). This means that the owner or operator of that source must be required to surrender allowances/credits to cover the source's emissions at the end of a compliance period. Restricting eligibility to projects that occur at covered sources in the Partner jurisdiction will help prevent double counting and will allow the distribution of ERAs to build upon the WCI's monitoring and reporting work to date.

ERAs should only be awarded when the source or facility can demonstrate that the reductions were the result of a clear project or action.

Government-controlled sources are eligible to receive ERAs for emissions reductions so long as they meet all of the requirements of this document, including that the owner or operator of that source is required to surrender allowances/credits to cover the source's emissions at the end of a compliance period, and that the reductions are voluntary.

Eligibility Period

A Partner jurisdiction may issue ERAs for a project that reduced emissions on or after January 1, 2008 and before January 1, 2012.[1]

Real

One WCI ERA represents a reduction or removal of one metric ton of carbon dioxide equivalent emissions (CO_2e) resulting from a clearly identified action or decision without an increase in emissions intensity. A reduction is not considered real if it comes from a decrease in production alone or from a shutdown or a closure of a source or a facility. Instead, the source or facility must demonstrate a reduction in emissions intensity <u>and</u> a reduction in absolute emissions for the period of time that ERAs are being sought. The source or facility that may be awarded ERAs must provide adequate information to demonstrate that a project has actually occurred.

[1] See Section 5, below, for discussion of special considerations applicable to jurisdictions that enter the cap-and-trade program after 2012.

In addition, a Partner jurisdiction may also require sources or facilities to show reductions are beyond best practice standards. Best practice standards can be defined by the jurisdiction for certain operations, sources or facilities who may be required to prepare an evaluation demonstrating their actions are beyond best practices in their industry.

Voluntary

A WCI ERA project and the accompanying reduction in emissions, both, must be the result of a clearly identified action or decision that is surplus to any requirements from existing legislation, regulation, executive order and other regulatory obligations.

Permanent

With respect to the issuance of ERAs, permanence means that reductions or removals are not reversible. To issue ERAs for carbon capture and storage projects, the Partner jurisdiction must (a) have in place monitoring and verification requirements that are sufficient to enable the Partner Jurisdiction to establish that the sequestration is permanent; (b) have the ability to assure that ERAs will be replaced where a reversal occurs; and (c) apply these requirements to the applicable project

Additional

ERAs will be awarded in addition to partner allowance budgets. Therefore, in order to preserve the emissions reduction goals of the WCI cap-and-trade program and to provide incentives for reductions to take place before the program starts, projects should be rewarded ERAs for reductions and sequestrations of greenhouse gases that might have been deferred without an ERA program. Because the ERA program is of limited duration, WCI Partners have adopted a streamlined approach to additionality which minimizes the administrative burden.

Specifically, with respect to the ERA program, a reduction or removal will be considered additional if the source or facility can demonstrate that:

1. the reduction or sequestration results from a clearly identified action or decision that was initiated during the eligibility period; and
2. the annual averages of absolute emissions and emission intensity for the period of time that ERAs are being sought, are below the annual averages of absolute emissions and emission intensity for the reference period (2005-2007).

Fuel switching projects will only be considered additional if the source or facility can also demonstrate that the fuel switched to was more costly during the ERA eligibility period than the fuel switched from, or if the regulated facility underwent an equipment change during the ERA period to enable the switch to a lower carbon fuel.

Verifiable

With respect to ERA projects, verifiable means that a GHG reduction or removal, or assertion thereof, is well documented and transparent such that it lends itself to an objective review by a Partner jurisdiction or a qualified verifier.

Ownership

A source or facility for which ERAs are being sought must demonstrate that they own the GHG emission reduction resulting from the ERA project. This will help the jurisdiction ensure that the ERA is awarded to the source or facility actually responsible for the reduction, and will help avoid double counting of those reductions by other parties through the ERA provisions, or as offsets in voluntary registries.

Enforceability

The source or facility seeking recognition for a project is accountable to the WCI Partner Jurisdiction issuing an ERA for all statements and information provided to the WCI Partner Jurisdiction regarding the ERA project. Jurisdictions should adopt any measures they deem necessary to ensure their ability to enforce against the source or facility receiving ERAs.

4. Quantification methodology

4.1.1. Quantification of Emission Reductions

The total number of ERAs attributed to a project is based on cumulative reductions over the ERA period for the eligible project, and is calculated as follows:

If $I_{base} \leq I_{ERA}$, then:

Total ERAs Awarded = 0

If $I_{base} > I_{ERA}$, then:

Total ERAs Awarded = $A \times (E_{base} - E_{ERA})$ If $P_{base} \leq P_{ERA}$

Total ERAs Awarded = $[A \times (E_{base} - E_{ERA})] \times (P_{ERA}/P_{base})$ If $P_{base} > P_{ERA}$

Where:

A is the number of consecutive calendar years from when the ERA project/action begins and the end of 2011. The source or facility will indicate the number of years for which ERAs are being sought.

$\mathbf{E_{base}}$ and $\mathbf{P_{base}}$ are the average yearly emissions and production from January 1, 2005 to the end of 2007.

$\mathbf{E_{ERA}}$ and $\mathbf{P_{ERA}}$ are the average yearly emissions and production during the years where the source or facility is seeking ERAs (i.e. the number of consecutive calendar years from when the ERA project/action begins and the end of 2011).

$\mathbf{I_{base}}$ is the average emission intensity (emissions per unit of output) of the base period (i.e. from January 1, 2005 to the end of 2007)

$\mathbf{I_{ERA}}$ is the average emission intensity (emissions per unit of output) during the years for which the source or facility is seeking ERAs (i.e. the number of consecutive calendar years from when the ERA project/action begins and the end of 2011).

When using the above equations, applicants should use entire calendar years. Thus, the ERA period must start either on January 1, 2008, January 1, 2009, January 1, 2010, or January 1, 2011.

4.1.2. Data requirements

Emissions

All quantification should be done using the WCI Essential Reporting Requirements or the equivalent methods approved by the Partner Jurisdictions.

Output

Output is the amount of a good or service produced by a covered source or facility. Electricity generators should report net MWh of electricity produced. Industrial sources or facilities should use standardized forms of reporting, where such data is available. For example, industrial units located in the U.S. could report production using the same metrics as provided to the Federal Reserve for their *Industrial Production and Capacity Utilization Report*. However, in the event that such metrics are not accurate measures of output for a particular class of sources or facilities, then WCI partner jurisdictions may wish to allow those sources or facilities to propose alternative metrics. To mitigate gaming, sources or facilities should use the same metric for approximating output in both the base period (January 1, 2005 to January 1, 2008) and the early reduction period (January 1, 2008 to January 1, 2012).

Verification

All emissions and output reports used to establish ERA baselines or generate ERAs must be verified by an independent third party or government entity. Third party verifiers must be accredited to a standard acceptable by the WCI Partner Jurisdiction in which the project is registered. The source or facility awarded ERAs for a reduction project must keep for a period of at least 7 years and submit, under request, all documents related to the quantification of the reduction or removal.

4.2. Specific requirements and description of the application process

WCI Partner jurisdictions who choose the application process will need all applications for ERAs to be submitted no later than July 1, 2012. This timeline will provide the applicants with sufficient time after their emissions data is finalized to complete their applications for ERAs. The timeline will also provide sufficient time to Partner jurisdictions to issue ERAs no later than the first quarter of 2013 and Partner jurisdictions will endeavor to award them before the end of 2012.

Applications for ERAs should be submitted to the WCI jurisdiction in which the source or facility has a compliance obligation and where the reductions or removal took place. To reduce the administrative burden of reviewing applications, the WCI will develop standardized forms that Partner jurisdictions can require applicants to use. In addition, some Partner jurisdictions may also provide pre-application consultation.

4.3. Specific requirements and description of the program authority review

The program authority review enables Partner jurisdictions that already have much of the facility-level information specified in sections 4.1.1 and 4.1.2 above to minimize their administrative burden by not requiring an application process.

Under this approach, a Partner jurisdiction estimates emission reductions based on this facility-level information to determine a Partner's maximum number of potential ERAs it is planning on distributing.

To ensure no ERA gets awarded for unrealized emission reductions, the information used to determine the number of ERAs the Partner jurisdiction expects to issue will be verified by a government agency or independent third party after the reductions take place. In the case emission reductions are lower than expected; the total number of ERAs the Partner jurisdiction plans to issue will be reduced to reflect actual reductions that took place during the eligibility period.

As with the application process, the Partner jurisdiction will issue ERAs no later than the first quarter of 2013 and will endeavor to award them before the end of 2012. Only verified emission reductions receive ERAs, even if this is less than the initial estimate. ERAs cannot be issued beyond the amount of the initial estimate or beyond verified emission reductions.

5. Special Considerations for Individual Project Types

This section provides additional guidance for project types that present unique challenges to ensuring that their emissions reductions are voluntary, additional, real, verifiable, permanent, and enforceable.

Fuel Switching

Switching from high to low carbon intensity fuels can help a source or facility reduce its GHG emissions. Sometimes fuel switching will occur naturally due to changes in relative fuel prices. To ensure that ERAs are only awarded for projects that might have been deferred without an ERA program, fuel switching projects should only qualify for reductions if the fuel switched to is more costly during the ERA period than the fuel switched from, or if the regulated facility underwent an equipment change during the ERA period to enable the switch to a lower carbon fuel. As discussed previously under the ownership guidelines, sources or facilities must demonstrate that they have ownership over the emissions reductions for which they are seeking ERAs. Therefore, if a source or facility is seeking ERAs for switching from a high to a low carbon fuel, then they must also demonstrate that the reductions are not also being claimed by the fuel provider and thus double counted in any other regulatory or voluntary program (e.g., to meet renewable fuel standards or low carbon fuel standards).

Fuel Providers

Fuel providers can receive ERAs for a reduction in on-site emissions. They can also receive ERAs for reductions that result from the reduction in the carbon intensity of the provided fuel, through the use of lower-carbon, or carbon-neutral sources. However, for such reductions to qualify for ERAs, they cannot contribute to compliance with any required low carbon fuel standard or renewable fuel standard. Reductions in fuel sales are not eligible for ERAs because such projects do not result in a reduction in the intensity of emissions. As discussed previously under the ownership guidelines, the source or facility must demonstrate that they have ownership over the emissions reductions for which they are seeking ERAs. Therefore, if a fuel provider is seeking ERAs for reducing the carbon intensity of their fuels, then they must demonstrate that the reductions are not also being claimed by the user of the fuel and thus double counted in any other regulatory or voluntary program (e.g., as ERAs or as offsets in a voluntary registry). Also, the fuel provider must demonstrate that the reductions are indeed voluntary, and are not being used to meet renewable or low carbon fuel standards.

Electricity Importers

Using the application process, ERAs may be issued for electricity imported into a WCI Partner jurisdiction that does not come from another WCI Partner jurisdiction as long as it meets all other criteria outlined in Section 3 above. An importer would apply to the Partner jurisdiction with whom they have a compliance obligation. To qualify as an ERA, the capped entity will need show ownership of a qualifying reduction in both absolute emissions and emissions intensity at a specific facility whose power is produced for consumption within the WCI Partner jurisdiction.

6. Issuance of ERAs

Allowance prices are the product of relative supply and demand. The issuance of ERAs increases allowance supply, and thus will impact allowance prices. Therefore, in order to minimize market volatility partner jurisdictions should announce the total number of ERAs that they intend to issue on the same day. That information should be posted publicly to maximize transparency, and to ensure that all parties have access to this market-relevant information. To ensure that regulated entities can adequately factor ERAs issued into their compliance planning, WCI partners should publicly post the number of ERAs to be issued.

WCI Partner jurisdictions will review the applications and/or supporting material, and issue ERAs no later than the first quarter of 2013, and will endeavor to award them before the end of 2012.

7. ERA Implications for Budget Setting

Please see CSAD Task 2 documents for a discussion on the relationship between ERAs and Budget Setting.

8. Considerations for Jurisdictions that Implement the WCI Cap-and-Trade Program After 2012.

The September 2008 Design Document identified two mechanisms for recognizing early action. First, WCI Partner jurisdictions may issue Early Reduction Allowances in 2012 that are in addition to each WCI Partner jurisdiction's 2012 allowance budget. The other is early action and set asides allowances that come out of the individual Partner jurisdiction's allowance budget. The latter may be issued by any Partner including those that enter the cap-and-trade program after 2012. In addition, the Partners will evaluate and consider mechanisms to incentivize GHG reductions prior to the commencement of the program such as benchmarking.

1 Executive Summary

In January of 2010 the Western Climate Initiative released an initial version of this paper, *Voluntary Renewable Energy Market: Issues and Draft Recommendations*. It was released for stakeholder comment and discussed at a stakeholder meeting on January 21st, 2010. This final version of the paper reflects stakeholder comment that was received at that session and through the comment period, as well as further reflection by the WCI electricity team.

Voluntary purchases of renewable energy products have played an important role in expanding the renewable energy market in many WCI Partner jurisdictions. However, the voluntary renewable energy (VRE) market may be impacted by the implementation of a greenhouse gas cap-and-trade program. The impact on the VRE market depends in part on expectations that VRE consumers may have about the emission reduction benefits associated with their purchases. Renewable generators located in capped jurisdictions no longer contribute to greenhouse gas emission reductions once a cap is in effect because the level of allowable emissions is determined by the cap. In light of this, consumers motivated primarily by the desire to reduce greenhouse gases may choose to opt out of the VRE market or direct their purchases to uncapped jurisdictions. WCI Partner jurisdictions that wish to address potential impacts on the VRE market from the cap-and-trade program have the option to adjust their baseline allowance budget to reserve (or "set aside") a pool of allowances for retirement that ensures that emission reductions occur for VRE market purchases. This type of VRE policy (a "VRE set aside") has been implemented in the cap-and-trade system in the US Northeast (the Regional Greenhouse Gas Initiative, or RGGI), and has been proposed in Australia. Conversely, no such program exists in the European cap-and-trade system or proposed federal US programs.

The WCI Design Recommendations provide that WCI Partner jurisdictions have broad discretion in determining whether to reserve their allowances for designated purposes. In accordance with these recommendations, no program-wide recommendation is made as to whether all Partner jurisdictions should implement a VRE set aside. While it is important, if not necessary, for linked cap and trade programs to harmonize on certain elements, it is not important for all Partner jurisdictions to harmonize on the choice of whether to implement a VRE set aside.

This paper focuses on discussing the key design elements of VRE set asides and provides recommendations to those WCI Partner jurisdictions that do choose to implement a VRE set aside. Elements on which it is important for the WCI Partner jurisdictions to harmonize are highlighted. These recommendations are summarized below in Table 1. Differences between the draft recommendations proposed in January 2010 and the final recommendations made in this paper are also noted in the table. Stakeholder comments on the original draft recommendations are summarized at the end of this report.

Table 1: Summary of Draft and Final Recommendations on VRE Set Aside Design Elements

Design Element	Draft Versus Final Recommendation	WCI Partner jurisdictions that choose to implement a VRE set aside should:	Importance of Harmonization
Accounting Mechanism for VRE Set Aside Program	Draft Recommendation	Include a requirement that the measurement of voluntary renewable energy purchases that form the basis of any allowance retirement be based, first and foremost, on transactions verified through established REC tracking systems that span some or all of the WCI region (e.g., WREGIS). In addition, to account for those purchases that are not tracked through an established system (or for regions without such a system) provision should be made to accept transactions that are certified through a third-party verification system for voluntary renewable energy that includes, at a minimum, a requirement that the seller must attest to not having previously sold or otherwise transferred the greenhouse gas benefits of the renewable energy product.	High
	Final Recommendation	Include a requirement that the measurement of voluntary renewable energy purchases that form the basis of any allowance retirement be based on transactions verified through established REC tracking systems that span some or all of the WCI region (e.g., WREGIS).	
Defining Eligible Renewable Energy Project Types	No Change	Define their own eligibility requirements for their VRE set aside programs. They may choose to mirror existing RPS or other statutory definitions or to define a separate list of qualifying project types.	Low
Jurisdictional Retirement Responsibility	Draft Recommendation	Retire allowances using a generator-based approach in which allowances are retired whenever RECs from a facility in that WCI Partner jurisdiction's territory are purchased and retired by a customer in the VRE market with no limitation on the customer's location. Alternatively, the retirement should be based on VRE sales if RECs are not used.	High
	Final Recommendation	Retire allowances using a generator-based approach in which allowances are retired whenever RECs from a facility in that WCI Partner jurisdiction's territory are purchased and retired by a customer in the VRE market with no limitation on the customer's location. WCI Partner jurisdictions should also consider requiring that renewable energy produced by VRE-eligible facilities in a non-WCI Partner jurisdictions and sold on a specified basis to the WCI Partner jurisdiction be counted as if those facilities were located in the WCI Partner jurisdiction.	

Upper Limit on Retirement Amount	Draft Recommendation	Choose whatever upper limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions must determine if they will cover shortfalls by either borrowing allowances from a future year or lowering the per MWh retirement rate.	Low
	Final Recommendation	Choose whatever upper limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions should cover shortfalls that do occur in a compliance period by moving any remaining allowances not dedicated to other purposes into the set aside account or borrowing allowances from future years' VRE set aside accounts. In addition, when the number of allowances to be retired approaches the chosen limit, the WCI Partner jurisdiction could choose to close the eligibility of the VRE set aside to new projects and therefore restrict the supply to near the level of the limit to ensure long-term stability for existing projects.	
Time Limit on VRE Set Aside Program	Draft Recommendation	Choose whatever time limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions may choose to base time limits on periodic reviews of the cost-competitiveness of the technologies supported by the set aside program.	Low
	Final Recommendation	Choose whatever time limit (if any) that is found appropriate for that jurisdiction. However, to provide greater certainty to project developers, Partner jurisdictions should consider a minimum length of time from the date a VRE-eligible facility commences operations that it will be supported by the set aside. Partner jurisdictions may choose to delist technologies from eligibility based on periodic reviews of the cost-competitiveness of the technologies supported by the set aside program, but the last eligibility date for delisted project types should be announced well in advance.	
Emission Attribution for VRE Purchases	No Change	Work together to develop a rate based on a marginal dispatch analysis, such as the WCI Default Emission Factor Calculator, for each major grid region. However, use of this rate should be optional and specific assignment of emissions left to jurisdictional discretion.	Medium

2 Background

The WCI Partner jurisdictions committed to a set of principles when designing the WCI Regional Cap-and-Trade Program. A theme in those principles is the support of renewable energy by "diversifying energy sources" and "stimulating investment … in low carbon technologies"[1]. Therefore, increasing the amount of energy generated by renewable energy sources in the WCI region is a key goal of the WCI Partners. Much of the growth in renewable energy in the WCI region will happen through the economic incentives created by cap-and-trade, government mandates on load-serving entities to obtain renewable energy, and other complementary policies such as direct procurement or feed-in tariffs. Additional growth may come from energy consumers that make individual, voluntary decisions to purchase renewable energy in the voluntary renewable energy (VRE) market.

At present individual decisions to purchase renewable energy in the WCI region can potentially lead to reductions in greenhouse gas emissions.[2] Implementing a cap-and-trade program changes that dynamic because under a cap-and-trade program the amount of greenhouse gas emissions allowed in the region are pre-established by the cap level. As a result, decisions to purchase renewable energy – beyond what is cost-effective after imposition of a carbon price – free up emission allowances that would have been needed to generate electricity from fossil fuels, allowing other regulated entities to emit more than they could have otherwise. In essence, the voluntary purchase of renewable energy lessens the regulatory burden on greenhouse gas emitters. A large number of such VRE purchases has the potential to marginally decrease the cost of the program by eliminating the need for what may have otherwise been the most expensive[3] mitigation measure necessary to meet the cap. Therefore, in order for VRE purchases from facilities in the WCI region to deliver climate benefits beyond those achieved by the cap, those purchases must either lead to a reduction in the total number of allowances in the system or the emissions value of the allowances in the WCI system must be reduced.[4]

VRE consumers may be motivated to support renewable energy due to any one of various benefits renewable energy provides. These benefits include economic development ("green

[1] Western Climate Initiative, "Design Recommendations for the WCI Regional Cap-and-Trade Program", September 23, 2008.

[2] This assumes that those decisions happen in the context of a program structure that can guarantee incremental increases in renewable energy generation. Without a firm program structure the same generation mix may simply be allocated differently; zero-carbon electricity may get diverted to interested customers while the energy mix to indifferent customers may become slightly more carbon intensive as zero-emission sources are stripped out.

[3] And therefore likely the price setting mitigation measure.

[4] For example, starting in 2010 the SO_2 allowances, which were allocated in perpetuity by the Acid Rain program, are worth less than a ton under EPA's more recent Clean Air Interstate Rule in order to reduce emissions more rapidly than envisioned when the Acid Rain program was established.

jobs"), reduced dependence on fossil fuels ("energy independence"), reduced use of nuclear power, and numerous environmental benefits, including reduced (or avoided) greenhouse gas emissions.[5] Customers in the VRE market that are largely motivated by the desire to reduce greenhouse gas emissions, and that are aware that the presence of a cap and trade system will undermine those emissions benefits, may either stop purchasing VRE products or direct their purchases to sources in uncapped areas. As a result, the VRE market in the WCI region may be significantly impacted by the introduction of a cap-and-trade system. However, the extent of the impact on the VRE market is difficult to predict.

Support of the VRE market through a policy mechanism may be necessary to support a robust VRE market if consumer expectations of greenhouse gas reductions through voluntary purchases of renewable energy are not sufficiently met. This paper focuses on the key issues in deciding whether the VRE market should be actively supported by jurisdictions in the WCI cap-and-trade program and if so, how a policy mechanism that supports the VRE market should be designed and implemented.

3 Current Status of the Voluntary Renewable Energy Market

The VRE market started when some utilities began offering green power programs to their customers. These programs enabled their customers to support the development of "green power"—wind and other renewable energy generation—by paying the incremental cost of renewable energy above the cost of the conventional generation sources the utility would otherwise build. The utility in turn used the revenue to purchase electricity from renewable generators or to build renewable resources of its own. The introduction of renewable energy credits (RECs) which allowed the renewable attributes to be sold separately from the power enabled other players besides utility customers to participate by allowing buyers to pay for renewable energy generated anywhere in the United States. Renewable developers and utilities could sell RECs to anyone who wanted to be able to claim that, in principle, large percentages of their electricity came from green resources.

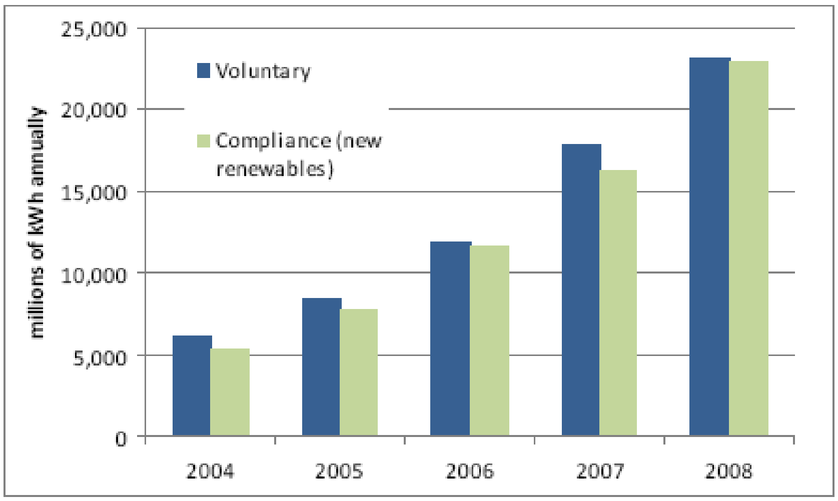
Today, green power programs are flourishing in the United States. More than 750 utilities offer them nationwide and 13 states mandate that their utilities offer them to customers, including the WCI Partner jurisdictions of Washington, Oregon, Montana, and New Mexico.[6] The average rate of participation in 2008 among eligible customers was 2.2% with the top ten programs reaching from 5% of customers up to a high of 21%. Actual energy sales amounted to almost 5 million MWh in regulated energy markets. In restructured markets, sales of green power tend

---

[5] Another factor driving VRE purchase decisions is whether they are perceived as producing incremental growth to the renewable energy market. For purposes of this paper, it is assumed that the VRE market provides enough value to the renewable energy market to produce additional renewable capacity beyond business-as-usual levels.
[6] See http://apps3.eere.energy.gov/greenpower/markets/state_policies.shtml.

to be in the form of RECs, which accounted for over 80% of VRE sales. Direct renewable energy sales in restructured markets and voluntary RECs combined amounted to almost 20 million MWh in 2008. Total VRE direct sales and RECs accounted for 0.7% of electricity sales nationally.[7] Residential customers dominated the markets for sales of energy while commercial customers dominated the REC markets, which have been growing much faster than the market for green energy products.

Figure 1: Comparison of Voluntary and Compliance Markets for Renewable Energy in the United States (Source: NREL)[1]

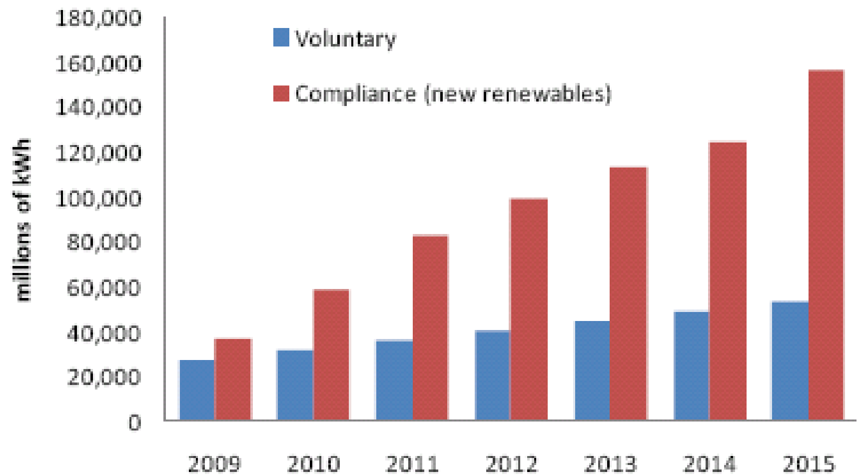


Note: Compliance market data sourced from Lawrence Berkeley National Laboratory (LBNL) (Barbose 2009)

Although green power programs have grown rapidly over the last ten years, renewable portfolio standards (RPS) in many states have served to drive a comparable amount of new renewable generation capacity (See Figure 1). Twenty nine states plus the District of Columbia now have legislation requiring load serving entities to supply increasing percentages of their resource portfolios with renewable energy with targets ranging from 10-25% by the 2020s. It is projected that these amounts will soon overtake the voluntary market (See Figure 2).

[7] US. DOE/EIA, 2009. Electric Power Monthly – Retail Sales of Electricity to Ultimate Customers: Total by End-Use Sector. http://www.eia.doe.gov/cneaf/electricity/epm/table5_1.html

Figure 2: Projected Voluntary Renewable Energy Market Relative to Compliance Market to 2015 in the United States (Source: NREL[1])



The voluntary market in Canada is relatively small compared to the US. A minority of provinces have utility green pricing programs or private green marketing programs. This reflects the fact that electricity generation already incorporates a large renewables component in most provinces. In addition, most provinces have adopted renewables procurement programs through government-owned utilities, with results similar to an RPS but without RECs, leaving limited opportunity for voluntary renewables. The degree of government ownership may also pose a barrier, in that private sector investment opportunities are limited in many provinces. Nonetheless a small number of retailers have been successful in establishing a voluntary market for renewable energy in some provinces. Voluntary renewables marketing has been most prevalent in the provinces with greater private ownership, including Ontario. The voluntary market for renewables in Canada today is estimated to be around 500,000 MWh/year[8].

4 Overview of VRE Support Policies under Cap-and-Trade

Because a significant portion of the VRE market has been driven by purchasers motivated by a desire to reduce greenhouse gas emissions[9], the implementation of cap and trade may harm the VRE market. WCI Partner jurisdictions must decide whether to support the VRE market to ensure that it is not disadvantaged by the adoption of a cap-and-trade program. The alternative is to simply allow the VRE market to adapt to the presence of cap and trade programs. These two approaches are described and discussed in detail below.

---

[8] Commission for Environmental Cooperation, *Fostering Electricity Markets in North America,* April 2007, http://www.cec.org/files/pdf/ECONOMY/Fostering-RE-MarketsinNA_en.pdf

[9] Historically a small number of VRE market participants (largely corporate buyers) have been responsible for the majority of VRE sales, while the majority of VRE market participants are individual residential green power customers with minimal purchases. The market behavior of these two groups of VRE market participants may vary, which greatly complicates predicting how the VRE market will respond to cap-and-trade programs.

4.1 Allowance Budget Adjustment Approach ("VRE Set Aside")

One possible policy response to support a VRE market would be to implement a VRE budget adjustment mechanism to allow the desired emission reductions to occur when VRE products are purchased from facilities subject to the cap. This is achieved by carving out a number of allowances from the Partner's base budget and setting those allowances aside to potentially be retired based on the estimated amount of voluntary renewable energy expected to either come on line in that Partner's state or province, or the amount of VRE products purchased by consumers in that state or province. Once the expected energy sales (in terms of MWhs) have been verified, allowances would be permanently retired. If there is a balance, those allowances could be released, or rolled over to the set aside for the following time period.

Historically programs that reserve a portion of an overall budget of allowances for a certain purpose within a cap-and-trade system have been called a "set aside", referring to the fact that this portion of the allowances are reserved and literally set aside for the designated purpose. Once allowances are set aside their value can be directed to support the designated purpose, or the allowances can be retired depending on how the program is designed. In the case of implementing a VRE budget adjustment mechanism for the purposes of ensuring that emission reductions accompany the VRE products in the marketplace, it is necessary that the allowances be retired. Following this tradition, most of the literature on addressing the VRE market focuses on "VRE set asides" to describe the VRE budget adjustment mechanism described here. This paper will continue this tradition and refer to the policy option described in this section as a "VRE set aside". It is important to understand that the VRE set aside referred to in this paper is what is known as an "unallocated set aside" because the allowances are specifically intended to be retired (and not allocated to a programmatic use). Using the allowances set aside from the jurisdiction's overall budget for other purposes, such as selling them and using the revenue (except for any unused balance), would defeat the purpose of the VRE set aside program.

Determining the number of allowances to set aside requires two steps. First, the implementing jurisdiction must estimate the future size of the VRE market in its jurisdiction. Market data and tracking systems can be used to estimate, track and verify voluntary renewable energy expected to come on line and enter the VRE marketplace. These estimates can assist WCI Partner jurisdictions in establishing the number of allowances to set aside for a given year. For example, WCI Partner jurisdictions could use data from their energy agencies or organizations such as the Center for Resource Solutions.[10] The second step is the use of an emission factor to convert the MWh estimate of VRE sales to metric tons of greenhouse gases. Emissions factors are discussed further in Section 6.5.

[10] Center for Resource Solutions; 2008 Green E Verification Report; http://www.green-e.org/docs/2008%20Green-e%20Verification%20Report.pdf

In order for allowances to be retired from the set aside, VRE market participants will need to submit verification reports of the VRE sales. This could be accomplished via tracking systems such as the Western Renewable Energy Generation Information System (WREGIS). WREGIS covers the Western Electricity Coordinating Council region (the western grid) and generates a REC for every MWh of renewable energy generation that is verified.

Table 2: Example of Voluntary Renewable Energy Set Aside Mechanism

Estimated VRE MWh sold in 2012	Example Set Aside Emission Factor	Allowances in 2012 Reserve	Actual VRE MWh sold in 2012	2012 Allowances Retired by Jurisdiction	2012 Allowances Unused
1,000,000	0.40 tCO2e	400,000	900,000	360,000	40,000

Table 2 provides an example of how a voluntary renewable energy set aside mechanism could work. Based on information provided by VRE vendors, the state or province estimates approximately 1,000,000 MWh of electricity (or a combination of direct energy sales and RECs) will be sold into the voluntary renewable energy market in 2012. The jurisdiction has determined that 0.40 metric tons CO_2e per MWh will be the emission rate used to retire allowances from the set aside for every MWh of voluntary renewable energy generated annually. Thus, the jurisdiction sets 400,000 allowances aside in the VRE reserve account. At the end of the year, the jurisdiction certifies that only 900,000 MWh of VRE were sold in 2012. In this case, only 360,000 allowances will be retired and the remainder is released or rolled over to 2013.

If a set aside is created for the VRE market, it may set an interesting precedent. Assuming that most VRE buyers are primarily motivated by a desire to reduce greenhouse gas emissions, the rationale for creating a VRE set aside could apply equally to other products and actions that reduce emissions. For example, many households and firms undertake measures to reduce their energy consumption. Without a set aside for energy efficiency, it could be argued that some of these households and firms may no longer implement efficiency measures knowing that if they do, total greenhouse gas emissions will not change.

A counterargument to this example is that energy efficiency is generally cost-effective, and those who implement efficiency measures benefit from their actions. Purchasers of VRE products, on the other hand, pay a premium for the superior environmental attributes of renewable energy, in effect providing a public good at their own expense. This difference may justify the creation of a set aside for VRE but not energy efficiency. However, there are other examples where consumers pay a premium for environmental attributes that are not cost-effective. Presumably, purchasers of hybrid vehicles do so largely for the environmental advantages that such vehicles provide because in most cases, these vehicles only recoup their price premiums over long time horizons (if ever). If a VRE set aside is established, vendors of hybrid vehicles may also ask for a hybrid-vehicle set aside using similar logic.

For these reasons, WCI Partner jurisdictions that choose to implement a VRE set aside may need to provide a rationale for limiting such a set aside mechanism to only VRE products. Otherwise additional set asides for different classes of products may be required, necessitating tracking the sales of a wide variety of products, and potentially leading to an unacceptably large pool of unallocated allowances dedicated to set asides.

4.2 No Intervention Approach

There are various reasons that WCI Partner jurisdictions may choose not to create a VRE set aside. Some jurisdictions may have little VRE market activity or no VRE market at all. Others may decide that the future growth of renewable energy will be driven mostly by mandatory renewable portfolio standards or other policies that put a price on greenhouse gas emissions. Others may not want to establish a program that potentially reduces the number of total allowances available for distribution or auction, including the possibility of losing the value of those allowances to support other types of programs for promoting renewable energy[11]. A VRE set aside may also impact allowance prices (which may in fact help to offset the fiscal impact of a reduced number of allowances), and can potentially have some impact on the opportunity for firms that reduce their emissions to sell excess allowances. However, the economic effects of a VRE set aside – both positive and negative -- are exceedingly difficult to predict and depend on the complex interactions of the supply and demand of allowances. Finally, some jurisdictions may conclude that the VRE market will continue to be viable for a number of reasons regardless of whether total greenhouse gas emissions reductions can be guaranteed to take place when purchases of renewable energy occur.

One reason the VRE market may continue to be viable is that some buyers may value other environmental or socioeconomic benefits associated with renewable energy more than greenhouse gas reductions and would continue to buy VRE products from jurisdictions participating in a cap-and-trade system even if greenhouse gas reductions are not ensured. Other buyers may be more concerned with their personal “carbon footprints” than with the impacts that their purchase decision have on total greenhouse gas emissions. This is because from the perspective of an individual consumer, buying VRE products still reduces the carbon footprint of the individual buyer even if total emissions (at the jurisdictional or regional level) do not fall.[12] However, it is important to note that these motivations would seem to be more likely for residential and commercial consumers, which have historically made up a small

[11] For example, increased funds for existing public purpose funds supporting renewable energy projects.
[12] This assumes the purchase is from a jurisdiction participating in the cap-and-trade program.

proportion of the total volume of VRE purchases. Large corporations have appeared to be more focused on greenhouse gas reduction benefits[13], although the behavior of large corporate customers in the VRE market in the future is unclear (especially when some of these corporate customers may be regulated entities in any future cap-and-trade program).

In the jurisdictions that choose not to implement a VRE set aside, VRE markets may adapt in several ways. VRE certifiers face the option of either de-certifying renewable generators from eligibility in their programs or changing the way they market VRE from capped jurisdictions. For example, VRE marketers could sell RECs from capped jurisdictions with the understanding that no emission reductions claims can be made when those RECs are used. Purchasers of these RECs should understand that while claims of using "renewable" or "zero-greenhouse gas" power would continue to be valid, any claim to an emission reduction would not be valid. Alternatively, generators or marketers of VRE products can potentially obtain and retire a sufficient number of emission allowances within the cap-and-trade system to provide the emissions reduction advertised or otherwise conveyed to the buyer of those renewable energy products (if there is an auction or other means to obtain allowances). It would be up to each seller in the VRE market to decide whether or not they want to package a given amount of greenhouse gas emission reductions with their renewable energy products, and they would obtain the appropriate amount of allowances and bundle or retire them to meet that claim.

If there is concern that, in the absence of a VRE set aside program, some sellers of VRE products may claim emission reductions for which they have no basis there are several options. One option may be to simply enforce existing consumer protection law at the state or provincial level. In the USA the National Association of Attorneys General's (NAAG) has already determined that making invalid claims to emission reductions may violate existing consumer protection laws and has promulgated guidance for states on enforcement options[14]. Therefore, it may not be necessary for a WCI Partner Jurisdiction to take any additional action in order to ensure that a legal basis exists for enforcing the market to ensure that valid emission reduction claims are tied to actual emission reductions.

Government intervention in the form of an explicit requirement to obtain allowances before making emission reduction claims may be an another option if it is felt that existing law or rules are not sufficient to ensure that false claims are not made in the VRE market. Since it is likely that the provisions for this type of government-backed guarantee would happen in a legal or regulatory framework outside of the cap-and-trade system (e.g., consumer fraud rules) this approach would likely not involve including a program element specific to the VRE market in the cap-and-trade program. Therefore, even if a VRE set aside program is silent on how

[13] Based on corporate press releases (see submitted comments), but more precise data are lacking.
[14] NAAG, *Environmental Marketing Guidelines For Electricity*, December 1999.

environmental claims of VRE marketers are addressed, it is important to understand that VRE marketers may be subject to rules or regulations outside of the cap-and-trade system that will likely prevent them from making false emission reduction claims in the VRE market.

It is important to note that an approach of requiring that allowances be obtained (either explicitly or implicitly through existing law or regulations) for VRE products sold to consumers would increase the price premium for VRE products and disadvantage renewable facilities in capped jurisdictions that seek to compete in the VRE market. Even if it is not required by law or regulation, it is possible that many VRE sellers would include allowances as part of their VRE product offering. As a result, the VRE market in the WCI region would be impacted, although it is difficult to predict the extent to which the overall market would be reduced.

5 Status of VRE Approaches in Other Trading Schemes and Proposed Federal Legislation

The following existing or proposed cap-and-trade programs were reviewed to identify how they address the VRE market prior to the development of the recommendations in this paper.

- Regional Greenhouse Gas Initiative (RGGI), the greenhouse gas emissions cap-and-trade program currently in place in the Northeastern United States.
- European Union Emissions Trading Scheme.
- American Clean Energy and Security Act of 2009 (H.R.2454), commonly referred to as Waxman-Markey, which was passed by the U.S. House of Representatives.
- Kerry-Lieberman, the U.S. Senate version of American Clean Energy and Security Act of 2009 that is still undergoing debate and revision in the US Senate.
- The proposed Australian Carbon Pollution Reduction Scheme.

Table 3 below summarizes how these proposals or programs address the VRE market:

Table 3: Treatment of Voluntary Renewable Energy in Cap-and-Trade Systems and Proposals

Cap-and-trade program or proposed legislation	Voluntary Renewable Energy Market Directly Addressed?	Policy Mechanism Used to Address VRE Market	Potential Indirect Means of Addressing VRE Market
US Regional			
Regional GHG Initiative (RGGI)	Yes	Set aside as optional element of RGGI Model Rule.	Not necessary
European Union			
EU Emissions Trading System (EU ETS)	No	None	Unclear
US National Legislation and Proposals			
American Clean Energy And Security Act of 2009 (Waxman-Markey)	No	None	Allowances are distributed to states for renewable energy. States may use those allowances to implement a program like a VRE set aside at a state-by-state level.
Kerry-Lieberman (Senate version of ACES)	No	None	Discussion draft only, presumably similar to Waxman-Markey
Australia National Legislation			
Carbon Pollution Reduction Scheme (proposed)	Yes	By taking GreenPower (official VRE program) purchases above 2009 levels into account when setting program's emission caps.	Not necessary

5.1 Overview of the Australian VRE Market Approach

Australia's proposed greenhouse gas emission trading scheme is referred to as the Carbon Pollution Reduction Scheme (CPRS). This trading scheme would potentially reduce emissions from approximately 5 to 25 percent of 2000 levels by 2020, depending on the status of international treaty negotiations on a new binding global emissions reduction treaty.

The framework contains a provision for tightening the cap to recognize the contribution of additional renewable energy purchases.[15,16] The scheme sets a baseline for renewable energy purchases at the 2009 levels and factors renewable energy into setting the cap. If purchases go over that baseline the cap will be adjusted to recognize these contributions. If purchases fall below the baseline there will not be an adjustment of the cap.

Twice in 2009 the Australian Senate voted against establishing the program. The new Australian Prime Minister Julia Gillard has indicated she intends to pursue the legislation again.

[16] http://whitepaper.climatechange.gov.au/emissionstrading/householdassistance/pubs/fs_GreenPower.pdf

5.2 Overview of the RGGI Model of a VRE Set Aside

The RGGI Model Rule contains a provision for a VRE set aside program. In RGGI the number of allowances retired is pegged to the CO_2 emissions that would have been avoided in the absence of the cap. This is calculated using two types of data:

- The amount of voluntary renewable energy purchased (typically in megawatt-hours, or MWh); and,
- The emissions rate of the electric generating source that would have run had the renewable energy not been purchased (expressed in tons CO_2/MWh).

Because the number of allowances reserved for the set aside is based on *ex ante* estimates of VRE sales, it is possible that the number may be too high or too low in any given year. The Model Rule contains provisions to adjust the size of the VRE set aside in subsequent years accordingly.

These set aside provisions are an optional part of the RGGI Model Rule, and therefore participating jurisdictions are not obligated to adopt them. However, at this time 9 of the 10 RGGI states have adopted them.

6 Implementation of VRE Set Asides in WCI Jurisdictions

A key decision made by the WCI Partner jurisdictions in the "Design Recommendations for the WCI Regional Cap-and-Trade Program" is that each jurisdiction has discretion over how the allowances apportioned to that jurisdiction are to be used. Other than agreeing that "some portion" of the apportioned allowances will be used for purposes like supporting renewable energy, which a VRE set aside would fit under, there is currently no common agreement among the Partner jurisdictions to require a VRE set aside in the design of each jurisdiction's cap and trade program. In keeping with the WCI design recommendations, it is therefore up to each individual WCI Partner jurisdiction whether or not to implement a VRE set aside program in their jurisdiction. For those jurisdictions that do choose to put in place a VRE set aside program there are a number of design issues associated with implementation. The remainder of this paper focuses on those key design issues that will need to be examined by any WCI Partner jurisdiction that chooses to implement a VRE set aside program.

An important consideration in examining the design elements of a VRE set aside program is the extent to which certain elements need to be harmonized across participating jurisdictions. In other words, for each of the design elements examined below can each jurisdiction make its own policy choice without impacting the effectiveness of a VRE set aside program in either another WCI Partner jurisdiction or the WCI region as a whole? Particular attention to this question is given as each design issue is addressed. For comparison, the approach that RGGI took for each of these points of implementation is also summarized. Finally, the draft recommendation originally proposed to WCI Partner jurisdictions for each design question is given, as well as the final recommendation of the WCI Partners, after considering stakeholder comments.

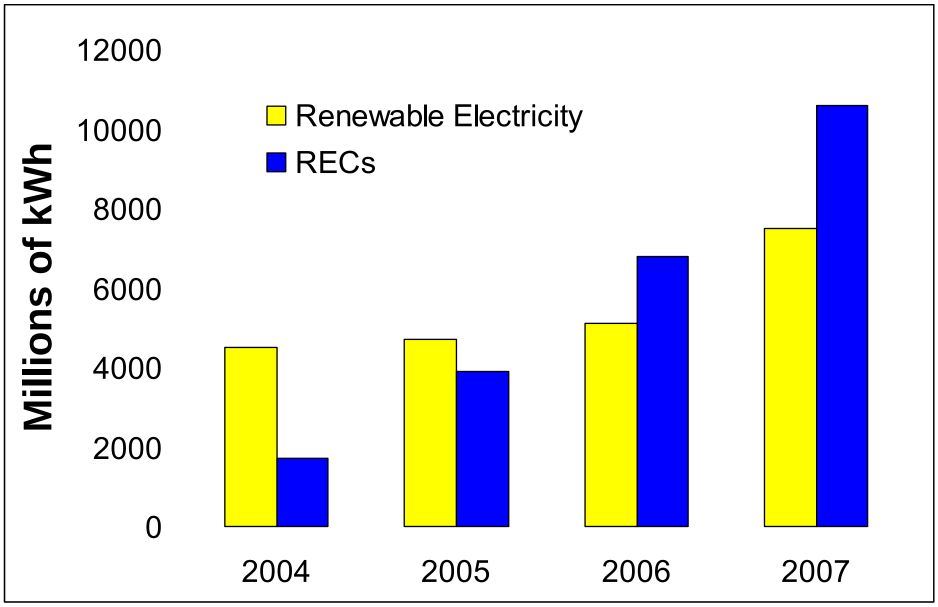
6.1 Accounting Mechanism for the VRE Set Aside

There are two broad classes of products in the voluntary renewable electricity market: renewable electricity and renewable energy credits (RECs). RECs are the renewable attributes created by the generation of electricity from a renewable source and serve as proof of generation of (typically) one MWh of renewable energy generation. They can be sold bundled with the electricity underlying the REC or unbundled and bought and sold independently of the electricity produced. Unbundled RECs are often re-bundled with generic electricity to rebrand the generic electricity as green electricity. RECs may be defined solely by their primary attribute (i.e., that a MWh of renewable electricity was generated) or they may include reference to secondary attributes such as the greenhouse gas emissions avoided by displacing conventional generation. The inclusion of secondary attributes varies across states with respect to RECs used for compliance with renewable portfolio standards, but RECs used in the secondary market generally include reference to the secondary attributes.

When implementing a VRE set aside program, a decision has to be made as to what "currency" the program should use. One option is to base the program on actual renewable energy sales, and typically the basis for measuring VRE transactions are documents such as the sales receipt, sales contract, or other similar proof of the transaction. Another option is to use RECs as the currency to serve as the proof of renewable generation. This is convenient since the primary purpose of a REC is to serve as an easily transferable and trackable proxy for other legal documents (such as sales contracts) which provide the legal basis for ownership of the renewable energy in the voluntary renewable energy market. For this reason, renewable energy programs of all types (voluntary and mandatory) are increasingly using RECs. According to the National Renewable Energy Laboratory[17], about 95 percent of residential consumers purchased renewable electricity (typically through green power utility programs) instead of unbundled RECs in 2007. However, nonresidential customers clearly prefer unbundled RECs, which amount to over 90 percent of sales for these customers. REC sales (99% of which are to nonresidential consumers) accounted for nearly three-quarters of all voluntary renewable product sales in 2007 (see Figure 3).

[17] Lori Bird, Claire Kreycik, and Barry Friedman. Green Power Marketing in the United States: A Status Report (11th Edition). National Renewable Energy Laboratory. http://www.nrel.gov/docs/fy09osti/44094.pdf

Figure 3: Estimated Annual Green Power Sales 2004-2007[18,19]



RGGI Model Rule

The RGGI model rule allows the use of both renewable electricity[20] and unbundled RECs. Some RGGI states rely primarily on the use of RECs for tracking VRE purchases but others allow purchases of both renewable electricity and unbundled RECs to qualify for their programs.[21]

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should include a requirement that the measurement of voluntary renewable energy purchases that form the basis of any allowance distribution be based, first and foremost, on transactions verified through established REC tracking systems that span some or all of the WCI region (e.g., WREGIS). In addition, to account for those purchases that are not tracked through an established system (or for regions without such a system) provision should be made to accept transactions that are certified through a third-party verification system for voluntary renewable energy that includes, at a minimum, a requirement that the seller must attest to not having previously sold or otherwise transferred the greenhouse gas benefits of the renewable energy product.*

---

[18] Ibid.
[19] 2006 sale figures for renewable electricity may be underestimated because of data gaps (Ibid).
[20] Note that this means both renewable electricity purchased directly and bundled RECs (REC + electricity).
[21] RGGI State Set-Aside Provisions for Voluntary Renewable Energy (VRE). Draft August 21, 2009. http://www.epa.gov/greenpower/documents/events/rggi_status_table.pdf

The decision as to whether to use RECs or the renewable electricity (i.e., using contracts as the proof of generation) as the principal mechanism for tracking the quantity of VRE applicable to the set aside is one design feature where harmonization across WCI Partner jurisdictions is critical. Non-harmonization raises the potential for double-counting the renewable attribute because one jurisdiction may retire allowances for the electricity generated while another retires allowances for the RECs purchased for the same electricity. Harmonization ensures that each MWh of renewable energy in the voluntary market is claimed only once by a final user.

Final Recommendation

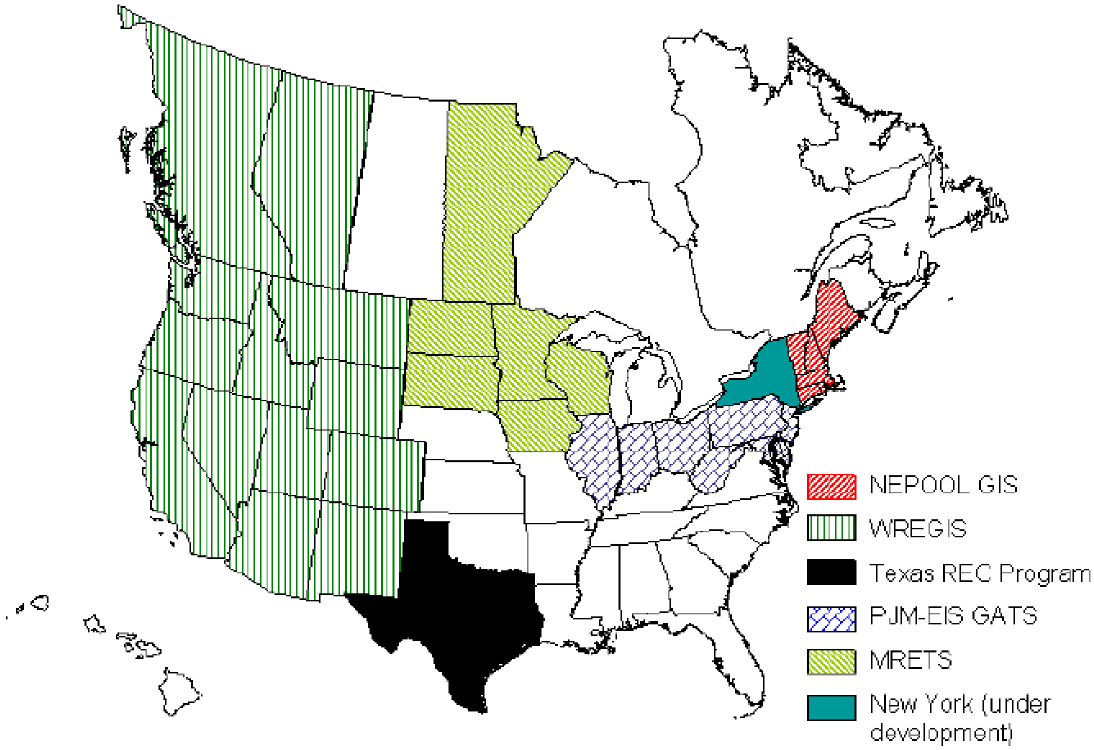
> *WCI Partner jurisdictions that choose to implement a VRE set aside should Include a requirement that the measurement of voluntary renewable energy purchases that form the basis of any allowance retirement be based on transactions verified through established REC tracking systems that span some or all of the WCI region (e.g., WREGIS).*

With the launch of the North American Renewables Registry, and the general growth of REC tracking systems throughout the US and Canada, it was felt that the original draft recommendation that allowed for both REC tracking systems and third-party verification systems was unnecessarily broad. The added assurance provided by formal REC tracking systems is worth requiring for any VRE set-aside program, especially since all renewable energy projects in North America now have access to at least one formal REC tracking system.

6.2 Defining Eligible Renewable Energy Project Types

WCI Partner jurisdictions will need to decide which types of voluntary renewable energy projects should be encouraged through a VRE set aside. Establishing common criteria is challenging as jurisdictional RPS criteria vary, suggesting disparity about the types of renewable energy that each region wants to encourage. Requiring that renewable projects meet RPS criteria where applicable may provide additional assurance that allowances are only retired for desired projects so long as those RECs can be retired in a regional or North America-wide tracking system (see Figure 4).

Figure 4 -- Map of Regional Tracking Systems (Source: NREL)[22]



In addition, VRE certifying organizations (typically independent non-profit organizations or government agencies) have their own eligibility criteria that they are likely to overlay on any state or jurisdictional eligibility criteria.[23,24] In both cases, the eligibility criteria are likely to address not only the types of eligible renewable energy, but also provide some assurances that the renewable projects used for voluntary program purposes are authentic and also meet additional criteria which consumers may find desirable. For example, both the Canadian EcoLogo and the Green-E certification program for VRE certify that the projects that meet their requirements are "additional", i.e., that those projects were not required by government mandate and that the VRE purchase is helping to advance the renewable energy market above and beyond what would be happening without the purchase.

One issue worth noting, which is an ongoing concern with tracking and verification systems used in both the mandatory and voluntary renewable energy markets, is some of the market barriers that small-scale "behind the meter" renewable energy systems (typically residential

[22] Lori Bird and Elizabeth Lokey. Interaction of Compliance and Voluntary Renewable Energy Markets. National Renewable Energy Laboratory. October 2007. http://apps3.eere.energy.gov/greenpower/pdfs/42096.pdf
[23] Green-e certification criteria can be found at http://www.green-e.org/docs/energy/Appendix%20D_Green-e%20Energy%20National%20Standard.pdf
[24] An example of this can be found in Green-e's RGGI update http://www.resource-solutions.org/pressreleases/2008/120508-2.htm.

solar photovoltaic systems) have encountered in entering the VRE marketplace. In some cases the additional administrative costs or process issues associated with either (or both) the REC tracking systems used for the mandatory renewable market or the certification programs in the voluntary market have prevented the owners of these installations from becoming VRE market participants. If the VRE set aside policy option is focused solely on addressing the traditional VRE market, the VRE set aside option may not be of direct assistance to all entities that voluntarily produce renewable energy. Nonetheless, the decisions to install these smaller systems may be driven by similar motivations as in the VRE product market (i.e., greenhouse gas emission reductions). Therefore it may be worth including behind the meter distributed resources, such as residential systems, in the list of eligible resources for the VRE set aside to further encourage their growth. Since these systems are generally not registered with generation information systems like WREGIS and may not be configured to report output data at all, quantifying these systems for inclusion in the VRE set aside can be a challenge. WCI Partner jurisdictions that include small-scale solar or wind systems among their VRE set aside eligible resources will have to determine whether to limit eligibility to systems with metered output or whether to accept generation estimates for unmetered systems.

<u>RGGI Model Rule</u>

The RGGI Model Rule limits eligibility for retirement from the VRE set aside to electricity generated from biomass, wind, solar thermal, photovoltaic, geothermal, hydroelectric facilities certified by the Low Impact Hydropower Institute, wave and tidal action, and fuel cells powered by renewable fuels. However, this particular definition was intended to be optional. Several states have adopted it, while others have limited eligibility to renewables that meet their own RPS standards.

Draft and Final Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should define their own eligibility requirements for their VRE set aside programs. They may choose to mirror existing RPS or other statutory definitions or to define a separate list of qualifying project types.*

Unlike the choice of accounting mechanism, jurisdictional consistency on eligibility criteria is less important. Marketers of VRE products will adapt to whatever eligibility criteria jurisdictions adopt. If a facility is eligible for set aside retirements, marketers will know that emission reduction claims are supported and can market energy or RECs from the facility accordingly. A modest advantage to harmonization is that potential project developers would not have to keep track of eleven different sets of eligibility criteria when financing and developing projects in WCI Partner jurisdictions.

6.3 Jurisdictional Retirement Responsibility

Another variable to consider when designing a VRE set aside is whether the jurisdiction responsible for retiring allowances is determined by the location of the purchaser or the generator. For example, when a renewable facility in a WCI Partner jurisdiction produces RECs that are used in the VRE market and then retired by an entity in another WCI Partner jurisdiction, which jurisdiction bears the responsibility for retiring allowances? Either approach is feasible, but the underlying rationale and effect differ. The purchaser-based approach serves to assure consumers in the jurisdiction where the VRE set aside is based that emission reductions occur regardless of the location of the renewable electricity facility. The generator-based approach supports renewable energy development in the jurisdiction where the VRE set aside is based by allowing emission reduction claims in the marketing of the VRE product to customers.

6.3.1 Purchaser-Based Responsibility

Under the purchaser-based approach, a WCI Partner jurisdiction retires allowances whenever a retail customer, utility, or VRE aggregator serving customers in the jurisdiction retires RECs from the VRE market from a facility in a capped jurisdiction.[25] The application of the set aside could be limited by various geographic criteria. If the goal is to both protect in-jurisdiction consumers and promote renewable development in the jurisdiction, the set aside could be limited to purchases from in-jurisdiction generators. If adoption of the set asides is widespread in the WCI Partner jurisdictions then jurisdictions may opt to apply the set aside to purchases from sources in any WCI Partner jurisdiction. Alternatively, this reciprocity could extend further to apply the set aside to purchases from any capped source (assuming that the capped source selling RECs in the VRE market is not already supported by a generator-based set aside).

This system is relatively simple where there is a direct connection between the in-jurisdiction person or entity retiring the RECs (or purchasing the electricity) and the facility. However, the fact that some VRE products consist of RECs purchased from a large number of facilities by VRE marketers complicates matters. If, for example, a REC retailer buys 5,000 RECs from capped jurisdictions and 5,000 RECs from uncapped jurisdictions, and then sells 5,000 RECs to customers in uncapped jurisdictions and 5,000 RECs to customers in a capped jurisdiction with a purchaser-based set aside, how many RECs should the set aside jurisdiction count when it retires allowances?

One option would be to assume that all customers receive the same share of RECs from each facility, that is, that all of the RECs are thoroughly mixed and then sold to customers. If the set aside jurisdiction assumes that all customers receive the same mix of renewables, then the

[25] Renewables from uncapped regions do not require allowance retirement because their generation does avoid additional fossil-based electric generation.

jurisdiction would apply 2,500 RECs toward its set aside on the basis that half of the 5,000 RECs used by customers in the jurisdiction came from capped areas and half came from uncapped areas. However, that would entail that 2,500 RECs from a capped area were sold to customers in uncapped jurisdictions, necessitating that those RECs could not be associated with claims of emission reductions.

Another option would be to allow REC marketers to specify the renewable generators used to supply RECs to their various customers. Under this approach, REC marketers in a purchaser-based model are likely to direct the maximum amount of RECs from capped areas to those jurisdictions that implement a set aside to ensure that no RECs are left without credible emission reduction claims.

The participation of large organizations with locations in multiple jurisdictions may add further complication to accounting under the purchaser-based approach. For example, if the headquarters of a large corporation is located in a set aside jurisdiction, and the headquarters coordinates the purchase of several hundred thousand RECs for its facilities throughout North America, a VRE marketer might report all of those RECs as being consumed in the set aside jurisdiction. If the jurisdiction does not believe that it should have responsibility for retiring allowances for all of the RECs in this example, either the marketer or the customer could provide information on the customer organization's consumption within the jurisdiction.

If the rationale for the set aside is to protect consumers in WCI Partner jurisdictions, VRE consumers based in a WCI Partner jurisdiction could simply buy RECs from uncapped jurisdictions. However, to the extent that demand for VRE is driven by customers primarily motivated by contributing to absolute greenhouse gas reductions, this "no action" solution to protecting consumers will push investment in renewable facilities serving the voluntary market toward uncapped jurisdictions. Purchaser-based retirement responsibility would not cover sales of RECs from facilities in the jurisdiction to VRE consumers in uncapped areas or capped areas without a set aside.

Because the RGGI Model Rule provisions do not retire allowances for exported renewable products, renewable energy generated inside the RGGI region will not have an emissions benefit when sold outside the RGGI region unless allowances are purchased and retired by the renewable energy marketers. This has led Green-e to announce that they are no longer certifying renewable energy generated inside the RGGI region and sold outside the RGGI region.[26] It is not clear whether this will have practical implications for the RGGI states in the short-term. High REC prices inside several RGGI states indicate that in-region supply of certain

[26] Green-e Energy Policy Update: RGGI State Set-Aside Provisions for Voluntary Renewable Energy Sales and Green-e Energy Eligibility. Green-e. December 5, 2008. http://www.resource-solutions.org/where/pressreleases/2008/120508-2.htm

types of renewables is already struggling to meet demand. This may be an indicator that the RGGI states are not currently strongly situated as net exporters of renewable energy products.

Purchase and generation data for WCI partner states available from Green-e and the National Renewable Energy Laboratory suggest that WCI Partner US States on the whole appear to generate more renewable products for sale on the voluntary market than they purchase from it, meaning that they are a net exporter of voluntary renewable energy products. Constraining retirement to in-region purchases could disrupt the market for renewable generation in WCI Partner jurisdictions.

Unfortunately, comparable data do not appear to be available for the Canadian WCI Partner jurisdictions, making it challenging to determine whether constraining retirement to in-region purchases would disrupt the market for renewable generation in Canada.

6.3.2 Generator-Based Responsibility

Under the generator-based approach to retirement responsibility, a WCI Partner jurisdiction would retire allowances whenever RECs from a facility in its territory were retired by customers in the voluntary market. Like the purchaser-based approach, the set aside could be limited to purchases by customers in the same jurisdiction, other WCI Partner jurisdictions, other capped jurisdictions, or to apply regardless of the customer's location. One advantage to a generator-based approach with no limitation on the customer's location is that it enables renewable generators in the jurisdictions to be certified for the VRE market without any further need to track where VRE sales ultimately occur (i.e., where RECs are retired). If set aside jurisdictions impose a geographic limitation, then generators participating in the VRE market risk having some portion of their output being decertified (or marketed as a different "no avoided emissions" product) based on the purchaser's location. All other options introduce an additional complication of having to track either where the RECs used in each jurisdiction were generated or where the purchasers of RECs from generators in each jurisdiction are located.[27]

The WCI Partners have recommended that no greenhouse gas emissions be attributed to "null" renewable energy from which RECs have been unbundled and sold separately.[28] Consequently, renewable facilities that are not located in a WCI Partner jurisdiction but sell their power on a specified basis into a Partner jurisdiction also would not avoid greenhouse gas emissions. WCI Partner jurisdictions could consider expanding the scope of facilities eligible for their VRE set asides to include the output, or portion thereof, imported into their jurisdictions from renewable energy facilities that participate in the VRE market.

[27] Or where the renewable energy is generated if the accounting system for the VRE set aside is not based on RECs.
[28] Treatment of Renewable Energy Certificates in the WCI Cap-and-Trade Program.
http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/

Table 4 summarizes the combinations of jurisdictional retirement responsibility and geographic eligibility.

Table 4: Comparison of Options for Geographic Treatment of Voluntary Renewable Energy

Limitation→ ↓ Responsibility	Purchased from/sold to own jurisdiction	Purchased from/sold to any WCI jurisdiction	Purchased from/sold to any capped jurisdiction	Purchased from/sold to any jurisdiction
Purchaser-Based	Equivalent to gen-based, need to account for number of RECs from in-jurisdiction sources	Need to account for number of RECs used from sources in WCI Partner jurisdictions	Need to account for number of RECs used from all capped (e.g. RGGI) sources	N/A (no need to have purchaser-based version because purchases from uncapped jurisdictions do not need set aside)
Generator-Based	Equivalent to purchaser-based, need to track where RECs are retired	Need to track where RECs are retired	Expands application to sales to entities in other capped jurisdiction such as RGGI or Midwestern Accord jurisdictions, need to track where RECs are retired	Generators receive one certification, good for sales to all jurisdictions, no need to track where RECs retired

6.3.3 Implications of Geographic Treatment Options

In-region renewable development may be maximized under a purchase approach by retiring allowances only for renewable energy generated in the region, and under a generator approach by retiring allowances for all renewable generation including exports. Retirement for out-of-region generation is only necessary when renewables are located in a capped state, and then the question is which program should bear the responsibility for the retirement.

<u>RGGI Model Rule</u>

The RGGI Model Rule uses a purchaser-based responsibility in which each state retires allowances for VRE purchases occurring in the state. The RGGI Model Rule provides for the retirement of allowances for in-state sales regardless of where the REC is generated. Because these RECs may come from uncapped states, the RGGI Model Rule may be retiring too many allowances for in-region purchases. However, some RGGI states have adopted VRE set aside provisions that only retire allowances for generation in RGGI states, which avoids this problem.[29]

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should retire allowances using a generator-based approach in which allowances are retired whenever RECs from a facility in that Partner jurisdiction's territory are purchased and retired by a customer in the VRE market with no limitation on the customer's location. Alternatively, the retirement should be based on VRE sales if RECs are not used.*

Harmonization on the jurisdictional responsibility is essential to avoid introducing considerable and unnecessary confusion into the VRE market. Consider two WCI Partner jurisdictions states, one with a purchaser-based set aside (Jurisdiction A) and the other with a generator-based set aside (Jurisdiction B). If RECs from a generator in Jurisdiction B are retired by an entity in Jurisdiction A, then both jurisdictions would retire allowances for the same MWhs. If RECs from a generator in Jurisdiction A are retired by an entity in Jurisdiction B, then neither jurisdiction would retire allowances.

This draft recommendation has some interesting implications for both the WCI Partner jurisdictions and RGGI states. There is considerable variation among the RGGI states in how they treat voluntary purchases of renewable energy generated outside their borders. While some states only retire allowances for renewable energy generated within the RGGI states, others do not constrain geographic scope in this manner. The RGGI voluntary renewable energy program is purchaser-based. Therefore, no RGGI state retires allowances to account for in-state renewable generation that meets out of state voluntary renewable energy demand. As a result, the RGGI rule does not contemplate a scenario under which allowances have already been retired to account for renewable energy sold into the voluntary market. Therefore, it is not clear whether those states would retire allowances for renewable energy based in a WCI Partner jurisdiction that is sold into the RGGI market if a WCI Partner jurisdiction has already retired allowances to account for that electricity. While there is an environmental benefit to retiring more allowances than is warranted for an individual purchase of voluntary renewable energy, the RGGI and WCI Partner jurisdictions have a financial interest in not retiring more allowances than is warranted. Therefore, it could be advantageous for any WCI Partner jurisdictions that plan on adopting a generation-based VRE program to work with the RGGI states that retire allowances for generation outside the RGGI region to collaboratively determine an appropriate path forward.

---

[29] RGGI State Set-Aside Provisions for Voluntary Renewable Energy (VRE). Draft August 21, 2009. http://www.epa.gov/greenpower/documents/events/rggi_status_table.pdf

Final Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should retire allowances using a generator-based approach in which allowances are retired whenever RECs from a facility in that WCI Partner jurisdiction's territory are purchased and retired by a customer in the VRE market with no limitation on the customer's location. WCI Partner jurisdictions should also consider requiring that renewable energy produced by VRE-eligible facilities in a non-WCI Partner jurisdictions and sold on a specified basis to the WCI Partner jurisdiction be counted as if those facilities were located in the WCI Partner jurisdiction.*

The final recommendation was expanded with an additional option for jurisdictions to consider that reflects the concerns raised by some stakeholders about facilities located in non-Partner jurisdictions that sell their energy into Partner jurisdictions. Because this additional program option focuses only on facilities that import electricity on a specified basis it is not critical that this additional option be harmonized among Partner jurisdictions, i.e, double counting would not be an issue since only the portion of renewable imports relevant to that jurisdiction are included. Therefore, this final recommendation calls for the harmonized use of a generator-based approach to accounting for the VRE set aside, but allows for an optional expansion of that set aside to capture all renewable facilities that are not reducing capped emissions.

6.4 Retirement Limits

Because establishing a VRE set aside involves removing allowances that could be used for other purposes, such as funding energy efficiency or R&D, jurisdictions may wish to limit the amount of allowances placed in the VRE reserve. In addition, jurisdictions may consider limiting the number of compliance periods the program will remain in effect.

6.4.1 Upper Limit on Retirement Amount

As described in Section 4.1, a key component to establishing a VRE set aside is determining the total allowances that would be dedicated for retirement to support the VRE market. However, the need to access allowances for compliance purposes may lead covered entities to resist dedicating a large number of allowances to support one sector of the economy. For that reason WCI Partner jurisdictions may choose to limit the amount of allowances that are dedicated to supporting the VRE market.

Many of the RGGI states have adopted either a constant limit on the number of allowances reserved for the VRE set aside or a portion of the budget, ranging from 1 to 2 percent. Given the regional strength as an exporter of voluntary renewable products, if the WCI Partner jurisdictions adopt VRE set aside provisions that acknowledge out-of-region purchases of in-region renewable generation, then a larger set aside might be appropriate (as a fraction of electricity emissions). However, it is important to note that the WCI program is an economy-wide program and therefore its base budget is much larger than electric sector emissions. This means that more VRE sales can be supported with 1% of the budget from the economy-wide WCI program than 1% of the budget from the RGGI program, which only covers the electric sector.

Establishing limits does provide planning certainty to regulated entities. However, while short-term predictions about the amount of electricity generated in a jurisdiction for the VRE market may be reasonably accurate, uncertainty increases substantially the further out in time predictions are made. It is helpful to divide the issue of setting limits into long-term and short-term timeframes. In the long-term, a limit can be maintained by closing off the VRE set aside to new projects once the amount of VRE generation supported by the set aside begins to approach the limit. In order to provide certainty to VRE project developers, jurisdictions that set limits should make updated estimates of the remaining VRE capacity readily available and announce in advance what cut-off date for new generation facilities will be used. If a project that had previously sold its RECs in the voluntary market begins to sell its RECs in the compliance market, it would free up capacity for additional projects to be supported by the VRE set aside.

Because the generation from many renewable resources is variable, a year with unusually high wind or small hydro production could lead to more demand for retirement of allowances than the number of allowances in the set aside. There are three ways that a Partner jurisdiction with a VRE set aside may respond if a shortfall in the number of allowances reserved for the set aside occurs. As many of the RGGI states have chosen, allowances may be retired on a first-come, first-served basis as verification reports are submitted. However, such a provision would introduce considerable uncertainty in the VRE market about the ability to make emission reduction claims. A second approach would pro-rate the reductions by lowering the per MWh rate at which allowances are retired rather than exclude some VRE transactions from set aside eligibility after the fact. While this approach would eliminate uncertainty about whether some transactions will be excluded from the set aside, it introduces uncertainty about the amount the amount of greenhouse gas reductions that can be claimed. This would give the jurisdiction time to re-evaluate the retirement limits and avoid having some transactions disqualified from the set aside eligibility assumed by parties at the time those transactions were arranged. If a jurisdiction has hit its limit for several years and compensated by adjusting the de facto retirement rate downward, it is possible that VRE certifiers may respond by decertifying facilities located in that jurisdiction. The third approach is essentially to guarantee that all projects approved for VRE set aside eligibility will have allowances retired at the *ex ante* rate announced by the jurisdiction. To do so, a jurisdiction that reaches the retirement limit in a given year could retire any allowances remaining from previous years' set aside. If there are no remaining allowances, the jurisdiction could transfer unallocated current-year allowances from other accounts within the allowance budget. Generally, these allowances would have to come from a general auction account or other account where allowances have not been dedicated to a specific purpose. A jurisdiction could also borrow some allowances from a future period to make up the shortfall. While estimating the number of allowances needed for the set aside would still be useful for planning purposes, this approach means that effectively no firm limit on the VRE set aside exists.

RGGI Model Rule

The VRE set aside provisions in the RGGI Model Rule provide for states to retire enough allowances to make all voluntary renewable energy purchases whole. However, all nine states that have adopted a VRE set aside have limited the total number of allowances that may be retired to around 1% to 2% of the state allowance budget. Most states adopted these limits expecting that this limit would be adequate to satisfy demand for the next several years.

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should choose whatever upper limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions must determine if they will cover shortfalls by either borrowing allowances from a future year or lowering the per MWh retirement rate.*

It is not important for jurisdictions to harmonize on the issue of limits to allowances in the set aside. Because there is significant disparity in member jurisdictions' renewable capacity, then if retirement limits are pursued, each jurisdiction may wish to calculate its own.

Final Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should choose whatever upper limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions should cover shortfalls that do occur in a compliance period by moving any remaining allowances not dedicated to other purposes into the set aside account or borrowing allowances from future years' VRE set aside accounts. In addition, when the number of allowances to be retired approaches the chosen limit, the WCI Partner jurisdiction could choose to close the eligibility of the VRE set aside to new projects and therefore restrict the supply to near the level of the limit to ensure long-term stability for existing projects.*

Based on stakeholder comment and further reflection it was decided that lowering the per MWh retirement rate was not a practice that should be recommended for harmonization across the WCI Partner jurisdictions. Therefore the recommendation now emphasizes an approach that would keep the VRE market whole by redirecting allowances or borrowing allowances from future years. Additionally, it includes a process for maintaining the long-term demand for VRE set aside allowances at the approximate level of the limit.

6.4.2 Time Limit on VRE Set Aside Program

In determining whether or not a set aside is necessary, consideration may be given to how long a set aside for this purpose should be available. If the price premium for renewable energy is a central justification for a VRE set aside, then the rationale for the program, or certain technologies covered by the program, may weaken over time. Cap and trade programs work by putting a price on the right to emit greenhouse gases, thereby incentivizing conservation, efficiency, and alternative sources of energy. As a price signal propagates through the economy, additional investments in energy efficiency and alternative energy become cost-effective. Thus, there is greater prevalence of low-carbon investments and purchases because such decisions are economically beneficial, as well as environmentally beneficial. If the price of allowances is low and/or renewable energy technology has not progressed enough to make renewable energy cost-competitive, a VRE set aside could be justified to encourage those willing to pay a premium to cover the spread between conventional and renewable energy. But what happens when renewable energy technology advances and rising allowance prices make renewable energy cost-competitive? In other words, if the rationale used to justify a VRE set aside is that VRE consumers are willing to pay a premium to provide a public good, what happens when a premium is no longer needed?

If the public goods aspect of the VRE market serves as the primary justification of a set aside, then WCI Partner jurisdictions that choose to implement them should consider making them contingent on a continued price premium for the technologies supported by the set aside. The set aside program should be re-evaluated periodically to determine whether the technologies supported by the set aside have attained price parity with conventional alternatives. Presumably, with the combination of rising costs for fossil fuels (as a result of the cap and trade price signal or other factors) and technological progress many sources of renewable energy will be cost-competitive in the next ten to fifteen years. As renewable technologies become cost-competitive, they would be removed from the list of eligible sources.

It is important to note that the delisting of an eligible technology should apply to the date that a project receives its final permits for construction (or some other project milestone). Once a project has been deemed eligible for the set aside, Partner jurisdictions should consider giving projects a lengthy window of time, perhaps ten to twenty years, during which allowances will be retired on the facility's behalf, even if the technology is later removed from the eligible list of technologies. Additionally, the decision to delist a technology should be made well in advance of the final operational date of eligibility. This is necessary to provide certainty for renewable energy developers whose projects wish to participate in the VRE market.

RGGI Model Rule

There is no time limit in the model rule, and at present no RGGI states have adopted one.

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should choose whatever time limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions may choose to base time limits on periodic reviews of the cost-competitiveness of the technologies supported by the set aside program.*

This is not an area where harmonization among WCI Partner jurisdictions is important.

Final Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should choose whatever time limit (if any) that is found appropriate for that jurisdiction. However, to provide greater certainty to project developers, Partner jurisdictions should consider a minimum length of time from the date a VRE-eligible facility commences operations that it will be supported by the set aside. Partner jurisdictions may choose to delist technologies from eligibility based on periodic reviews of the cost-competitiveness of the technologies supported by the set aside program, but the last eligibility date for delisted project types should be announced well in advance.*

It is not important that WCI Partner jurisdictions harmonize regarding whether they implement a time limit. However, it is important for jurisdictions that decide to remove a technology from the list of VRE eligible technologies to follow the recommended procedure or develop an alternative approach that provides similar certainty for the VRE market.

6.5 Attributing Emissions to Voluntary Renewable Energy Purchases

A central feature of designing a VRE set aside is determining the rate at which allowances will be retired for every MWh of verified eligible VRE. If the goal of the VRE set aside is to preserve the right to make legitimate emission reduction claims comparable to the claims that could be made before implementation of a cap, that suggests basing the allowance retirement rate on the emissions that would have been avoided by VRE facilities in the absence of a cap. However, estimating the emissions avoided by renewable electricity requires a complex analysis of the resources serving the grid region where the facility is located.

Power from many generating units is dispatched to meet fluctuating demand, and the impact of a given renewable energy facility could cause one or more plants to reduce their output. This effect is referred to as the "operating margin." In the longer term, investment in renewable energy capacity could displace the construction of a new fossil-fired plant altogether. This effect is referred to as the "build margin."[30]

Since the exact units affected by the output from a renewable energy facility cannot be known at every moment, estimated avoided emissions rates are necessary. One method of estimating the emissions rate is to use the average emissions rate for the jurisdiction in which the VRE purchase is made or the jurisdiction where the renewable energy was generated. This calculation is straightforward, but it is unlikely to be very accurate.[31] Marginal emission factors better reflect the generation sources displaced by output from renewable energy facilities. Use of an emission factor for the region where the electricity was generated would be consistent with the generator-based responsibility recommended in section 6.3.

One option may be to use the Default Emissions Factor Calculators that the WCI Electricity Team is developing for the purpose of attributing emissions to electricity imported into the WCI region. The Calculators are designed to calculate marginal emission factors based on operating margins of existing plants. Therefore, they do not capture the build margin effect. Because the build margin effect is more speculative and reflects the longer term effects of adding hundreds of megawatts of renewable energy capacity, the Calculators or other operating margin analysis tools should provide adequate accuracy for purposes of the VRE set aside.

<u>RGGI Model Rule</u>

The RGGI Model Rule defines the benefit of a voluntary renewable energy purchase as the marginal CO_2 emissions rate (lbs CO_2/MWh) in the control area where the generation occurred. However, if the data necessary to determine the marginal emissions rate is unavailable, then the average emissions rate can be used.

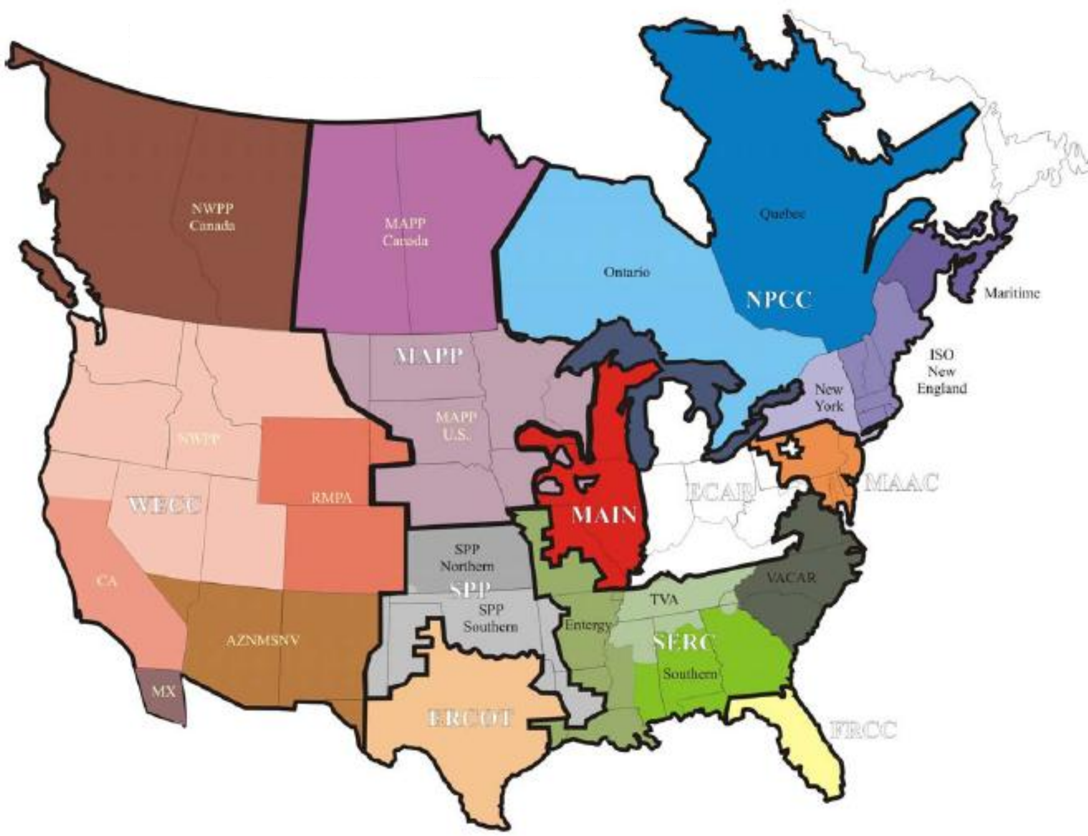
The RGGI Model Rule simply refers to a "control area." The interconnection of electric grids seems to make state and provincial borders less relevant than NERC regions (e.g., WECC) and

[30] Derik Broekhoff, 2007. *Guidelines for Quantifying GHG Reductions from Grid-Connected Electricity Projects.* World Resources Institute/World Business Council for Sustainable Development. http://www.wri.org/publication/guidelines-quantifying-ghg-reductions-grid-connected-electricity-projects
[31] Ibid.

NERC sub-regions (e.g., AZNMSNV) (See Figure 5). If allowance retirement is tied to use of renewable energy products, then a broader region may be desirable as RECs are likely to come from sub-regions different than where they are "used." However, if allowance retirement is tied to generation, than smaller sub-regions may be useful. At this time, it is not yet clear whether marginal emissions rates are calculated for each NERC region and sub-region.

Several of the RGGI states intend to use the marginal emissions rate calculated by their NERC Sub-region, ISO New England (ISO-NE). ISO New England (ISO-NE) began calculating marginal emissions rates in 1994 in order to analyze the impact of Demand Side Management programs. This analysis continues today, though the methodology has changed over time. Currently, ISO-NE calculates the marginal emissions rate using the actual hourly generation and monthly air emissions rate[32] of marginal fossil units, which are defined as all units whose primary fuel is oil or natural gas.

Figure 5: NERC Regions and Sub-Regions (Source: NERC)



[32] The emission rates are mainly based on actual emissions reported in the EPA Clean Air Markets database, along with some data from the NEPOOL Generation Information System (GIS), and some rates from EPA's eGRID.

Previously, the ISO-NE marginal emissions rate was based on the emissions rate of units that would have run had demand been higher. This employed a production simulation model developed to replicate system operations for the previous year. The marginal emissions rate was calculated as the difference between modeled historical emissions and modeled emissions when load was 500 MW higher in each hour. According to the 2006 Marginal Emissions Rate Analysis, ISO-NE moved away from the production simulation model because "the reference case never exactly matched the previous year's unit level energy production because of numerous modeling reasons including market dynamics, specific outages and deratings." [33] Additional communications with ISO-NE indicate that prior to switching methods, a comparison of the two methods was performed and yielded "very similar" results, and therefore, they decided to go with the "more straightforward" approach of evaluating actual emissions from oil and gas fired units.[34]

Draft and Final Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should work together to develop a rate based on a marginal dispatch analysis, such as the WCI Default Emission Factor Calculator, for each major grid region. However, use of this rate should be optional and specific assignment of emissions left to jurisdictional discretion.*

Harmonization on the allowance retirement rate is not essential, and in the current market, avoided emissions rates are either not quantified or vary by location.

7 Stakeholder Comments on Draft Recommendations

Stakeholders provided written comments on the original draft recommendation in January and February of 2010, and discussed with the WCI Partners their comments during the WCI Electricity Collaborative on January 21, 2010 in Phoenix, AZ. The Western Climate Initiative would like to thank everyone who took the time to comment on the original version of this paper, as well as contribute comments on this topic in general throughout the WCI process. Taken together, this paper and the submitted comments have helped fill an important void in the literature on this topic and will hopefully be helpful in the future as this topic is addressed by other regions and at the federal level.

Table 5 on the following pages summarizes the comments that were received by the WCI Partners on the original paper:

[33] 2006 New England Marginal Emission Rate Analysis. ISO New England. September 2008. http://www.iso-ne.com/genrtion_resrcs/reports/emission/2006_mea_report.pdf

[34] Email communication. Kurt Dahdah. Customer Service. ISO New England. 12/30/08.

Table 5: Stakeholder Comments on VRE Issues and Draft Recommendations Paper

Topic	Comment	Submitted By	Additional Information
7.1 Accounting Mechanism for the VRE Set Aside	Opposes pre-determined limits on the size of the set-aside	Center for Resource Solutions	
	Set-aside should reduce the number of allowances in WCI Partner jurisdictions and not simply lower the per MWh retirement rate	Western Climate Advocates Network (WeCAN)	Risk that a purchase of VRE's could generate fewer avoided emissions than expected, or lead to no actual avoided emissions.
	Set-aside should be estimated in advance of each compliance period, then removed from the total pool of allowances created under the cap.	Nextera Energy	Data available from the National Renewable Energy Laboratory, the Western Region Electricity Generation information system etc. Include an "off the top" rule similar to RGGI which sets aside and retires allowances to account for voluntary action on renewable energy.
	Free allocations to Local Distribution Companies (LDCs) should be differentiated	West Associates	Since LDCs are regulated, any benefits of free allowances will be passed onto consumers
	Jurisdictions should create set-asides for demand side measures and ensure value accrues to those that incur the costs of delivering demand side programs	Power Workers' Union	Ensure generators do not benefit from windfall profits at the expense of LDCs
	Calculate future set-aside needs based on baseline of demand, reviewed annually and compared with certificates issued, to adjust for recent growth	Renewable Energy Markets Association	
	Ensure mechanism for set-aside of allowances based on voluntary demand for eligible renewable energy.	Renewable Energy Markets Association	Create certainty that a purchase of voluntary renewable energy will result in retirement of equivalent allowances.
	Set-asides should not be available for energy efficiency or hybrid vehicles	Renewable Energy Markets Association	Building / hybrid vehicle owners derive economic advantage from efficiency measures and do not require an allowance set-aside

	Set-aside should be allowed to be determined by market demand; no predetermined limit on the size of the VRE set-aside	Renewable Energy Markets Association; Western Climate Advocates Network (WeCAN)	Reduced need for allowances resulting from more renewable supply should result in a cost-neutral policy; estimated size of VRE market demand should guide allowance set-asides
	Likely size of set-aside markets should be estimated by those jurisdictions who decide to implement a set-aside program, and baseline allowance adjusted accordingly.	Southern California Edison Company	
	Ensure sufficient set-asides are allocated to renewable energy producers to ensure voluntary purchases fully displace carbon-sourced electricity.	Southwest Energy Efficiency Project (SWEEP)	Consider effects on the sale of EHV if those investments are not seen to displace carbon-generated electricity, as those purchasers are largely motivated by climate considerations.
	Adopt a uniform approach across WCI Partner jurisdictions	Western Climate Advocates Network (WeCAN)	Simplify implementation and compliance for the VRE market
	Set-asides should not be monetized, but retired when actual voluntary activity takes place	Southern California Edison Company	Concern is around increasing costs without seeing a corresponding benefit
7.2 Defining Eligible Renewable Energy Project Types	Adopt a uniform approach for eligibility requirements across WCI Partner jurisdictions	Renewable Energy Markets Association	Lack of uniform criteria could result in unintended consequences for renewable energy development
	Eligibility should be based on location of the renewable energy purchaser, not the generator	Nextera Energy	
	Treatment of renewable energy in mandatory/voluntary markets must be uniform	Southern California Edison Company	Definition/evaluation of a voluntary renewable energy purchase in the voluntary market must be the same as in compliance market on order to ensure emissions reductions from VRE are real, verifiable and additional.
	Supports WCI Partner jurisdictions requiring VRE marketers to acquire allowances from the market on the same basis as carbon-sourced generators	West Associates	Allows VRE marketers to include the cost of acquiring and retiring allowances in the cost of their VRE products, in the amount of GHG emissions displaced by each VRE product

	Recommends measures that require VRE marketers to acquire GHG allowances to fully cover emissions attributed to VRE electricity products	West Associates	This approach efficiently embeds the costs of covering GHG emissions attributed to the VRE electricity products in their cost to VRE customers.
7.3 Jurisdictional Retirement Responsibility	Agrees with recommended approach based on location of generator, not purchaser, for jurisdictional retirement responsibility.	Renewable Energy Markets Association; Center for Resource Solutions; Western Climate Advocates Network (WeCAN)	Encourages out-of-jurisdiction demand, generates positive effects both within and outside WCI Partner jurisdictions
	Bundling emissions allowances with renewable energy is unacceptable	Renewable Energy Markets Association; West Associates	Adds expense and creates confusion for consumers; concern that VRE electricity products could be double counted, thus increasing emissions under the cap
	Adopt a uniform approach across WCI Partner jurisdictions on coverage for shortfalls	Renewable Energy Markets Association	Transparency/ consumers can be certain purchase will result in allowance retirement
7.4 Retirement Limits	Oppose a time limit or "sunset" to implementation of the VRE approach	Center for Resource Solutions; Renewable Energy Markets Association; Western Climate Advocates Network (WeCAN)	Unnecessary at this time; increasing adoption of renewable generation will reduce the need for allowances in future. May need further review but not conceivably before 2020.
	Supports retirement of allowances and borrowing from a future time period; oppose lowering the per MWh retirement rate	Center for Resource Solutions	
7.5 Attributing Emissions to Voluntary Renewable Energy Purchasers	Adopt a uniform approach across WCI Partner jurisdictions for treatment of emissions factors	Renewable Energy Markets Association	Transparency/ consumers credited consistent with energy that is displaced; use Green-E's standard requires MWhs must contain all the GHG emission reduction benefits associated with the MWh of renewable energy when it was generated.
	Use marginal emission avoided (not average emissions factor)	Renewable Energy Markets Association	Average emission factors may discount carbon benefits of renewable generation, reduce individual generator responsibility for determining allowance requirements

OTHER	Comment	Submitted By	Additional Information
Compliance	Adopt uniform dates across WCI Partner jurisdictions for filing deadlines	Renewable Energy Markets Association	Reduce burden on marketers to track multiple filing deadlines
	Recognize only established tracking authorities	Renewable Energy Markets Association	Generators and claimants would be required to register with established tracking authority
	Environmental claims about purchase of VRE's must be verifiable	Renewable Energy Markets Association	To avoid optics of greenwashing, ensure reporting requirements follow consistent with NAAG guidelines
Potential effect of VRE approach on Markets	Recommend measures that recognize large purchasers as the drivers of VRE market growth	Center for Resource Solutions	15 largest business purchasers (US) can demonstrate specific, quantitiative claims with respect to avoided carbon emissions
	Economic benefits should be more clearly highlighted; recognize demand-side effects on demand for and supply of allowances and the cumulative, interactive effects on allowances prices.	Center for Resource Solutions; Western Climate Advocates Network (WeCAN)	Lowered demand for allowances due to fossil fuel-based avoided generation; jobs benefit of not undercutting a growing market are examples. Highlights the overall benefit to implementing a VRE set-aside
	White paper should model effect of VRE set aside on allowance prices	Independent Energy Producers Association	White paper is unclear on what potential impacts on allowance prices may be from including VRE set aside approach within the cap and trade program
Adoption of VRE set-aside approach	Advise that WCI Partner jurisdictions proceed with caution in regard to linking RECs to a cap and trade system so as not to disrupt the renewable markets	Waste Management	Potential to confuse and duplicate renewable energy programs that currently work well
	Treatment of renewable energy in mandatory/voluntary markets	West Associates	LDCs may incur additional compliance costs under RPS as they may be left to purchase allowances to offset GHG emissions imputed to power not sold directly byVRE marketers to customers, from which the environmental attributes have been stripped.
	Recognize that growth of the VRE market would likely be undermined by introduction of cap and trade without a VRE set-aside	Western Climate Advocates Network (WeCAN)	Marketing environment would be more challenging under cap and trade without a VRE set-aside

	Generally supportive; advocate a uniform approach across WCI Partner jurisdictions	Center for Resource Solutions, Renewable Energy Markets Association, West Associates	Adds certainty and ensures equity for both the allowance market and the VRE market
	Generally supportive; allow jurisdictions to decide whether or not to implement	Power Workers' Union	Addresses differing needs of jurisdictions
	Not needed - effective GHG emissions reductions can be achieved through existing measures such as RPS and cap and trade programs.	Southern California Edison Company	
	Opposes VRE approach as proposed	Southern California Public Power Authority	Not necessary to support voluntary renewable energy; raises difficult issues regarding elements to be harmonized, treatment of other voluntary measures; reduces the size and value of the allowance pool
	Rewrite those portions that address alternatives to no set-aside	Renewable Energy Markets Association	Seeks a straightforward recommendation to support each jurisdiction adopting a VRE set-aside
General	Environmental Attributes are not a "secondary attribute" of RECs.	Center for Resource Solutions	RECs were developed to enable commoditization of claims to the benefits of renewable energy.
	White paper should not work from the assumption that individual jurisdictions will choose to implement a VRE; it should present details that will allow stakeholders to assess the effect of including a VRE set-aside within the cap and trade system	Independent Energy Producers Association	Since each jurisdiction will make its own decision, paper should focus on guidance on the data and details that must be presented
	WCI Partner jurisdictions should negotiate reciprocity if linking with other programs	Nextera Energy	
	Strike paragraph headlined "RGGI Model Rule" from bottom of page 15 to top of page 16 from the paper	Renewable Energy Markets Association	Believes this leaves incorrect impression that it is problematic to use unbundled RECs to qualify for the VRE set-aside under RGGI.
	Strike paragraph headlined from bottom of page 3 to top of page 4 which discusses the voluntary market for carbon offsets.	Renewable Energy Markets Association	Commenter believes this paragraph is confusing and irrelevant (see REMA letter pg 14)

Annex: Optional VRE Set aside Language in RGGI Model Rule[35]

Voluntary renewable energy purchase. A purchase of electricity from renewable energy generation or renewable energy attribute credits by a retail electricity customer on a voluntary basis. Renewable energy includes electricity generated from biomass, wind, solar thermal, photovoltaic, geothermal, hydroelectric facilities certified by the Low Impact Hydropower Institute, wave and tidal action, and fuel cells powered by renewable fuels. The renewable energy generation or renewable energy attribute credits related to such purchases may not be used by the generator or purchaser to meet any regulatory mandate, such as a renewable portfolio standard.

(d) Voluntary renewable energy market set-aside allocation. For each control period, the REGULATORY AGENCY shall allocate to the voluntary renewable energy market set-aside account a certain number of tons, calculated as set forth in this subdivision, from the NAME OF RELEVANT RGGI STATE CO_2 Budget Trading Program base budget set forth in section XX5.1, as applicable. The REGULATORY AGENCY shall administer the voluntary renewable energy set-aside in accordance with this subdivision.

(1) The REGULATORY AGENCY will open and manage a general account for the voluntary renewable energy market set-aside for each control period.

(2) The number of tons that will be allocated to the voluntary renewable energy market set-aside account in a specific control period will be determined as set out in this paragraph.

(i) Any person may submit data to the REGULATORY AGENCY documenting purchases of voluntary renewable energy that meet the requirements of this subdivision by no later than the July 30 prior to the beginning of a control period. Such data must be from reputable sources, which may include retail electricity providers, organizations that certify renewable energy products, and other parties as determined by the REGULATORY AGENCY. To be considered, data must be verifiable and document the following for voluntary renewable energy purchases.

(a) Documentation of voluntary renewable energy or renewable energy attribute credit purchases by retail customers, by customer class, in the State during the most recent three-year period for which data are available.

(b) Documentation that the renewable energy or renewable energy attributes related to voluntary renewable energy or renewable energy attribute credit sales was procured by the retail provider.

(c) Time period when the retail purchase(s) was made.

(d) State where the electricity was generated or the renewable energy attribute credit was created, including documentation of facility name, unique generator identification number, and fuel type.

(e) Time period when the electricity was generated or the renewable energy attribute credit was created.

[35] Regional Greenhouse Gas Initiative Model Rule. 1/5/07 Final with Corrections. http://rggi.org/docs/model_rule_corrected_1_5_07.pdf

(ii) Subject to the timely receipt of adequate data pursuant to subparagraph (i) of this paragraph, and based on such data, the REGULATORY AGENCY shall project the voluntary renewable energy purchases in the State during a control period that represents renewable energy generation in one or more participating states. The megawatthours (MWh) of projected voluntary renewable energy purchases in a control period shall be multiplied by the marginal CO_2 emissions rate (lbs. CO_2/MWh) in the control area where the generation occurred, as determined by the REGULATORY AGENCY. If data to determine the marginal emissions rate is unavailable, the average emissions rate shall be used, as determined by the REGULATORY AGENCY.

(iii) The CO2 tons to be allocated to the voluntary renewable energy set-aside account shall be calculated as follows:

CO2 tons = MP x EF

where:

CO2 tons, rounded down to the nearest whole ton, is the number of allowances to be placed in the reserve account.

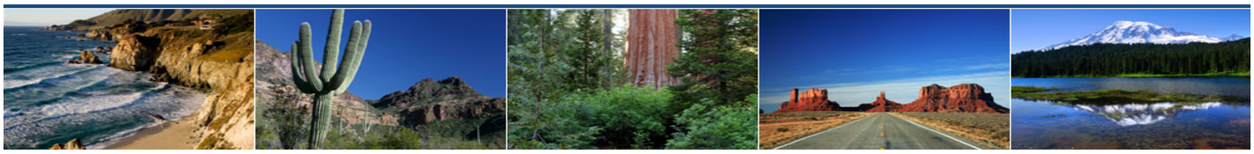
MP is the projected MWh of voluntary renewable energy purchases in the State during the future control period that meets the requirements of this subdivision.

EF is the CO2 emissions factor for the control area where the electricity represented by the sale was generated.

(iv) If following the end of a control period, the number of CO2 allowances allocated to the voluntary renewable energy set-aside account is less than the number of CO2 tons represented by the actual MWh of voluntary renewable energy purchases during the control period, the REGULATORY AGENCY will add the difference between CO2 tons represented by actual purchases, as calculated in accordance with subparagraph (iii) of this paragraph, and CO2 allowances held in the set-aside account to the projection for the following control period, pursuant to paragraph (2) of this subdivision. If following the end of a control period, the number of CO2 allowances allocated to the voluntary renewable energy set-aside account is greater than the number of CO2 tons represented by the actual MWh of voluntary renewable energy purchases during the control period, the REGULATORY AGENCY will subtract the difference between CO2 tons represented by actual purchases, as calculated in accordance with subparagraph (iii) of this paragraph, and CO2 allowances held in the set-aside account from the projection for the following control period, pursuant to paragraph (2) of this subdivision. In no event shall the size of the voluntary renewable set-aside exceed ___________ tons.

(3) As of the December 31 that is after the end of a control period for which an allocation has been made to the voluntary renewable energy set-aside account, the REGULATORY AGENCY shall determine the actual MWh of voluntary renewable energy purchases that occurred during the control period. The REGULATORY AGENCY shall retire CO2 allowances in the voluntary renewable energy set-aside account in an amount up to the number of tons of CO2 represented by actual voluntary renewable energy purchases, based on actual MWh purchases and the emissions factor determined pursuant to paragraph (2) of this subdivision.

Western Climate Initiative



Design for the WCI Regional Program

July 2010

Western Climate Initiative

July 27, 2010

To All Interested Parties:

Today, the Partner jurisdictions of the Western Climate Initiative are pleased to release the “Design for the WCI Regional Program.” Since the release of the WCI Design Recommendations in September 2008, we have been working together to develop these design details which are needed to implement the program.

This document provides a roadmap to inform the WCI Partner jurisdictions in their development of implementing regulations. It has been developed by the WCI Partner jurisdictions working collaboratively with stakeholders, advisors, and outside experts who have all made invaluable contributions. We especially want to recognize Franz Litz and Nicholas Bianco at the World Resources Institute in Washington, D.C. and Lydia Dobrovolny at Ross & Associates in Seattle, WA for their outstanding efforts in the preparation of this document.

The release of this Program Design is a major milestone for the WCI. Between now and the program start date of January 2012, the WCI Partners will continue working together to resolve outstanding design issues and begin putting in place the administrative systems and infrastructure needed to operate the program.

While not all WCI Partner jurisdictions will implement the cap-and-trade program when it begins in January 2012, those currently expecting to move ahead at the start will create a robust market for achieving GHG emissions reductions in the western U.S. and Canada. It is also important to recognize that all WCI Partners have participated in crafting the program design and that the program is structured so that additional Partners can join in the future.

From the beginning, the Partners’ strategy for addressing climate change has recognized the need for broad collaborative action to reduce GHG emissions. All of the WCI Partner jurisdictions have adopted climate action plans, and are taking steps to reduce emissions. In addition to our efforts to implement a cap-and-trade program, we are working to advance other policies needed to reduce GHG emissions. WCI Partner jurisdictions are also working closely with our federal governments to promote national and international action and ensure coordination among state, provincial, regional, and national programs.

On behalf of the governors and premiers of the Western Climate Initiative jurisdictions, we thank you for your interest in this work and for your ongoing contributions to our effort. We know that together we can meet the challenge of climate change while promoting economic vitality throughout the region.

Sincerely,
The WCI Partners

DESIGN SUMMARY

1. Introduction

The Western Climate Initiative (WCI) is a collaboration of seven U.S. states and four Canadian provinces that have been working together since 2007 to identify, evaluate, and implement policies to address climate change.[1] The WCI Partner jurisdictions reflect diverse geographies, climates, populations, industries, and energy and transportation infrastructures (see Figure 1). Nevertheless, the Partners share a commitment to tackling the economic, energy, and environmental challenges associated with greenhouse gas (GHG) emissions, recognizing that:

- Adverse impacts of climate change are already being experienced in our states and provinces.
- Acting now reduces the risk of far more significant adverse climate change impacts and associated unacceptable economic harm.
- Acting now reduces costs for future generations and provides substantial economic opportunities for the residents of our jurisdictions, contributing to job growth and economic recovery, and reducing reliance on imported fossil fuels.

A Comprehensive Initiative

The WCI Partner jurisdictions have developed a comprehensive strategy to reduce regional GHG emissions to 15 percent below 2005 levels by 2020. This goal is based on the individual GHG emission reduction goals of the Partner jurisdictions. Our strategy will also spur investment in and development of clean-energy technologies, create green jobs, and protect public health. The WCI Partner jurisdictions' plan includes the following elements:

- **Using the power of the market.** A market-based approach that caps GHG emissions and uses tradable permits will provide incentives for companies and inventors to create new technologies that increase efficiency, promote greater use of renewable or lower-polluting fuels, and foster process improvements that reduce dependence on fossil fuels.
- **Encouraging reductions throughout the economy.** To reduce compliance costs and encourage emissions reductions, offset certificates will reward emissions reductions in sectors such as forestry and agriculture that are not covered by emissions caps.

[1] Memorandum of Understanding establishing the Western Regional Climate Action Initiative. February 26, 2007.

- **Advancing core policies and programs to speed the transition to a clean energy economy** by targeting cost-effective emissions reductions, including:
  - Expanding energy efficiency programs that reduce customer utility bills;
  - Encouraging additional renewable energy sources that diversify supply resources and reduce air and water pollution;
  - Tackling transportation emissions through vehicle emissions standards, fuel standards, and incentives for improved community and transportation planning;
  - Establishing performance benchmarks and standards for high-emitting industries to spur innovation and improve competitiveness; and
  - Identifying best practices in workforce and community programs to help individuals transition to new jobs in the clean energy economy.

The WCI Partner jurisdictions' comprehensive strategy is good for the environment and good for the economy. It encourages the lowest cost reductions in GHG emissions and improved energy efficiency. Economic modeling conducted by the Partner jurisdictions indicates that the program will result in modest cost savings between 2012 and 2020. The strategy balances the principles adopted by the WCI Partner jurisdictions to maximize total benefits throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts.

From the beginning, the Partner jurisdictions' strategy for addressing climate change has recognized the need for broad collaborative action to reduce GHG emissions. All of the WCI Partner jurisdictions have adopted climate action plans, and are taking steps to reduce emissions. We also are in discussions with other regional greenhouse gas initiatives—the Regional Greenhouse Gas Initiative (RGGI) and the Midwestern Greenhouse Gas Reduction Accord—to further broaden the collaboration on mitigation activities. In addition, WCI Partner jurisdictions are working closely with our federal governments to promote national and international action, and to ensure coordination among state, provincial, regional, and national programs.

The WCI Partner jurisdictions understand that even if it were possible to substantially reduce or even eliminate GHG emissions today, our jurisdictions would still feel the impacts of climate change due to emissions that have already occurred. Scientific research continues to confirm that our water resources, natural ecosystems, air quality, and environment-dependent industries like agriculture and tourism will be significantly impacted by changes in climate. Consequently, in addition to limiting GHG emissions, efforts are needed to address the impacts of climate change. The WCI Partner jurisdictions are therefore also committed to undertaking preparation and adaptation efforts.

Expanding Collaborative Action on Climate Change

GHG emissions are emitted from a broad range of activities worldwide. Unlike other air pollutants, GHG emissions contribute equally to climate change regardless of source or location. Efforts to mitigate climate change must ultimately address emissions from all major sources on a global basis.

As the WCI Partner jurisdictions move forward in the months and years ahead, the Partners will continue collaborating to develop a portfolio of core policies and programs to reduce GHG emissions. The governors and premiers of the Partner jurisdictions invite their colleagues across North America, including leaders of Native American tribes and Canada's First Nations, to join us to expand our effort to reduce GHG emissions and limit the impacts of a changing climate.

Sharing Our Progress through this Report

This document updates the design for the WCI Regional Cap-and-Trade Program, providing a roadmap to inform the WCI Partner jurisdictions in their development of implementing regulations. During the nearly two years since *Design Recommendations for the WCI Regional Cap-and-Trade Program* was released, the WCI Partner jurisdictions have worked collaboratively with stakeholders, advisors, and experts to develop the details needed to put the program in place. The WCI Partner jurisdictions have also had the benefit of building on the experience of program operations in Europe and RGGI, as well as proposed programs in other regions and countries.

The remainder of this document is organized as follows:

Design Summary: The Design Summary provides the highlights of the WCI Cap-and-Trade Program. The presentation is organized around the primary policy recommendations for the program, as follows:

- The WCI Cap-and-Trade Program
- Relying on High-Quality Emissions Data From Rigorous Reporting
- Setting the Program Emissions Limits
- Enhancing Compliance Flexibility and Program Adaptability to Manage Compliance Costs
- Maintaining Competitiveness and Preventing Emissions Leakage
- Electricity Sector
- Designing for High-Quality Offsets
- Designing a Fair and Transparent Auction
- Ensuring a Well-Functioning Market
- Linking Programs
- Coordinating Program Administration

Documentation: Referenced throughout the document are materials prepared by WCI committees and teams that form the basis for the program design recommendations. In most instances, the relevant white papers and/or draft recommendations were released for stakeholder comment and were discussed in public conference calls and/or meetings. These materials are listed at the end of the Design Summary and are available on the WCI website.[2]

[2] See www.westernclimateinitiative.org.

Detailed Design: The Detailed Design is organized around the primary operational components of the program. As the WCI Partner jurisdictions developed the Detailed Design, we found that variations in jurisdictional authorities, regulatory procedures, and administrative requirements inevitably lead to differences in the manner in which program rules are written. Consequently, the Detailed Design was prepared with the understanding and expectation that each jurisdiction's rule language may vary from the material included here. The intent, however, is that even with differences in language or approach, the ability to implement the core program design in a compatible manner across jurisdictions is preserved, so that the integrity of the regional effort is assured.

2. The WCI Cap-and-Trade Program

As part of a comprehensive strategy to reduce GHG emissions, the WCI Partner jurisdictions have recommended a market-based program that provides an incentive to limit emissions and promotes technological innovation.[3] Cap-and-trade has proven to be a successful means of reducing air pollution. It also is considered one of the most cost-effective and reliable strategies for pricing carbon emissions and providing emitters of GHG emissions with an incentive to limit pollution. With the trading component, cap-and-trade allows emitters to be flexible and creative in how to make needed reductions (see Figure 2).

The WCI program design includes a broad scope, encompassing nearly 90 percent of economy-wide emissions in the WCI Partner jurisdictions. The merits of pricing emissions broadly throughout the economy have been recognized in most of the recent federal proposals in the U.S. A forthcoming study by the National Research Council also recommends a broad scope, stating: "An economy-wide carbon pricing policy would provide the most cost-effective reduction opportunities, would lower the likelihood of significant emissions leakage, and could be designed with a capacity to adapt in response to new knowledge."[4] Similarly, in 2009 the National Round Table on the Environment and the Economy published a report on carbon pricing in Canada, including: "To achieve stated reduction targets at the least possible cost, all emissions must be covered as fully as possible. This requires a unified pricing policy that consciously takes into account all emissions across all sectors and all jurisdictions."[5]

The WCI Partner jurisdictions understand that in addition to covering most sectors of the economy, a broad geographic scope will also reduce overall

[3] In September 2008, following 18 months of stakeholder consultation, analysis, and Partner deliberations, the WCI released *Design Recommendations for the WCI Regional Cap-and-Trade Program*.

[4] National Research Council of the National Academies, Limiting the Magnitude of Future Climate Change, The National Academies Press, Washington, D.C., forthcoming, p. 5. Prepublication summary available at: www.nap.edu/catalog/12785.html.

[5] The National Round Table on the Environment and the Economy, *Achieving 2050 : A Carbon Pricing Policy for Canada*, *2009*, p.29.

compliance costs and can help mitigate leakage risks. A larger carbon market across a diverse set of emission sources provides a wider range of reduction opportunities. There are multiple paths for achieving the broad geographic and economy-wide coverage that is preferred for a cap-and-trade program. The WCI Partner jurisdictions also recognize alternative schedules for implementation can be accommodated and will continue to encourage additional jurisdictions to join the program after the expected start date of January 1, 2012.

Figure 2: How the WCI Cap-and-Trade Program Works

The WCI Cap-and-Trade Program will be composed of the individual jurisdictions' cap-and-trade programs implemented through state and provincial regulations. Each WCI Partner jurisdiction implementing the cap-and-trade program design will issue "emission allowances" to meet its jurisdiction-specific emissions goal. The total number of available allowances serves as the "cap" on emissions. The allowances can be bought and sold ("traded"). A regional allowance market is created by the Partner jurisdictions recognizing one another's allowances for compliance. Through this recognition, the emissions allowances issued by each jurisdiction will be usable throughout the jurisdictions for compliance purposes.

The WCI Cap-and-Trade Program includes rigorous emissions reporting requirements that ensure accurate and timely measurement and recording of GHG emissions by the entities included in the program. At least once each three years, covered entities are required to turn into the state or province one "emission allowance" for each metric ton of carbon dioxide equivalent (CO_2e) emissions they emit and report. To reduce the total amount of emissions, the number of allowances issued will be reduced over time.

There is no restriction on who can own emission allowances—they can be sold between and among covered entities or third parties. Entities that reduce their emissions below the number of allowances they hold can sell their excess allowances or hold them for later use. Selling excess allowances allows entities to recoup some of their emissions reduction costs, while holding allowances for later use will lessen future compliance costs. This "trading" of emission allowances keeps compliance costs lower than would otherwise be the case because it provides flexibility in how and when reductions are made. It also puts a price on the emissions, which provides an incentive to innovate and find new ways to reduce emissions.

The WCI program design includes important features to ensure that the participating jurisdictions achieve their emissions goals affordably and cost-effectively. Emission offsets, representing emissions reductions from sources not covered by the program, can be used for compliance in limited quantity along with allowances from other trading programs that have been recognized by the WCI Partner jurisdictions. There is no limitation on how long an emission allowance may be held for future use. Allowing entities to turn in allowances in three-year periods provides flexibility as to when emissions reductions are made.

3. Relying on High-Quality Emissions Data from Rigorous Reporting

Accurate, timely, and consistent GHG emissions data is essential for an effective GHG emissions reduction effort. A cap-and-trade program in particular requires that all emitters in the program have high-quality emissions data so they can submit the correct number of emission allowances to cover their emissions. Accordingly, the WCI Partner jurisdictions have developed a reporting program that specifies quantification methods that are rigorous, technically feasible, cost-effective, and sufficiently accurate to support the cap-and-trade program.[6]

To minimize the reporting burden in the U.S., the WCI Partners' reporting requirements are harmonized with the U.S. EPA Mandatory Reporting Rule for GHG emissions[7] so that a facility will be able to submit a single report satisfying both the WCI Partners' requirements and the U.S. EPA rule. Because the U.S. EPA reporting rule is not designed to support a cap-and-trade program, it includes a range of quantification and measurement methods. The WCI Partners' specifications often require the more rigorous methods among the options included in the U.S. EPA rule in order to achieve the accuracy required in the WCI Partners' program.

The WCI Partner jurisdictions are also developing a Canadian version of the reporting requirements. Any necessary adjustments to existing requirements will be phased in over time. Several Canadian WCI Partners are developing a one-window GHG emissions reporting interface with Environment Canada. A report by a facility to the one window interface would meet the requirements of both the federal and provincial government, thus obviating the need for duplicate reporting.

The WCI Partner jurisdictions are continuing to develop reporting protocols for some emission sources that do not yet have adequate quantification methods. Chief among these are oil and gas production, natural gas processing, and natural gas transmission and distribution, which are significant sources of GHG emissions in some WCI Partner jurisdictions. In the spring of 2010, U.S. EPA released proposed requirements for GHG emissions reporting for oil and gas operations. To support the U.S. EPA's effort to require reporting in this sector and to align U.S. EPA reporting requirements with WCI Partner needs, the WCI Partner jurisdictions evaluated the proposed rule and submitted extensive comments to EPA.[8]

---

[6] *Final Essential Requirements for Mandatory Reporting*. July 2009.

[7] *Proposed Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule*. June 2010. Information about the U.S. EPA Greenhouse Gas Reporting Program is available at: http://www.epa.gov/climatechange/emissions/ghgrulemaking.html.

[8] *WCI Comments on the Proposed Mandatory Reporting of GHG Emissions from Proposed Reporting for Oil and Gas Operations (Subpart W)*. June 2010.

For Canadian jurisdictions, specific quantification methods may be required for some sources due to different royalty data systems, equipment specifications, and metering requirements. The WCI Partner jurisdictions will review EPA's final reporting rule for the oil and gas sector and determine its appropriateness for a regional cap-and-trade program.

4. Setting the Program Emissions Limits

The WCI Cap-and-Trade Program is designed to reduce GHG emissions to 15 percent below 2005 levels by 2020, which is the sum of the emissions goals of the Partner jurisdictions. The emissions limit is created by each jurisdiction issuing a limited number of "emission allowances," referred to as the jurisdiction's allowance budget, and requiring emitters to:

- Report their emissions annually;[9] and
- Submit sufficient emission allowances and offset certificates[10] to cover their reported emissions.

The jurisdiction's allowance budget therefore is the primary determinant of the total limit on the emissions from all the emitters in the program in the jurisdiction, along with the number of offset certificates that can be used.

The WCI Partner jurisdictions recommend that each jurisdiction develop its allowance budget in the same manner to ensure consistency and transparency throughout the program.[11] Additionally, the Partner jurisdictions recommend a common limit on the use of offset certificates be applied uniformly.[12]

Partner Allowance Budgets

The WCI Partner jurisdictions recommend setting allowance budgets to provide for a gradual emission reduction to the 2020 emission target. Accordingly, the Partners recommend that each Partner's 2012 allowance budget for emitters covered in 2012 be the best estimate of actual emissions anticipated in 2012. With this approach, the allowance budgets are sufficient to enable emissions to continue as expected in the first year of the program.

In 2015, the program is designed to expand to cover providers of transportation fuels and residential and commercial fuels.[13] Consequently, Partners' allowance budgets increase in 2015 to reflect the addition of these emissions. The increase in the allowance budgets in 2015 to cover these emissions is recommended to be the best

[9] Reporting is discussed above in section 3.

[10] Offsets are discussed below in section 8.

[11] *Guidance for Developing WCI Partner Allowance Budgets*. June 2010.

[12] *WCI Recommendations for Implementing the Offset Limit*. March 2010.

[13] The WCI Partner jurisdictions acknowledge that individual jurisdictions may utilize other fiscal measures, such as British Columbia's carbon tax, to address transportation fuels and fuel use by residential and commercial sources that contribute to achieving overall comparable GHG emissions reductions and internalize the price of carbon as expected through the cap-and-trade program.

estimate of expected actual emissions from these sources. So, again, the allowance budgets are sufficient to cover expected emissions from the sources during the first year they are included in the program.

The remainder of the Partners' allowance budgets are defined by calculating the 2020 budget and the values from 2012 to 2015 and from 2015 to 2020. The WCI Partner jurisdictions recommend that the 2020 allowance budgets be set to achieve each jurisdiction's economy-wide 2020 emissions target, so that the number of allowances issued plus emissions from uncapped sectors will equal each jurisdiction's 2020 target. A linear decline from 2012 to 2015, and then from 2015 to 2020, is recommended to enable a gradual ramp-down.

WCI Partners' economic analysis has shown that this gradual linear decline can be achieved with a slight net savings.[14] Figure 3 graphically illustrates an allowance budget.

Recognizing Early GHG Reductions with Allowances

The WCI Partner jurisdictions recognize the value of reducing emissions as soon as possible, including prior to the start of the program. A number of approaches have been identified that some Partners may use to provide incentives for early action, including issuing Early Reduction Allowances (ERAs) for emissions reductions that occur during the period of 2008 through 2011. To be eligible to receive ERAs, the reductions must be voluntary, additional, real, verifiable, permanent, and enforceable.[15] Once issued, the ERAs may be used in the same manner as other emission allowances.

Offset Certificates and Instruments from Other Programs

The WCI Partner jurisdictions recommend that offset certificates and approved compliance instruments from other programs (such as another cap-and-trade program) be used along with emission allowances to comply with the program. The WCI Partners' economic analysis found that the use of such instruments can help reduce compliance costs for emitters. However, the WCI Partner jurisdictions believe that covered emitters should make the majority of the emissions reductions needed to achieve the 2020 emissions goal. Accordingly, the WCI Partner jurisdictions recommend that the use of offsets certificates and other approved instruments not exceed 49 percent of the aggregate required emissions reductions across all the Partner jurisdictions' programs.

Using the sum of the Partner allowance budgets, a total limit on the use of offset certificates and approved compliance instruments from other programs will be calculated and applied to all emitters in the program in all of the compliance periods. The limit will be expressed as a portion of the emitters' emissions that can be covered by offset certificates or approved compliance instruments from other programs. For example, if

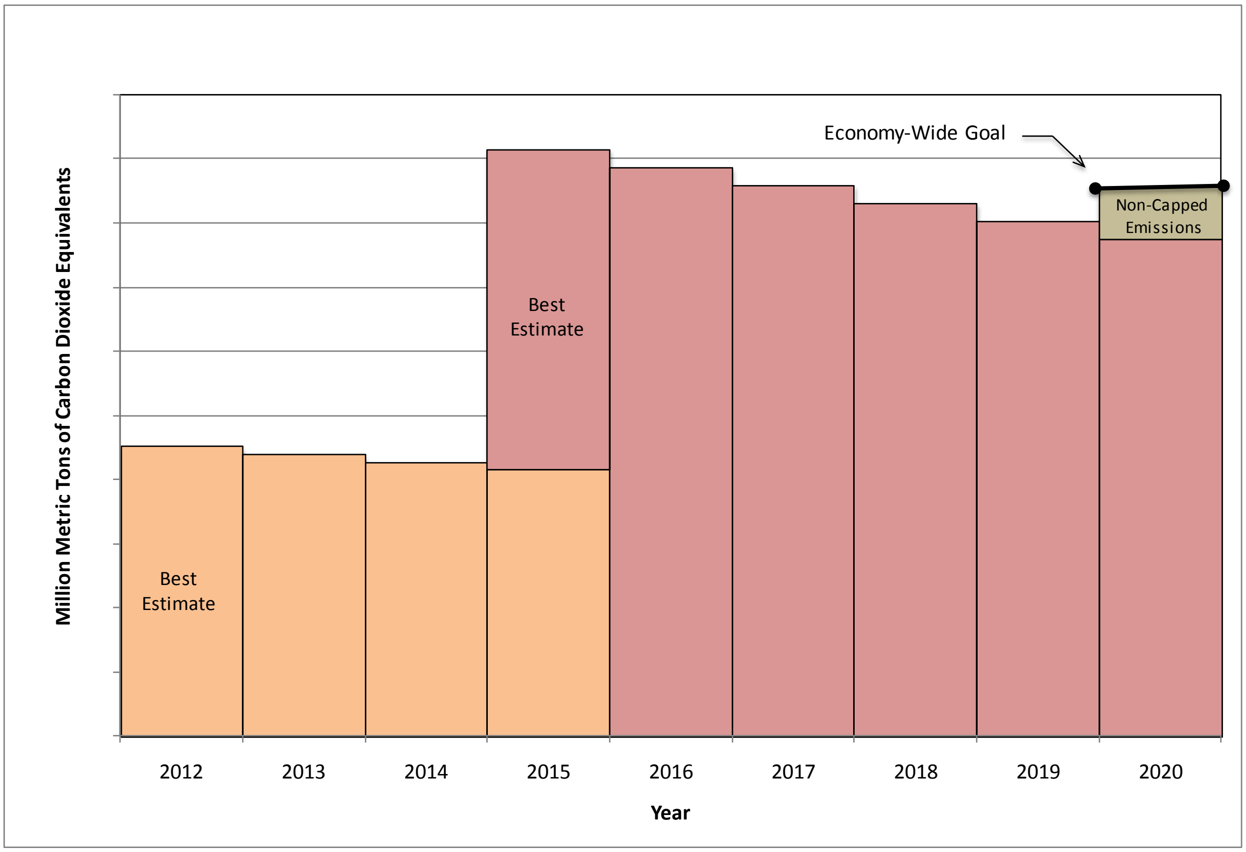
[14] *Updated Economic Analysis of the WCI Regional Cap-and-Trade Program*. July 2010.

[15] *Guidance for Distributing Early Reduction Allowances*. June 2010.

the limit is calculated to be 5 percent,[16] then an emitter of 100,000 metric tons of CO_2e could comply with the program using at most 5,000 offset certificates or approved compliance instruments from other programs. The remainder of the emissions (95,000 metric tons in this example) would need to be covered by emission allowances issued by a WCI Partner.

In sum, emission allowances, ERAs, offset certificates, and approved compliance instruments from other programs constitute the total allowable emissions from emitters in the WCI Cap-and-Trade Program.

Figure 3: Graphic Illustration of a Jurisdiction Allowance Budget



The 2012 allowance budget declines through 2015, when the newly covered emissions are added to the program. The budget then declines through 2020. The 2020 allowance budget is shown below the 2020 economy-wide goal because some emissions are not covered by the cap-and-trade program. The difference between the 2020 allowance budget and the economy-wide goal is the emissions that are not covered by the cap-and-trade program.

---

[16] Note that 49 percent of emissions reductions translates into a much smaller percentage of total emissions allowed under the program.

5. Enhancing Compliance Flexibility and Program Adaptability to Manage Compliance Costs

The WCI Cap-and-Trade Program is designed to achieve its environmental objectives reliably and cost effectively. Multiple program features provide compliance flexibility while ensuring that emission goals are achieved (see Figure 4). WCI Partners' analysis of the program design finds that these features ensure that the program is supportive of economic growth and job creation.[17]

WCI Partners' analysis also examined scenarios in which potential future conditions could lead to compliance costs being higher than expected. The findings show that combinations of circumstances could result in compliance cost increases that may impact consumers or industry competitiveness, and increase emissions leakage risk.[18] Examples of such conditions may include:

- Technology Costs: Technologies to reduce emissions may be more costly or may require more time to install than anticipated.
- Weather: Increased incidence or prolonged duration of droughts, possibly associated with the early physical impacts of climate change, may unexpectedly reduce the availability of hydroelectric power, requiring increased reliance on fossil fuel generating resources. Similarly, heat waves or periods of extreme cold associated with greater weather variability may increase demand for electricity or heating fuels.
- Electric Sector Upset: Disruptions to low-carbon electricity supplies, such as unplanned maintenance at a nuclear power facility or loss of transmission capacity to wind resources, could lead to temporary increases in reliance on fossil fuel generating resources.
- Uncertainty in Emissions Estimates: Continuing uncertainty about the strength and timing of the economic recovery makes estimates of expected emissions in 2012 and 2015 uncertain. Inadvertently setting the allowance budget too low due to this uncertainty may lead to greater emissions reductions being required than planned, and higher compliance costs.

The WCI Partner jurisdictions recognize that one or more of these types of conditions could occur, individually or in combination. Accordingly, approaches that enable the program to adapt to changing circumstances are under consideration, including the following:

1. Partners could establish allowance reserves from which emission allowances could be released under high-price conditions. Allowance reserves have been included in recent U.S. legislative proposals, which provide examples for consideration. The WCI Partner jurisdictions will further evaluate how allowance reserves might reduce the risks of high compliance costs, including examining:

[17] *Updated Economic Analysis of the WCI Regional Cap-and-Trade Program*. July 2010.

[18] Emissions leakage is discussed in section 6.

– The appropriate size of reserves;
– Methods for filling the reserves while maintaining the environmental integrity of the program;
– Conditions under which the reserves would be activated;
– Mechanisms for releasing allowances from the reserves; and
– Purposes for which allowances released from the reserves could be used.

2. Entities could be allowed to comply using a limited number of allowances from the next compliance period. The design recommends prohibiting borrowing allowances from future compliance periods to comply in the current period. However, this prohibition could be relaxed in recognition that some allowances from the next compliance period will already be in circulation at the time of the current compliance deadline. Consequently, some allowances from the next period will already be owned, and entities need not borrow them in order to use them to comply. Adding this provision to the program design could help reduce the risk of allowance prices spiking just prior to the compliance deadline. The WCI Partner jurisdictions will consider how this approach might be used, including:

   – The conditions under which allowances for the next compliance period could be used to comply in the current period;
   – Potential limits on the use of allowances from the next compliance period; and
   – Risks of increasing the stringency of the next compliance period and options for reducing these risks.

3. Special purpose allowance pools or other mechanisms could be created that target localized conditions that affect compliance costs locally. For example, allowances could be released in response to an electric sector upset in a jurisdiction. The WCI Partner jurisdictions will further consider the use of such special purpose allowance pools or other mechanisms in the context of:

   – The size needed to mitigate individual jurisdictional risks;
   – The conditions for activating allowance pools or mechanisms; and
   – Methods for filling and managing special pools at the individual jurisdiction level.

When combined with an auction floor price (see Figure 4), these mechanisms would help create boundaries on the range of allowance prices: new features under consideration would mitigate risks of high compliance costs and high allowance prices, while the auction floor price reduces the risks of low allowance prices. The auction floor price could also result in allowances remaining unsold at auction, which could be transferred to help fill allowance reserves. The WCI Partner jurisdictions recommend these types of mechanisms as preferred over hard price caps that have the potential to undermine the environmental integrity of the program and which could limit the ability to link to other cap-and-trade programs in the future.

Figure 4: WCI Program Design Recommendations that Provide Compliance Flexibility

Mechanisms	Impact
Allow a limited number of offset certificates and other approved compliance instruments for compliance	Allowing offset certificates and other approved compliance instruments for compliance can reduce compliance costs and reduce allowance prices. The limit on the use of offset certificates and other approved compliance instruments recommended by WCI Partner jurisdictions ensures that a majority of the required emissions reductions are achieved at the covered sources.
Unlimited banking	Unlimited banking allows compliance entities to decide how best to use emission allowances over time. This flexibility can substantially reduce compliance costs across compliance periods.
Multi-year compliance period	Multi-year compliance periods provide flexibility for compliance entities, and recognize that emission reduction efforts may take time to phase in, particularly in the early years of the program.
Linking among programs	Linking among cap-and-trade programs (such as among the WCI Partner jurisdictions), improves efficiency and reduces compliance costs by enlarging the carbon market across a diverse set of emissions sources with a range of emission reduction opportunities.
Broad scope	A broad scope for the cap-and-trade program helps improve efficiency and reduce compliance costs by covering a diverse set of sources with a range of emission reduction opportunities.
Other low-carbon core policies and programs	Other low-carbon core policies and programs can motivate or require emissions reductions that—due to market barriers—would not otherwise be undertaken solely in response to price considerations. These policies can reduce overall program compliance costs.
Auction floor price	The auction floor price keeps allowances out of the market, at least temporarily, in the event that the demand at auction results in a price that would be below an acceptable level. This feature helps correct an inadvertent over-allocation of allowances.

6. Maintaining Competitiveness and Preventing Emissions Leakage

The WCI Partner jurisdictions' recommendations are designed to maintain and enhance economic competitiveness while preventing emissions leakage. Competitiveness can be enhanced by early investments in cost-effective efficiency improvements, diversifying fuel supplies—particularly in the transportation sector—spurring innovation, and reducing exposure to fossil fuel price volatility. Improved air quality and public health also make our communities more livable, attracting families and businesses that create new economic opportunities and jobs.

Emissions leakage would occur if production activity shifts from WCI Partner jurisdictions to non-Partner jurisdictions so that emissions reductions in the WCI Partner jurisdictions are negated by comparable increases in another jurisdiction. Incentives may be used, particularly through the allocation of emission allowances, to minimize leakage risks and support WCI Partner jurisdictions' economic growth and jobs. Although the WCI Partner jurisdictions recommend that the value of the emission allowances be directed to enhance economic competitiveness and prevent emissions leakage, each Partner jurisdiction has the opportunity to apply these resources in the ways that best meet its needs.

> Benchmarking is an approach for promoting efficiency by evaluating GHG emissions performance among similar facilities or operations in an industrial sector. It uses an objective indicator of efficiency (a benchmark) to compare the facilities or operations to an industry standard or best practice metric. Benchmarking can be used in a cap-and-trade program as a basis for distributing allowances to industrial facilities covered by the program. Using benchmarks in this way can recognize and reward facilities that use best practices or that have already reduced emissions.

WCI Partner jurisdictions have been focusing on energy-intensive, trade-exposed ("EITE") industries, which may be particularly vulnerable to competition and leakage. Free distribution of emission allowances to EITE industries has been identified as one approach to promote competitiveness and minimize leakage, with benchmarking being considered as a basis for distributing allowances.[19] Free distribution based on benchmarking is the approach the EU proposes to take for its Phase III, and is embodied in leading national U.S. legislative proposals. A different approach would require imports into WCI Partner jurisdictions to comply with their cap-and-trade rules. This approach is recommended for the electricity sector and is described in more detail in the next section.

Differing allowance allocation methods could also affect competitiveness among WCI Partner jurisdictions, particularly for EITE industries. WCI Partner jurisdictions are continuing to examine harmonizing allowance distribution approaches, particularly among similar facilities or entities in the same industry. Use of common benchmarking approaches would facilitate this harmonization, thereby addressing potential competitiveness concerns prior to the program initiation.

If analysis demonstrates that allowance distribution to a particular sector could be harmonized by some WCI Partner jurisdictions to maintain competitiveness among similar facilities or entities—and if that analysis reveals that it is advisable to address those competitiveness issues—WCI Partner jurisdictions may recommend standardizing the distribution of allowances in those circumstances. Sectors where analysis is required include those with process (non-combustion) emissions where the greatest

[19] Two WCI co-sponsored workshops examined benchmarking issues. Materials from the September 17, 2009 Benchmarking Workshop in Toronto, ON are available: http://www.ene.gov.on.ca/en/air/climatechange/benchmarking.php. Materials from the May 19th, 2010 Greenhouse Gas Benchmarking Symposium in Seattle, WA are available at http://www.westernclimateinitiative.org/component/remository/Partner-Meeting-Materials/2010-05-19-(Seattle-Benchmarking-Symposium)/.

emission reduction potential is associated with large technology changes and high GHG emission intensity, such as aluminum, steel, cement, lime, pulp and paper, and oil refining.

7. Electricity Sector

The electricity sector has unique characteristics that are reflected in the WCI Cap-and-Trade Program design recommendations. The interconnected nature of the North American electricity grid creates the potential for leakage, and existing practices see considerable quantities of electricity transacted among jurisdictions. To maintain a level playing field and a consistent price for carbon, the emissions associated with imports of electricity are included in WCI Partner jurisdiction emissions. In addition, environmental requirements and voluntary initiatives have created existing markets for renewable energy in many jurisdictions, raising issues of their potential interaction with a cap-and-trade market. These issues have been examined and recommendations have been developed to address them.

Electricity Imports

The WCI Partner jurisdictions recommend that emissions from electricity generated outside the WCI Partner jurisdictions but consumed within them be included in the program. To include these emissions, the point of regulation is defined as the First Jurisdictional Deliverer (FJD), which is the first entity that delivers electricity over which the consuming WCI Partner jurisdiction has regulatory authority.[20]

Different approaches were examined in extensive consultations with stakeholders to determine how to define the boundary for FJD and treat transactions which pass through multiple jurisdictions. After considering practical, administrative, regulatory and enforcement aspects, the WCI Partner jurisdictions recommend the use of individual jurisdiction boundaries for FJD.[21] For jurisdictions that are not able to implement the full FJD approach, the Administrative Approach was developed as an alternative, under which the jurisdiction creates a reserve of allowances to cover emissions associated with imports.[22]

Imported power may be from a known generation source (with known emissions) or from an unspecified source. For the purposes of assigning emissions to unspecified sources, the *Default*

[20] The FJD recommendation and consequences have been further examined and refined in stakeholder consultations and consultant studies including the *Electricity Leakage Analysis Summary Report* (March 2009); *Draft Open Access Technologies Inc. (OATI) Analysis of Electricity Imports in the Western Electricity Coordinating Council (WECC) Region* (February 2010); and *Electricity Imports, Exports and Leakage in the Eastern WCI Partner jurisdictions: Quebec, Ontario and Manitoba* (July 2010).

[21] Considerations on the boundary issue are described in *Discussion Paper on FJD Boundary Options for Regulating Electricity Imports* (January 2009), and the decision laid out in *Announcement Regarding the FJD Approach* (July 2009).

[22] *Covering Emissions From Imported Electricity: An Administrative Approach*. May 2010.

Emissions Calculator[23] was developed and the concept validated with stakeholders. With this approach, all generators in a jurisdiction or area are identified along with their recent historical emissions. Using criteria on capacity factors and type of generation, marginal generation available to supply the imported power is identified and an emissions factor calculated.

Renewable Energy

To address the interaction between the WCI Cap-and-Trade Program and existing markets for renewable energy, WCI Partner jurisdictions recommend:

- Renewable Energy Certificates (RECs) will have no compliance role in the WCI Cap-and-Trade Program. This recommendation maintains the separate and distinct markets for RECs and GHG allowances, and avoids complications from overlap of the two regulatory regimes.[24]
- To recognize the impacts of voluntary investments in renewable energy, an optional mechanism was developed for use by WCI Partner jurisdictions. This approach employs a set-aside of allowances to be retired in recognition of voluntary renewable energy purchases, thus enabling voluntary investments to reduce GHG emissions under a cap-and-trade regime.[25]

Recognizing the importance of renewable energy in reducing GHG emissions, Partner jurisdictions can choose to freely allocate allowances from within their allowance budgets to entities that export renewable electricity (e.g., hydroelectricity) outside WCI Partner jurisdictions, in accordance with section 6 of the Detailed Design.

Competitiveness

The highly interconnected nature of the electricity sector in North America led to a focus on competitiveness in the electricity sector, and the recommendation that the distribution of allowance value or auction revenues in that sector could be standardized as a means to address competitiveness across WCI Partner jurisdictions.[26] While the FJD compliance obligation helps to maintain the competitiveness of electricity generation in WCI Partner jurisdictions with respect to imported electricity, for WCI Partner jurisdictions that currently export electricity, fossil-fired electricity exports that would be less competitive in non-WCI markets must also be considered.[27] The WCI Partner jurisdictions are examining potential options for mechanisms to address this issue.

---

[23] 2007 and 2006 *Draft Default Emission Factor Calculators*. February 2010.

[24] Considerations on the treatment of RECs are described in the discussion paper *Renewable Portfolio Standards, Renewable Energy Certificates, and GHG Accounting (RECs) Accounting* (December 2008). The decision is further explained in the announcement *Treatment of Renewable Energy Credits in the WCI Cap-and-Trade Program* (May 2010).

[25] This approach is described in *Voluntary Renewable Energy Market: Issues and Recommendations*. July 2010.

[26] This issue was explored in GHG Allowance Allocation Options in the Electricity Sector. January 2009.

[27] An example of this effect can be found in the report *Electricity Imports, Exports and Leakage in the Eastern WCI Partner Jurisdictions: Quebec, Ontario and Manitoba*. July 2010.

8. Designing for High-Quality Offsets

The WCI Partner jurisdictions include offsets in the WCI Cap-and-Trade Program design to reduce compliance costs by introducing a broader range of emissions reduction opportunities. The WCI Partner jurisdictions' recommendations for offsets maintain the integrity of the emissions cap by ensuring that emissions reductions or removals achieved through an offset project are functionally equivalent to emissions reductions achieved by a regulated emissions source. Emphasis is placed on assuring the quality of offsets, not only to ensure that the program's environmental goals are achieved, but also with the objective of informing the national and international deliberations on offsets.

The WCI Partner jurisdictions recommend the following for the definition of an offset and criteria to evaluate an offset project.

- **Definition**: A GHG offset is a reduction or removal of GHG emissions as a result of a project or activity that occurs outside the sectors regulated by the cap-and-trade program. An offset certificate issued by a WCI Partner jurisdiction represents a reduction or removal of one metric ton of CO_2e. To be issued an offset certificate by a WCI Partner jurisdiction, each reduction or removal must meet all recommended offset criteria, have clearly identified ownership, follow an accepted protocol, and result from a project located in Canada, the U.S., or Mexico.
- **Criteria**: Offset projects approved by WCI Partner jurisdictions will meet the criteria described in the *Offset System Essential Elements Final Recommendations*.[28] The criteria recommended by WCI Partner jurisdictions are consistent with the leading offset systems in use worldwide, and will allow the adoption of protocols that produce consistent offsets across the WCI region. The other North American emissions trading systems—RGGI and the Midwestern Greenhouse Gas Reduction Accord—share the goal of ensuring the quality of offsets. The three regional programs released a paper on offset quality that is consistent with the offset criteria recommended by the WCI Partner jurisdictions.[29]

WCI Partner jurisdictions will leverage existing protocols to align with the essential criteria and, through their rulemaking processes, make the protocols applicable for use in all WCI Partner jurisdictions. WCI Partner jurisdictions have evaluated existing protocols against WCI Partners' offset criteria,[30] and are continuing to establish key protocol components for each priority project type. This is being done in consultation with sector experts and stakeholders, enabling where possible the use of existing protocols and flexibility for the

---

[28] *Offsets System Essential Elements Final Recommendations*. June 2010.

[29] *Ensuring Offset Quality: Design and Implementation Criteria for a High Quality Offset Program*. May 2010.

[30] *Review of Existing Offset Protocols Against WCI Offset Criteria*. April 2010.

protocol authors and national or voluntary offset program developers to easily take advantage of and harmonize with WCI Partner jurisdiction progress.

Similar to the essential criteria, the process of offset project approval through certificate issuance contains important features to ensure offset quality. The WCI Partner jurisdictions are continuing to finalize the process, with the goal of having a streamlined process and protocols in time for adoption by Partners who need to incorporate these elements into their legislative and/or regulatory processes. These steps will include specific requirements for registration, validation, monitoring, quantification, reporting, verification, certification, and issuance of offsets. WCI Partner jurisdictions will harmonize the project approval process in consultation with stakeholders prior to the start of the program.

9. Designing a Fair and Transparent Auction

Selling emission allowances at auction is one mechanism for distributing allowances. Both the European program and RGGI use auctions, with RGGI relying almost exclusively on auctions for distributing allowances. The WCI Partner jurisdictions expect to auction allowances as one component of allowance distribution. The portion of allowances auctioned may vary across jurisdictions based on jurisdiction-specific authorities and circumstances, and may also change over time.

The WCI Partner jurisdictions plan to auction emission allowances in a regionally coordinated manner to ensure fairness and transparency, maximize efficiency, and ensure consistent application of state and provincial laws. To accomplish these objectives, the WCI Partner jurisdictions recommend the following for the design of a regionally coordinated auction:

- **Auction format, timing and frequency**: A sealed bid, single round, uniform price (lowest winning bid) auction that will take place quarterly. The sealed bid, single round auction format mitigates the potential for market manipulation and is relatively simple to understand. A quarterly auction balances the cost of running the auctions with flexibility for participants, and creates regular market price signals. This approach is consistent with auctions in other cap-and-trade programs.
- **Reserve price**: A reserve or "floor" price applied to all of the allowances on offer at the auction. As further described in section 10, this feature addresses an inadvertent over-allocation of allowances to the market and the risk of persistently low compliance costs. The method for determining a reserve price will be set in advance of the first auction.
- **Vintages**: Allowances from future compliance periods may be sold concurrently to aid market liquidity, reduce uncertainty, and contribute to market efficiency.
- **Lot size**: Allowances will be sold in lot sizes of 1,000 (equal to 1,000 metric tons),

allowing flexibility for auction participants. This lot size is not so large as to discourage participation by smaller entities, yet of sufficient size to make transaction costs manageable.

- **Participant access and financial assurance**: An auction that is open to anyone with an account in the tracking system and able to meet pre-qualification financial assurance requirements will ensure fairness. Requiring bidders to submit an approved form of financial assurance (e.g., cash, bond, letter of credit) that covers the full value of their bid will contribute to accountability and help prevent market manipulation. Such assurances are consistent with auction procedures in other cap-and-trade programs.
- **Information transparency**: The clearing price and total number of purchased allowances will be disclosed publicly after the auction. Disclosure of auction results contributes to both transparency and price discovery and is also consistent with other programs.
- **Mitigation of market manipulation**: Auctions will include a purchase limit and WCI Partner jurisdictions will undertake monitoring and reporting measures that will mitigate market manipulation.

WCI Partner jurisdictions continue to consult on several auction design elements that require additional analysis, including the following:

- Methods for determining reserve prices.
- A non-competitive auction component that would allow bidders to purchase a limited number of allowances, without submitting a bid schedule, at the clearing price as determined by the competitive bidding.
- The ability of Partner jurisdictions to incorporate a consignment option that would allow parties to make their allowances available for purchase in the auction.
- The level of detail to disclose when announcing the auction results, to balance the need for transparency while protecting auction participant information.
- Currency exchange issues relating to a potential bi-national auction.

Partner jurisdictions also continue to discuss recommendations for treatment of allowances that remain unsold at auction. WCI Partner jurisdictions can retire allowances, roll allowances to a future auction, or supply allowance reserves. In addition, the WCI Partner jurisdictions are developing a method for jurisdictions that are not auctioning allowances to manage their allowance budgets in a way that is equitable and supports the WCI Partner jurisdiction's cost containment goals.

10. Ensuring a Well-Functioning Market

The WCI Cap-and-Trade Program is designed to harness market forces to spur technological innovation and reduce GHG emissions at the lowest possible cost. For the program to achieve these goals, participants must be able to trade emission allowances and offset certificates in a well-functioning market. To accomplish this, the WCI Partner jurisdictions are recommending specific policies to ensure fair and equal access to the market, transparent operations and timely public disclosure of critical information to maintain public confidence, and a market free of manipulation so that prices reflect supply and demand conditions.

Recent market events in the U.S. and elsewhere underscore the need for comprehensive and effective market monitoring and oversight. To achieve the necessary level of effectiveness, the WCI Partner jurisdictions recommend coordinating among several institutions based on existing authorities and capabilities. Financial reform under consideration in the U.S. and Canada could alter existing authorities, with the expectation of enhancing oversight. As needed, these recommendations may be revised in light of financial reform to ensure comprehensive and effective oversight is maintained.

The WCI Partner jurisdictions' recommendations reflect the following roles:

- The U.S. and Canadian WCI Partner jurisdictions have primary responsibility for the auction market, including all aspects of its design, operation, monitoring, and enforcement.
- The U.S. and Canadian WCI Partner jurisdictions also have primary responsibility for oversight and enforcement of the "cash market" in which allowances and offset certificates are traded for immediate delivery. Oversight responsibility may be shared, however, with trading organizations.
- In the U.S., the Commodity Futures Trading Commission has primary responsibility for oversight of the derivatives market.[31] In Canada, provincial regulatory authorities provide derivative market oversight. The WCI Partner jurisdictions have been in discussions with these organizations to develop this approach, and recommend formalizing the coordination prior to the start of the program.

Recommendations for the areas in which WCI Partner jurisdictions have primary responsibility are to: [32] impose necessary requirements on all owners of allowances and offset certificates; encourage the use of effective trading venues; and conduct effective monitoring of market activity and conditions. The requirements that apply to owners of allowances and offset certificates focus

---

[31] A derivative is a financial instrument that derives its value from one or more other underlying assets. A contract to purchase an emission allowance in six months at a specific price is an example of a derivative. Derivatives are traded on exchanges and between individual parties (referred to as "over the counter" or OTC).

[32] The WCI Partner market oversight recommendations are listed in the *Market Oversight July Status Update*. For a discussion of market oversight options, see *Market Oversight Draft Recommendations*. April 2010.

on providing information that enables the WCI Partner jurisdictions to know the identity and inter-relationships of market participants and to evaluate their activity in the auction and cash markets. Key aspects of this information will be disclosed publicly so that the public will know how the markets are working.

Reporting and disclosure also will help regulators uncover conditions that may make manipulation possible. To further reduce the risk of manipulation, the WCI Partner jurisdictions are considering placing a limit on the allowances and offset certificates that any one entity can hold. [33] Such a limit would be in addition to the limit on purchases in any single auction, discussed above. The WCI Partner jurisdictions note that some of the information provided by allowance and offset certificate owners must be maintained as confidential to avoid revealing information that would assist market manipulation rather than prevent it.

Market participants' use of well organized and effectively managed trading venues (such as exchanges) will help ensure transparent and competitive pricing and equal access to the market, benefitting market participants and the public. Accordingly, the WCI Partner jurisdictions propose to encourage qualified venues to develop cash markets, provided the venues conduct effective oversight of their cash markets and enable access for regulatory oversight.

Vigilant market monitoring will be necessary across all aspects of these recommendations. The WCI Partner jurisdictions recommend that professional market intermediaries be identified and registered. Provisions for collaborative analysis and information sharing among Partner jurisdictions are also recommended to ensure effective and comprehensive monitoring across the program.

[33] For a discussion of holding limits under consideration by the WCI Partner jurisdictions, see *Report on Holdings Limits*. May 2010.

11. Linking Programs

The WCI Partner jurisdictions are committed to promoting broad collaborative action to reduce GHG emissions. Accordingly, the WCI program recommendations are designed to facilitate linking among the WCI Partner jurisdictions as well as linking with jurisdictions participating in other programs. Several benefits of linking include:

- Incorporating more opportunities to reduce GHG emissions can improve cost-effectiveness while also achieving greater emissions reductions.
- Expanding the geographic coverage of the price on GHG emissions can reduce the risk of emissions leakage and maintain competitiveness.
- Enlarging the market for emission allowances and offsets can improve market liquidity, reduce volatility, and reduce the likelihood of manipulation.
- Collaborating among jurisdictions can provide an opportunity to share administrative functions, reducing the costs of program operation and enhancing consistency across jurisdictions.

Linking among the WCI Partner jurisdictions will be achieved by recognizing each other's instruments for compliance purposes. Through this recognition, the emission allowances and offset certificates issued by each jurisdiction will be usable throughout the linked jurisdictions for compliance purposes. Prior to linking, a Partner jurisdiction will have the opportunity to review each jurisdiction's program to assess its consistency with the program design, including: allowance budgets; information requirements and tracking systems; emissions accounting for electricity traded between Partner jurisdictions; monitoring, reporting, verification, compliance, and enforcement provisions; and treatment of offsets. Ensuring consistency with the program design will protect the integrity of each jurisdiction's program and the regional effort as linking is instituted.

The WCI Partner jurisdictions are also actively exploring linkages with other government-approved cap-and-trade systems. Initially, WCI Partner jurisdictions will consider unilateral linking to accept compliance instruments from trading programs external to WCI Partner jurisdictions. Prior to initiating a unilateral link, external programs will also be evaluated to ensure that they exhibit the integrity inherent in the WCI Cap-and-Trade Program design recommendations. In particular, a mechanism will be developed to ensure the compliance instruments from external programs can only be used once.

WCI Partner jurisdictions will also consider the recognition of offsets that are not part of an external cap-and-trade program. In this case, the criteria that are relevant for offsets will be used to evaluate the acceptability of the external offset program.[34]

Over the longer term, WCI Partner jurisdictions will work with jurisdictions participating in other

[34] The specific mechanisms for recognizing offsets from other systems are still under consideration.

regional trading programs to explore bilateral or multilateral linkages so that compliance instruments from those jurisdictions and compliance instruments issued by WCI Partner jurisdictions are fully fungible. Jurisdictions participating in the three regional climate initiatives in North America—WCI, RGGI, and the Midwestern Greenhouse Gas Reduction Accord—have been working cooperatively to share experiences in the design and implementation of regional cap-and-trade programs, inform federal decision making on climate change policy, and explore the potential for further collaboration among the three regional programs. This work will provide a potential roadmap for developing bilateral or multilateral linkages.

12. Coordinating Program Administration

Implementation of the WCI Cap-and-Trade Program by Partner jurisdictions requires effective administrative processes. This section describes three areas of proposed coordination: the tracking system for emission allowances and other compliance instruments; compliance verification and enforcement; and a regional administrative organization.

Tracking System

The tracking system is an integral component of the WCI Cap-and-Trade Program. Its purpose is to ensure the accurate accounting of the issuance, holding, transfer, retirement, and cancellation of compliance instruments. The tracking system must be simple to use, secure, flexible in an evolving environment, consistent with legal requirements in WCI Partner jurisdictions, and meet the WCI Partner jurisdictions' transparency objectives. The WCI Partner jurisdictions will ensure a regional tracking system is in place prior to the start of the program.

The WCI Partner jurisdictions will establish and maintain a tracking system that enables an effective and transparent regional cap-and-trade program. The tracking system will notably:

- Be a standardized electronic database that is accessible online.
- Contain separate accounts to record the compliance instruments held by each person or entity and to whom and from whom they are issued or transferred.
- Ensure there are no transfers incompatible with the rules implementing the WCI Cap-and-Trade Program.
- Provide for public access to relevant information, as well as confidentiality of information as appropriate.
- Restrict certain functions to account holders, to authorized staff of regulatory authorities, or to system maintenance service providers.
- Have the ability to generate specific public reports.

Section 7 of the Detailed Design contains more information on the tracking system. The WCI Partner jurisdictions are evaluating the suitability of developing the tracking system from others already in use in other markets.

Compliance Verification and Enforcement

Each WCI Partner jurisdiction will use its authority to enforce compliance with the WCI Cap-and-Trade program within its own jurisdiction. The WCI Partner jurisdictions recognize that during the first compliance period, unforeseen issues are likely to arise. Each WCI Partner jurisdiction should aim for full compliance, and engage in compliance promotion to reduce the potential for non-compliance. Consequently, the WCI Partner jurisdictions are committed to providing appropriate technical and compliance assistance to the program participants.

A degree of harmonization and a necessary level of stringency for compliance verification and enforcement are essential in linking cap-and-trade programs among WCI Partner jurisdictions to ensure consistent programmatic outcomes and a level playing field for covered sources. The degree of harmonization is subject to each WCI Partner jurisdiction's legislative and administrative processes and acknowledges that each jurisdiction maintains sovereignty in the administration of its program.

Of particular importance is ensuring that all linked programs can take similarly effective steps in the event that a covered source does not have sufficient compliance instruments to cover its emissions for the previous compliance period. In such circumstances, requirements must apply that:

- Operate without requiring the cooperation of the covered source;
- Are non-discretionary; and
- Are of sufficient magnitude to incentivize compliance.

To achieve this common level of performance, the WCI Partner jurisdictions recommend that:

- One compliance instrument be submitted for each ton of emissions by the compliance deadline; and
- Emissions for which compliance instruments are not provided by the compliance deadline be considered "excess emissions," with the following increased compliance obligation:
  - One compliance instrument to cover each metric ton of excess emissions (the compliance requirement had compliance instruments been submitted on time); and
  - Three additional compliance instruments for each metric ton of excess emissions.

The increased compliance obligation for excess emissions does not preclude WCI Partner jurisdictions from also establishing administrative, civil and criminal penalties for non-compliance. If a WCI Partner jurisdiction is unable to implement the increased compliance obligation for excess emissions, the Partner jurisdiction may substitute a monetary payment that provides a comparable incentive for timely compliance.

Regional Administrative Organization

Implementation of a regional cap-and-trade program requires coordination between WCI Partner jurisdictions in order to ensure integrity, efficiency and consistency. This coordination may be achieved through a Regional Administrative

Organization that is designed to perform the following functions to support the WCI Cap-and-Trade Program:

- Coordinate the regional auction of allowances.
- Track emissions and provide public information on progress towards the WCI Partners' emissions goals.
- Report to Partners on market activity.
- Serve as a forum for WCI Partner jurisdictions to update one another on program progress.
- Coordinate Partner review and adoption of protocols of offsets.
- Coordinate Partner review and adoption of updated reporting protocols.
- Coordinate Partner review and issuing of offsets certificates.
- Suggest criteria and means for Partners to accredit service providers to deliver validation and verification services.

The WCI Partner jurisdictions are considering creating a regional organization or retaining an existing organization to provide these services. RGGI has created a non-profit corporation, RGGI Inc., which is an example of the type of organization that the WCI Partner jurisdictions are considering.

DOCUMENTATION

The following materials were developed by WCI committees and teams, and form the basis for the WCI program design recommendations. In most cases, white papers, technical documents, and draft recommendations were developed and/or reviewed in consultation with stakeholders through written comment, public conference calls, and meetings.

Reporting

  2007 and 2006 Draft Default Emission Factor Calculators. February 2010. Available at: http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/2007-Draft-Default-Emissions-Factor-Calculator and www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/2006-Draft-Default-Emissions-Factor-Calculator. Note: Various methodologies can be used to calculate default emission factors. The WCI Electricity Team discussed these options with stakeholders on a conference call in December 2008 and developed this simplified spreadsheet approach that approximates the load duration curve modeling methodology discussed with stakeholders. The Team will develop spreadsheets for additional years as needed, and use these spreadsheets to calculate the default emission factors that will be recommended to the Partners for use by WCI jurisdictions.

   - 9.2 Establishing Bilateral Link to Other Program 45
   - 9.3 Establish a Unilateral Link to Another Program 46

1. Purpose

Over the past 18 months, the Western Climate Initiative (WCI) Partner jurisdictions (the "Partners") have developed the detailed design necessary to implement the program described in their September 2008 Design Recommendations for the WCI Regional Cap-and-Trade Program. In addition to providing a detailed program design summary, this document sets out the process the Partners will use for continued cooperation in the design and implementation of individual Partner-level components of the program. This design summary represents a significant milestone in a more than 3-year cooperative effort to develop a regional cap-and-trade program that will reduce greenhouse gas (GHG) emissions and stimulate economic growth in participating Partner jurisdictions.

1.1 Brief History. This cap-and-trade design is one part of a broader cooperative effort among seven U.S. states and four Canadian provinces to reduce GHG emissions throughout their jurisdictions. The cooperative effort began in February 2007 between the governors of Arizona, California, New Mexico, Oregon and Washington, who have since been joined by the premiers of British Columbia, Manitoba, Ontario and Quebec, and the governors of Montana and Utah. These governors and premiers called for the Partners to collaborate on setting an overall regional GHG reduction goal consistent with the jurisdiction-by-jurisdiction goals, and a design for a regional multi-sector mechanism to achieve the GHG reduction goal. They also called for promotion of clean and renewable energy, increased energy efficiency, and national policies that reflect the needs and interests of the Partner jurisdictions.

1.2 Purpose and Use of this Document. Each Partner jurisdiction will seek any necessary legislative authority and develop its own administrative rules in order to participate in a WCI regional cap-and-trade program. This detailed program design is intended to inform the development of proposed legislation and/or regulatory language in Partner jurisdictions in order to enable those jurisdictions to implement state- and provincial-level cap-and-trade programs that can be linked together in a common market. This document specifies the areas of program design that are expected to be the same across all participating Partner jurisdictions in order to create that common market and those areas that may vary. This is not a model rule.

1.3 Process for Amending the Detailed Program Design. The Partners acknowledge that this detailed program design represents a starting point for individual Partner jurisdiction's participation in a WCI regional cap-and-trade program. The Partners further acknowledge that each Partner jurisdiction is subject to its own legislative and administrative processes. The basis of the WCI Regional Cap-and-Trade Program is to provide opportunities to obtain low-cost emissions reductions through emission trading on a common market, allowance banking, and inclusion of an offsets component. This common market provides for "allowances" or other compliance instruments issued by one jurisdiction to be recognized by another and "traded" across state and provincial borders. Certain elements of the program design need to be the same in order to create a functional multi-jurisdictional market, and to establish a single WCI-wide transparent carbon price. If during the development and implementation individual Partner jurisdictions find they must vary from the agreed upon design parameters but desire to remain linked to the other implementing Partner jurisdictions, the individual Partner jurisdiction will prepare a written proposal for how the variance will not adversely affect the regional carbon market.

2. Definitions

This section provides some of the key terms that a Partner jurisdiction may decide to use in the drafting of legislation or rule language. It is expected that individual Partner jurisdictions will have substantial flexibility in constructing definitions sections. Actual terms used within a Partner's law or regulation need not match the terms used here so long as they accomplish the same substantive end as the terms here defined. Partners will consider, however, instances in which the use of same terminology is beneficial to the functioning of the regional cap-and-trade market, and in those instances may recommend use of the same terminology.

2.1 Account number. The identification number given by the program authority or its agent to each WCI Tracking System (WTS) account in accordance with WCI's numbering system. This identification number is unique within the WCI Regional Cap-and-Trade Program, and will identify the jurisdiction that opened the account.

2.2 Allocate or allocation. The distribution by the program authority of a number of allowances, either by auction, sale, or at no cost, to a covered unit or other individual for any other reason, or temporarily to an allocation set-aside or other special purpose account.

2.3 Allowance. A type of compliance instrument that is a limited authorization by the program authority or a participating jurisdiction under the Partner jurisdiction's Cap-and-Trade Program to emit up to one metric ton in carbon dioxide equivalent (CO_2e) of GHGs, subject to all applicable limitations contained in this detailed program design summary, that may be allocated by the program authority out of its annual allowance budget under section 5.1.

2.4 Alternate authorized account representative. For a covered source and each covered unit at the source, the natural person who is authorized by the owners and operators of the source and all covered units at the source, in accordance with 4.3.2, to represent and legally bind each owner and operator in matters pertaining to the Partner jurisdiction's Cap-and-Trade Program or, for a general account, the natural person who is authorized, under section 7.2.2.2, to transfer or otherwise dispose of compliance instruments held in the general account.

2.5 Approved trading program. A system of reducing GHG emissions external to the WCI Cap-and-Trade Program that a Partner jurisdiction, in consultation with all other participating Partner jurisdictions, determines should be linked to the Partner jurisdiction's Cap-and-Trade program under section 9 of the detailed program design summary. An approved trading program may be a program focused exclusively on project-based reductions.

2.6 Approved program compliance units. The compliance instrument from an approved trading program that may be used for compliance purposes in the Partner jurisdiction's Cap-and-Trade program, subject to any limitations set out in this detailed program design. An approved program compliance unit can be a project-based reduction from an approved trading program.

2.7 Authorized account representative. For a covered source and each covered unit at the source, the natural person who is authorized by the owners and operators of the source and all covered units at the source, in accordance with section 4.3.1, to represent and legally bind each owner and operator in matters pertaining to the Partner jurisdiction's Cap-and-Trade Program or, for a general account, the natural person who is authorized, under 7.2.2.2, to hold, transfer, retire or cancel or otherwise dispose of compliance instruments held in the general account.

2.8 Award. The determination by the program authority of the number of Early Reduction Allowances to be issued into the compliance account of a covered unit or a covered source pursuant to section 5.2, or the determination by the program authority of the number of offset certificates to be recorded in the general account of a project sponsor pursuant to section 8.

2.9 Bilateral link or linking. The acceptance of approved program compliance units from an approved trading program to meet compliance obligations under the Partner jurisdiction's Cap-and-Trade Program, and the reciprocal approval of compliance instruments issued by participating Partner jurisdictions to meet compliance obligations in the approved trading program.

2.10 Budget emissions limitation. For a covered source, the metric-ton equivalent in verified emissions for the compliance period that is equal to the total quantity of compliance instruments in the source's compliance account and available for compliance surrender or deduction for the source on the compliance instrument surrender deadline.

2.11 Budget permit.[1] The legally binding and enforceable permit issued by the program authority pursuant to the program authority's permitting regulations, to a covered source or covered unit which specifies the Partner jurisdiction's Cap-and-Trade Program requirements applicable to the covered source and to each covered unit at the covered source, and to the owners and operators and the authorized account representative of the covered source and each covered unit.

2.12 CO_2 equivalent (CO_2e). A measure for comparing carbon dioxide with other GHGs, based on the quantity of any given GHG multiplied by its Global Warming Potential (GWP).

2.13 Combined cycle system. A system comprised of one or more combustion turbines, heat recovery steam generators, and steam turbines configured to improve overall efficiency of electricity generation or steam production.

2.14 Combustion turbine. An enclosed fossil or other fuel-fired device that is comprised of a compressor (if applicable), a combustor, and a turbine, and in which the flue gas resulting from the combustion of fuel in the combustor passes through the turbine, rotating the turbine.

[1] Some Partner jurisdictions will use permitting as one of the mechanisms for enforcing program requirements. Others will enforce requirements under their laws and regulations and through interaction with covered sources and holders of compliance instruments through the WTS.

2.15 Commence operation. To begin any mechanical, chemical, or electronic process, including, with regard to a unit, start-up of a unit's combustion chamber or start-up of any processes that produce GHG emissions. For First Jurisdictional Deliverers and fuel suppliers, to begin to deliver electricity or supply fuel into the Partner jurisdiction.

2.16 Compliance account. A WTS account, established by the program authority or its agent for a covered source under section 7.2.1, in which are held compliance instruments available for use by the source for a compliance period for the purpose of meeting the requirements of section 4.4.

2.17 Compliance instrument. An allowance, an offset certificate or an approved program compliance unit.

2.18 Compliance instruments held or hold compliance instruments. The compliance instruments recorded by the program authority or its agent, or submitted to the program authority or its agent for recordation, in accordance with section 7.2.4, in a WTS account.[2]

2.19 Compliance instrument deduction or deduct compliance instruments.[3] The permanent withdrawal of compliance instruments by the program authority or its agent from a WTS compliance account to cover the verified emissions from a covered source for a compliance period, determined in accordance with section 7.2.5, or for the forfeit or retirement of compliance instruments as provided for in this detailed program design. This constitutes the permanent removal of the compliance instrument from circulation or use in any participating Partner jurisdiction and cannot be reversed or altered by any person or jurisdiction, except to correct for compliance instruments erroneously deducted.

2.20 Compliance instrument surrender deadline.[4] Midnight of the June 30th occurring after the end of the relevant compliance period or, if that June 30th is not a business day, midnight of the first business day thereafter and is the deadline by which compliance instruments must be submitted for recordation in a covered source's compliance account surrendered in order for the source to meet the requirements of section 4.4 for the compliance period immediately preceding the deadline.[5]

---

[2] This provision is consistent with past practice in U.S. cap-and-trade programs. It is important to note that there will be differences in the way that participating partner jurisdictions in Canada implement the compliance mechanism for the program. The most significant of these differences will be noted throughout this document.

[3] This method of deducting compliance instruments from a source's compliance account represents current practice in the United States. An acceptable alternative method is contained in the British Columbia legislation, where a covered sources are required to transfer surrender compliance units into its compliance account, where the surrendered compliance units will be retired by the program authority where they cannot be removed except by the program authority for compliance deduction.

[4] At present, Partner jurisdictions are considering whether the June 30th deadline is practical. If the June 30th deadline is not practical, the Partner jurisdictions will agree on the earliest practical date for a common compliance instrument surrender deadline.

[5] Some Partner jurisdictions are considering whether to require interim surrender obligations in years prior to the end of the compliance periods. Prior to making a recommendation, the Partner jurisdictions are assessing potential impacts on the compliance instrument market and the implications of interim surrender requirements varying among Partner jurisdictions.

2.21 Compliance obligation. The requirement to surrender sufficient compliance instruments to cover verified emissions during the compliance period.

2.22 Compliance period. The compliance period is a three-calendar-year time period. The first compliance period is from January 1, 2012 to December 31, 2014. Each subsequent sequential three-calendar-year period is a separate compliance period.

2.23 Covered Entity. Any entity subject to the Partner jurisdiction's Cap-and-Trade program by meeting the applicability criteria of section 3.2.

2.24 Covered source. A source that includes one or more covered units and is subject to the Partner jurisdiction's Cap-and-Trade Program requirements under section 3.2.

2.25 Covered unit. A unit that is subject to the Partner jurisdiction's Cap-and-Trade Program requirements.

2.26 Early reduction allowance. A type of allowance that is awarded to the covered source that has implemented eligible projects or activities pursuant to section 5.2.

2.27 Electricity importer.[6] An owner of imported electricity as it is delivered to the first point of delivery in the Partner jurisdiction of the final point of delivery.

2.28 Electricity Source. A stationary source that emits greenhouse gases other than from eligible biomass in the process of producing electricity for sale.

2.29 Electricity transmission and distribution operation" means all electric power transmission and distribution systems that operate gas-insulated substations, circuit breakers, other switchgear, gas insulated lines, or power transformers containing SF6 or PFC that are part of an electric power system.

2.30 Eligible biomass. Each Partner jurisdiction will define eligible biomass in its discretion, provided it must be carbon neutral. CO_2 emissions from combustion of eligible biomass are not included in the Partner jurisdiction's Cap-and-Trade Program, except for purposes of reporting.

2.31 Excess emissions. Each metric ton of carbon dioxide equivalent (CO2e) emitted by a covered source for which the owner or operator has not surrendered compliance instruments by the compliance instrument surrender deadline, and which therefore exceeds the budget emissions limitation for the covered source.

2.32 First Jurisdictional Deliverer or FJD. The owner or operator of an electricity source in a Partner jurisdiction, or an electricity importer that is jurisdictional to the program authority or the immediate downstream purchaser or recipient of electricity from a non-jurisdictional electricity importer.

2.33 Fossil fuel. Natural gas, petroleum, coal, or any form of solid, liquid, or gaseous fuel derived from such material.

---

[6] Given the differences in electricity systems among Partner jurisdictions, it is likely that the definitions related to the first jurisdictional deliverer will vary from jurisdiction to jurisdiction.

2.34 Fossil fuel-fired. A fossil fuel-fired unit is a unit that, alone or in combination with any other fuel, combusts fossil fuels.

2.35 Fuel. A solid, liquid or gaseous combustible material.

2.36 Fuel supplier. Suppliers of petroleum products or natural gas, whether distributors or importers.

2.37 General account. A WTS account, established under section 7, which is not a compliance account and is not any other special purpose account created for this program. General accounts may be established for specific purposes required for program administration.

2.38 Greenhouse Gas or GHG. Any of the following atmospheric gases: carbon dioxide (CO_2), methane (CH_4), nitrogen trifluoride (NF_3), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), hydrofluorocarbons (HFCs), and perfluorocarbons (PFCs).

2.39 Global Warming Potential (GWP). A measure of the radiative forcing (heat-absorbing ability) of a particular gas relative to that of carbon dioxide (CO_2) after taking into account the decay rate of each gas (the amount removed from the atmosphere over a given number of years) relative to that of CO_2. Global Warming Potentials used in this design summary are defined in Table WCI.10-1 of the *Final Essential Requirement for Mandatory Reporting*[7].

2.40 Hydrofluorocarbons or HFCs. A class of GHGs consisting of hydrogen, fluorine, and carbon, including all HFCs listed in Table WCI.10-1 of the *Final Essential Requirement for Mandatory Reporting*.

2.41 Industrial Source. Any stationary source that:

2.41.1 is not an electricity source; and

2.41.2 is in—

2.41.2.1 the manufacturing sector or other industrial sectors as defined in North American Industrial Classification System codes 21, 31, 32, and 33; or

2.41.2.2 the natural gas processing or natural gas pipeline transportation sector (as defined in North American Industrial Classification System codes 211112 or 486210).

2.42 Imported electricity. Electricity brought into a participating Partner jurisdiction that did not originate in any participating Partner jurisdiction.

2.43 Link or linking. The process by which non-Partner-jurisdiction trading programs are approved by the Partner jurisdiction, thereby qualifying approved program compliance units for use as compliance instruments in the Partner jurisdiction's Cap-and-Trade Program.

---

[7] Available at: http://www.westernclimateinitiative.org/component/remository/Reporting-Committee-Documents/Final-Essential-Requirements-for-Mandatory-Reporting.

2.44 Multi-jurisdictional retail provider. A retail provider that provides electricity to consumers in the Partner jurisdiction and in one or more other participating Partner jurisdictions in a contiguous service territory.

2.45 Offset certificate. A type of compliance instrument that is awarded by the program authority in a participating Partner jurisdiction under the Partner jurisdiction's Cap-and-Trade program to the sponsor of a GHG emissions offset project subject to all applicable limitations contained in this detailed program design summary.

2.46 Offset project. An offset project includes all equipment, materials, items, or actions directly related to the reduction of GHG emissions or the sequestration of carbon specified in a registration submitted pursuant to section 8. Equipment, materials, items, or actions unrelated to an offset project reduction of GHG emissions or the sequestration of carbon, but occurring at a location where an offset project occurs, shall not be considered part of an offset project, unless specified in section 8.

2.47 Operator. Any person who operates, controls, or supervises a covered unit or a covered source and shall include, but not be limited to, any holding company, utility system, or plant manager of such a unit or source.

2.48 Output. The amount of a good or service, or intermediate feedstock, produced by a covered entity; for electricity sources, MWh of electricity produced, for industrial sources the units of production included in the Federal Reserve's Industrial Production and Capacity Utilization Report or another metric approved by the Partner jurisdiction.

2.49 Owner. Any of the following persons:

2.49.1 Any holder of any portion of the legal or equitable title in a covered unit; or

2.49.2 Any holder of a leasehold interest in a covered unit, other than either a passive lessor or a person who has an equitable interest through such lessor, whose rental payments are not based, either directly or indirectly, upon the revenues or income from the covered unit; or

2.49.3 Any purchaser of power from a covered unit under a life-of-the-unit contractual arrangement in which the purchaser controls the dispatch of the unit; or

2.49.4 With respect to any general account, any person who has an ownership interest with respect to the compliance instruments held in the general account and who is subject to the binding agreement for the authorized account representative to represent that person's ownership interest with respect to the compliance instruments.

2.50 Participating Partner jurisdiction. A jurisdiction that has adopted a corresponding regulation as part of the WCI Regional Cap-and-Trade Program and that has mutually acknowledged the compliance instruments of the Partner jurisdiction.

2.51 Partner jurisdiction's Cap-and-Trade Program. The regulatory system created in individual Partner jurisdictions informed by this detailed program design. When linked to other Partner jurisdictions' Cap-and-Trade Programs, the linked system is the WCI Regional Cap-and-Trade Program.

2.52 Perfluorocarbons or PFCs. Synthetic compounds derived from hydrocarbons through the replacement of hydrogen with fluorine atoms, including the PFCs listed in Table WCI.10-1 of the *Final Essential Requirement for Mandatory Reporting*.

2.53 Petroleum and natural gas system. Means (a) natural gas distribution facility as that term is proposed for definition in 40 CFR 98.238 in vol 75 Federal Register No. 69; (b) onshore petroleum and natural gas production facility as that term is proposed for definition in 40 CFR 98.238 in vol 75 Federal Register No. 69;[8] (c) onshore natural gas processing plants as that term is proposed for definition in 40 CFR 98.230 in vol 75 Federal Register No. 69; and (d) all other petroleum and natural gas systems that constitute a facility for purposes of application of the reporting thresholds under United States proposed regulations for reporting of GHG emissions

2.54 Point of delivery. A point on an electricity transmission or distribution system where a power supplier delivers electricity to the receiver of that electricity. This point can be an interconnection with another system or a substation where the transmission provider's transmission and distribution systems are connected to another system, or a distribution substation where electricity is imported into the Partner jurisdiction over a multi-jurisdictional retail provider's distribution system.

2.55 Process emissions. The emissions from industrial processes (e.g., cement production, ammonia production) involving chemical or physical transformations other than fuel combustion. For example, the calcination of carbonates in a kiln during cement production or the oxidation of methane in an ammonia process that results in the release of process GHG emissions to the atmosphere. Emissions from fuel combustion to provide process heat are not part of process emissions, whether the combustion is internal or external to the process equipment.

2.56 Program authority. The agency or government department charged with administering the Partner jurisdiction's Cap-and-Trade Program.

2.57 Province. Any Canadian province or territory.

2.58 Serial number. When referring to allowances and offset certificates, the unique identification number assigned to each allowance by the program authority or its agent under sections 6 and 7.2.4 in accordance with the WCI's numbering system.

2.59 Source.[9] Any governmental, institutional, commercial, or industrial structure, installation, plant, building, that emits or has the potential to emit any air pollutant; or any entity or installation that

---

[8] The proposed definition aggregates certain operations based on the three digit Geological Province Code of the American Association of Petroleum Geologists. WCI Partners may also choose to aggregate all operations that are otherwise within the definition of onshore petroleum and natural gas production facility that are within their jurisdiction.

[9] The definitions of source and unit should be read to prevent the splitting of physical facilities or entities into smaller facilities or entities to avoid triggering applicable emissions thresholds. The Partner jurisdictions intend, for example, to combine the emissions from units that are located on one or more contiguous or adjacent properties; are under common control of the same owner(s) or operator(s); and form a producing unit, function as a single integrated site, or have the same first two digits of the Standard Industrial Classification or same first three digits of the North American Industry Classification System.

distributes petroleum-based or coal-based liquid fuel, petroleum coke, or natural gas liquid that when combusted will emit any air pollutant; or any entity or installation that delivers electricity generated outside participating Partner jurisdictions into a Partner jurisdiction; or any electricity transmission and distribution operation or a petroleum and natural gas system. A "source" with multiple units shall be considered a single "source."

2.60 State. Any U.S. State, the District of Columbia, the Commonwealth of Puerto Rico, the Virgin Islands, Guam, and American Samoa and includes the Commonwealth of the Northern Mariana Islands.

2.61 Submit or serve. To send or transmit a document, information, or correspondence to the person specified in accordance with the applicable regulation.

2.62 Unit. A fossil fuel-fired stationary boiler, combustion turbine, combined cycle system, mobile non-road equipment, or any industrial process equipment that emits GHGs, or the entity or installation that distributes petroleum-based or coal-based liquid fuel, petroleum coke, or natural gas liquid that when combusted will emit any air pollutant; or the entity or installation that delivers into a Partner jurisdiction electricity generated outside participating Partner jurisdictions.

2.63 Unit operating day. A calendar day in which a unit emits any GHG.

2.64 Verification. A systematic, independent and documented process for the evaluation of a covered source's emissions data report against the Program Authority's reporting procedures and methods for calculating and reporting GHG emissions.

2.65 Verified emissions. The total number of metric tons of GHGs in CO_2e emitted by a covered source, or a covered unit, quantified, monitored, reported and verified in accordance with sections 4.1 and 7.1.

2.66 Voluntary renewable energy purchase.[10] The permanent retirement of renewable energy certificates by a retail electricity customer or by a load-serving entity on behalf of its customers. The renewable energy certificates retired for a voluntary renewable energy purchase must be tracked by the program authority and generated by a VRE-eligible facility and must not have been used to comply with a mandatory renewable energy standard.

2.67 VRE-eligible facility.[11] An electricity generation facility that uses renewable resources or fuels deemed eligible by the program authority.

2.68 WCI Numbering system. The method of assigning allowances and offset certificates identifiers to indicate the vintage year, the year allocated or awarded, the participating Partner jurisdiction and order issued, and of assigning identification numbers for each WTS account.

[10] This definition is necessary only if an optional voluntary renewable energy set-aside program is implemented by the participating Partner jurisdiction as described in 6.3.

[11] This definition is necessary only if an optional voluntary renewable energy set-aside program is implemented by the participating Partner jurisdiction as described in 6.3.

2.69 WCI Regional Cap-and-Trade Program. A multi-jurisdiction GHG emissions reduction program established consistent with this detailed program design on carbon pricing within participating Partner jurisdictions and corresponding regulations in other participating Partner jurisdictions as a means of reducing GHG emissions from covered sources.

2.70 WCI tracking system, or WTS. The tracking system that enables accounts to be established for the creation, issuance, cancellation, banking, transfer, surrendering, and deletion of compliance instruments.

3. Program Coverage

Section 3 establishes the coverage of the program, including the emissions and covered emissions sources. It is expected that Partners will attempt to adhere to these coverage provisions, including the timing of coverage, and that deviations from coverage and timing requirements would need to be proposed to other Partners before linking with other Partner jurisdictions. The sections below detail the greenhouse gases covered (section 3.1), the emissions and sources covered (section 3.2) and the liability provisions for owners, and operators and first deliverers (section 3.3).

This document does not repeat the descriptions of the emissions reporting requirements, the foundation of the Cap-and-Trade Program that are already been described in the Final Essential Requirements for Mandatory Reporting[12]*. It is expected that each participating Partner jurisdiction will implement emissions reporting requirements consistent with the Final Essential Requirements for Mandatory Reporting.*

3.1 Covered Gases

3.1.1 The Partner jurisdiction's Cap-and-Trade Program covers the following greenhouse gases: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), nitrogen trifluoride (NF_3), sulfur hexafluoride (SF_6), hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs).

3.1.2 If, from time to time, the Partners determine that an additional GHG should be covered by the program, they will confer and make a recommendation to add the GHG.

3.2 Covered Emissions Sources

Any source that, at any time, meets the requirements of paragraph 3.2.1, 3.2.2, or 3.2.3 below, shall be a covered unit or a covered source and be subject to the requirements of the Partner jurisdiction's Cap-and-Trade Program, provided if a source demonstrates that its verified emissions have fallen below the 25,000-metric-ton CO_2e threshold for three consecutive calendar years, then the source may apply to the program authority for a determination that the source is no longer subject to

[12] Available at: http://www.westernclimateinitiative.org/component/remository/Reporting-Committee-Documents/Final-Essential-Requirements-for-Mandatory-Reporting.

the Partner jurisdiction's Cap-and-Trade Program.[13] In the event that a program authority determines that a source is no longer covered by the Partner jurisdiction's Cap-and-Trade Program, then it may, as a condition of its determination, require that the source return any allowances that have been distributed to the source's compliance account for years that the source will not have a compliance obligation. A program authority may also require a source receiving such a determination to accept an enforceable condition, in a permit or otherwise, limiting the source's emissions to a level below the 25,000-metric-ton CO_2e threshold and/or to continue monitoring and reporting its emissions under section 4.1 below. In the event that a source receiving a determination of non-applicability under this section emits 25,000 metric tons CO_2e or more in any year subsequent to the determination, that source will be once again subject to the requirements of the Partner jurisdiction's Cap-and-Trade Program beginning in the year the source reaches or exceeds the threshold.

3.2.1 Any source that emits 25,000 or more metric-tons CO_2e in any calendar year in total verified emissions, excluding emissions from combustion of eligible biomass, from one or more of the activities listed in this paragraph.[14,15] This determination shall be based on the source's highest verified emissions during any year after January 1, 2009, collected pursuant to sections 4.1 and 7.1. A source will be subject to a compliance obligation beginning in 2012, or commencing in the year the source first emits 25,000 metric tons CO_2e in verified emissions, whichever is later.

3.2.1.1 General stationary fuel combustion at sources.

3.2.1.2 Process or other emissions from industrial activities at sources in the following categories:

3.2.1.2.1 Adipic acid manufacturing

3.2.1.2.2 Aluminum manufacturing

3.2.1.2.3 Ammonia manufacturing

3.2.1.2.4 Cement manufacturing

3.2.1.2.5 Electricity generation

3.2.1.2.6 Electronics manufacturing

---

[13] Individual Partner jurisdictions may implement requirements that are more stringent for covered sources that seek a determination that the Partner jurisdiction's Cap-and-Trade Program no longer applies to them.

[14] Individual emission points within the listed sources will be examined by the Partners for applicability to the 25,000-metric-ton threshold and may be withheld if quantification methods do not form a suitable basis for market trading. Additional activities (e.g., magnesium production, underground coal mines, wastewater treatment, etc.) may be added once appropriate quantification methods have been developed.

[15] A source emitting more than 25,000 metric tons CO2e for the first time in a calendar year starting in 2012 will have reported its GHG emissions in the following calendar year. This delay might create some administrative issues when trying to cover the source for this first year it emits more than the threshold and Partner jurisdictions will work together to find ways to mitigate those issues.

3.2.1.2.7 Ferroalloy production

3.2.1.2.8 Fluorinated GHG production

3.2.1.2.9 Glass Production and other uses of carbonates

3.2.1.2.10 HCFC-22 production and HFC-23 Destruction

3.2.1.2.11 Hydrogen production

3.2.1.2.12 Iron and steel manufacturing

3.2.1.2.13 Lead production

3.2.1.2.14 Lime manufacturing

3.2.1.2.15 Nitric acid manufacturing

3.2.1.2.16 Petrochemical production

3.2.1.2.17 Petroleum and natural gas systems

3.2.1.2.18 Petroleum refineries

3.2.1.2.19 Phosphoric acid production

3.2.1.2.20 Pulp and paper manufacturing

3.2.1.2.21 SF6 emissions from electrical equipment

3.2.1.2.22 Soda ash manufacturing

3.2.1.2.23 Zinc production

3.2.1.2.24 Ore pelletization

3.2.1.2.25 Titanium dioxide production

3.2.1.2.26 Ethanol production

3.2.1.2.27 Silicon carbide production

3.2.1.2.28 Any other industrial facilities

3.2.2 Any first jurisdictional deliverer of electricity,[16] including generators, retail providers, and marketers, that provide electricity into the participating Partner jurisdiction, the production of which generates 25,000 metric tons CO_2e or more in any calendar year in total verified emissions, excluding emissions from combustion of eligible biomass.[17] This determination shall be based on the source's

[16] Partner jurisdictions will consider provisions necessary to prevent entities from circumventing applicability by dividing electricity deliveries in a manner designed to stay below the applicability threshold. Partners may also chose to address electricity imports through an administrative approach, detailed below in section 6.4.

[17] A source emitting more than 25,000 metric tons CO2e for the first time in a calendar year starting in 2012 will have reported its GHG emissions in the following calendar year. This delay might create some administrative issues when trying to cover the

highest verified emissions during any year after January 1, 2009, collected pursuant to sections 4.1 and 7.1. A source will be subject to a compliance obligation beginning in 2012, or commencing in the year the source first emits 25,000 metric tons CO_2e in verified emissions, whichever is later.

3.2.3 From and after January 1, 2015, any fuel supplier within the participating Partner jurisdiction that distributes liquid transportation fuel, petroleum coke, natural gas, propane, heating fuel, or any other fossil fuel sold or imported for consumption in the participating Partner jurisdiction in quantities that when combusted would emit 25,000 metric tons CO_2e or more in any calendar in total verified emissions, excluding emissions from combustion of eligible biomass.[18,19] This determination shall be based on the source's highest verified emissions during any year after January 1, 2009, collected pursuant to sections 4.1 and 7.1. A source will be subject to a compliance obligation beginning in 2015, or commencing in the year the source first emits 25,000 metric tons CO_2e in verified emissions, whichever is later.

3.2.4 In the event that a source does not have verified emissions data meeting the requirements of sections 4.1 and 7.1, the program authority may make the determination of applicability based on available emissions data collected pursuant to sections 4.1 and 7.1.

3.2.5 If the program authority determines that emissions data collected pursuant to the requirements of sections 4.1 and 7.1, is not available for any year after 2009, a source that commenced operation prior to January 1, 2012 may apply to use other emissions data acceptable to the program authority for that year to demonstrate that the requirements of the Partner jurisdiction's Cap-and-Trade Program do not apply.

3.3 Compliance Liability

Any provision of the Partner jurisdiction's Cap-and-Trade Program that applies to a covered source or covered unit (including those requirements applicable to the authorized account representative of a covered source or unit) shall also apply to the owners and operators of such source or unit, except that the requirements applicable to first jurisdictional deliverers and deliverers of fuel from outside the participating Partner jurisdiction shall apply only to the owners of the electricity or the fuel at the time it enters the participating Partner jurisdiction.

---

source for this first year it emits more than the threshold and Partner jurisdictions will work together to find ways to mitigate those issues.

18 WCI Partners acknowledge that individual jurisdictions may utilize other fiscal measures, such as British Columbia's carbon tax, to address transportation fuels and fuel use by residential and commercial sources that contribute to achieving overall comparable GHG emissions reductions and internalize the price of carbon as expected through the WCI Regional Cap-and-Trade Program.

19 A source emitting more than 25,000 metric tons CO2e for the first time in a calendar year starting in 2015 will have reported its GHG emissions in the following calendar year. This delay might create some administrative issues when trying to cover the source for this first year it emits more than the threshold and Partner jurisdictions will work together to find ways to mitigate those issues.

4. Requirements for Covered Sources

Section 4 details all of the requirements applicable to covered sources under the Partner jurisdiction's Cap-and-Trade Program. Although implementing language may vary from what is presented here, it is expected that Partner jurisdictions will adhere to the substance of these minimum requirements when drafting individual Partner jurisdiction laws and regulations. Partner jurisdictions may impose additional requirements on their sources. Partners jurisdictions are expected to require a covered source or entity to: (a) quantify, monitor, report, and verify emissions for purposes of determining the compliance instrument surrender requirement (section 4.1); (b) take all necessary actions to make the program requirements enforceable (section 4.2); (c) adhere to the requirements of the WTS (section 4.3); (d) surrender compliance instruments to cover emissions in the compliance period (sections 4.4 and 4.5); (e) comply with requirements to surrender additional compliance instruments in the event the source fails to meet surrender requirements by the compliance instrument surrender deadline (section 4.6); and (f) keep records available for inspection by the Partner jurisdiction for a minimum number of years (section 4.7).

4.1 Quantification, monitoring, reporting and verification requirements

4.1.1 The owners and operators and, to the extent applicable, the authorized account representative of each covered source and each covered unit at the source shall comply with the requirements of Section 7.1 of this detailed program design summary.

4.1.2 The emissions measurements recorded and reported in accordance with Section 7.1 shall be used to determine the number of compliance instruments that must be surrendered under Section 4.4.

4.2 Making Cap-and-Trade Program requirements enforceable

Participating Partner jurisdictions will enforce program requirements contained in their laws and regulations, and through interaction with covered sources and holders of compliance instruments in the WCI tracking system. Some participating Partner jurisdictions may also incorporate program requirements in the permits of covered sources.

4.3 Authorized account representative requirements

4.3.1 Authorization and responsibilities of the authorized account representative

4.3.1.1 Except as provided under section 4.3.2, each covered source, including all covered units at the source, shall authorize as their agent one and only one authorized account representative, with regard to all matters under the Partner jurisdiction's Cap-and-Trade Program concerning the source or any covered unit at the source.

4.3.1.2 As determined by each Partner jurisdiction, the authorized account representative of the covered source shall be selected by an agreement binding on the owners and operators of the source and all covered units at the source.

4.3.1.3 Upon receipt by the program authority or its agent of a complete account certificate of representation under section 4.3., the authorized account representative of the source shall represent and, by his or her representations, actions, inactions, or submissions, legally bind each owner and operator of the covered source represented and each covered unit at the source in all matters pertaining to the Partner jurisdiction's Cap-and-Trade Program, notwithstanding any agreement between the authorized account representative and such owners and operators. The owners and operators shall be bound by any decision or order issued to the authorized account representative, by the program authority, or a court regarding the source or unit.

4.3.1.4 No WTS account shall be established for a covered source or covered unit, until the program authority or its agent has received a complete account certificate of representation under section 4.3.4 for an authorized account representative of the source and the covered units at the source.

4.3.1.5 Each submission under the Partner jurisdiction's Cap-and-Trade Program shall be submitted, signed, and certified by the authorized account representative for each covered source and covered unit on behalf of which the submission is made. Each such submission shall include the following certification statement by the authorized account representative: "I am authorized to make this submission on behalf of the owners and operators of the covered sources or covered units for which the submission is made. I certify under penalty of law that I have personally examined, and am familiar with, the statements and information submitted in this document and all its attachments. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment."

4.3.1.6 The program authority or its agent will accept or act on a submission made on behalf of owners or operators of a covered source or a covered unit only if the submission has been made, signed, and certified in accordance with section 4.3.1.5.

4.3.2 Alternate authorized account representative

4.3.2.1 An account certificate of representation may designate one and only one alternate authorized account representative who may act on behalf of the authorized account representative. The agreement by which the alternate authorized account representative is selected shall include a procedure for authorizing the alternate authorized account representative to act in lieu of the authorized account representative.

4.3.2.2 Upon receipt by the program authority or its agent of a complete account certificate of representation under section 4.3.3, any representation, action, inaction, or submission by the alternate authorized account representative shall be deemed to be a representation, action, inaction, or submission by the authorized account representative.

4.3.2.3 Except in this section and sections 4.3.1.1, 4.3.2, 4.3.3, and 7.2.2.2, whenever the term "authorized account representative" is used in this detailed program design, the term shall be construed to include the alternate authorized account representative.

4.3.3 Changing the authorized account representative and the alternate authorized account representative; changes in owners or operators

4.3.3.1 Changing the authorized account representative. The authorized account representative may be changed at any time upon receipt by the program authority or its agent of a superseding complete account certificate of representation under section 4.3.4. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous authorized account representative or alternate authorized account representative prior to the time and date when the program authority or its agent receives the superseding account certificate of representation shall be binding on the new authorized account representative and the owners and operators of the covered source and the covered units at the source.

4.3.3.2 Changing the alternate authorized account representative. The alternate authorized account representative may be changed at any time upon receipt by the program authority or its agent of a superseding complete account certificate of representation under section 4.3.4. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous or alternate authorized account representative or alternate authorized account representative prior to the time and date when the program authority or its agent receives the superseding account certificate of representation shall be binding on the new alternate authorized account representative and the owners and operators of the covered source and the covered units at the source.

4.3.3.3 Changes in the owners and operators

4.3.3.3.1 In the event a new owner or operator of a covered source or a covered unit is not included in the list of owners and operators submitted in the account certificate of representation, such new owner or operator shall be deemed to be subject to and bound by the account certificate of representation, the representations, actions, inactions, and submissions of the authorized account representative and any alternate authorized account representative of the source or unit, and the decisions, orders, actions, and inactions of the program authority, as if the new owner or operator were included in such list.

4.3.3.3.2 Within 30 days following any change in the owners and operators of a covered source or a covered unit, including the addition of a new owner or operator, the authorized account representative or alternate authorized account representative shall submit a revision to the account certificate of representation amending the list of owners and operators to include the change.

4.3.4 Account certificate of representation

4.3.4.1 A complete account certificate of representation for an authorized account representative or an alternate authorized account representative shall include the following elements in a format prescribed by the program authority or its agent:

4.3.4.1.1 Identification of the covered source and each covered unit at the source for which the account certificate of representation is submitted;

4.3.4.1.2 The name, address, email address, telephone number, and facsimile transmission number of the authorized account representative and any alternate authorized account representative;

4.3.4.1.3 A list of the owners and operators of the covered source and of each covered unit at the source;

4.3.4.1.4 The following certification statement by the authorized account representative and any alternate authorized account representative: "I certify that I was selected as the authorized account representative or alternate authorized account representative, as applicable, by an agreement binding on the owners and operators of the covered source and each covered unit at the source. I certify that I have all the necessary authority to carry out my duties and responsibilities under the Partner jurisdiction's Cap-and-Trade Program the owners and operators of the covered source and of each covered unit at the source and that each such owner and operator shall be fully bound by my representations, actions, inactions, or submissions and by any decision or order issued to me by the program authority or a court regarding the source or unit."; and

4.3.4.1.5 The signature of the authorized account representative and any alternate authorized account representative and the dates signed.

4.3.4.2 Unless otherwise required by the program authority or its agent, documents of agreement referred to in the account certificate of representation shall be submitted to the program authority or its agent. Neither the program authority nor its agent shall be under any obligation to review or evaluate the sufficiency of such documents when submitted.

4.3.5 Objections concerning the authorized account representative

4.3.5.1 Once a complete account certificate of representation under section 4.3.4 has been submitted and received, the program authority and its agent will rely on the account certificate of representation unless and until the program authority or its agent receives a superseding complete account certificate of representation under section 4.3.4.

4.3.5.2 Except as provided in subdivision 4.3.3.1 and 4.3.3.2, no objection or other communication submitted to the program authority or its agent concerning the authorization, or any representation, action, inaction, or submission of the authorized account representative shall affect any representation, action, inaction, or submission of the authorized account representative or the finality of any decision or order by the program authority or its agent under the Partner jurisdiction's Cap-and-Trade Program.

4.3.5.3 Neither the program authority nor its agent will adjudicate any private legal dispute concerning the authorization or any representation, action, inaction, or submission of any authorized account representative, including private legal disputes concerning the proceeds of compliance instrument transfers.

4.3.6 Delegation by authorized account representative and alternate authorized account representative

4.3.6.1 An authorized account representative may delegate, to one or more natural persons, his or her authority to make an electronic submission to the program authority or its agent under this program.

4.3.6.2 An alternate authorized account representative may delegate, to one or more natural persons, his or her authority to make an electronic submission to the program authority or its agent under this program.

4.3.6.3 In order to delegate authority to make an electronic submission to the program authority or its agent in accordance with sections 4.3.6.1 and 4.3.6.2, the authorized account representative or alternate authorized account representative, as appropriate, must submit to the program authority or its agent a notice of delegation, in a format prescribed by the program authority that includes the following elements:

4.3.6.3.1 The name, address, email address, telephone number, and facsimile transmission number of such authorized account representative or alternate authorized account representative;

4.3.6.3.2 The name, address, email address, telephone number and facsimile transmission number of each such natural person;

4.3.6.3.3 For each such natural person, a list of the type of electronic submissions under sections 4.3.6.1 and 4.3.6.2 for which authority is delegated to him or her; and

4.3.6.3.4 The following certification statements by such authorized account representative or alternate authorized account representative:

4.3.6.3.4.1 "I agree that any electronic submission to the program authority or its agent that is by a natural person identified in this notice of delegation and of a type listed for such electronic submission agent in this notice of delegation and that is made when I am an authorized account representative or alternate authorized account representative, as appropriate, and before this notice of delegation is superseded by another notice of delegation under section 4.3.6.4 shall be deemed to be an electronic submission by me."

4.3.6.3.4.2 "Until this notice of delegation is superseded by another notice of delegation under section 4.3.6.4, I agree to maintain an email account and to notify the program authority or its agent immediately of any change in my email address unless all delegation authority by me under section 4.3.6 is terminated."

4.3.6.4 A notice of delegation submitted under section 4.3.6.3 shall be effective, with regard to the authorized account representative or alternate authorized account representative identified in such notice, upon receipt of such notice by the program authority or its agent and until receipt by the program authority or its agent of a superseding notice of delegation by such authorized account representative or alternate authorized account representative as appropriate. The superseding notice of delegation may replace any previously identified electronic submission agent, add a new electronic submission agent, or eliminate entirely any delegation of authority.

4.3.6.5 Any electronic submission covered by the certification statement in section 4.3.6.3.4.1, and made in accordance with a notice of delegation effective under section 4.3.6.4, shall be deemed to be an electronic submission by the authorized account representative or alternate authorized account representative submitting such notice of delegation.

4.3.7 Following the establishment of a WTS account under section 7.2, all submissions to the program authority or its agent pertaining to the account, including, but not limited to, submissions concerning the deduction or requests to surrender or transfer of compliance instruments from in the account, shall be made only by the authorized account representative for the account or someone with delegated authority under section 4.3.6.

4.4 Compliance instrument surrender requirement

4.4.1 The owners and operators of each covered source and each covered unit shall surrender a number of compliance instruments equal to the total verified emissions from that covered source by available for compliance deductions under section 7.2.5, not exceeding the offset certificate usage limit established by the program authority, as of the compliance instrument surrender deadline at the latest.

4.4.2 Each metric ton of verified emissions emitted in excess of the number of compliance instruments surrendered or deducted (i.e., emissions exceeding the budget emissions limitation) shall constitute a separate violation of program requirements and applicable law.

4.4.3 A covered unit shall be subject to the requirements under section 4.4.1 starting on the later of January 1, 2012 or the date on which the unit commences operation and meets the applicability requirements of section 3.2.

4.4.4 Compliance instruments shall be held in, surrendered to or deducted from, or transferred among WTS accounts in accordance with sections 4.3, 4.4, 4.5, 4.6, and 7.2.

4.4.5 A compliance instrument shall not be surrendered/deducted, in order to comply with the requirements under section 4.4.1, for a compliance period that ends prior to the year for which the compliance instrument was allocated or issued.[20] An offset certificate or an approved program compliance unit shall not be surrendered or deducted, in order to comply with the requirements under section 4.4.1, beyond the applicable percent limitations on the use of offsets established by the program authority.

4.4.6 A compliance instrument under the Partner jurisdiction's Cap-and-Trade Program is a limited authorization by the program authority or a participating Partner jurisdiction to emit one metric ton of CO_2e in accordance with the Partner jurisdiction's Cap-and-Trade Program. The program authority or a participating Partner jurisdiction shall retain the right to terminate or limit such authorization.

[20] Partner jurisdictions are considering additional mechanisms to address cost risks. Among the options under consideration is the limited use for compliance of allowances that are already owned and that were allocated or issued for future compliance periods.

4.4.7 A compliance instrument under the Partner jurisdiction's Cap-and-Trade Program does not constitute a property right for any purpose.

4.5 Compliance certification requirement[21]

4.5.1 Applicability and deadline for submission. For each compliance period in which a covered source is subject to the surrender requirements of section 4.5.3, the authorized account representative of the source shall submit to the program authority or its agent by midnight on June 30th following the relevant compliance period, a compliance certification report.[22]

4.5.2 Contents of report. The authorized account representative shall include in the compliance certification report under section 4.5.1 the following elements, in a format prescribed by the program authority:

4.5.2.1 Identification of the source and each covered unit at the source;

4.5.2.2 The total metric tons of GHG emissions in CO_2e from the source and each covered unit at the source, monitored, reported, and verified in compliance with sections 4.1 and 7.1;

4.5.2.3 At the authorized account representative's option, the serial numbers of the compliance instruments that are to be surrendered and/or deducted from the covered source's compliance account under section 7.2.5 for the compliance period, including the serial numbers of any offset certificates that are to be surrendered and/or deducted subject to the limit on the use of offsets certificates established by the program authority; and

4.5.2.4 The compliance certification under section 4.5.3.

4.5.3 Compliance certification. In the compliance certification report under 4.5.3.1 of this section, the authorized account representative shall certify, based on reasonable inquiry of those persons with primary responsibility for operating the source and the covered units at the source in compliance with the Partner jurisdiction's Cap-and-Trade Program, whether the source and each covered unit at the source for which the compliance certification is submitted was operated during the calendar years covered by the report in compliance with the requirements of the Partner jurisdiction's Cap-and-Trade Program. The compliance certification report shall include the following information:

4.5.3.1 Whether the covered source was operated in compliance with the requirements of section 4.4 (compliance instrument surrender requirements); and

---

[21] This requirement to provide a certification report is included as just one example of how compliance instrument surrender and deductions might be handled by a Partner jurisdiction. It is possible to carry out this mechanism without a certification statement.

[22] At present, Partner jurisdictions are considering whether the June 30th deadline is practical. If the June 30th deadline is not practical, the Partner jurisdictions will agree on the earliest practical date for a common compliance instrument surrender deadline. Some Partner jurisdictions are also considering whether to require interim surrender obligations in years prior to the end of the compliance periods. Prior to making a recommendation, the Partner jurisdictions are assessing potential impacts on the compliance instrument market and the implications of interim surrender requirements varying among Partner jurisdictions.

4.5.3.2 Whether the source was operated in compliance with the requirements of section 4.1 (emissions monitoring and reporting requirements).

4.6 Additional requirements in the event of non-compliance. The owners and operators of a covered source that has excess emissions in any compliance period shall:

4.6.1 Forfeit the compliance instruments required for surrender and/or deduction under section 7.2.5.4, provided offset certificates shall not be used to cover such excess emissions; and

4.6.2 Pay any fine, penalty, or assessment or comply with any other remedy imposed under the Partner jurisdiction's other laws and regulations.

4.7 Recordkeeping requirements

4.7.1 Unless otherwise provided, the owners and operators of the covered source and each covered unit at the source shall keep on site at the source each of the following documents for a period of 7 years from the date the document is created. This period may be extended for cause, at any time prior to the end of 7 years, in writing by the program authority.

4.7.1.1 The account certificate of representation for the authorized account representative for the source and each covered unit at the source and all documents relied on as a basis for the statements in the account certificate of representation, in accordance with section 4.5.3, provided that the certificate and documents shall be retained on site at the source beyond such 7-year period until such documents are superseded because of the submission of a new account certificate of representation changing the authorized account representative.

4.7.1.2 All emissions monitoring information, (including information regarding gaps in or a lack of monitoring) in accordance with [*Refer to program authority's reporting rule*].

4.7.1.3 Copies of all reports, compliance certifications, and other submissions and all records made or required under the Partner jurisdiction's Cap-and-Trade Program.

4.7.1.4 Copies of all documents referenced or relied on to complete a covered permit application (if applicable) and any other submission under the Partner jurisdiction's Cap-and-Trade Program or to demonstrate compliance with the requirements of the Partner jurisdiction's Cap-and-Trade Program.

4.7.2 The authorized account representative of a covered source and each covered unit at the source shall submit the compliance reports and compliance certifications to the program authority required under the Partner jurisdiction's Cap-and-Trade Program, including those under section 4.5.3.

5. Compliance Instruments

Section 5 details the compliance instruments that may be issued and recognized in the Partner jurisdiction's Cap-and-Trade Program. It is expected that each participating Partner jurisdiction will adopt allowance budget-setting processes (section 5.1), as well as provisions to issue and accept early *reduction allowances (section 5.2), issue offset certificates (section 5.3) and accept approved compliance unit provisions (section 5.4) of this detailed program summary. In the event that a participating Partner jurisdiction wishes to issue a compliance instrument not agreed to below, or to recognize as a compliance instrument allowances or offsets that are not contemplated in this design summary, the participating Partner jurisdiction will first raise the proposal with the other participating Partner jurisdictions to ensure that any linking arrangements can be preserved.*

5.1. Establishing annual allowance budgets

The process for establishing annual allowance budgets for each Partner jurisdiction is detailed in *Guidance for Developing WCI Partner Allowance Budgets.*[23]

5.2. Early reduction allowances (ERAs)

The program authority may award early reduction allowances (ERAs) to a covered source for certain reductions in the covered source's GHG emissions that are achieved by the source during the early reduction eligibility period in accordance with the requirements of this section.

5.2.1. Eligibility

5.2.1.1. General requirements. Early reduction allowances may be awarded for a clearly identified project or action carried out at a covered source during the eligibility period that meets all criteria under this Section 5.2.

5.2.1.2. Government-controlled covered sources. Covered sources that are government controlled are eligible to receive ERAs provided they meet all requirements of this section 5.2.

5.2.1.3. Eligibility period. The program authority may issue ERAs for eligible ERA projects that reduce emissions on or after January 1, 2008 and prior to January 1, 2012.

5.2.2. Criteria applicable to all ERA projects

5.2.2.1. Real. To be eligible for the award of ERAs, the project must produce a reduction or removal of one metric ton of CO_2e for each ERA, without any increase in emissions intensity at the covered source. A reduction is not considered real if it comes from a decrease in production alone or from a shutdown or a closure of a source or a facility. Instead, the covered source must demonstrate a reduction in emissions intensity and a reduction in absolute emissions during the eligibility period. A Partner jurisdiction may also require sources or facilities to show reductions are beyond best practice standards. Best practice standards can be defined by the Partner jurisdiction for certain types of covered sources. An applicant covered source may be required to prepare an evaluation demonstrating their actions are beyond best practices in their industry.

[23] Available at http://www.westernclimateinitiative.org/component/remository/Cap-Setting--and--Allowance-Distribution-Committee-Documents/Guidance-for-Developing-WCI-Partner-Allowance-Budgets/.

5.2.2.2. Voluntary. An ERA project and the accompanying reductions in emissions must be surplus to any requirements from existing legislation, regulation, executive order and other regulatory obligations.

5.2.2.3. Permanent. To be eligible for the award of ERAs, the project must produce a reduction or removal that is permanent. For ERAs, permanent means that the reductions or removals are not reversible.[24]

5.2.2.4. Additional. To be eligible for the award of ERAs, the project must produce a reduction or removal that might have been deferred until after the start of the Partner jurisdiction's Cap-and-Trade Program. A reduction or removal will be deemed additional if:

5.2.2.4.1. The ERA project was initiated during the eligibility period;

5.2.2.4.2. The annual GHG emissions and emissions intensity for the period of time ERAs are requested are below the annual averages of absolute emissions and emission intensity for the years 2005 to 2007; and

5.2.2.4.3. If the project or action is fuel switching, the fuel to which the covered source switched was more costly during the eligibility period than the fuel from which the covered source switched, or the covered source underwent an equipment change during the eligibility period to enable the switch to a lower-carbon fuel.

5.2.2.5. Verifiable. To be eligible for the award of ERAs, the project must produce a reduction or removal that is verifiable. For ERAs, verifiable means that the reduction or removal has been well documented and transparent, such that an objective review is possible by a Partner jurisdiction or a certified verifier.

5.2.2.6. Ownership. To be eligible for the award of ERAs, the applicant covered source must demonstrate that it owns the emissions reductions resulting from the project or action.

5.2.2.7. Enforceable. To be eligible for the award of ERAs, the applicant covered source must be accountable to the Partner jurisdiction for all statements and information provided regarding the application for ERAs.

5.2.3. Application by covered source

5.2.3.1. Application deadline. All applications for the award of ERAs must be filed with the Partner jurisdiction where the reductions and removals that are the subject of the application took place no later than July 1, 2012.

[24] For carbon capture and storage projects, the Partner jurisdiction must (a) have in place monitoring and verification requirements that are sufficient to enable the Partner jurisdiction to establish that the sequestration is permanent; (b) have the ability to assure that ERAs will be replaced where a reversal occurs; and (c) apply these requirements to the applicable project.

5.2.3.2. Application forms and consultation. Partner jurisdictions may request any applications be made using forms developed in consultation with other participating Partner jurisdictions. Applicants may also be provided with pre-application consultation with the Partner jurisdiction.

5.2.4. Quantification of reductions

5.2.4.1. Data requirements

5.2.4.1.1. Emissions. All quantification of reductions under this section 5.2 shall be done using verified emissions data or equivalent methods approved by the Partner jurisdiction.

5.2.4.1.2. Output.[25] Reliable measures of covered source output will be prescribed by the Partner jurisdiction for purposes of quantifying reductions. Output is the amount of a good or service produced by a covered source.

5.2.4.1.3. Verification and recordkeeping. All emissions and output reports used to establish ERA baselines or calculate ERAs must be verified by an independent third party approved by the Partner jurisdiction or the program authority. The applicant covered source must retain all records relating to the ERA application for a period of at least 7 years and submit, under request, all documents related to the quantification of the reduction or removal.

5.2.4.2. Quantification by covered source. ERAs will be calculated based on the cumulative reductions during the eligibility period at the covered source, to be calculated as follows:

If $I_{base} \leq I_{ERA}$, then:
Total ERAs Awarded = 0

If $I_{base} > I_{ERA}$, then:
Total ERAs Awarded = $A \times (E_{base} - E_{ERA})$ If $P_{base} \leq P_{ERA}$
Total ERAs Awarded = $[A \times (E_{base} - E_{ERA})] \times (P_{ERA}/P_{base})$ If $P_{base} > P_{ERA}$

Where:

A is the number of consecutive calendar years from when the ERA project/action begins and the end of 2011. The applicant will indicate the number of years for which he requests ERAs.

$\mathbf{E_{base}}$ and $\mathbf{P_{base}}$ are the average yearly emissions and production from January 1, 2005 to the end of 2007.

$\mathbf{E_{ERA}}$ and $\mathbf{P_{ERA}}$ are the average yearly emissions and production during the years where the applicant covered source is seeking ERAs (i.e. the number of consecutive calendar years from when the ERA project begins and the end of 2011).

[25] Electricity generators should report net MWh of electricity produced. Industrial sources should use standardized forms of reporting, where such data is available. For example, industrial sources located in the U.S. could report production using the same metrics as provided to the Federal Reserve for their *Industrial Production and Capacity Utilization Report*. However, in the event that such metrics are not accurate measures of output for a particularly class of sources, then WCI partner jurisdictions may wish to allow those sources to propose alternative metrics. To mitigate gaming, facilities should use the same metric for approximating output in both the base period (years 2005 to 2007) and the early reduction period (years 2008 to 2012).

I_{base} is the average emission intensity (emissions per unit of output) of the base period (2005-2007) for the applicant covered source

I_{ERA} is the average emission intensity (emissions per unit of output) during the years for which the applicant the applicant covered source is seeking ERAs (i.e. the number of consecutive calendar years from when the ERA project begins and the end of 2011).

When using the above equations, the applicant covered source should use entire calendar years. Thus, the ERA period must start either on January 1, 2008, January 1, 2009, January 1, 2010, or January 1, 2011.

5.2.5. Award by program authority without application

5.2.5.1. Requirements. A Partner jurisdiction may, in lieu of requiring an application from a covered source, award ERAs to a covered source upon a finding that the covered source has undertaken a project or action meeting the requirements of sections 5.2.1 and 5.2.2.

5.2.5.2. Quantification of ERAs by program authority. A Partner jurisdiction may quantify ERAs on its own motion, provided the Partner jurisdiction has access to the data required in section 5.2.4.1, and utilizes the quantification methodology prescribed in section 5.2.4.2, and the information used is verified by a government agency or independent third party.

5.2.5.3. The information used to determine the number of ERAs a Partner jurisdiction expects to award will be verified by a government agency or independent third party after the reductions take place. In the case emissions reductions are lower than expected; the total number of ERAs to be awarded will be reduced to reflect actual reductions that took place during the eligibility period.

5.2.6. Special provisions for specific ERA types

This section provides additional guidance for project types that present unique challenges to ensuring that their emissions reductions are voluntary, additional, real, verifiable, permanent, and enforceable.

5.2.6.1. Fuel switching. Switching from high to low carbon intensity fuels can help a covered source reduce its GHG emissions. Sometimes fuel switching will occur naturally due to changes in relative fuel prices. To ensure that ERAs are only rewarded for projects adopted due to the ERA program, fuel switching projects should only qualify for reductions if the fuel switched to is more costly during the ERA period than the fuel switched from, or if the covered source underwent an equipment change during the ERA period to enable the switch to a lower carbon fuel. As discussed previously under section 5.2.2.6, applicants must demonstrate that they have ownership over the emissions reductions for which they are applying for ERAs. Therefore, if an applicant covered source wishes to receive ERAs for switching from a high to a low carbon fuel, then they must demonstrate that the reductions are not also being claimed by the fuel provider and thus double counted in any other regulatory or voluntary program (e.g., to meet renewable fuel standards or low carbon fuel standards).

5.2.6.2. Fuel providers. Fuel providers can receive ERAs for a reduction in on-site emissions. They can also receive ERAs for reductions that result from the reduction in the carbon intensity of the provided fuel, through the use of lower-carbon, or carbon-neutral sources. However, for such reductions to qualify for ERAs, they cannot contribute to compliance with any required low carbon fuel standard or renewable fuel standard. Reductions in fuel sales are not eligible for ERAs because such projects do not result in a reduction in the intensity of emissions. As discussed previously under section 5.2.2.6, applicants must demonstrate that they have ownership over the emissions reductions for which they are applying for ERAs. Therefore, if an applicant covered source wishes to receive ERAs for reducing the carbon intensity of their fuels, then they must demonstrate that the reductions are not also being claimed by the user of the fuel and thus double counted in any other regulatory or voluntary program (e.g., as ERAs or as offsets in a voluntary registry). Also, the applicant must demonstrate that the reductions are indeed voluntary, and are not being used to meet renewable or low carbon fuel standards.

5.2.6.3. Electricity importers. ERAs may be issued to first jurisdictional deliverers of electricity imported into a participating Partner jurisdiction originating outside of participating Partner jurisdictions, assuming it meets all other criteria outlined in this section 5.2. A first jurisdictional deliverer would apply to the Partner jurisdiction with which they have a compliance obligation. To qualify as an ERA, the FJD will need to show ownership of a qualifying reduction in both absolute emissions and emissions intensity at a specific facility whose power is produced for consumption within the WCI Partner jurisdiction.

5.2.7. Timing of award among participating Partner jurisdictions. The award of ERAs will occur on the same day no later than the first quarter of 2013 after information concerning the number of ERAs to be issued is announced publicly.

5.3 Offset certificates

The program authority may accept offset certificates as a compliance instrument awarded in accordance with Section 8, provided acceptance of offset certificates is subject to the limitation to be established by the program authority.

5.4 Approved program compliance units

The program authority may accept approved program compliance units as a compliance instrument, provided acceptance of approved program compliance units is subject to the limitation on the use of such units to be established by the program authority. The Partner jurisdiction will develop, in consultation with other participating Partner jurisdictions, a mechanism to ensure the validity of external compliance units and to make sure those units can only be used once for compliance by any program.

6. Distributing Allowances

Section 6 relates to the distribution of allowances. The Partner jurisdictions have largely left allowance distribution decisions open to the discretion of each Partner jurisdiction, with the exception of the process-related agreements detailed below concerning timing and notice of distributions (section 6.1), and the use of a common auction platform (section 6.2). In addition, two optional set-aside provisions are included relating to recognition of voluntary renewable energy purchases (section 6.3) and the administrative approach to covering electricity imports (section 6.4).Participating Partner jurisdictions can choose to freely allocate allowances from within their allowance budgets (e.g., to entities that export *renewable hydroelectricity outside participating Partner jurisdictions in order to acknowledge the importance of renewable energy in reducing GHG emissions).*

6.1 Allowance decisions and competitiveness

Each Partner jurisdiction will (a) notify other Partners in advance of the first compliance period, and at least one year before the beginning of each subsequent compliance period, about the total quantity of allowances it will allocate for that period; how and when it proposes allowances will be distributed, including if and how it will take into account the need to provide access to allowances for new entrants; and what will happen to allowances if a covered source shuts down; and (b) discuss and seek to address any competitiveness issues or concerns another Partner may have about the Partner's allowance distribution method. WCI Partner jurisdictions may standardize the distribution of allowances as necessary to address competitive impacts in advance of the first compliance period. After January 1, 2012, any public disclosure of information pertaining to the quantity of allowances that will be allocated; how and when those allowances will be distributed, including allowances for new entrants and the treatment of covered sources that have shut down, will be done in a coordinated manner among Partner jurisdictions to minimize the risk of inappropriate market impacts.

6.2 Coordinated auctions

Allowances to be auctioned will be sold through regionally coordinated auctions, which would be run in accordance with the auction design recommendations contained in Section 9 of the Detailed Summary.

6.3 Voluntary renewable energy set-aside allocation[26]

6.3.1 For each compliance period in which the WCI Partner jurisdiction chooses to maintain the program, the Partner Jurisdiction shall allocate to the voluntary renewable energy set-aside account a certain number of allowances, calculated as set forth below, from the Partner jurisdiction's Cap-and-Trade Program base budget. The program authority will open an account and administer the voluntary renewable energy set-aside program.

6.3.1.1 The number of allowances allocated to the voluntary renewable energy market set-aside account in a specific compliance period is determined by first projecting the amount of electricity used for voluntary renewable energy purchases produced by VRE-eligible facilities in that WCI Partner jurisdiction.[27] Each WCI Partner jurisdiction shall determine which technologies or fuel sources are eligible for its program. The estimate of voluntary renewable energy purchases shall be made regardless of the location of the purchaser. The megawatt-hours (MWh) of projected voluntary renewable energy purchases in the compliance period shall be multiplied by an appropriate greenhouse gas

[26] Implementation of the voluntary renewable energy set-aside program is optional at the discretion of each Partner jurisdiction.

[27] A WCI Partner jurisdiction may also wish to add the following program element to the end of this sentence, "or produced by VRE-eligible facilities not located in a participating Partner jurisdiction and sold on a specified basis in the Partner jurisdiction." See the discussion in *Voluntary Renewable Energy Market: Issues and Recommendations* for more information.

emissions rate, as determined by the program authority. A Partner jurisdiction may elect to limit the total allowances allocated to such an account.

6.3.1.2 As of the December 31 that is after the end of a compliance period for which an allocation has been made to the voluntary renewable energy set-aside account, the program authority shall determine the actual MWh of voluntary renewable energy purchases that occurred during the compliance period. To the extent possible, the program authority will use established renewable energy credit tracking systems that span some or all of the participating Partner jurisdictions, such as the Western Renewable Energy Generation Information System. The program authority shall retire allowances in the voluntary renewable energy set-aside account in an amount up to the number of allowances represented by actual voluntary renewable energy purchases multiplied by the emissions factor used in 6.3.1.1 above.

6.3.1.3 If following the end of a compliance period, the number of allowances allocated to the voluntary renewable energy set-aside account is less than the number of allowances represented by the actual MWh of voluntary renewable energy purchases during the compliance period multiplied by the emissions factor, the program authority will make up the difference by retiring unallocated allowances remaining from the previous compliance period, adding the difference between allowances represented by actual purchases and allowances held in the set-aside account to the projection for the following compliance period, or a combination of the two. If following the end of a compliance period, the number of allowances allocated to the voluntary renewable energy set-aside account is greater than the number of allowances represented by the actual MWh of voluntary renewable energy purchases during the compliance period, the program authority will add the allowances remaining in the set-aside from the previous compliance period to the allowances dedicated to a purpose chosen by the Partner jurisdiction.

6.4 Administrative approach to covering first jurisdictional deliverers

In lieu of covering first jurisdictional deliverers as covered sources under the Partner jurisdiction Cap-and-Trade Program, a Partner jurisdiction may chose to cover emissions attributable to imported electricity through the administrative approach detailed in *Covering Emissions from Imported Electricity: An Administrative Approach.*[28] This approach calls for the creation of an optional reserve pool of allowances, a portion of which are to be retired to cover the emissions attributable to imported electricity during the compliance period.

[28] Available at http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/Covering-Emissions-From-Imported-Electricity-An-Administrative-Approach.

7. Administration of the Program by the Program Authority

Section 7 details the implementation responsibilities of the participating Partner jurisdiction, including: (a) the rules for emissions monitoring and reporting (section 7.1), and (b) the operating parameters for the emissions and allowance tracking system (section 7.2).

7.1 Quantification, monitoring, verification, reporting and recordkeeping requirements

Owners and operators, and to the extent applicable, the authorized account representative of a covered unit, shall comply with the monitoring, recordkeeping and reporting requirements as provided in the Essential Requirements of Mandatory Reporting.

7.2 Emissions and compliance instrument tracking system.[29]

This section relates the tracking system that participating Partner jurisdictions will establish and maintain. The tracking system will (a) be a standardized electronic database, accessible online; (b) contain separate accounts to record the compliance instruments held by each person; (c) ensure there are no transfers that are incompatible with the rules implementing the cap-and-trade program in different jurisdictions; (d) provide for public access to certain information and confidentiality as appropriate; (e) restrict certain functions to account holders, to authorized staff of regulatory authorities, or to system maintenance service providers; and (f) have the ability to generate specific public reports and customized reports for regulatory authorities.

7.2.1 Establish compliance accounts for covered sources

7.2.1.1 Nature and function of compliance accounts. Consistent with section 7.2.1.2, the program authority or its agent will establish (or require each covered source to establish) one compliance account for each covered source. Surrenders, deductions or transfers of compliance instruments pursuant to sections 7.2.5 and 7.2.6 will be recorded in the tracking system. *[Allowances allocated to covered sources under sections 6 and 7.2.4 will be recorded in the compliance or general accounts.]*

7.2.1.2 Establishment of compliance accounts. Upon receipt of a complete account certificate of representation under section 4.3.4, the program authority or its agent will establish a compliance account for each covered source for which the account certificate of representation was submitted.

7.2.2 Establish general accounts

7.2.2.1 Nature and function of general accounts. Consistent with section 7.2.2.2, the program authority or its agent will establish, upon request, a general account that any person that meets the requirements outlined in 7.2.2 can obtain. Transfers of compliance instruments under this section will be recorded in the tracking system.

---

[29] Wherever submissions are required in the tracking system, electronic submissions are anticipated.

7.2.2.2 Establishment of general accounts upon application. Any person may apply to open a general account for the purpose of holding and transferring compliance instruments. An application for a general account must designate a single authorized account representative and a single alternate authorized account representative who may act on behalf of the authorized account representative. The agreement by which the alternate authorized account representative is selected shall include a procedure for authorizing the alternate authorized account representative to act in lieu of the authorized account representative. A complete application for a general account shall be submitted to the program authority or its agent and shall include the following elements in a format prescribed by the program authority or its agent:

7.2.2.2.1 Name, address, email address, telephone number, and facsimile transmission number of the authorized account representative and any alternate authorized account representative;

7.2.2.2.2 At the option of the authorized account representative, organization name and type of organization;

7.2.2.2.3 A list of all persons subject to a binding agreement for the authorized account representative or any alternate authorized account representative to represent their ownership interest with respect to the compliance instruments held in the general account, including a statement of each beneficial owner's percentage ownership interest and a statement of affiliations between beneficial owners;

7.2.2.2.4 The following certification statement by the authorized account representative and any alternate authorized account representative: "I certify that I was selected as the authorized account representative or the alternate authorized account representative, as applicable, by an agreement that is binding on all persons who have an ownership interest with respect to compliance instruments held in the general account. I certify that I have all the necessary authority to carry out my duties and responsibilities under the Partner jurisdiction's Cap-and-Trade Program on behalf of such persons and that each such person shall be fully bound by my representations, actions, inactions, or submissions and by any order or decision issued to me by the program authority or its agent or a court regarding the general account.";

7.2.2.2.5 The signature of the authorized account representative and any alternate authorized account representative and the dates signed; and

7.2.2.2.6 Unless otherwise required by the program authority or its agent, documents of agreement referred to in the application for a general account shall not be submitted to the program authority or its agent. Neither the program authority nor its agent shall be under any obligation to review or evaluate the sufficiency of such documents, if submitted.

7.2.2.3 Authorization of authorized account representative

7.2.2.3.1 Upon receipt by the program authority or its agent of a complete application for a general account under section 7.2.2.2:

7.2.2.3.1.1 The program authority or its agent will establish a general account for the person or persons for whom the application is submitted.

7.2.2.3.1.2 The authorized account representative and any alternate authorized account representative for the general account shall represent and, by his or her representations, actions, inactions, or submissions, legally bind each person who has an ownership interest with respect to compliance instruments held in the general account in all matters pertaining to the Partner jurisdiction's Cap-and-Trade Program, notwithstanding any agreement between the authorized account representative or any alternate authorized account representative and such person. Any such person shall be bound by any decision or order issued to the authorized account representative or any alternate authorized account representative by the program authority or its agent or a court regarding the general account.

7.2.2.3.1.3 Any representation, action, inaction, or submission by any alternate authorized account representative shall be deemed to be a representation, action, inaction, or submission by the authorized account representative.

7.2.2.3.2 Each submission concerning the general account shall be submitted, signed, and certified by the authorized account representative or any alternate authorized account representative for the persons having an ownership interest with respect to compliance instruments held in the general account. Each such submission shall include the following certification statement by the authorized account representative or any alternate authorized account representative: "I am authorized to make this submission on behalf of the persons having an ownership interest with respect to the compliance instruments held in the general account. I certify under penalty of law that I have personally examined, and am familiar with, the statements and information submitted in this document and all its attachments. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I consent to the jurisdiction of the [Insert name of State or Province] and its courts for purposes of enforcement of the laws, rules and regulations pertaining to the Partner jurisdiction's Cap-and-Trade Program and the WTS, and I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment."

7.2.2.3.3 The program authority or its agent will accept or act on a submission concerning the general account only if the submission has been made, signed, and certified in accordance with section 7.2.2.4.

7.2.2.4 Changing authorized account representative and alternate authorized account representative; changes in persons with ownership interest.

7.2.2.4.1 The authorized account representative for a general account may be changed at any time upon receipt by the program authority or its agent of a superseding complete application for a general account under section 7.2.2.2. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous authorized account representative, or the previous alternate authorized account representative prior to the time and date when the program authority or its agent receives the superseding application for a general account shall be binding on the new authorized account representative and the persons with an ownership interest with respect to the compliance instruments in the general account.

7.2.2.4.2 The alternate authorized account representative for a general account may be changed at any time upon receipt by the program authority or its agent of a superseding complete application for a general account under section 7.2.2.2. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous authorized account representative, or the previous alternate authorized account representative, prior to the time and date when the program authority or its agent receives the superseding application for a general account shall be binding on the new alternate authorized account representative and the persons with an ownership interest with respect to the compliance instruments in the general account.

7.2.2.4.3 In the event a new person having an ownership interest with respect to compliance instruments in the general account is not included in the list of such persons in the application for a general account, such new person shall be deemed to be subject to and bound by the application for a general account, the representations, actions, inactions, and submissions of the authorized account representative and any alternate authorized account representative, and the decisions, orders, actions, and inactions of the program authority or its agent, as if the new person were included in such list.

7.2.2.4.4 Within 1 day following any change in the persons having an ownership interest with respect to compliance instruments in the general account, including the addition or deletion of persons, the authorized account representative or any alternate authorized account representative shall submit a revision to the application for a general account amending the list of persons having an ownership interest with respect to the compliance instruments in the general account to include the change.

7.2.2.5 Objections concerning authorized account representative

7.2.2.5.1 Once a complete application for a general account under section 7.2.2.2 has been submitted and received, the program authority or its agent will rely on the application unless and until a superseding complete application for a general account under section 7.2.2.2 is received by the program authority or its agent.

7.2.2.5.2 Except as provided in sections 7.2.2.4.1 and 7.2.2.4.2, no objection or other communication submitted to the program authority or its agent concerning the authorization, or any representation, action, inaction, or submission of the authorized account representative or any alternate authorized account representative for a general account shall affect any representation, action, inaction, or submission of the authorized account representative or any alternate authorized account representative or the finality of any decision or order by the program authority or its agent under the Partner jurisdiction's Cap-and-Trade Program.

7.2.2.5.3 Neither the program authority nor its agent will adjudicate any private legal dispute concerning the authorization or any representation, action, inaction, or submission of the authorized account representative or any alternate authorized account representative for a general account, including private legal disputes concerning the proceeds of compliance instrument transfers.

7.2.2.6 Delegation by authorized account representative and alternate authorized account representative

7.2.2.6.1 An authorized account representative may delegate, to one or more natural persons, his or her authority to make an electronic submission to the program authority or its agent provided for under section 7.2.2 and 7.2.5.

7.2.2.6.2 An alternate authorized account representative may delegate, to one or more natural persons, his or her authority to make an electronic submission to the program authority or its agent provided for under sections 7.2.2 and 7.2.5.

7.2.2.6.3 In order to delegate authority to make an electronic submission to the program authority or its agent in accordance with sections 7.2.2.6.1 and 7.2.2.6.2, the authorized account representative or alternate authorized account representative, as appropriate, must submit to the program authority or its agent a notice of delegation, in a format prescribed by the program authority that includes the following elements:

7.2.2.6.3.1 The name, address, email address, telephone number, and facsimile transmission number of such authorized account representative or alternate authorized account representative;

7.2.2.6.3.2 The name, address, email address, telephone number and facsimile transmission number of each such natural person, herein referred to as "electronic submission agent";

7.2.2.6.3.3 For each such natural person, a list of the type of electronic submissions for which authority is delegated to him or her; and

7.2.2.6.3.4 The following certification statements by such authorized account representative or alternate authorized account representative:

7.2.2.6.3.4.1 "I agree that any electronic submission to the program authority or its agent that is by a natural person identified in this notice of delegation and of a type listed for such electronic submission agent in this notice of delegation and that is made when I am a authorized account representative or alternate authorized account representative, as appropriate, and before this notice of delegation is superseded by another notice of delegation under 7.2.2.6.3 shall be deemed to be an electronic submission by me."

7.2.2.6.3.4.2 "Until this notice of delegation is superseded by another notice of delegation under section 7.2.2.6.3, I agree to maintain an email account and to notify the program authority or its agent immediately of any change in my email address unless all delegation authority by me is terminated."

7.2.2.6.4 A notice of delegation submitted under section 7.2.2.6.3 shall be effective, with regard to the authorized account representative or alternate authorized account representative identified in such notice, upon receipt of such notice by the program authority or its agent and until receipt by the program authority or its agent of a superseding notice of delegation by such authorized account representative or alternate authorized account representative as appropriate. The superseding notice of delegation may replace any previously identified electronic submission agent, add a new electronic submission agent, or eliminate entirely any delegation of authority.

7.2.2.6.5 Any electronic submission covered by the certification in section 7.2.2.6.3.4 and made in accordance with a notice of delegation effective under section 7.2.2.6.3 shall be deemed to be an electronic submission by the authorized account representative or alternate authorized account representative submitting such notice of delegation.

7.2.3 Account identification. The program authority or its agent will assign an identifying number that is unique within the WCI Regional Cap-and-Trade Program and in accordance with the WCI Numbering System to each account established under sections 7.2.1 and 7.2.2.

7.2.4 Provide for recordation of allowances in accounts

7.2.5 Provide for the surrender and/or deduction of compliance instruments from compliance accounts using compliance certification statements and/or default method.[30]

7.2.5.1 Compliance instruments available for compliance surrender and/or deduction. Compliance instruments that meet the following criteria are available to be surrendered and/or deducted in order for a covered source to comply with the requirements of section 4.4 for a compliance period.

7.2.5.1.1 The allowances, other than offset certificates, are of allocation years that fall within a prior compliance period or the same compliance period for which the allowances will be surrendered and/or deducted.

7.2.5.1.2 The compliance instruments are held in the covered source's compliance account as of the compliance instrument surrender deadline for that compliance period or are transferred into the compliance account by a compliance instrument transfer correctly submitted for recordation under section 7.2.6 by the compliance instrument surrender deadline for that compliance period.

[30] As discussed above, a Partner jurisdiction could implement the allowance deduction mechanism in alternative ways. The method provided here as an example is the approach taken by the U.S. Environmental Protection Agency in its cap-and-trade programs. 40 CFR Part 96.

7.2.5.1.3 For offset certificates, the number of offset certificates that are available to be surrendered and/or deducted in order for a covered source to comply with the requirements of section 4.4 for a compliance period may not exceed the limit established by the program authority as a percentage of the covered source's compliance obligation for that compliance period, as determined in accordance with section 4.1 and 7.1.

7.2.5.1.4 The compliance instruments are not necessary for surrender and/or deductions for excess emissions for a prior compliance period under section 7.2.6.

7.2.5.2 Surrender and/or Deductions for compliance. Following the recordation, in accordance with section 7.2.6, of compliance instrument transfers submitted for recordation in the covered source's compliance account by the compliance instrument surrender deadline for a compliance period, the program authority or its agent will surrender and/or deduct compliance instruments available under section 7.2.5.1 to cover the covered source's verified GHG emissions (as determined in accordance with section 7.1) for the compliance period, as follows:

7.2.5.2.1 Until the amount of compliance instruments deducted equals the number of metric tons of total verified emissions, determined in accordance with section 7.1, from all covered units at the covered source for the compliance period; or

7.2.5.2.2 If there are insufficient compliance instruments to complete the compliance instrument surrender and/or deductions in section 7.2.5.2.1, the source shall exhaust all compliance instruments available under section 7.2.5.1 remaining in the compliance account.

7.2.5.3 Identification of available compliance instruments by serial number; default compliance instrument surrender and/or deductions

7.2.5.3.1 The authorized account representative for a source's compliance account may request that specific compliance instruments, identified by serial number, in the compliance account be surrendered and/or deducted for emissions or excess emissions for a compliance period in accordance with sections 7.2.5.2 and 7.2.5.4. Such identification shall be made in the compliance certification report submitted in accordance with section 4.5.

7.2.5.3.2 The program authority or its agent will deduct compliance instruments for a compliance period from the covered source's compliance account, in the absence of an identification or in the case of a partial identification of available compliance instruments by serial number under section 7.2.5.3.1, in the following order:

7.2.5.3.2.1 First, subject to the relevant compliance instrument surrender and/or deduction limitations under sections 7.2.5.1.3 and 7.2.5.4, offset certificates and approved program compliance units. Offset certificates and approved program compliance units shall be surrendered and/or deducted in chronological order (i.e., those from earlier years shall be surrendered and/or deducted before those from later years).

7.2.5.3.2.2 Second, any allowances that are available for surrender and/or deduction under section 7.2.5.1. Allowances shall be surrendered and/or deducted in chronological order (i.e., allowances from earlier allocation years shall be surrendered and/or deducted before compliance instruments from later allocation years). In the event that some, but not all, allowances from a particular allocation year are to be surrendered and/or deducted, allowances shall be surrendered and/or deducted by serial number, with lower serial number compliance instruments surrendered and/or deducted before higher serial number compliance instruments.

7.2.5.4 Surrender and/or Deductions for excess emissions

7.2.5.4.1 After making the deductions for compliance under section 7.2.5.3, the program authority or its agent will deduct from the covered source's compliance account a number of compliance instruments, from allocation years that occur after the compliance period in which the source has excess emissions, equal to three times the number of the source's excess emissions (3x the allowances shortage). In the event that a source has insufficient compliance instruments to cover three times the number of the source's excess emissions, the source shall be required to immediately transfer sufficient compliance instruments into its compliance account. Offset certificates and/or approved program compliance units shall not be used cover excess emissions.

7.2.5.4.2 The program authority may prevent any transfer of allowances from any general account held by the owners and operators of the covered source or covered units that has excess verified emissions.

7.2.5.4.3 Any compliance instrument deduction required under section 7.2.5.4.1 shall not affect the liability of the owners and operators of the covered source or the covered units at the source for any fine, penalty, or assessment, or their obligation to comply with any other remedy, for the same failure to timely comply with the surrender obligation, as imposed under applicable Jurisdiction law. The following guidelines will be followed in assessing fines, penalties, assessments or other remedies.[31]

7.2.5.4.3.1 For purposes of determining the number of days of violation for a fine, penalty or assessment, if a covered source has excess emissions for a compliance period, each day after the compliance period that the source remains out of compliance constitutes a day in violation unless the owners and operators of the unit demonstrate that a lesser number of days should be considered.

7.2.5.4.3.2 Each metric ton of excess verified emissions is also a separate violation.

7.2.5.4.4 The propriety of the program authority's or its agent's determination that a covered source had excess emissions and the concomitant deduction of compliance instruments from that GHG covered source's account may be later challenged in the context of the initial administrative enforcement, or any civil or criminal judicial action arising from or encompassing that

---

[31] It should be noted that the provisions of section 7.2.5.4.3 apply to enforcement actions that may be taken by the program authority and not to the requirement to surrender three additional allowances to cover each metric ton of excess emissions.

excess emissions violation. The commencement or pendency of any administrative enforcement, or civil or criminal judicial action arising from or encompassing that excess emissions violation will not act to prevent the program authority or its agent from initially deducting the compliance instruments resulting from the program authority's original determination that the relevant covered source has had excess emissions. Should the program authority's or its agent's determination of the existence or extent of the covered source's excess emissions be revised either by a settlement or final conclusion of any administrative or judicial action, the program authority or its agent will act as follows:

7.2.5.4.4.1 In any instance where the program authority's or its agent's determination of the extent of excess emissions was too low, the program authority or the agent will take further action under sections 7.2.5.4.1 and 7.2.5.4.2 to address the expanded violation.

7.2.5.4.4.2 In any instance where the program authority's or its agent's determination of the extent of excess emissions was too high, the program authority or the agent will distribute to the relevant covered source a number of compliance instruments equaling the number of compliance instruments deducted which are attributable to the difference between the original and final quantity of excess emissions. Should such covered source's compliance account no longer exist, the compliance instruments will be provided to a general account selected by the owner or operator of the covered source from which they were originally deducted.

7.2.5.5 The program authority or its agent will record in the appropriate compliance account all deductions from such an account pursuant to sections 7.2.5.1 and 7.2.5.4.

7.2.5.6 Action by the program authority on submissions

7.2.5.6.1 The program authority may review and conduct independent audits concerning any submission under the Partner jurisdiction's Cap-and-Trade Program and make appropriate adjustments of the information in the submissions.

7.2.5.6.2 The program authority may deduct compliance instruments from or transfer compliance instruments to a source's compliance account based on information in the submissions, as adjusted under section 7.2.5.4.3.

7.2.6 Provide for compliance instrument transfers

7.2.6.1 Submission of compliance instrument transfers. The authorized account representatives wanting to transfer compliance instruments shall propose the transfer through the online tracking system. When proposing a transfer, the following information will need to be provided in a format specified by the program authority or its agent:[32]

[32] The information required for transfer of compliance instruments will be used to execute the transfer in the WTS, to conduct market oversight, and to support transparency. Information that could be used to identify parties to a transaction will be maintained confidential and not released to the public. Aggregate volume data and aggregate price data (that do not reveal individual trade data) are expected to be released publicly on a coordinated basis at regular intervals, such as daily or weekly.

7.2.6.1.1 The numbers identifying both the transferor and transferee accounts;

7.2.6.1.2 A specification by serial number of each compliance instrument to be transferred; and

7.2.6.1.3 The printed name and signature of the authorized account representative of the transferor account and the date signed;

7.2.6.1.4 The purchase price for each instrument or group of instruments transferred, except when the transfers were from affiliates disclosed on the affiliated entities list.

7.2.6.2 Recordation

7.2.6.2.1 Within five business days of receiving an compliance instrument transfer, except as provided section 7.2.6.2.2, the program authority or its agent will record a compliance instrument transfer by moving each compliance instrument from the transferor account to the transferee account as specified by the submission, provided that the transfer is correctly submitted section 7.2.6.1; and the transferor account includes each compliance instrument identified by serial number in the transfer.

7.2.6.2.2 A compliance instrument transfer into or out of a compliance account that is submitted for recordation following the compliance instrument surrender deadline and that includes any compliance instruments that are of allocation years that fall within a compliance period prior to or the same as the compliance period to which the compliance instrument surrender deadline applies will not be recorded until after completion of the deduction process under section 7.2.5.

7.2.6.2.3 Where a compliance instrument transfer submitted for recordation fails to meet the requirements of section 7.2.6.1, the program authority or its agent will not record such transfer.

7.2.6.3 Notification

7.2.6.3.1 Notification of recordation. Within five business days of recordation of a compliance instrument transfer under section 7.2.6.2, the program authority or its agent will notify each party to the transfer. Notice will be given to the authorized account representatives of both the transferor and transferee accounts.

7.2.6.3.2 Notification of non-recordation. Within 10 business days of receipt of a compliance instrument transfer that fails to meet the requirements of 7.2.6.1, the program authority or its agent will notify the authorized account representatives of both accounts subject to the transfer of a decision not to record the transfer, and the reasons for such non-recordation.

See Section 10 of the Design Summary and the *Market Oversight July Status Update* for a description of the market oversight recommendations.

7.2.6.3.3 Nothing in this section shall preclude the resubmission of a compliance instrument transfer for recordation following notification of non-recordation.

7.2.7 Provide for banking of compliance instruments not deducted or transferred. Each compliance instrument that is held in a compliance account or a general account will remain in such account unless and until the compliance instrument is surrendered and/or deducted, or transferred.

7.2.8 Correcting account errors. The program authority or its agent may, at its sole discretion and on his or her own motion, correct any error in any WTS account. Immediately, and in no event later than 10 business days of making such correction, the program authority or its agent will notify the authorized account representative for the account.

7.2.9 Allow for closing of general accounts

7.2.9.1 An authorized account representative of a general account may instruct the program authority or its agent to close the account by submitting a statement requesting deletion of the account from the WTS and by correctly submitting for recordation under section 7.2.6 a compliance instrument transfer of all compliance instruments in the account to one or more other WTS accounts.

7.2.9.2 If a general account shows no activity for a period of six years or more and does not contain any compliance instruments, the program authority or its agent may notify the authorized account representative for the account that the account will be closed in the WTS 20 business days after the notice is sent. The account will be closed after the 20-day period unless before the end of the 20-day period the program authority or its agent receives a correctly submitted transfer of compliance instruments into the account under section 7.2.6 or a statement submitted by the authorized account representative demonstrating to the satisfaction of the program authority or its agent good cause as to why the account should not be closed. The program authority or its agent will have sole discretion to determine if the authorized account representative demonstrated that the account should not be closed.

8. Offsets Program

Section 8 sets out the essential criteria for the issuance of offset certificates. The steps for Partner jurisdictions to create offset certificate include specific requirements for registration, validation, monitoring, quantification, reporting, verification, certification and issuance of offsets. These requirements are detailed in an upcoming WCI paper on Offset Process Draft Recommendations on which WCI Partners will solicit stakeholder input.

8.1 Offset certificates will be issued only for reductions that are real, additional, permanent, verifiable and enforceable, as described in the definitions for each in the table below.

Criteria	Definition
Real	The offset certificate represents a reduction or removal of one metric ton of CO_2e that results from a clearly identified action or decision. The offset project's reduction or removal is quantified using accurate and conservative methodologies that appropriately account for all relevant greenhouse gas sources and sinks and leakage risks. Offset projects result in emissions reductions or removals that take place at sources controlled by the project proponent.
Quantification, Uncertainty, and Accuracy	Quantification: WCI Partner jurisdictions shall ensure that net emissions reductions or removals are capable of being measured or modeled in a reliable and repeatable manner that includes all relevant sources and sinks. Quantification methodologies for GHG emissions or emissions reductions shall: • Be appropriate to the GHG source or sink • Be current at the time of quantification • Consider local conditions, whenever applicable • Account for uncertainty—be calculated in a manner that yields accurate and reproducible results When uncertainty is above the defined threshold, apply the principle of conservativeness to GHG. During quantification procedures, project proponents shall convert each type of GHG to metric tons of CO_2e. In addition, offset protocols shall use uniform quantification methods whenever feasible. Uncertainty and accuracy: Quantification methodologies and measurement techniques shall set standards for acceptable statistical precision and be based on the best available science. They shall also reduce bias, except for promoting conservative estimates. When uncertainty remains high in quantifying the amount of a greenhouse gas emission reduction or removal, the principle of conservativeness shall be applied. Principle of conservativeness: Where uncertainties are above the defined threshold, offset quantification methods should use more conservative quantification parameters, assumptions, and measurement techniques that minimize the risk of overestimating emissions reductions and removals credited for a given project. The principle should be employed when significant uncertainties arise to ensure a higher level of confidence that all calculated reductions are real.
Leakage	To address activity-shifting and market leakage, WCI Partner jurisdictions will require assessments of whether functional equivalence has been maintained within projects and require that WCI offset protocols include methods for leakage assessments. Offset protocols will evaluate functional equivalence for each project. Offset protocols will also require an assessment of potential leakage associated with each project type. In general, WCI Partner jurisdictions prefer the following methods to review leakage risk: • A quantitative assessment of leakage will be performed whenever possible. • When a quantitative assessment is not feasible, a qualitative risk assessment will determine whether the risk of systematic leakage is significant or not. • Offset protocols will include a threshold to identify significant leakage. If leakage is found to be above the threshold, the offset protocol quantification methodology will include a factor to account for leakage.

Criteria	Definition
Additional	Offset certificates will be awarded only for the portion of greenhouse gas emissions reductions or removals that would not have happened under a baseline scenario. The WCI Partner jurisdictions intend for additionality to be established in a manner that will require offset projects to be evaluated against a baseline that reflects conservative assumptions that are consistent across all WCI Partner jurisdictions. These assumptions will be described in the procedures for setting a baseline in offset protocols. Modeling or other methods of developing the baseline shall use assumptions, methodologies, and values which assure that GHG reductions or removals from a project are not over-estimated. When possible, the baseline shall be set using a sector-specific or activity-specific performance standard which is set in offset protocols based on a regional assessment of project performance or common practice. WCI Partners intend that all baselines will reflect the most stringent regulatory and legal requirements of any WCI Partner jurisdiction (those requirements leading to the most conservative calculation of emissions reductions). When a baseline based on the most stringent regulatory requirement is not practical because of regional differences, the WCI Partners may recommend a protocol using an alternative method. When it is not possible to set a baseline using a performance standard, a project-specific baseline may be used. Then the baseline will be set to reflect all binding agreements, regulatory requirements and legal requirements applicable to the project and also to ensure that the project is beyond business as usual.
Eligibility Date	Offsets may be awarded only for projects that are initially commenced on or after January 1, 2007, the date of the original WCI Memorandum of Understanding (MOU) beginning the development of the WCI cap-and-trade program. An offset project proponent must apply to register its project with a WCI Partner Jurisdiction within one year of project commencement. Projects that commenced prior to finalization of the applicable offset protocol must apply within one year of that protocol's finalization.
Crediting Period	The crediting period for non-sequestration offset projects will be 10 years. At the end of a crediting period a project proponent may renew a project subject to the current offset protocol for that project type. Renewal of a project at the end of a crediting period will include a reevaluation of a project's additionality and reevaluation of how the reductions are quantified and verified. Thus, the baseline scenario will be reevaluated at each renewal. The crediting period for sequestration projects will be specified by the applicable offset protocol. However, any individual crediting period may not exceed 25 years before a renewal, and the total crediting period including all renewals may not exceed 100 years for sequestration projects. The applicable offset protocol will also lay out the requirements for project renewal. At a minimum, the project must reevaluate quantification and monitoring methods based on the current offset protocol. If possible, projects will also need to reassess project additionality and baselines in order to renew the project.
Permanent	With respect to offset project activities, permanence means either that reductions or removals are not reversible or that, if reductions or removals are reversed, the provisions outlined in the remainder of this recommendation must be met. Sequestration projects must be designed so that the net atmospheric effect of their greenhouse gas removal is comparable to the atmospheric effect achieved by non-sequestration projects. The atmospheric effect will be based on the current

Criteria	Definition
	international standard established by the UNFCCC, which is currently 100 years. This international standard may be updated from time to time. If an emission reduction is reversed after credits are issued, the project developer must either replace the reversed credits with other compliance units from within the system or return credits that were issued to the project. Applicable approaches to assuring permanence for a project type will be included in the appropriate offset protocol. In conformance with the applicable offset protocols, project proponents shall follow or establish effective (i) monitoring systems, (ii) risk mitigation approaches, and (iii) contingency plans which address how, in the event of a reversal that is the result of proponent intention or negligence, any affected offset certificates will be replaced. The contingency plan shall include specific mechanisms that are exercisable at the time a reversal is identified whether or not the proponent is solvent, exists in its original form, and/or has ownership of or responsibility for the project. WCI Partner jurisdictions will establish mechanisms to address reversals that are not the result of proponent intention or negligence and where proponents' contingency measures prove inadequate.
Verifiable	With respect to offset project activities, verifiable means that a GHG reduction or removal, or assertion thereof, is well documented and transparent such that it lends itself to an objective review by a qualified verifier. Verifiers for offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner jurisdiction in which the project is registered.
Validation	Validation is a required review by an accredited independent third party or the WCI Partner jurisdiction to assess conformance of a proposed project to WCI requirements, criteria and an offset protocol. The WCI Partner jurisdictions may not require third party validation in all cases but may approve protocols that require a validation step.
Enforceable	Each Partner jurisdiction will, to the extent permissible by law, put in place sufficient compliance/enforcement mechanisms and detail for the jurisdiction to compel compliance with its requirements and with offset protocols.
Material	Material misstatement means that errors, omissions or an aggregation of both in the reported GHG reductions or assertion exceeds a +5% threshold. The verifier must be able to state with reasonable assurance the total reported reductions or removals are free of material misstatement.
Transparency	The offset system will provide transparency such that sufficient and appropriate protocol, project and certificate information is disclosed in a timely manner to allow offset system participants and the general public to make decisions with reasonable confidence.
Assessment of Environmental or Social Impacts	Offset projects must meet all applicable local environmental regulations and be in compliance with all applicable laws in the jurisdiction where the project is located. Offset protocols for specific offset project types may require analysis of environmental and socioeconomic impacts beyond what the local jurisdiction would otherwise require and may require additional mitigation of potential negative impacts.

9. Linking to Other Programs

Section 9 relates to whether and how Partner jurisdictions will link their individual trading programs with other Partner jurisdictions, as well as whether and how Partner jurisdictions will accept compliance units from Non-WCI programs.

9.1 Approval of link to another program

In evaluating another program for purposes of determining whether to link the Partner jurisdiction's Cap-and-Trade program to the other program, the Partner jurisdiction will consult with other participating Partner jurisdictions and consider whether the other program:

9.1.1 Implements a binding and annually declining aggregate total greenhouse gas emissions cap that limits the quantity of allowances that can be issued and covers one or more economic sectors; and

9.1.2 Includes the following, to the extent deemed necessary under the circumstances:

9.1.2.1 The transparent allocation of allowances;

9.1.2.2 Provisions to avoid the double counting of emissions or allowances in the electric sector;

9.1.2.3 A standardized and secured tracking system in the form of an electronic database containing common data elements to track the issuance, holding, transfer and cancellation of compliance instruments, to provide for public access and confidentiality as appropriate, and to ensure that there are no transfers which are incompatible with the Partner jurisdiction's implementation of the Cap-and-Trade program;

9.1.2.4 A comprehensive account registration requirement for all tracking system accounts;

9.1.2.5 The capability to transfer relevant and necessary information on all transactions and transfers between accounts in linked jurisdictions;

9.1.2.6 Provisions to ensure that offset certificates accepted into the system provide equal or greater assurance of the integrity of such offset certificates to that called for in the detailed program design;

9.1.2.7 Restrictions to the use of offset certificates comparable to the quantitative usage limit established in the detailed program design;

9.1.2.8 Provisions for comparable monitoring, reporting, verification, compliance, and enforcement of its greenhouse gas emissions to that set forth in the *Final Essential Requirements for Mandatory Reporting*; and

9.1.2.9 Provisions that compliance instruments that are voluntarily retired or used to meet an obligation to surrender compliance instruments equal to verified emissions are disqualified from further use in any system.

9.1.2.10 Existing links with other programs meet similar criteria

9.1.3 Includes enforcement mechanisms that:

9.1.3.1 Provide general market surveillance, identify suspect transactions, and provide for investigations and enforcement actions;

9.1.3.2 Ensure consequences for noncompliance are comparable between the systems to be linked, and in particular that the consequences of failing to meet compliance unit surrender requirements are automatic;

9.1.3.3 Respond in a timely manner to requests by enforcement agencies in the Partner jurisdiction and all jurisdictions approved by the Partner jurisdiction for relevant and necessary information on market participants under investigation; and

9.1.3.4 Transfer between systems in a timely manner relevant and necessary notice and information concerning all relevant enforcement actions undertaken by the system's jurisdictional enforcement authority

9.1.4 Is capable of transferring between linked jurisdictions all information necessary to monitor market trends on a regional basis, including:

9.1.4.1 Aggregate verified emissions data, the compliance status of entities covered by the cap and trade program and expected issuance of offset certificates;

9.1.4.2 Information that can be released to the public in a coordinated and consistent manner; and

9.1.4.3 Information necessary to collaborate on market oversight functions.

9.1.5 Provides an equal degree of protection for confidential business information.

9.2 Establishing a bilateral link to another program

Once a Partner jurisdiction determines that another program meets the criteria in section 9.1, the Partner jurisdiction and the other jurisdiction will mutually acknowledge that their programs are compatible and will:

9.2.1. Allow the mutual recognition of compliance instruments issued to meet compliance obligations;

9.2.2. Provide that after any compliance instrument is used to meet an obligation to surrender compliance instruments, it shall be disqualified for subsequent use under any system, whether such use is a sale, exchange, or submission to meet an obligation to surrender compliance instruments under a cap-and-trade program; and

9.2.3. Ensure that the tracking system (or systems) permits the transfer of compliance instruments from one jurisdiction to another, that a jurisdiction will record when a compliance instrument is transferred out of its tracking system, and that the system can be counted on to sever the linking relationship should severance be necessary.

9.3 Establishing a unilateral link to another program

9.3.1 In the absence of mutual recognition of compliance instruments between a Partner jurisdiction and another trading program, unilateral linking can be accomplished by allowing sources with a compliance obligation to surrender compliance instruments from an approved trading program. The same criteria can be applied in determining whether to approve the external trading program. In the case of a unilateral link to an external program that generates offsets but is otherwise not a cap-and-trade program, the Partner jurisdiction will apply only those criteria that are relevant to offset programs.

9.3.2 In the case of unilateral links, the Partner jurisdictions will develop a suitable mechanism to ensure the validity of external compliance units and to make sure those units can only be used once for compliance in any program.

Western Climate Initiative

Program Design Recommendations for the WCI Regional Program

WCI Stakeholder Call

July 27, 2010

Today's Release

- Comprehensive strategy to reduce greenhouse gases and spur a clean-energy economy
- Culmination of two years of work since WCI released initial design recommendations in 2008
- Program Design and supporting material available at: http://westernclimateinitiative.org/program-design
- WCI Partners include *Arizona, British Columbia, California, Manitoba, Montana, New Mexico, Ontario, Oregon, Québec, Utah, and Washington*

The Program Design

- Reduce greenhouse gas emissions to 15% below 2005 levels by 2020
- Includes an emissions cap and other core policies that are affordable, gradual, and support economic growth
- Based on extensive analysis and stakeholder consultation
- Provides a roadmap to inform Partners in their development of implementing regulations

Program Benefits

- Reduces costly impacts that climate change will have on water resources, natural ecosystems, air quality, and environment-dependent industries like agriculture and tourism
- Provides incentives for clean-energy technologies
- Creates green jobs
- Increases energy security
- Protects public health

Program Specifics

- The WCI Partners are advancing core policies and programs that:
  - Use a market-based approach to cap most emissions
  - Encourage reductions throughout the economy
  - Expand energy efficiency programs
  - Encourage additional renewable energy sources
  - Tackle transportation emissions

Program Specifics

- Economically- and geographically-broad cap covers nearly 90% of the region's emissions, providing flexibility to achieve least-cost emission reductions
- Jurisdictions with caps beginning in 2012 will include most of the region's emissions
- The WCI program accommodates jurisdictions with alternative schedules

Document Organization

- Design Summary
  - Highlights
  - Policy Recommendations
- Documentation
- Detailed Design
  - Operational Components

Next Steps

- Develop outstanding program design issues
- Put in place administrative systems and infrastructure
- Continue advancing core policies and programs
- Work closely with federal governments to promote national and international action and ensure coordination among state, provincial, regional and national programs

September 8, 2010 Harmonization Mandatory Reporting in Canadian Jurisdictions with the WCI Essential Requirements and the EPA Greenhouse Gas Reporting Program

Appendices

1 Introduction

On July 16, 2009, the WCI published the Final Essential Requirements for Mandatory Reporting (the "ERs") to be implemented by the WCI Partner jurisdictions. On September 22, 2009, U.S. EPA adopted its final Mandatory Greenhouse Gas Reporting Rule (the "EPA rule"), implementing the GHG Reporting Program. Many U.S. facilities in the WCI region will be subject to both reporting programs. Specifically, most facilities with emissions of CO_2e greater than or equal to 25,000 metric tons per year in WCI states will be subject to both programs.

The WCI Partners were concerned that the existence of two different reporting systems in a U.S. WCI state could result in the imposition of duplicative or conflicting reporting obligations on facilities subject to both programs. In order to avoid the imposition of this burden on reporting facilities, the Partners directed the WCI Reporting Committee to develop amended ERs that are harmonized with the EPA rule. Finalization of the harmonized ERs is expected in the near future. The harmonized ERs will be in the same format as the EPA rule, and include some recommended changes to ensure a level of accuracy in reported emissions sufficient for a cap-and-trade program.

In order to maintain consistency across all WCI jurisdictions, it was necessary for the Canadian WCI provinces to adopt harmonized ERs containing emission estimation methods and monitoring requirements equivalent to the harmonized ERs nearing approval by the WCI Partners.

Therefore, the Reporting Committee has developed amended WCI ERs that are methodically consistent with the WCI harmonized ERs but appropriate for use in the Canadian jurisdictions. The format of the harmonized Canadian ERs follows the original WCI format, a format that had already been used in guidance documents and regulations in several Canadian WCI jurisdictions.

The remainder of this document provides the principles applied to the harmonization process and approach used, and summarizes the changes made from the original WCI ERs.

2 Canadian Harmonization Principles

In developing harmonized ERs for use in Canadian jurisdictions that modify the existing ERs, the WCI Canadian Reporting Committee members applied the following principles:

1. A Canadian facility should apply the same functions, equations, sampling protocols and measurement criteria as U.S. facilities subject to the U.S. version of the

harmonized ERs. This means that the harmonized ERs will achieve the same level of reporting accuracy for Canadian and U.S. facilities, but the U.S. version may require more data elements to be reported to harmonize with the EPA rule.

2. The quantification methods included in the harmonized ERs must remain sufficiently reliable and accurate to be employed in a greenhouse gas (GHG) cap-and-trade program.

3. The WCI reporting system must remain suitable for use in Canadian jurisdictions. For example, it must allow reporting in metric as well as English units and must where necessary include Canada-specific emission factors.

4. The harmonized ERs should facilitate harmonization with Canadian federal reporting. Some Canadian jurisdictions are working with Environment Canada to develop a one-window reporting tool for provincial and national GHG reporting requirements.

3 Canadian Harmonization Approach

For the Canadian jurisdictions, the key requirement is that the WCI reporting system as a whole require the use of comparable methodologies and produce comparable results for facilities of the same type, so that a “ton is a ton” in both the U.S. and Canada. For Canadian jurisdictions it is not nearly as important to avoid small differences between the ERs and the EPA rule as it is for the U.S. jurisdictions, where differences create a risk of inadvertent non-compliance.

Canadian Partners have invested substantial resources in developing regulations to implement the existing WCI ERs. In addition, the provinces face technical and legal issues with the incorporation by reference of the EPA rule that do not apply to the states. The WCI is therefore proposing amendments to the existing WCI ERs to assure that they conform in substance with the U.S. version of the harmonized ERs as well as the interest provinces have in harmonizing their reporting programs with Environment Canada’s.

In the U.S. harmonization package a series of emission sources were listed as reporting only. The following list expands upon those sources based on the increased scope of the Canadian harmonization package:

Items Identified as Reporting Only in Harmonized ERs

Section(s)	Reporting Requirement
WCI.040 (EPA 98.32(b), 98.33(f))	Fugitive HFC emissions from cooling units at electricity generators
WCI.200 (EPA 98.253(h))	GHG emissions from asphalt blowing operations at petroleum refineries
WCI.200 (EPA 98.253(l))	CH_4 from equipment leaks at petroleum refineries
WCI.200 (98.253(m))	CH_4 from storage tanks at petroleum refineries
WCI.200 (98.253(n))	CH_4 from crude oil, intermediate, or product loading operations at petroleum refineries
WCI.100	Coal storage emissions
WCI.280	Mobile equipment

3.1 Verification

The amount of data to be reported by facilities in Canadian jurisdictions is less than the data required to be reported under the harmonized U.S. ERs. Canadian facilities that are subject to third party verification will have emissions reports evaluated by accredited third-party verifiers, whereas U.S. facilities reporting under the EPA rule and harmonized U.S. ERs will have their reports verified internally by EPA. Therefore, given the requirement for third-party verification, there is less of a need for detailed unit level data to be submitted online to the Canadian jurisdictions, as compared to what is required to be reported to the EPA for their internal verification.

3.2 Missing Data Procedures

The EPA rule includes procedures in each subpart for replacing missing data resulting from monitoring failures. With the exception of methodologies for facilities subject to 40 Code of Federal Regulation (CFR) Part 75 (the Acid Rain Program), these missing data procedures do not appear to be sufficiently rigorous to support a cap-and-trade system. There is no limitation on the amount of data that may be missing, and replacement methods appear to be both inadequate (e.g., many use only one or two available data points) and inequitable (e.g., Part 75 power plants have to apply punitive methods, while other facilities do not).

In order to move forward with a harmonization proposal in time to allow implementation for the 2011 reporting year, the proposed harmonized ERs retain the EPA missing data procedures. The proposed Canadian harmonized ERs also adopt the EPA missing data procedures.

Before implementation of the cap-and-trade program, WCI intends to revisit this issue. The WCI will investigate whether the EPA missing data procedures can be modified to be more consistent with the needs of a cap-and-trade program while adhering to the harmonization principles in section.

Missing data procedures are intended to provide flexibility due to unforeseen operational failures; however, some facilities may use them to avoid the regulatory requirements (or to under-report actual emissions). As a partial measure to address the possibility of avoiding requirements or gaming, the harmonized U.S. ERs include a provision making it clear that the use of a missing data procedure does not excuse a facility's failure to follow the monitoring requirements of the rule. This provision is being considered for adoption in the Canadian ERs.

4 Summary of Changes to WCI ERs

The table on pages 7 through 9 of this document summarizes the changes to the WCI ERs that the WCI Canadian Partners are proposing to implement in WCI Canadian jurisdictions. The specific language for the changes is set forth in the Appendices.

5 Other Changes to the Proposal

The Reporting Committee is currently developing the Canadian ER harmonization methods for upstream oil and gas and natural gas transmission and distribution. These are expected to be ready for stakeholder review by early October. Several other newly proposed or finalized U.S. EPA quantification methods (e.g. magnesium production, underground coal mining, electronics manufacturing) are under consideration for Canadian harmonization by the WCI, they may be released for stakeholder comment at the same time or at a later date. Due to time constraints, the WCI have not yet included these subparts in the final harmonized ERs for U.S. States.

The industrial wastewater treatment method recently finalized by the EPA has been adopted as part of the Canadian WCI petroleum refineries quantification method (for logistical reasons), but is required to be reported for all facilities.

Also, the Reporting Committee is considering some modifications to the WCI general provisions (i.e. WCI 1 to 9), to harmonize with the provisions in Subpart A of the U.S. harmonization package. The potential modifications under consideration would cover provisions on monitor calibration and definitions (such as pipeline quality natural gas).

Further EPA rule revisions, such as conforming changes to Subpart A, are expected to be finalized and go into effect later this year. To ensure the harmonized ERs are consistent with the EPA rule, Subpart A of the harmonized ERs was recently updated to reflect these changes. Additional consequential modifications to the Canadian ERs may therefore be required for harmonization.

Deadlines for the submission of verification statements were added to the U.S. version of WCI.8. These deadlines were initially established by WCI.2, which is not included in U.S. harmonized ERs.

6 Stakeholder Comments

This section to be completed after the public consultation period is over.

Summary of Changes to the WCI ERs for Purposes of Reporting in Canadian Jurisdictions

Source Category	§	Change Summary
General Stationary Combustion	WCI.20	• Several changes to harmonize with EPA Part 98, Subpart C, including added exemptions for portable equipment, emergency generators, and emergency equipment (including emergency flares). • Reduced sampling frequency for some types of fuels. • Relaxed biomass methods by allowing use of emission factors. • Very large combustion sources (greater than 250 million BTU of heat input) will have to measure fuel carbon content or put CEMs in place. • Method 4 (CEMS) now incorporates Canadian standards. • Clarification of many methodologies to explain applicability to sources.
Refinery Fuel Gas Use within a Petroleum Refinery	WCI.30	• Removed method based on HHV for estimating CO_2 from refinery fuel gas, flexigas, and low heat content gas. • Reduced sampling frequency • Reference to WCI.26 for procedures for estimating missing data.
Electricity Generation and Cogeneration	WCI.40	Added new definitions and procedures for estimating missing data.
Adipic Acid Manufacturing	WCI.50	• Added option to estimate emissions based on continuous process monitors. • Require annual performance test including measurement of production rate. • Require monthly calculations on productions, emissions and controls if continuous process monitors are used. • More specific method for determination of site-specific emission factor based on performance test. • Added requirement to determine N_2O abatement efficiency, if applicable. • Expanded and more specific monitoring requirements. • Added procedures for estimating missing data.
Electricity Imports	WCI.60	• No changes made; original methods stand and not re-released at this time.
Primary Aluminum Manufacturing	WCI.70	• Expanded reporting requirements to be consistent with Part 98, Subpart F. • CF_4 and C_2F_6 emissions estimation methods changed from requirement for daily production data to monthly production data. • Added procedures for estimating missing data.
Ammonia Manufacturing	WCI.80	WCI.80 was never finalized; therefore a new section based on EPA 98, subpart G was developed.
Cement Manufacturing	WCI.90	• Removed reporting requirement for plant-specific CKD calcination rate. • Changed equation for estimating CKD emission factor based on Part 98, Subpart H. • Added procedures for estimating missing data.
Coal Storage	WCI.100	Added procedures for estimating missing data.

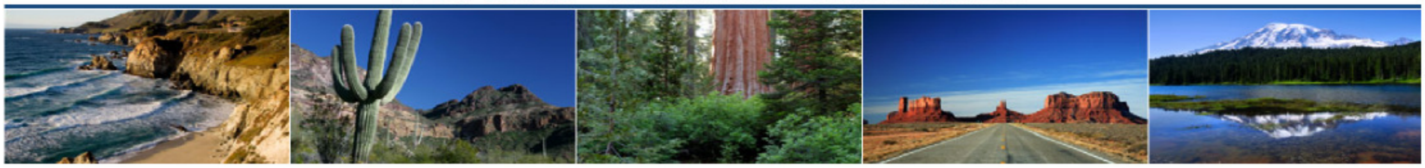
Summary of Changes to the WCI ERs for Purposes of Reporting in Canadian Jurisdictions (Continued)

Source Category	§	Change Summary
HCFC-22 Production	WCI.120	WCI.120 was never finalized; therefore a new section based on EPA 98, subpart O was developed.
Hydrogen Production	WCI.130	• Added requirement to report amount of carbon in unconverted feedstock. • Modified equations to separate calculations for liquid, gaseous and solid fuels and feedstocks. • Added specific sampling and analytical methods.
Glass Production	WCI.140	WCI.140 was never finalized, therefore a new WCI section based on EPA 98, subpart N, was developed
Iron and Steel Manufacturing	WCI.150	• Revised all reporting requirements, calculation methods, and monitoring requirements to match Part 98, Subpart Q. Now provides more specific breakdown of methods for discrete processes. • Allow coke oven gas and blast furnace gas to be reported upstream at the point of generation, rather than at the combustion unit. • Added new procedures for estimating missing data.
Lead Production	WCI.160	• Expanded and clarified monitoring requirements. • Added new procedures for estimating missing data.
Lime Manufacturing	WCI.170	• Changed reporting requirements for byproducts and wastes from monthly to quarterly. • Changed byproduct quantity sampling from quarterly to monthly. • Added procedures for estimating missing data.
Carbonates Use	WCI.180 (new)	Adopted EPA method in WCI format; no changes.
Petroleum Refineries (including Industrial Waste Water Treatment)	WCI.200	• Several changes made to harmonize with EPA Part 98, Subpart Y, which provide greater flexibility on the major sources such as flares, startup and shutdown conductions, and malfunctions. • Clarified source definition. • Clarified methods to be used for uncontrolled and controlled emissions from some sources, such as asphalt production. • More sources explicitly listed in reporting requirements. • Added methods for several new sources to harmonize with Subpart Y, including delayed coking and coke calcining. • Added procedures for estimating missing data.
Pulp and Paper Manufacturing	WCI.210	Made changes to be consistent with Part 98, Subpart AA: • Changed to use methods in WCI.20 (General Stationary Combustion) for fossil-fuel combustion (CO_2, CH_4, N_2O emissions). • For biogenic emissions from kraft or soda chemical recovery furnaces, added method based on high heat value of spent liquor solids. • Added new method for estimating CO_2 emissions from make-up chemical use.

Summary of Changes to the WCI ERs for Purposes of Reporting in Canadian Jurisdictions (Continued)

Source Category	§	Change Summary
Soda Ash Manufacturing	WCI.220	• Changed reporting requirements slightly to match Part 98, Subpart C. • More options for estimating CO_2 emissions if a CEMS is not used. • Expanded sampling, analysis, and measurement requirements. • Added new procedures for estimating missing data.
Electricity Transmission (and SF_6 from Electrical Equipment in Electricity Generation)	WCI.230	WCI.230 was never finalized, therefore a new WCI section was developed by BC for Canadian WCI jurisdictions based on EPA Part 98, Subpart DD and Canadian industry standard methods.
Zinc Production	WCI.240	• Additional requirements to report carbon content of input materials if missing data procedures are used • Equation variables clarified • Updated carbon content sampling and analysis methods • Added new procedures for estimating missing data.
Copper and Nickel Production	WCI.260 (new)	WCI.260 was never finalized, therefore a new WCI section was developed by Ontario for Canadian WCI jurisdictions. The method is based on the EC method with some clarifications on sampling frequencies but no significant differences.
Ferroalloy Production	WCI.270	New method developed for Canadian WCI jurisdictions based on EPA Part 98, Subpart K.
Mobile (Nonroad) Equipment	WCI.280 (new)	WCI.280 was never finalized, therefore a new WCI section based on methods developed by BC for Canadian WCI jurisdictions was used.
Petrochemical Manufacturing	WCI.300	• Clarified and expanded definition of petrochemical facilities. • Changed calculation methods (and some monitoring methods) to refer to refinery methods (WCI.203) for flares, and general combustion methods (WCI.20) for non-flare combustion sources and process vents. • Added new methods for gaseous, liquid, and solid feedstocks and products to be consistent with EPA part 98, Subpart X. • Added procedures for estimating missing data.
Nitric Acid Manufacturing	WCI.310	Made all changes similar as those made to adipic acid manufacturing
Phosphoric Acid Production	WCI.340	New section developed for Canadian WCI jurisdictions based on EPA Part 98, Subpart Z (with no changes except to drop requirement for estimating emissions by source of phosphate rock.)
Natural Gas Transmission, Distribution, and Storage	WCI.350 (new)	New section being developed for Canadian WCI jurisdictions based on EPA Part 98, Subpart W, WCI Reporting Committee, Oil and Gas Subcommittee recommendations to EPA (May 2010) and Canada-specific methods, sampling and measurement protocols and emission factors.
Petroleum and Natural Gas Production and Gas Processing	WCI.360 (new)	New section being developed for Canadian WCI jurisdictions based on EPA Part 98, Subpart W, WCI Reporting Committee, Oil and Gas Subcommittee recommendations to EPA (May 2010) and Canada-specific methods, sampling and measurement protocols and emission factors.

APPENDICES



§ WCI.20 GENERAL STATIONARY COMBUSTION

§ WCI.21 Source Category Definition

Stationary fuel combustion sources are devices that combust solid, liquid, or gaseous fuel generally for the purpose of producing electricity, generating steam or providing useful heat or energy for industrial, commercial, or institutional use; or reducing the volume of waste by removing combustible matter. Stationary fuel combustion sources are boilers, simple and combined cycle combustion turbines, engines, incinerators (including units that combust hazardous waste), and process heaters. This source category does not include portable equipment, emergency generators, and emergency equipment (including emergency flares).

§ WCI.22 Greenhouse Gas Reporting Requirements

The emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

(1) Total CO_2 emissions for fossil and biomass fuels, reported by fuel type. For units that burn both fossil fuels and biomass, the annual CO_2 emissions from combustion of all fossil fuels combined and the annual CO_2 emissions from combustion of all biomass fuels combined; reporting CO_2 emissions by type of fuel for these units is not required.

(2) Total CH_4 emissions, reported by fuel type.

(3) Total N_2O emissions, reported by fuel type.

(b) Annual fuel consumption:

(1) For gases, report in units of standard cubic meters.

(2) For liquids, report in units of kiloliters.

(3) For non-biomass solids, report in units of metric tons.

(4) For biomass solid fuels, report in units of bone dry metric tons.

(c) Annual weighted average carbon content of each fuel, if used to compute CO_2 emissions.

(d) Annual weighted average high heat value of each fuel, if used to compute CO_2 emissions.

(e) Annual steam generation in kilograms, for units that burn biomass fuels or municipal solid waste and generate steam.

§ WCI.23 Calculation of CO_2 Emissions

For each fuel, calculate CO_2 mass emissions using one of the four calculation methodologies specified in this section, subject to the restrictions in WCI.23(e).

(a) Calculation Methodology 1. Calculate the annual CO_2 mass emissions for each type of fuel by substituting a fuel-specific default CO_2 emission factor, a default high heat value, and the annual fuel consumption into Equation 20-1:

Equation 20-1

$$CO_2 = Fuel \times HHV \times EF \times 0.001$$

Where:

CO_2	=	Annual CO_2 mass emissions for the specific fuel type (metric tons).
Fuel	=	Mass or volume of fuel combusted per year (express mass in metric tons for solid fuel, volume in standard cubic meters for gaseous fuel, and volume in kiloliters for liquid fuel).
HHV	=	Default high heat value of the fuel, from Table 20-1 and 20-1a (GJ per metric ton for solid fuel, GJ per kiloliter for liquid fuel, or GJ per cubic meter for gaseous fuel).
EF	=	Fuel-specific default CO_2 emission factor, from Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable (kg CO_2/GJ).
0.001	=	Conversion factor from kilograms to metric tons.

(b) Calculation Methodology 2. Calculate the annual CO_2 mass emissions using a default fuel-specific CO_2 emission factor, a high heat value provided by the supplier or measured by the operator, using Equation 20-2, except for emissions from the combustion of biomass fuels, for which the operator may instead elect to use the method shown in Equation 20-3. For use of calculation methodology 2 for municipal solid waste, Equation 20-3 must be used.

(1) For any type of fuel for which an emission factor is provided in Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable, except biomass fuels when the operator elects to use the method in WCI.23(b)(2), use Equation 20-2:

Equation 20-2

$$CO_2 = \sum_{p=1}^{n} Fuel_p \times HHV_p \times EF \times 0.001$$

Where:

CO_2	=	Annual CO_2 mass emissions for a specific fuel type (metric tons).
n	=	Number of required heat content measurements for the year as specified in WCI.25.
$Fuel_p$	=	Mass or volume of the fuel combusted during the measurement period "p" (express mass in metric tons for solid fuel, volume in standard cubic meters for gaseous fuel, and volume in kiloliters for liquid fuel).
HHV_p	=	High heat value of the fuel for the measurement period (GJ per metric ton for solid fuel, GJ per kiloliter for liquid fuel, or GJ per cubic meter for gaseous fuel).
EF	=	Fuel-specific default CO_2 emission factor, from Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable (kg CO_2/GJ).
0.001	=	Conversion factor from kilograms to metric tons.

(2) For units that combust municipal solid waste and that produce steam, use Equation 20-3. Equation 20-3 of this section may also be used for any solid biomass fuel listed in Table 20-2 of this subpart provided that steam is generated by the unit.

$$CO_2 = Steam \times B \times EF \times 0.001$$ **Equation 20-3**

Where:

CO_2	=	Annual CO_2 mass emissions from biomass solid fuel or municipal solid waste combustion (metric tons).
Steam	=	Total mass of steam generated by biomass solid fuel or municipal solid waste combustion during the reporting year (metric tons steam).
B	=	Ratio of the boiler's design rated heat input capacity to its design rated steam output capacity (GJ/metric ton steam).
EF	=	Default emission factor for biomass solid fuel or municipal solid waste, from Table 20-2 or Table 20-7, as applicable (kg CO_2/GJ).[1]
0.001	=	Conversion factor from kilograms to metric tons.

(c) Calculation Methodology 3. Calculate the annual CO_2 mass emissions for each fuel by using measurements of fuel carbon content or molar fraction (for gaseous fuels only), conducted by the operator or provided by the fuel supplier, and the quantity of fuel combusted.

(1) For a solid fuel, except for the combustion of municipal solid waste, use Equation 20-4 of this section:

Equation 20-4

$$CO_2 = \sum_{i=1}^{n} Fuel_i \times CC_i \times 3.664$$

Where:

CO_2	=	Annual CO_2 mass emissions from the combustion of the specific solid fuel (metric tons).
n	=	Number of carbon content determinations for the year.
$Fuel_i$	=	Mass of the solid fuel combusted in measurement period "i" (metric tons).
CC_i	=	Carbon content of the solid fuel, from the fuel analysis results for measurement period "i" (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).
3.664	=	Ratio of molecular weights, CO_2 to carbon.

(2) For biomass fuels, in units that produce steam, use either Equation 20-4 above or Equation 20-5; for municipal solid waste combustion in units that produce steam, use Equation 20-5:

$$CO_2 = Steam \times B \times EF \times 0.001$$ **Equation 20-5**

Where:

CO_2	=	Annual CO_2 mass emissions from biomass solid fuel or municipal solid waste combustion (metric tons).
Steam	=	Total mass of steam generated by biomass solid fuel or municipal solid waste combustion during the reporting year (metric tons steam).

[1] The ER required development of a site-specific emission factor for MSW. For harmonization with Part 98, Subpart C, this requirement was deleted. However, jurisdictions may allow or require testing to develop a site-specific emission factor as an alternative to the default emission factors in Subpart C, Table C-1.

B = Ratio of the boiler's design rated heat input capacity to its design rated steam output capacity (GJ/metric ton steam).
EF = Default emission factor for biomass solid fuel or municipal solid waste, from Table 20-2 or 20-7, as applicable (kg CO_2/GJ), adjusted no less often than every third year as provided in WCI.25(a)(7)(B).
0.001 = Conversion factor from kilograms to metric tons.

(3) For a liquid fuel, use Equation 20-6 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \qquad \textbf{Equation 20-6}$$

Where:
CO_2 = Annual CO_2 mass emissions from the combustion of the specific liquid fuel (metric tons).
n = Number of required carbon content determinations for the year, as specified in WCI.25.
$Fuel_i$ = Volume of the liquid fuel combusted in measurement period "i" (kiloliters).
CC_i = Carbon content of the liquid fuel, from the fuel analysis results for measurement period "i" (metric ton C per kiloliter of fuel).
3.664 = Ratio of molecular weights, CO_2 to carbon.

(4) For a gaseous fuel, use Equation 20-7 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \times \frac{MW}{MVC} \times 0.001 \qquad \textbf{Equation 20-7}$$

Where:
CO_2 = Annual CO_2 mass emissions from combustion of the specific gaseous fuel (metric tons).
n = Number of required carbon content and molecular weight determinations for the year, as specified in WCI.25.
$Fuel_i$ = Volume of the gaseous fuel combusted in period "i" (a day or month, as applicable) (scm).
CC_i = Average carbon content of the gaseous fuel, from the fuel analysis results for the period "i" (day or month, as applicable) (kg C per kg of fuel).
MW = Molecular weight of the gaseous fuel, from fuel analysis (kg/kg-mole).
MVC = Molar volume conversion factor (24.1 scm per kg-mole for STP of 20°C and 1 atmosphere or 23.7 scm per kg-mole for STP of 60°F, and 1 atmosphere).
3.664 = Ratio of molecular weights, CO_2 to carbon.
0.001 = Conversion factor from kg to metric tons.

(d) Calculation Methodology 4. Calculate the annual CO_2 mass emissions from all fuels combusted in a unit, by using data from continuous emission monitoring systems (CEMS) as specified in (d)(1) through (d)(7). This methodology requires a CO_2 concentration monitor and a stack gas volumetric flow monitor, except as otherwise provided in paragraph (d)(2) of this section.

(1) For a facility that operates CEMS in response to federal, state, provincial, or local regulation, use CO_2 or O_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded).

(2) The operator shall report CO_2 emissions for the reporting year in metric tons based on the sum of hourly CO_2 mass emissions over the year, converted to metric tons.

(3) An oxygen (O_2) concentration monitor may be used in lieu of a CO_2 concentration monitor in a CEMS installed before January 1, 2012, to determine the hourly CO_2 concentrations, if the effluent gas stream monitored by the CEMS consists solely of combustion products (i.e., no process CO_2 emissions or CO_2 emissions from acid gas control are mixed with the combustion products) and if only the following fuels are combusted in the unit: coal, petroleum coke, oil, natural gas, propane, butane, wood bark, or wood residue.

   (A) If the unit combusts waste derived fuels (as defined in the General Provisions and including municipal solid waste), emissions calculations shall not be based on O_2 concentrations.

   (B) If the operator of a facility that combusts biomass fuels uses O_2 concentrations to calculate CO_2 concentrations, annual source testing must demonstrate that calculated CO_2 concentrations when compared to measured CO_2 concentrations meet the Relative Accuracy Test Audit (RATA) requirements in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded),

(4) If both biomass fuel (including fuels that are partially biomass) and fossil fuel are combusted during the year, determine and report the biogenic CO_2 mass emissions separately, as described in paragraph (f) of this section.

(5) For any units for which CO_2 emissions are reported using CEMS data, the operator is relieved of the requirement to separately report process emissions from combustion emissions for that unit or to report emissions separately for different fossil fuels for that unit when only fossil fuels are co-fired. In this circumstance, operators shall still report fuel use by fuel type as otherwise required.

(6) If a facility is subject to requirements for continuous monitoring of gaseous emissions, and the operator chooses to add devices to an existing CEMS for the purpose of measuring CO_2 concentrations or flue gas flow, the operator shall select and operate the added devices pursuant to the appropriate requirements for the facility as applicable in Canada.

(7) If a facility does not have a CEMS and the operator chooses to add one in order to measure CO_2 concentrations, the operator shall select and operate the CEMS pursuant to the appropriate requirements or equivalent requirements as applicable in Canada.

Operators who add CEMS under this paragraph are subject to the specifications in paragraphs (d)(1) through (d)(5), if applicable.

(e) Use of the Four CO_2 Calculation Methodologies. Use of the four CO_2 emissions calculation methodologies described in paragraphs (a) through (d) of this section is subject to the following requirements and restrictions:

(1) Calculation Methodology 1 (Equation 20-1).

(A) May be used by a facility that is not subject to the verification requirements by regulation for any type of fuel for which a default high heat value for the fuel (Table 20-1 and 20-1a) and a default CO_2 emission factor (Tables 20-1a, 20-2, 20-3, or 20-5, as applicable) is specified.

(B) May be used for a facility emitting at any level for the combustion of natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter, and for the combustion of any of the fuels listed in Table 20-1a.

(C) May be used for a facility emitting at any level for the combustion of municipal solid waste in a unit that does not generate steam.

(D) May not be used at a facility emitting at any level for a fuel for which you routinely perform fuel sampling and analysis for the fuel high heat value or can obtain the results of fuel sampling and analysis for the fuel high heat value from the fuel supplier at the minimum frequency specified in WCI.25(a), or at a greater frequency. In such cases, Calculation Method 2 or higher shall be used for those fuels.

(2) Calculation Methodology 2 (Equations 20-2 and 20-3).

(A) May not be used by a facility that is subject to the verification requirements by regulation, except as specified in paragraphs (e)(2)(B) through (E) of this section. Otherwise, Calculation Methodology 2 may be used for any type of fuel combusted for which a default CO_2 emission factor for the fuel is specified in Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable.

(B) Calculation Methodology 2 may be used for the combustion of natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter at a facility emitting at any level.

(C) Calculation Methodology 2 may be used at a facility emitting at any level for the combustion of any of the fuels listed in Table 20-1a, and for biomass that has been determined by [the jurisdiction] not to be subject to a compliance obligation under the cap-and-trade program.

(D) Equation 20-3 may be used for the combustion of municipal solid waste only at facilities that are not subject to verification by regulation.

(E) Equation 20-2 may not be used for the combustion of municipal solid waste.

(3) Calculation Methodology 3 (Equations 20-4 through 20-7) may be used for the combustion of any type of fuel, except as specified in paragraph (e)(3)(A) through (E) of this section.

(A) Notwithstanding the provisions in paragraph (e)(1) and (e)(2) of this section, Calculation Methodology 3 must be used at a facility subject to verification for all combustion in any unit with a rated heat input capacity greater than 264 GJ/hr (250mmBtu/hr) and that has operated for more than 1,000 hours in any of the past three years, except when the fuel is natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter, the fuel is listed in Table 20-1a, or the fuel is biomass that has been determined by [the jurisdiction] not to be subject to a compliance obligation under the cap-and-trade program.

(B) Must be used for all other combustion at a facility subject to verification, except for combustion of fuels for which Calculation Methodology 1 or 2 is permitted, as described in paragraphs (e)(1) and (e)(2) of this section.

(C) May not be used when the use of Calculation Methodology 4 is required.

(D) Equation 20-4 may not be used for the calculation of emissions from combustion of municipal solid waste.

(E) Equation 20-5 may be used for the combustion of municipal solid waste at a facility emitting at any level; however, it must be used for the combustion of municipal solid waste if the facility is subject to verification by regulation, unless Calculation Methodology 4 is required.

(4) Calculation Methodology 4 may be used for a unit combusting any type of fuel. Notwithstanding the provisions in paragraphs (e)(1) through (3) of this section, Calculation Methodology 4 must be used for a combustion unit with a CEMS that is required by any federal, provincial, or local regulation and that includes both a stack gas volumetric flow rate monitor and a CO_2 concentration monitor.

(5) You may elect to use any applicable higher calculation methodology for one or more of the fuels combusted in a unit. For example, if a unit combusts natural gas and distillate fuel oil, you may elect to use Calculation Method 1 for natural gas and Calculation Method 2 for the fuel oil, even though Calculation Method 1 could have been used for both fuels. However, for units that use Calculation Method 4, CO_2 emissions from the combustion of all fuels shall be based solely on CEMS measurements.

(f) CO_2 emissions from combustion of mixtures of biomass or biomass fuel and fossil fuel. Use the procedures of this paragraph (g) to estimate biogenic CO_2 emissions from units that combust a combination of biomass and fossil fuels, including combustion of waste-derived fuels (e.g., municipal solid waste or tires) that are partially biomass. .

(1) If CEMS are not used to measure CO_2 and the facility combusts biomass fuels that do not include waste-derived fuels (e.g., municipal solid waste and tires), use Methods 1, 2, or 3, as applicable, to calculate the annual biogenic CO_2 mass emissions from the combustion of biomass fuels. Determine the mass of biomass combusted using either company records, or, for premixed fuels that contain biomass and fossil fuels (e.g., mixtures containing biodiesel), use best available information to determine the mass of biomass fuels and document the procedure.

(2) If a CEMS is used to measure CO_2 (or O_2 as a surrogate) and the facility combusts biomass fuels that do not include waste-derived fuels (as defined in the General Provisions), use Calculation Methods 1, 2, or 3 to calculate the annual CO_2 mass

emissions from the combustion of fossil fuels. Calculate biomass fuel emissions by subtracting the fossil fuel-related emissions from the total CO_2 emissions determined from the CEMS-based methodology.

(3) If the owner or operator that combusts fuels or fuel mixtures for which the biomass fraction is unknown or cannot be documented (e.g., municipal solid waste, tire-derived fuel), or if the owner or operator combusts a biomass fuel for which a CO_2 emission factor is not provided in Table 20-2, use the following to estimate biogenic CO_2 emissions:

(A) Use Calculation Methods 1, 2, 3, or 4 to calculate the total annual CO_2 mass emissions, as applicable.

(B) Determine the biogenic portion of the CO_2 emissions using ASTM D6866-06a, as specified in this paragraph. This procedure is not required for fuels that contain less than 5 percent biomass by weight or for waste-derived fuels that are less than 30 percent by weight of total fuels combusted in the year for which emissions are being reported, except where the operator wishes to report a biomass fuel fraction of CO_2 emissions.

(C) The operator shall conduct ASTM D6866-06a analysis on a representative fuel or exhaust gas sample at least every three months, and shall collect exhaust gas samples over at least 24 consecutive hours following the standard practice specified by ASTM D7459-08. If municipal solid waste is combusted, the ASTM D6866-06a analysis must be performed on the exhaust gas stream.

(D) The operator shall divide total CO_2 emissions between biomass fuel emissions and non-biomass fuel emissions using the average proportions of the samples analyzed for the year for which emissions are being reported.

(E) If there is a common fuel source to multiple units at the facility, the operator may elect to conduct ASTM D6866-06a testing for only one of the units sharing the common fuel source.

(4) If Equation 20-1 of this section is selected to calculate the annual biogenic mass emissions for wood, wood waste, or other solid biomass-derived fuel, Equation 20-8 of this section may be used to quantify biogenic fuel consumption, provided that all of the required input parameters are accurately quantified. Similar equations and calculation methodologies based on steam generation and boiler efficiency may be used, provided that they are documented.

$$(Fuel)_p = \frac{[H * S] - (HI)_{nb}}{(HHV)_{bio} \ (Eff)_{bio}}$$ **Equation 20-8**

Where:

$(Fuel)_p$	=	Quantity of biomass consumed during the measurement period “p” (metric tons/year or metric tons/month, as applicable).
H	=	Average enthalpy of the boiler steam for the measurement period (GJ/metric ton).
S	=	Total boiler steam production for the measurement period (metric ton/month or metric ton/year, as applicable).

$(HI)_{nb}$ = Heat input from co-fired fossil fuels and non-biomass-derived fuels for the measurement period, based on company records of fuel usage and default or measured HHV values (GJ/month or GJ/year, as applicable).
$(HHV)_{bio}$ = Default or measured high heat value of the biomass fuel (GJ/metric ton).
$(Eff)_{bio}$ = Percent efficiency of biomass-to-energy conversion, expressed as a decimal fraction.

(g) Calculation of CO_2 from sorbent.

(1) When a unit is a fluidized bed boiler, is equipped with a wet flue gas desulfurization system, or uses other acid gas emission controls with sorbent injection, use Equation 20-9 of this section to calculate the CO_2 emissions from the sorbent, if those CO_2 emissions are not monitored by CEMS:

$$CO_2 = S * R * \left(\frac{MW_{CO2}}{MW_S} \right) \quad \textbf{Equation 20-9}$$

Where:

CO_2 = CO_2 emitted from sorbent for the reporting year (metric tons).
S = Limestone or other sorbent used in the reporting year, from company records (metric tons).
R = 1.00, the calcium-to-sulfur stoichiometric ratio.
MW_{CO2} = Molecular weight of carbon dioxide.
MW_S = Molecular weight of sorbent.

(2) The annual CO_2 mass emissions for the unit shall be the sum of the CO_2 emissions from the combustion process and the CO_2 emissions from the sorbent.

§ WCI.24 Calculation of CH_4 and N_2O Emissions

Calculate the annual CH_4 and N_2O mass emissions from stationary fuel combustion sources using the procedures in paragraph (a), (b), or (c), as appropriate.

(a) If the high heat value of the fuel is not measured for CO_2 estimation, calculate CH_4 and N_2O emissions using Equation 20-10 for all fuels except coal. For coal, use Equation 20-11:

$$CH_4 \ or \ N_2O = Fuel \times HHV_D \times EF \times 0.000001 \quad \textbf{Equation 20-10}$$

$$CH_4 \ or \ N_2O = Fuel \times EF_c \times 0.001 \quad \textbf{Equation 20-11}$$

Where:
CH_4 or N_2O = Combustion emissions from specific fuel type, metric tons CH_4 or N_2O per year.
Fuel = Mass or volume of fuel combusted per year (express mass in metric tons for solid fuel, volume in standard cubic meters for gaseous fuel, and volume in kiloliters for liquid fuel).
HHV_D = Default high heat value specified by fuel type provided in Table 20-1, (GJ per metric ton for solid fuel, GJ per kiloliter for liquid fuel, or GJ per cubic meter for gaseous fuel).

EF = Default CH_4 or N_2O emission factor provided in Tables 20-2 or 20-4, as applicable, grams CH_4 or N_2O per GJ.

EF_c = Default CH_4 or N_2O emission factor for coal provided in Table 20-6 (grams CH_4 or N_2O per kg of coal)

0.000001 = Factor to convert grams to metric tons in Equation 20-8.

0.001 = Factor to convert g/kg to metric ton/metric ton in Equation 20-9.

(b) If the high heat value of the fuel is measured or provided by the fuel supplier for CO_2 estimation, calculate CH_4 and N_2O emissions using Equation 20-12 for all fuels except coal. For coal, use Equation 20-13:

$$CH_4 \; or \; N_2O = \sum_{p=1}^{n} Fuel_p \times HHV_p \times EF \times 0.000001 \qquad \textbf{Equation 20-12}$$

$$CH_4 \; or \; N_2O = \sum_{p=1}^{n} Fuel_p \times EF_c \times 0.000001 \qquad \textbf{Equation 20-13}$$

Where:

CH_4 or N_2O = CH_4 or N_2O emissions from a specific fuel type, metric tons CH_4 or N_2O per year.

$Fuel_p$ = Mass or volume of the fuel combusted during the measurement period "p" (express mass in metric tons for solid fuel, volume in standard cubic meters for gaseous fuel, and volume in kiloliters for liquid fuel)..

HHV_p = High heat value measured directly or provided by the fuel supplier for the measurement period, p, specified by fuel type (GJ per metric ton for solid fuel, GJ per kiloliter for liquid fuel, or GJ per cubic meter for gaseous fuel).

EF = Default CH_4 or N_2O emission factor provided in Tables 20-2 or 20-4, as applicable, grams CH_4 or N_2O per GJ.

EF_c = CH_4 or N_2O emission factor for coal, either measured directly or provided by the fuel supplier, grams CH_4 or N_2O per metric ton of coal

0.000001 = Factor to convert grams to metric tons.

(c) For biomass and municipal solid waste combustion where Equation 20-3 or 20-5 are used to calculate CO_2 emissions, use Equation 20-14 of this section to estimate CH_4 and N_2O emissions:

$$CH_4 \; or \; N_2O = Steam \times B \times EF \times 0.000001 \qquad \textbf{Equation 20-14}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a municipal solid waste (metric tons).

Steam = Total mass of steam generated by municipal solid waste combustion during the reporting year (metric tons steam).

B = Ratio of the boiler's design rated heat input capacity to its design rated steam output (GJ/metric ton steam).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Tables 20-2, 20-4 or 20-6, as applicable (grams CH_4 or N_2O per GJ).

0.000001 = Conversion factor from grams to metric tons.

(d) Use Equation 20-15 of this section for units that use Calculation Methodology 4 and for which heat input is monitored on a year round basis.

$$CH_4 \text{ or } N_2O = 0.001 * (HI)_A * EF$$ **Equation 20-15**

Where:

CH_4 or N_2O	=	Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (metric tons).
$(HI)_A$	=	Cumulative annual heat input from the fuel (GJ), derived from the electronic data reports or estimated from the best available information (e.g., fuel feed rate measurements, fuel heating values, engineering analysis).
EF	=	Fuel-specific emission factor for CH_4 or N_2O, from Tables 20-2, 20-4 or 20-6, as applicable (grams CH_4 or N_2O per GJ).
0.001	=	Conversion factor from kg to metric tons.

(1) If only one type of fuel is combusted during normal operation, substitute the cumulative annual heat input from combustion of the fuel into Equation 20-15 of this section to calculate the annual CH_4 or N_2O emissions.

(2) If more than one type of fuel listed is combusted during normal operation, use Equation 20-15 of this section separately for each type of fuel.

(e) When multiple fuels are combusted during the reporting year, sum the fuel-specific results from Equations 20-8, 20-9, 20-10, or 20-11 of this section (as applicable) to obtain the total annual CH_4 and N_2O emissions, in metric tons.

(f) The operator may elect to calculate CH_4 or N_2O emissions using source-specific emission factors derived from source tests conducted at least annually under the supervision of the regulator. Upon approval of a source test plan, the source test procedures in that plan shall be repeated in each future year to update the source specific emission factors annually.

(g) Use of the four CH_4 and N_2O Calculation Methodologies. Use of the four CH_4 and N_2O emissions calculation methodologies described in paragraphs (a) through (d) of this section is subject to the following requirements and restrictions:

(1) WCI.24(a) may not be used by a facility that is subject to the verification requirements of WCI.8, except for stationary combustion units that combust natural gas with a higher heating value between 36.3 and 40.98 MJ per cubic meter. Otherwise, WCI.24(a) may be used for any type of fuel for which a default CH_4 or N_2O emission factor (Tables 20-2, 20-4, 20-6, 20-7) and a default higher heat value (Table 20-1 and 20-1a) is specified.

(2) WCI.24(b) may be used for a unit of any size combusting any type of fuel.

(3) WCI.24(c) may only be used for biomass or municipal solid waste combustion. WCI.24(c) must be used instead of WCI.24(a) for any unit combusting municipal solid waste that generates steam.

(4) WCI.24(d) may be used for a unit of any size combusting any type of fuel, and must be used for any units for which Calculation Methodology 4 is used to estimate CO_2 emissions and heat input is monitored on a year round basis.

§ WCI.25 Sampling, Analysis, and Measurement Requirements

(a) Fuel Sampling Requirements. Fuel sampling must be conducted or fuel sampling results must be received from the fuel supplier at the frequency specified in paragraphs (a)(1) through (a)(4) of this section, subjected to the requirements of WCI.23(e) and WCI.24(g).

(1) Once for each new fuel shipment or delivery for coal.

(2) Once for each new fuel shipment or delivery of fuels, or quarterly for each of the fuels listed in Table 20-1a (when required).

(3) Semiannually for natural gas (when required).

(4) Quarterly for liquid fuels and fossil fuel derived gaseous fuels other than fuels listed in Table 20-1a (when Table 20-1a is used).

(5) Quarterly for gases derived from biomass including landfill gas and biogas from wastewater treatment or agricultural processes.

(6) Monthly for solid fuels other than coal and municipal solid waste, as specified below:

(A) The monthly solid fuel sample shall be a composite sample of weekly samples.

(B) The solid fuel shall be sampled at a location after all fuel treatment operations but before fuel mixing and the samples shall be representative of the fuel chemical and physical characteristics immediately prior to combustion.

(C) Each weekly sub-sample shall be collected at a time (day and hour) of the week when the fuel consumption rate is representative and unbiased.

(D) Four weekly samples (or a sample collected during each week of operation during the month) of equal mass shall be combined to form the monthly composite sample.

(E) The monthly composite sample shall be homogenized and well mixed prior to withdrawal of a sample for analysis.

(F) One in twelve composite samples shall be randomly selected for additional analysis of its discrete constituent samples. This information will be used to monitor the homogeneity of the composite.

(7) For biomass fuels and waste-derived fuels (including municipal solid waste), the following may apply in lieu of WCI.25(a)(5):

(A) If CO_2 emissions are calculated using Equation 20-4 in WCI.23(c)(1), the source-specific carbon content is determined annually.

(B) If CO_2 emissions are calculated using Equation 20-5 in WCI.23(c)(2) (biomass fuels and municipal solid waste only), the operator shall adjust the emission factor, in kg CO_2/MJ not less frequently than every third year, through a stack test measurement of CO_2 and use of the applicable ASME Performance Test Code to determine heat input from all heat outputs, including the steam, flue gases, ash and losses.

(b) Fuel Consumption Monitoring Requirements.

(1) Facilities may determine fuel consumption on the basis of direct measurement or recorded fuel purchase or sales invoices measuring any stock change (measured in MJ, liters, million standard cubic meters, metric tons or bone dry metric tons) using the following equation:

Fuel Consumption in the Report Year = Total Fuel Purchases – Total Fuel Sales + Amount Stored at Beginning of Year – Amount Stored at Year End

(2) Fuel consumption measured in MJ values shall be converted to the required metrics of mass or volume using heat content values that are either provided by the supplier, measured by the facility, or provided in Table 20-1.

(3) All oil and gas flow meters (except for gas billing meters) shall be calibrated prior to the first year for which GHG emissions are reported under this rule, using an applicable flow meter test method listed in by regulation or the calibration procedures specified by the flow meter manufacturer. Fuel flow meters shall be recalibrated either annually or at the minimum frequency specified by the manufacturer.

(4) For fuel oil, tank drop measurements may also be used.

(5) Fuel flow meters that measure mass flow rates may be used for liquid fuels, provided that the fuel density is used to convert the readings to volumetric flow rates. The density shall be measured at the same frequency as the carbon content, using ASTM D1298-99 (Reapproved 2005) "Standard Test Method for Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and Liquid Petroleum Products by Hydrometer Method."

(6) Facilities using Calculation Methods 1 or 2 for CO_2 emissions may use the following default density values for fuel oil, in lieu of using the ASTM method in paragraph (b)(5) of this section: 0.81 kg/liter for No. 1 oil; 0.86 kg/liter for No. 2 oil; 0.97 kg/liter for No. 6 oil. These default densities may not be used for facilities using Calculation Method 3.

(c) Fuel Heat Content Monitoring Requirements. High heat values shall be based on the results of fuel sampling and analysis received from the fuel supplier or determined by the operator, in either case using an applicable analytical method listed by regulation.

(1) For gases, use ASTM D1826-94 (Reapproved 2003), ASTM D3588-98 (Reapproved 2003), ASTM D4891-89 (Reapproved 2006), GPA Standard 2261-00 "Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography." The operator may alternatively elect to use on-line instrumentation that determines heating value accurate to within ± 5.0 percent. Where existing on-line instrumentation provides only low heat value, the operator shall convert the value to high heat value as follows:

$$HHV = LHV \times CF$$ **Equation 20-16**

Where:

HHV = fuel or fuel mixture high heat value (MJ/scm).
LHV = fuel or fuel mixture low heat value (MJ/scm).
CF = conversion factor.

For natural gas, a CF of 1.11 shall be used. For refinery fuel gas and mixtures of refinery fuel gas, a weekly average fuel system-specific CF shall be derived as follows:

(A) By concurrent LHV instrumentation measurements and HHV determined by on-line instrumentation or laboratory analysis as part of the daily carbon content determination; or,

(B) By the HHV/LHV ratio obtained from the laboratory analysis of the daily samples.

(2) For middle distillates and oil, or liquid waste-derived fuels, use ASTM D240-02 (Reapproved 2007), or ASTM D4809-06 (Reapproved 2005).

(3) For solid biomass-derived fuels, use ASTM D5865-07a.

(4) For waste-derived fuels, use ASTM D5865-07a or ASTM D5468-02 (Reapproved 2007). Operators who combust waste-derived fuels that are not pure biomass fuels shall determine the biomass fuel portion of CO_2 emissions using the method specified in WCI.23(f), if applicable

(5) Use Equation 20-17 to calculate the weighted annual average heat content of the fuel, if the measured heat content is used to calculate CO_2 emissions.

$$(HHV)_{annual} = \frac{\sum_{p=1}^{n} (HHV)_p * (Fuel)_p}{\sum_{p=1}^{n} (Fuel)_p} \quad \textbf{Equation 20-17}$$

Where:

$(HHV)_{annual}$ = Weighted annual average high heat value of the fuel (GJ per metric ton for solid fuel, GJ per kiloliter for liquid fuel, or GJ per cubic meter for gaseous fuel).

$(HHV)_p$ = High heat value of the fuel, for measurement period "p" (GJ per metric ton for solid fuel, GJ per kiloliter for liquid fuel, or GJ per cubic meter for gaseous fuel).

$(Fuel)_p$ = Mass or volume of the fuel combusted during measurement period "p" (express mass in metric tons for solid fuel, volume in standard cubic meters for gaseous fuel, and volume in kiloliters for liquid fuel).

n = Number of measurement periods in the year that fuel is burned in the unit.

(d) Fuel Carbon Content Monitoring Requirements. Fuel carbon content and either molecular weight or molar fraction for gaseous fuels shall be based on the results of fuel sampling and analysis received from the fuel supplier or determined by the operator, in either case using an applicable analytical method listed by regulation.

(1) For coal and coke, solid biomass fuels, and waste-derived fuels; use ASTM 5373-08.

(2) For liquid fuels, use the following ASTM methods: For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291-02 (Reapproved 2007) "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants," ultimate analysis of oil or computations based on

ASTM D3238-95 (Reapproved 2005) and either ASTM D2502-04 or ASTM D2503-92 (Reapproved 2007).

(3) For gaseous fuels, use ASTM D1945-03 (Reapproved 2006) or ASTM D1946-90 (Reapproved 2006). For gaseous fuels other than natural gas and biogas, daily sampling and analysis to determine the carbon content and molecular weight of the fuel is required if the necessary equipment is in place to make these measurements. Otherwise, weekly sampling and analysis shall be performed. If on-line instrumentation is to be used, the equipment necessary to perform daily sampling and analysis of carbon content and molecular weight for refinery fuel gas must be installed no later than January 1, 2012, and must determine fuel carbon content accurate to ± 5 percent.

(4) Use Equation 20-18 to calculate the weighted annual average carbon content of the fuel, if the measured carbon content is used to calculate CO_2 emissions.

$$(CC)_{annual} = \frac{\sum_{p=1}^{n}(CC)_p * (Fuel)_p}{\sum_{p=1}^{n}(Fuel)_p} \qquad \textbf{Equation 20-18}$$

Where:

$(CC)_{annual}$ = Weighted annual average carbon content of the fuel (percent C by weight for solid fuel, metric ton C per kiloliter for liquid fuel, or kg C per kg fuel for gaseous fuel).

$(CC)_p$ = Carbon content of the fuel, for measurement period "p" (percent C by weight for solid fuel, metric ton C per kiloliter for liquid fuel, or kg C per kg fuel for gaseous fuel).

$(Fuel)_p$ = Mass or volume of the fuel combusted during measurement period "p" (express mass in metric tons for solid fuel, volume in standard cubic meters for gaseous fuel, and volume in kiloliters for liquid fuel).

n = Number of measurement periods in the years that fuel is burned in the unit.

(e) Fuel Analytical Data Capture. When the applicable emissions estimation methodologies in WCI.23 and WCI.24 require periodic collection of fuel analytical data for an emissions source, the operator shall demonstrate every reasonable effort to obtain a fuel analytical data capture rate of 100 percent for each report year.

(1) If the operator is unable to obtain fuel analytical data such that more than 20 percent of emissions from a source cannot be directly accounted for, the emissions from that source shall be considered unverifiable for the report year.

(2) If the fuel analytical data capture rate is at least 80 percent but less than 100 percent for any emissions source identified in WCI.23 and WCI.24, the operator shall use the methods in WCI.26(b) to substitute for the missing values for the period of missing data.

(f) Procedure for Interim Fuel Analytical Data Collection.

(1) In the event of an unforeseen breakdown of fuel analytical data monitoring equipment required for the emissions estimation methodologies in WCI.23 and WCI.24, the regulator may authorize an operator to use an interim data collection procedure if the regulator determines that the operator has satisfactorily demonstrated that:

(A) The breakdown may result in a loss of more than 20 percent of the source's fuel data for the reporting year, such that emissions for the affected source could not be verified under the verification provisions of the regulation;

(B) The fuel analytical data monitoring equipment cannot be promptly repaired or replaced without shutting down a process unit significantly affecting facility operations, or that the monitoring equipment must be replaced and replacement equipment is not immediately available;

(C) The interim procedure will not remain in effect longer than is reasonably necessary for repair or replacement of the malfunctioning data monitoring equipment; and

(D) The request was submitted within 30 calendar days of the breakdown of the fuel analytical data monitoring equipment.

(2) An operator seeking approval of an interim data collection procedure must, within 30 days of the monitoring equipment breakdown, submit a written request to the regulator] that includes all of the following:

(A) The proposed start date and end date of the interim procedure;

(B) A detailed description of what data are affected by the breakdown;

(C) A discussion of the accuracy of data collected during the interim procedure compared with the data collected under the operator's usual equipment-based method;

(D) A demonstration that no feasible alternative procedure exists that would provide more accurate emissions data; and

(E) A demonstration that the proposed interim procedure meets the criteria specified in WCI.25(f)(1).

(3) The regulator may limit the duration of the interim data collection procedure or include other conditions of approval to ensure the criteria in WCI.25(f)(1) are met.

(4) When approving an interim data collection procedure, the regulator shall determine whether the accuracy of data collected under the procedure is reasonably equivalent to data collected from properly functioning monitoring equipment, and if it is not, the relative accuracy to assign for purposes of assessing possible material misstatement under the verification provisions of the regulation.

§ WCI.26 Procedures for estimating missing data.

Whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For all units subject to the requirements of WCI.20 that monitor and report emissions using a CEMS, the missing data backfilling procedures in *Protocols And Performance Specifications*

For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded) shall be followed for CO_2 concentration, stack gas flow rate, fuel flow rate, high heating value, and fuel carbon content.

(b) For units that use Calculation Methodologies 1, 2, 3, or 4, perform missing data substitution as follows for each parameter:

(1) For each missing value of the high heating value, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the "after" value has not been obtained by the time that the GHG emissions must be calculated, you may use the "before" value for missing data substitution or the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production, operating hours). If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(2) For missing records of CO_2 concentration, stack gas flow rate, percent moisture, fuel usage, and sorbent usage, the substitute data value shall be the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production, operating hours, etc.). You must document and retain records of the procedures used for all such estimates.

§ WCI.27 Definitions

Except as specified in this section, all terms used in this subpart have the same meaning given in the General Provisions.

<u>Emergency generator</u> means a stationary combustion device, such as a reciprocating internal combustion engine or turbine that serves solely as a secondary source of mechanical or electrical power whenever the primary energy supply is disrupted or discontinued during power outages or natural disasters that are beyond the control of the owner or operator of a facility. An emergency generator operates only during emergency situations, for training of personnel under simulated emergency conditions, as part of emergency demand response procedures, or for standard performance testing procedures as required by law or by the generator manufacturer. A generator that serves as a back-up power source under conditions of load shedding, peak shaving, power interruptions pursuant to an interruptible power service agreement, or scheduled facility maintenance shall not be considered an emergency generator.

<u>Emergency equipment</u> means any auxiliary fossil fuel-powered equipment, such as a fire pump, that is used only in emergency situations.

<u>Pipeline quality natural gas</u> means natural gas having a high heat value equal to or greater than 36.1 MJ/m3 or less than 40.98 MJ/m3, and which is at least ninety percent methane by volume, and which is less than five percent carbon dioxide by volume.

<u>Portable</u> means designed and capable of being carried or moved from one location to another. Indications of portability include but are not limited to wheels, skids, carrying handles, dolly, trailer, or platform. Equipment is not portable if any one of the following conditions exists:

(1) The equipment is attached to a foundation.

(2) The equipment or a replacement resides at the same location for more than 12 consecutive months.

(3) The equipment is located at a seasonal facility and operates during the full annual operating period of the seasonal facility, remains at the facility for at least two years, and operates at that facility for at least three months each year.

(4) The equipment is moved from one location to another in an attempt to circumvent the portable residence time requirements of this definition.

Table 20-1: Default High Heat Value by Fuel Type

Liquid Fuels	**High Heat Value (GJ/kl)**
Asphalt & Road Oil	44.46
Aviation Gasoline	33.52
Diesel	38.3
Aviation Turbo Fuel	37.4
Kerosene	37.68
Propane	25.31
Ethane	17.22
Butane	28.44
Lubricants	39.16
Motor Gasoline - Off-Road	35
Light Fuel Oil	38.8
Residual Fuel Oil (#5 & 6)	42.5
Crude Oil	38.32
Naphtha	35.17
Petrochemical Feedstocks	35.17
Petroleum Coke - Refinery Use	46.35
Petroleum Coke – Upgrader Use	40.57
Solid Fuels	**High Heat Value (GJ/metric ton)**
Anthracite Coal	27.7
Bituminous Coal	26.33
Foreign Bituminous Coal	29.82
Sub-Bituminous Coal	19.15
Lignite	15
Coal Coke	28.83
Solid Wood Waste	18
Spent Pulping Liquor	14
Municipal Solid Waste	11.57
Gaseous Fuels	**High Heat Value (GJ/m3)**
Natural Gas	0.03832
Coke Oven Gas	0.01914
Still Gas – Refineries	0.03608
Still Gas – Upgraders	0.04324
Landfill Gas (captured methane)	0.0359

[1] The default high heat value for "propane" is only for the pure gas species. For the product commercially sold as propane, the value for liquefied petroleum gas in Table 20-1a should be used instead.

Table 20-1a—Fuels for which Calculation Methodologies 1 or 2 may be used at a facility emitting at any level.

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Petroleum Products	**GJ/kiloliter**	**kg CO_2 /GJ**
Distillate Fuel Oil No. 1	38.78	69.37
Distillate Fuel Oil No. 2	38.50	70.05
Distillate Fuel Oil No. 4	40.73	71.07
Kerosene	37.68	67.25
Liquefied petroleum gases (LPG)	25.66	59.65
Propane (pure, not mixtures of LPGs)[1]	25.31	59.66
Propylene	25.39	62.46
Ethane	17.22	56.68
Ethylene	27.90	63.86
Isobutane	27.06	61.48
Isobutylene	28.73	64.16
Butane	28.44	60.83
Butylene	28.73	64.15
Natural Gasoline	30.69	63.29
Motor Gasoline	34.87	65.40
Aviation Gasoline	33.52	69.87
Kerosene-Type Jet Fuel	37.66	68.40

[1] The default factors for "propane" are only for the pure gas species. For the product commercially sold as propane, the values for LPG should be used instead.

Table 20-2: Default Emission Factors by Fuel Type

Liquid Fuels	CO_2 Emission Factor (kg /L)	CO_2 Emission Factor (kg /GJ)	CH_4 Emission Factor (g/L)	CH_4 Emission Factor (g/GJ)	N_20 Emission Factor (g/L)	N_20 Emission Factor (g/GJ)
Aviation Gasoline	2.342	69.87	2.2	65.63	0.23	6.862
Diesel	2.663	69.53	0.133	3.473	0.4	10.44

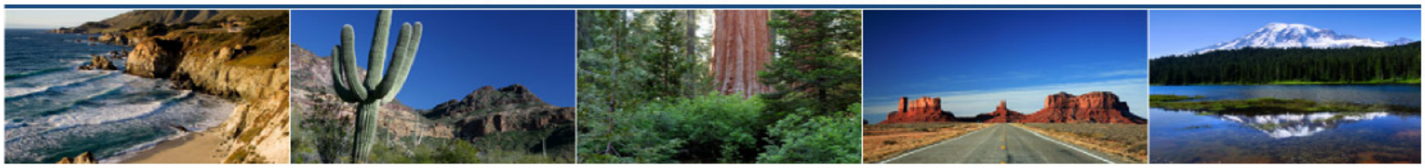
The WCI notes the significant difference in both the black liquor and solid biomass emission factors published by the EPA and Environment Canada (as well as those submitted by industry associations). In lieu of recommending a single emission factor at this time (as there is no certainty as to which is most accurate) the RC is presenting both for information purposes. The RC will be working with experts in the two federal agencies and other organizations to ascertain the most accurate emission factor to use for both Metric and English unit versions of the Essential Requirements of Mandatory Reporting.



§ WCI.30 REFINERY FUEL GAS COMBUSTION

§ WCI.31 Source Category Definition

This source category consists of any combustion device that is located at a petroleum refinery and that combusts refinery fuel gas, still gas, flexigas, or associated gas.

§ WCI.32 Greenhouse Gas Reporting Requirements

In addition to the information required by the regulation, the emissions data report shall include the following information at the facility level:

(a) Annual CO_2, CH_4, and N_2O emissions from refinery fuel gas combustion in metric tons.

(b) Annual fuel consumption in units of standard cubic meters.

(c) Average carbon content of each fuel used to compute CO_2 emissions.

§ WCI.33 Calculation of Greenhouse Gas Emissions

(a) Calculation of CO_2 Emissions. Owners and operators shall calculate daily CO_2 emissions for each fuel gas system using any of the methods specified in paragraphs (a)(1) through (a)(4) of this section. Calculate the total annual CO_2 emissions from combustion of all fuel gas by summing the CO_2 emissions from each fuel gas system.

(1) Use a CEMS that complies with the provisions in section WCI.23(d).

(2) Calculate CO_2 emissions from each refinery fuel gas system and flexigas system using measured carbon content and molecular weight of the gas and Equation 30-1.

$$CO_2 = \sum_{i=1}^{n} Fuel_i \times CC_i \times \frac{MW}{MVC} \times 3.664 \times 0.001$$ **Equation 30-1**

Where:

CO_2 = Carbon dioxide emissions, metric tons/year.
$Fuel_i$ = Daily refinery fuel or flexigas combusted (scm).
CC_i = Daily sample of carbon content of the fuel (kg C/kg fuel).
MW = Daily sample of molecular weight of fuel (kg/kg-mole).
MVC = Molar volume conversion factor (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 60°F and 1 atmosphere).
3.664 = Conversion factor for carbon to carbon dioxide.
0.001 = Conversion factor for kg to metric tons.
n = Number of days in a year.

(3) For associated gas, low heat content gas, or other fossil fuels; follow the requirements for general stationary source combustion sources in WCI .23(b) or (c), as appropriate for each fuel.

(4) Where individual fuels are mixed prior to combustion, the operator may choose to calculate CO_2 emissions for each fuel prior to mixing instead of using the methods in paragraphs (a)(1) or (a)(2) of this section. In this case, the operator must determine the fuel flow rate and appropriate fuel specific parameters (e.g. carbon content, HHV) of each fuel stream prior to mixing, calculate CO_2 emissions for each fuel stream, and sum the emissions of the individual fuel streams to determine total CO_2 emissions from the mixture. CO_2 emissions for each fuel stream must be estimated using the following methods:

(A) For natural gas and associated gas, use the appropriate methodology specified in section WCI.23(b) or (c).

(B) For refinery fuel gas, flexigas, and low heat content gas, use the methodology in paragraph (a)(2) of this section.

(b) Calculation of CH_4 and N_2O Emissions. Owners and operators shall use the methods specified in section WCI.24 to calculate the annual CH_4 and N_2O emissions.

§ WCI.34 Sampling, Analysis, and Measurement Requirements

(a) Measure the fuel consumption rate daily using methods specified in WCI.25(b).

(b) Daily sampling and analysis to determine the carbon content and molecular weight of the fuel is required if the necessary equipment is in place to make these measurements. Otherwise, weekly sampling and analysis of carbon content and molecular weight shall be performed. The equipment necessary to perform daily sampling and analysis of carbon content and molecular weight for refinery fuel gas must be installed no later than January 1, 2012.

(c)Measure the carbon content for fuel gas and flexigas using either ASTM D1945-03 (Reapproved 2006) or ASTM D1946-90 (Reapproved 2006). Where these methods do not adequately quantify all major hydrocarbons, then an owner or operator may request use of an alternative ASTM or other method to be approved by *the regulator*.

§ WCI.35 Procedures for estimating missing data.

Whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations by following the requirements of WCI.26.

§ WCI.40 ELECTRICITY GENERATION

§ WCI.41 Source Category Definition

An electricity generating unit is any combustion device that combusts solid, liquid, or gaseous fuel for the purpose of producing electricity either for sale or for use onsite. This source category includes cogeneration (combined heat and power) units. This source category does not include portable or emergency generators less than 10 MW in nameplate generating capacity as defined in section WCI.27.

§ WCI.42 Greenhouse Gas Reporting Requirements

For each electricity generating unit, the emissions data report shall include the following information:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

(1) Total CO_2 emissions for fossil fuels, reported by fuel type.

(2) Total CO_2 emissions for all biomass fuels combined.

(3) Total CH_4 emissions for all fuels combined.

(4) Total N_2O emissions for all fuels combined.

(b) Annual fuel consumption:

(1) For gases, report in units of standard cubic meters.

(2) For liquids, report in units of kiloliters.

(3) For non-biomass solids, report in units of metric tons.

(4) For biomass-derived solid fuels, report in units of bone dry metric tons.

(c) Annual weighted average carbon content of each fuel, if used to compute CO_2 emissions as specified in WCI.43.

(d) Annual weighted average high heating value of each fuel, if used to compute CO_2 emissions as specified WCI.43.

(e) The nameplate generating capacity in megawatts (MW) and net power generated in the reporting year in megawatt hours (MWh).

(f) For each cogeneration unit, indicate whether topping or bottoming cycle and provide useful thermal output as applicable, in MJ. Where steam or heat is acquired from another facility for the generation of electricity, report the provider and amount of acquired steam or heat in MJ. Where supplemental firing has been applied to support electricity generation or industrial output, report this purpose and fuel consumption by fuel type using the units in WCI.42(b).

(g) Process CO_2 emissions from acid gas scrubbers and acid gas reagent.

(h) Fugitive emissions of HFC from cooling units that support power generation.

(i) Fugitive CO_2 emissions from geothermal facilities.

(j) Fugitive CO_2 emissions from coal storage at coal-fired electricity generating facilities shall be reported as specified in section WCI.100.

§ WCI.43 Calculation of Greenhouse Gas Emissions

(a) Calculation of CO_2 Emissions. Operators shall use CEMS to measure CO_2 emissions if required to operate a CEMS by any other federal, provincial, or local regulation and that includes both a stack gas volumetric flow rate monitor and a CO_2 concentration monitor. Operators not required to operate a CEMS by another regulation may use either CEMS or the calculation methods specified in paragraphs (a)(1) through (a)(7). Operators using CEMS to determine CO_2 emissions shall comply with the provisions in section WCI.23(d).

(1) Natural Gas. For electric generating units combusting natural gas, use one of the following methods:

(A) If the high heat value is greater than or equal to 36.3 and less than or equal to 40.98 MJ/scm use either:

(i) The measured carbon content of the fuel and calculation methodology 3 in section WCI.23(c); or

(ii) The measured heat content of the fuel and the calculation methodology 2 in section WCI.23(b), provided the facility is not subject to verification requirements by regulation.

(B) If the high heat value is less than 36.3 or greater than 40.98 MJ/scm, use the measured carbon content of the fuel and the calculation methodology 3 in section WCI.23(c).

(2) Coal or Petroleum Coke. For electric generating units combusting coal or petroleum coke, use the measured carbon content of the fuel and calculation methodology 3 in section WCI.23(c).

(3) Middle Distillates, Gasoline, Residual Oil, or Liquid Petroleum Gases. For electric generating units combusting middle distillates (such as diesel, fuel oil, or kerosene), gasoline, residual oil, or LPG (such as ethane, propane, isobutene, n-butane, or unspecified LPG), use one of the following methods:

(A) The measured carbon content of the fuel and calculation methodology 3 in section WCI.23(c); or

(B) The measured heat content of the fuel and calculation methodology 2 in section WCI.23(b) provided the facility is not subject to verification requirements by regulation.

(4) Refinery Fuel Gas, Flexigas, or Associated Gas. For electric generating units combusting refinery fuel gas, flexigas, or associated gas, use the methods specified in section WCI.30.

(5) Landfill Gas, Biogas, or Biomass. For electric generating units combusting landfill gas, biogas, or biomass, use one of the following methods:

(A) The measured carbon content of the fuel and calculation methodology 3 provided in section WCI.23(c); or

(B) The measured heat content of the fuel and calculation methodology 2 in section WCI.23(b) provided the facility is not subject to verification requirements by regulation.

(6) Municipal Solid Waste. Electric generating units combusting municipal solid waste, may use the measured steam generated, the default emission factor in WCI.20 Table 20-7, and the calculation methodology in section WCI.23(b)(2) provided the facility is not subject to verification requirements by regulation. If the facility is subject to verification requirements by regulation, the operator shall use CEMS to measure CO_2 emissions in accordance with WCI.23(d), or calculate emissions using steam flow and a CO_2 emission factor according to the provisions of WCI.23(c)(2).

(7) Start-up Fuels. The operators of generating facilities that primarily combust biomass-derived fuels but combust fossil fuels during start-up, shut-down, or malfunction operating periods only, shall calculate CO_2 emissions from fossil fuel combustion using one of the following methods:

(A) The default emission factors from Tables 20-1a, 20-2, 20-3, 20-5 or 20-7, and default HHV from Tables 20-1 or 20-1a, as applicable, and calculation methodology 1 provided in section WCI.23(a);

(B) The measured heat content of the fuel and calculation methodology 2 provided in section WCI.23(b);

(C) The measured carbon content of the fuel and calculation methodology 3 provided in section WCI.23(c); or

(D) For combustion of refinery fuel gas, the measured heat content and carbon content of the fuel, and the calculation methodology provided in section WCI.30.

(8) Co-fired Electricity Generating Units. For electricity generating units that combust more than one type of fuel, the operator shall calculate CO_2 emissions as follows.

(A) For co-fired electricity generators that burn only fossil fuels, CO_2 emissions shall be determined using one of the following methods:

(i) A continuous emission monitoring system in accordance with calculation methodology 4 in section WCI.23(d). Operators using this method need not report emissions separately for each fossil fuel.

(ii) For units not equipped with a continuous emission system, calculate the CO_2 emissions separately for each fuel type using the methods specified in paragraphs (a)(1) through (a)(4) of this section.

(B) For co-fired electricity generators that burn biomass-derived fuel with a fossil fuel, CO_2 emissions shall be determined using one of the following methods:

(i) A continuous emission monitoring system in accordance with calculation methodology 4 in section WCI.23(d). Operators using this method shall determine the portion of the total CO_2 emissions attributable to the biomass-derived fuel and portion of the total CO_2 emissions attributable to the fossil fuel using the methods specified in section WCI.23(d)(4).

(ii) For units not equipped with a continuous emission system, calculate the CO_2 emissions separately for each fuel type using the methods specified in paragraphs (a)(1) through (a)(7) of this section.

(b) Calculation of CH_4 and N_2O Emissions. Operators of electricity generating units shall use the methods specified in section WCI.24 to calculate the annual CH_4 and N_2O emissions. For coal combustion, use the default CH_4 emission factor(s) in Table 20-6.

(c) Calculation of CO_2 Emissions from Acid Gas Scrubbing. Operators of electricity generating units that use acid gas scrubbers or add an acid gas reagent to the combustion unit shall calculate the annual CO_2 emissions from these processes using Equation 40-1 if these emissions are not already captured in CO_2 emissions determined using a continuous emissions monitoring system.

$$CO_2 = S \times R \times \left(CO_{2\,MW} / Sorbent_{MW} \right)$$ **Equation 40-1**

Where:

CO_2	=	CO_2 emitted from sorbent for the report year, metric tons;
S	=	Limestone or other sorbent used in the report year, metric tons;
R	=	Ratio of moles of CO_2 released upon capture of one mole of acid gas;
$CO_{2\ MW}$	=	Molecular weight of carbon dioxide (44);
$Sorbent_{MW}$	=	Molecular weight of sorbent (if calcium carbonate, 100).

(d) Calculating Fugitive HFC Emissions from Cooling Units. Operators of electricity generating facilities shall calculate fugitive HFC emissions for each HFC compound used in cooling units that support power generation or are used in heat transfers to cool stack gases using either the methodology in paragraph (d)(1) or (d)(2). The Operator is not required to report GHG emissions from air or water cooling systems or condensers that do not contain HFCs.

(1) Use Equation 40-2 to calculate annual HFC emissions:

$$HFC = HFC_{inventory} + HFC_{purchases/acquisitions} - HFC_{sales/disbursements} + HFC_{\Delta capacity}$$ **Equation 40-2**

Where:

HFC	=	Annual fugitive HFC emission, metric tons;
$HFC_{inventory}$	=	The difference between the quantity of HFC in storage at the beginning of the year and the quantity in storage at the end of the year. Stored HFC includes HFC contained in cylinders (such as 115-pound storage cylinders), gas carts, and other storage containers. It does not include HFC gas held in operating equipment. The change in inventory will be

negative if the quantity of HFC in storage increases over the course of the year.

$HFC_{purchases/acquisitions}$ = The sum of all HFC acquired from other entities during the year either in storage containers or in equipment.

$HFC_{sales/disbursements}$ = The sum of all the HFC sold or otherwise transferred offsite to other entities during the year either in storage containers or in equipment.

$HFC_{\Delta capacity}$ = The net change in the total nameplate capacity (i.e. the full and proper charge) of the cooling equipment. The net change in capacity will be negative if the total nameplate capacity at the end of the year is less than the total nameplate capacity at the beginning of the year.

(2) Use service logs to document HFC usage and emissions from each cooling unit. Service logs should document all maintenance and service performed on the unit during the report year, including the quantity of HFCs added to or removed from the unit, and include a record at the beginning and end of each report year. The operator may use service log information along with the following simplified material balance equations to quantify fugitive HFCs from unit installation, servicing, and retirement, as applicable. The operator shall include the sum of HFC emissions from the applicable equations in the greenhouse gas emissions data report.

$$HFC_{Install} = R_{new} - C_{new}$$

$$HFC_{Service} = R_{recharge} - R_{Recover}$$

$$HFC_{Retire} = C_{retire} - R_{retire}$$

Where:

$HFC_{Install}$ = HFC emitted during initial charging/installation of the unit, kilograms;

$HFC_{Service}$ = HFC emitted during use and servicing of the unit for the report year, kilograms;

HFC_{Retire} = HFC emitted during the removal from service/retirement of the unit, kilograms;

R_{new} = HFC used to fill new unit (omit if unit was pre-charged by the manufacturer), kilograms;

C_{new} = Nameplate capacity of new unit (omit if unit was pre-charged by the manufacturer), kilograms;

$R_{recharge}$ = HFC used to recharge the unit during maintenance and service, kilograms;

$R_{recover}$ = HFC recovered from the unit during maintenance and service, kilograms;

C_{retire} = Nameplate capacity of the retired unit, kilograms; and

R_{retire} = HFC recovered from the retired unit, kilograms.

(e) Fugitive CO_2 Emissions from Geothermal Facilities. Operators of geothermal electricity generating facilities shall calculate the fugitive CO_2 emissions using one of the following methods:

(1) Calculate the fugitive CO_2 emissions using Equation 40-3:

$$CO_2 = 7.14 \times Heat \times 0.001$$ **Equation 40-3**

Where:

CO_2 = CO_2 emissions, metric tons per year;
7.14 = Default fugitive CO_2 emission factor for geothermal facilities, kg per GJ; and
Heat = Heat taken from geothermal steam and/or fluid, GJ/yr.

(2) Calculate CO_2 emissions using source specific emission factor approved by the regulator for this rule..

§ WCI.44 Sampling, Analysis, and Measurement Requirements

(a) CO_2, CH_4 and N_2O Emissions from Fuel Combustion. Operators using CEMS to estimate CO_2 emissions from fuel combustion shall comply with the requirements in section WCI.23(d). Operators using methods other than CEMS shall comply with the applicable fuel sampling, fuel consumption monitoring, heat content monitoring, carbon content monitoring, and calculation methods specified in section WCI.25.

(b) CO_2 Emissions from Acid Gas Scrubbing. Operators of electricity generating units that use acid gas scrubbers or add an acid gas reagent to the combustion unit shall measure the amount of limestone or other sorbent used during the reporting year.

(c) CO_2 Emissions from Geothermal Facilities. Operators of geothermal facilities shall measure the heat recovered from geothermal steam. If using source specific emission factor instead of the default factor, the operator shall conduct an annual test of the CO_2 emission rate using a method approved by the regulator The operator shall submit a test plan to the regulator for approval. Once approved, the annual tests shall be conducted in accordance with the approved test plan under the supervision of the regulator

§ WCI.45 Procedures for estimating missing data.

Whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For all units using CEMS to measure CO_2 emissions, follow the missing data procedures in section WCI.26(a)

(b) For all other missing parameters used to calculate GHG emissions, follow the missing data procedures in section WCI.26(b).

§ WCI.46 Definitions

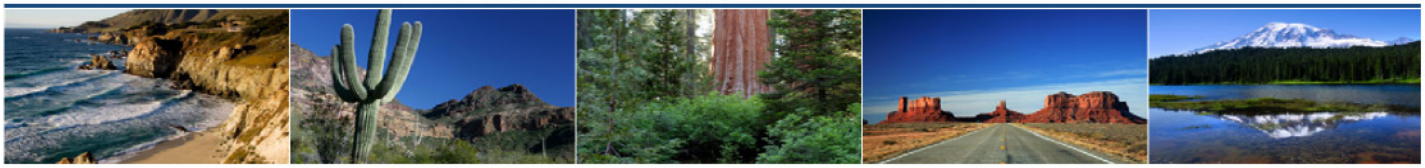
Except as specified in this section, all terms used in this subpart have the same meaning given in the General Provisions.

Bottoming cycle plant means a cogeneration plant in which the energy input to the system is first applied to a useful thermal energy application or process, and at least some of the reject heat emerging from the application or process is then used for electricity production.

Cogeneration unit means a stationary fuel combustion device which simultaneously generates electrical and thermal energy that is (i) used by the operator of the facility where the cogeneration unit is located; or (ii) transferred to another facility for use by that facility.

Cogeneration system means individual cogeneration components including the prime mover (heat engine), generator, heat recovery, and electrical interconnection, configured into an integrated system that provides sequential generation of multiple forms of useful energy (usually electrical and thermal), at least one form of which the facility consumes on-site or makes available to other users for an end-use other than electricity generation.

Topping cycle plant means a cogeneration plant in which the energy input to the plant is first used to produce electricity, and at least some of the reject heat from the electricity production process is then used to provide useful thermal output.



§ WCI.50 ADIPIC ACID MANUFACTURING

§ WCI.51 Source Category Definition

The adipic acid production source category consists of all adipic acid production facilities that use oxidation to produce adipic acid.

§ WCI.52 Greenhouse Gas Reporting Requirements

For the purpose of of the Regulation the annual emissions data report for adipic acid manufacturing shall include the following information at the facility level calculated in accordance this method:

(a) Annual process N_2O emissions from adipic acid production (tonnes).

(b) Annual adipic acid production (tonnes).

(c) Emissions of CO_2, CH_4, and N_2O from stationary combustion must report under WCI.20 (General Stationary Fuel Combustion Sources) following the requirements of WCI.20.

§ WCI.53 Calculation of N_2O Emissions

(a) You must determine annual N_2O emissions from adipic acid production according to paragraphs (a)(1) or (a)(2) of this section.

(1) Use a site-specific emission factor and production data according to paragraphs (b) through (g) of this section.

(2) Request approval by the Director for an alternative method of determining N_2O emissions.

(b) You must conduct an annual performance test or use continuous monitors according to paragraphs (b)(1) through (b)(3) of this section.

(1) You must conduct the test on the waste gas stream from the nitric acid oxidation step of the process using the methods specified in WCI.54 (b) through (d) or use a continuous monitoring system.

(2) You must conduct the performance test under normal process operating conditions and without using N_2O abatement technology or use a continuous monitoring system.

(3) You must measure the adipic acid production rate during the test and calculate the production rate for the test period or the continuous monitoring period in tonnes per hour.

(c) You must determine an N_2O emissions factor to use in Equation 50-2 of this section according to paragraphs (c)(1) or (c)(2) of this section.

(1) You may request Director approval for an alternative method of determining N_2O concentration according to the procedures in paragraphs (a)(2) of this section.

(2) Using the results of the test or continuous monitors in paragraph (b) of this section, you must calculate a facility-specific emissions factor according to Equation 50-1 for performance testing and 50-1a for continuous monitors of this section:

$$EF_{N2O} = \frac{\sum_{1}^{n} \frac{C_{N2O} * 1.826\times10^{-6} * Q}{P}}{n} \qquad \text{(Eq. 50-1)}$$

$$EF_{N2O} = \frac{C_{N2O} * 1.826\times10^{-6} * Q}{P} \qquad \text{(Equation 50-1a)}$$

Where:

EF_{N2O} = Average facility-specific N_2O emissions factor (kg N_2O generated/tonne adipic acid produced).

C_{N2O} = N_2O concentration per test run during the performance test o average hourly concentrations for continuous monitors (ppm N_2O).

$1.828x10^{-6}$ = Conversion factor (kg/dsm^3-ppm N_2O).

Q = Volumetric flow rate of effluent gas per test run during the performance test or hourly readings for continuous monitor (dsm^3/hr).

P = Production rate per test run during the performance test or the average hourly production rate for continuous monitors (tonnes adipic acid produced/hr).

n = Number of test runs.

(d) If applicable, you must determine the destruction efficiency for each N_2O abatement technology used at your facility according to paragraphs (d)(1), (d)(2), (d)(3) or (d)(4)of this section.

(1) Use the manufacturer's specified destruction efficiency.

(2) Estimate the destruction efficiency through process knowledge. Examples of information that could constitute process knowledge include calculations based on material balances, process stoichiometry, or previous test results provided the results are still relevant to the current vent stream conditions. You must document how process knowledge was used to determine the destruction efficiency.

(3) Calculate the destruction efficiency by conducting an additional performance test on the emissions stream following the N_2O abatement technology.

(4) Calculate the destruction efficiency by the use of continuous monitors on the controlled and uncontrolled emissions.

(e) If applicable, you must determine the abatement factor for each N_2O abatement technology used at your facility. The abatement factor is calculated for each adipic acid facility according to Equation 50-2 of this section.

$$AF = \frac{P_{a\ Abate}}{P_a} \qquad \text{(Eq. 50-2)}$$

Where:

AF	=	Abatement factor of N_2O abatement technology (fraction of annual production that abatement technology is operating).
Pa Abate	=	Annual adipic acid production during which N_2O abatement was used (tonne acid produced).
Pa	=	Total annual adipic acid production (tonne acid produced).

(f) You must determine the annual amount of adipic acid produced and the annual adipic acid production during which N_2O abatement is operating.

(g) You must calculate annual adipic acid production process emissions of N_2O by multiplying the emissions factor (determined using Equation 50-1 of this section) by the adipic acid production for each period and accounting for N_2O abatement, according to Equation 50-3 of this section:

$$N_2O = \sum_{i=1}^{N} \frac{EF_{N20i} * P_{ai} * (1-(DF_i * AF_i))}{1000} \qquad \text{(Eq. 50-3)}$$

Where:

N_2O	=	Annual N_2O mass emissions from adipic acid production (tonnes).
EF_{N2O}	=	Facility-specific N_2O emissions factor for the period (kg N_2O generated/tonne adipic acid produced).
P_a	=	Adipic acid produced in the period (tonnes).
DF_N	=	Destruction efficiency of N_2O abatement technology N (abatement device destruction efficiency, percent of N_2O removed from air stream).
AF_N	=	Abatement factor of N_2O abatement technology N (fraction of annual production abatement technology is operating).
1000	=	Conversion factor (kg/tonne).
N	=	Number of different periods in the year. For performance test, the period would be the time between each test (e.g., N is 1 year if performance test conducted annually). For continuous monitors, N would be the number of months in the year (or more) with P_{ai}, EF_{N2Oi}, DF_i and AF_i to be calculated for each month.

(a) You must conduct a new performance test and calculate a new facility-specific emissions factor according to the frequency specified in paragraphs (a)(1) of this section, or use continuous monitors to calculate a facility-specific emissions factor and destruction efficiency according to paragraphs (a)(2) of this section.

(1) Performance Test

(i) Conduct the performance test annually.

(ii) Conduct the performance test when your adipic acid production process is changed either by altering the ratio of cyclohexanone to cyclohexanol or by installing abatement equipment.

(2) Continuous Monitors

(i) Continuous monitors to determine the uncontrolled emissions and the controlled N_2O emissions to derive an N_2O emission factor and abatement system destruction factor.

(ii) The continuous monitors shall be operated in accordance with quality assurance and quality control program approved by the Director.

(b) You must measure the N_2O concentration during the performance test using one of the methods in paragraphs (b)(1) through (b)(3) of this section.

(1) EPA Method 320, Measurement of Vapor Phase Organic and Inorganic Emissions by Extractive Fourier Transform Infrared (FTIR) Spectroscopy in 40 CFR part 63 (U.S.), Appendix A;

(2) ASTM D6348-03 Standard Test Method for Determination of Gaseous Compounds by Extractive Direct Interface Fourier Transform Infrared (FTIR) Spectroscopy (incorporated by reference, see §98.7); or

(3) An equivalent method or continuous monitors, with Director approval.

(c) You must determine the production rate(s) during the performance test according to paragraph (c)(1) or (c)(2) of this section.

(1) Direct measurement (such as using flow meters or weigh scales).

(2) Existing plant procedures used for accounting purposes.

(d) You must conduct all required performance tests according to the methods in WCI.54(b). For each test, the facility must prepare an emissions factor determination report that must include the items in paragraphs (d)(1) through (d)(3) of this section:

(1) Analysis of samples, determination of emissions, and raw data.

(2) All information and data used to derive the emissions factor.

(3) The production rate(s) during the performance test and how each production rate was determined.

(e) You must determine the monthly adipic acid production quantity and the monthly adipic acid production during which N_2O abatement technology is operating according to the methods in paragraphs (c)(1) or (c)(2) of this section.

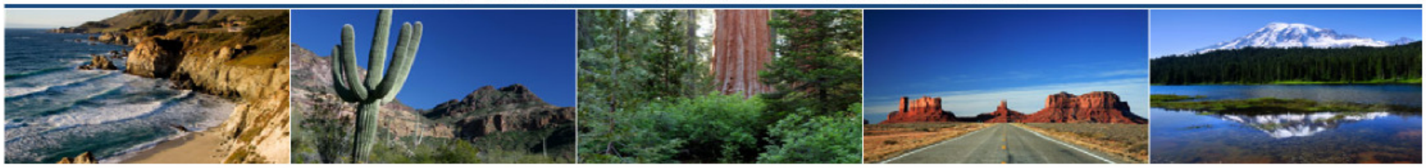
(f) You must determine the annual adipic acid production quantity and the annual adipic production quantity during which N_2O abatement technology is operating by summing the respective monthly adipic acid production quantities.

§ WCI.54 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section.

(a) For each missing value of monthly adipic acid production, the substitute data shall be the best available estimate based on all available process data or data used for accounting purposes (such as sales records).

(b) For missing values related to the performance test, including emission factors, production rate, and N_2O concentration, you must conduct a new performance test according to the procedures in §98.54 (a) through (d).



§ WCI.70 PRIMARY ALUMINUM PRODUCTION

§ WCI.71 Source Category Definition

A primary aluminum production process converts alumina mineral to aluminum metal using the Hall-Héroult manufacturing process, which includes electrolysis in prebake and Søderberg cells and anode baking for prebake cells. Experimental cells or research and development process units are not included.

§ WCI.72 Greenhouse Gas Reporting Requirements

For each facility that includes a primary aluminum production process, the emissions data report must contain the following information:

(a) CO_2 emissions from anode consumption from prebaked and Søderberg electrolysis cells.

(b) CO_2 emissions from anode and cathode baking.

(c) CF_4 and C_2F_6 emissions for anode effects.

(d) CO_2 emissions from green coke calcination.

(e) SF_6 emissions from cover gas consumption.

(f) CO_2, N_2O, and CH_4 emissions from stationary combustion units as specified in WCI.20.

(g) Annual aluminum production.

(h) Type of smelter technology used.

(i) CF_4 and C_2F_6 emissions from anode effects in all prebake and all Søderberg electrolysis cells combined.

(j) Anode effect minutes per cell-day (AE-mins/cell-day), anode effect frequency (AE/cell-day), and anode effect duration (minutes); alternatively, anode effect overvoltage factor (kg CF_4/metric ton Al) , potline overvoltage (mV/cell day), and current efficiency (%).

(k) Smelter-specific slope coefficients (or overvoltage emission factors) and the last date when the smelter-specific slope coefficients (or overvoltage emission factors) were measured.

(l) Method used to measure the frequency and duration of anode effects (or overvoltage).

(m) Annual anode consumption for prebake cells.

(n) Annual CO_2 emissions from the smelter for prebake cells.

(o) Annual paste consumption for Søderberg cells.

(p) Annual CO_2 emissions from the smelter for Søderberg cells.

(q) Smelter-specific inputs to the CO_2 process equations (e.g., levels of Sulphur and ash) that were used in the calculation, on an annual basis.

§ WCI.73 Calculation of GHG Emissions

(a) Calculate CO_2 emissions from anode consumption using either Equation 70-1 or 70-2, as applicable.

(1) For Prebaked Anodes:

$$E_{CO_2} = \sum_{i=1}^{12}[NCC \times MP \times \frac{(100 - S_a - Ash_a)}{100} \times 3.664]_i \qquad \textbf{Equation 70-1}$$

Where:

E_{CO2}	=	Annual CO_2 emissions (metric tons).
NCC	=	Net anode consumption per metric ton of aluminum for month i (metric ton/ metric ton aluminum).
MP	=	Aluminum production for month i (metric ton).
S_a	=	Sulphur content in baked anodes for month i (wt %).
Ash_a	=	Ash content in baked anodes for month i (wt %).
3.664	=	Conversion factor from carbon to CO_2.

(2) For Søderberg Anodes:

$$E_{CO_2} = \sum_{i=1}^{12} \begin{bmatrix} (PC \times MP) - \left(BSM \times \frac{MP}{1000}\right) - \left(\frac{BC}{100} \times PC \times MP \times \left(\frac{S_p + Ash_p + H_p}{100}\right)\right) \\ -\left(\frac{100 - BC}{100} \times PC \times MP \times \frac{S_c + Ash_c}{100}\right) - (CD \times MP) \end{bmatrix}_i \times 3.664 \qquad \textbf{Equation 70-2}$$

Where:

E_{CO2}	=	Annual CO_2 emissions (metric tons).
PC	=	Paste consumption for month i (metric tons paste/metric ton aluminum).
MP	=	Aluminum production for month i (metric tons).
BSM	=	Emissions of benzene-soluble matter (kilograms benzene-soluble matter/metric ton aluminum).
BC	=	Average binder (pitch) content in paste for month i (wt %).
S_p	=	Sulphur content in pitch for month i (wt %).
Ash_p	=	Ash content in pitch (wt %).
H_p	=	Hydrogen content in pitch (wt %).
S_c	=	Sulphur content in calcinated coke (wt %).
Ash_c	=	Ash content in calcinated coke (wt %).
CD	=	Carbon in skimmed dust from Søderberg cells (metric ton C/metric ton aluminum).
3.664	=	Conversion factor from carbon to CO_2.

(b) If anode or cathode baking is performed onsite, calculate CO_2 emissions as specified in paragraphs (b)(1) or (2) as applicable. Total emissions as specified in paragraph (b)(3) if both (b)(1) and (2) are applicable.

(1) Calculate CO_2 emissions from packing coke using Equation 70-3.

$$EC_{CO_2} = \sum_{i=1}^{12} \left(PCC \times BAP \times \frac{100 - Ash_{pc} - S_{pc}}{100} \right)_i \times 3.664$$ **Equation 70-3**

Where:

EC_{CO2} = Annual CO_2 emissions (metric tons pre year).
PCC = Packing coke consumption per metric ton of baked anode for month i (metric tons coke/metric ton anodes).
BAP = Baked anode production for month i (metric tons).
Ash_{pc} = Ash content in packing coke for month i (wt %).
S_{pc} = Sulphur content in packing coke for month i (wt %).
3.664 = Conversion factor from carbon to CO_2.

(2) Calculate CO_2 emissions from pitch coking using Equation 70-4.

$$EP_{CO_2} = \sum_{i=1}^{12} \left(GAW - BAP - \left(\frac{H_p}{100} \times \frac{PC}{100} \times GAW \right) - RT \right)_i \times 3.664$$ **Equation 70-4**

Where:

EP_{CO2} = CO_2 emissions (metric tons pre year).
GAW = Green anode consumption for month i (metric tons).
BAP = Baked anode production for month i (metric tons).
H_p = Hydrogen content in pitch for moth i (wt %).
PC = Pitch content in green anode for month i (wt %).
RT = Recovered tar for month i (metric tons).
3.664 = Conversion factor from carbon to CO_2.

(3) Calculate total CO_2 emissions for anode baking using Equation 70-5.

$$E_{anodebaking} = EC_{CO2} + EP_{CO2}$$ **Equation 70-5**

Where:

$E_{anodebaking}$ = Total annual CO_2 emissions from anode baking (metric tons).
EC_{CO2} = Annual CO_2 emissions from packing coke (metric tons).
EP_{CO2} = Annual CO_2 emissions from pitch coking (metric tons).

(c) Calculate CF_4 emissions using either paragraph (c)(1) or (c)(2) and calculate C_2F_6 emissions using paragraph (c)(3).

(1) Calculate CF_4 emissions from anode effect duration using Equation 70-6.

$$E_{CF_4} = \sum_{i=1}^{12} [S_{CF4} \times AEM \times MP]_i$$ **Equation 70-6**

Where:

E_{CF4} = Annual emissions of CF_4 (metric tons/yr).
S_{CF4} = Slope coefficient ([Metric tons of CF_4/metric ton aluminum]/[AE minutes/cell-days]).

AEM = Anode effect frequency (AE-minutes/cell-day), calculated monthly.
MP = Monthly aluminum production (metric tons).

(2) Calculate CF_4 emissions from overvoltage using Equation 70-7.

$$E_{CF_4} = \sum_{i=1}^{12} [EF_{CF_4} \times MP]_i \quad \textbf{Equation 70-7}$$

Where:
E_{CF4} = Annual emissions of CF_4 (metric tons/yr).
EF_{CF4} = Overvoltage emission factor (Metric tons of CF_4/metric ton aluminum).
MP = Monthly aluminum production (metric tons).

(3) Calculate C_2F_6 emissions from anode effects using Equation 70-8.

$$E_{C_2F_6} = \sum_{i=1}^{12} [E_{CF_4} \times F_{C_2F_6/CF_4}]_i \quad \textbf{Equation 70-8}$$

Where:
E_{C2F6} = Annual emissions of C_2F_6 (metric tons/yr).
E_{CF4} = Monthly emissions of CF_4 (metric tons/yr).
$F_{C2F6/CF4}$ = Weight fraction of C_2F_6/CF_4 (kg C_2F_6/kg CF_4).

(d) Calculate CO_2 emissions from onsite green coke calcination furnaces using Equation 70-9.

$$E_{CO_2} = \sum_{n=1}^{12} \left[\left[GC \times \frac{(100 - H_2O_{gc} - V_{gc} - S_{gc})}{100} - (CC + UCC + DE) \times \frac{(100 - S_{cc})}{100} \right] \times 3.664 \right]_i + \left[GC \times 0.035 \times \frac{44}{16} \right]_i \quad \textbf{Equation 70-9}$$

Where:
E_{CO2} = CO_2 emissions (metric tons pre year).
GC = Green coke feed for month i (metric tons).
H_2O_{gc} = Humidity in green coke feed for month i (wt %).
V_{gc} = Volatiles in green coke feed for month i (wt %).
S_{gc} = Sulphur content in green coke feed in month i (wt %).
S_{cc} = Sulphur content in calcinated coke in month i (wt %).
CC = Calcinated coke produced in month i (metric tons).
UCC = Under-calcinated coke produced in month i (metric tons).
DE = Coke dust emissions for month i (metric tons).
3.664 = Conversion factor from carbon to CO_2.
0.035 = Assumed CH_4 and tar content in coke volatiles, contributing to CO_2 emissions.
44/16 = Conversion factor from methane to CO_2.

(e) Calculate SF_6 emissions from cover gas consumption using one of the following methods:

(1) Calculate the annual SF_6 emissions using inventory records and Equation 70-10:

$$E_{SF6} = S_{Inv-Begin} - S_{Inv-End} + S_{Purchased} - S_{Shipped}$$ **Equation 70-10**

Where:

E_{SF6}	=	SF_6 emissions from cover gas (metric tons).
$S_{Purchased}$	=	Quantity of SF_6 purchased (metric tons).
$S_{Shipped}$	=	Quantity of SF_6 shipped offsite (metric tons).
$S_{Inv-Begin}$	=	Quantity of SF_6 in storage at the beginning of the year, (metric tons).
$S_{Inv-End}$	=	Quantity of SF_6 in storage at the end of the year (metric tons).

(2) Calculate the annual SF_6 emissions using Equation 70-11 and direct measurement of the SF_6 input to electrolysis cells and the SF_6 waste gases collected and transferred off-site:

$$E_{SF6} = \sum_{i=1}^{12} [(Q_{Input} \times C_{Input}) - (Q_{Output} \times C_{Output})]_i$$ **Equation 70-11**

Where:

E_{SF6}	=	SF_6 emissions from cover gas (metric tons).
$Q_{in;put}$	=	Quantity of SF_6 input to the electrolysis cell for month i (metric tons).
C_{Input}	=	Concentration of SF_6 input to the electrolysis cell for month i (metric tons).
Q_{Output}	=	Quantity of SF_6 gas collected during month i (if applicable) (metric tons).
C_{Output}	=	Concentration of SF_6 gas collected and sent off-site during month i (metric tons).

§ WCI.74 Monitoring Requirements

(a) Except as specified in paragraphs (b) through (c) of this section, all parameters must be measured monthly.

(b) Conduct performance tests once every 36 months to determine the slope or Pechiney coefficients for each pot line using the *Protocol for Measurement of Tetrafluoromethane and Hexafluoroethane Emissions from Primary Aluminum Production,* U.S. Environmental Protection Agency and International Aluminum Institute. April 2008. The test must be repeated whenever:

(1) Thirty-six months have passed since the last measurements;

(2) A change occurs in the control algorithm that affects the mix of types of anode effects or the nature of the anode effect termination routine; or

(3) Changes occur in the distribution or duration of anode effects (e.g. when the percentage of manual kills changes or if, over time, the number of anode effects decreases and results in a fewer number of longer anode effects) or, for Rio Tinto Alcan control technology, when the algorithm for bridge movements and anode effect overvoltage accounting changes.

(c) If using the direct measurement approach in WCI.73(e)(2) to calculate SF_6 emissions from cover gas consumption, the quantity of SF_6 gas input to the electrolysis cell month and the quantity and SF_6 concentration of any waste gas collected and sent off-site must be measured.

§ WCI.75 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For each missing value of the carbon content and molecular weight, the substitute data value shall be the arithmetic average of the quality assured values of the parameter immediately preceding and immediately following the missing data incident. If no quality assured data are available prior to the missing data incident, the substitute data value shall be the first quality assured data value obtained after the missing data period.

(b) For missing feedstock and production values, the substitute data value shall be the best available estimate of the parameter, based on all available process data. You must document and retain records of the procedures used for all such estimates.

§ WCI.80 AMMONIA MANUFACTURING

§ WCI.81 Source Category Definition

The ammonia manufacturing source category comprises the process units listed in paragraphs (a) and (b) of this section.

(a) Ammonia manufacturing processes in which ammonia is manufactured from a fossil-based feedstock produced via steam reforming of a hydrocarbon.

(b) Ammonia manufacturing processes in which ammonia is manufactured through the gasification of solid and liquid raw material.

§ WCI.82 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation the annual emissions data report for ammonia acid manufacturing shall include the following information at the facility level calculated in accordance this method:

(a) CO_2 process emissions from steam reforming of a hydrocarbon or the gasification of solid and liquid raw material following the requirements in this subpart.

(b) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit. You must report these emissions under WCI.20 (General Stationary Fuel Combustion Sources), by following the requirements of WCI.20.

(c) If a CEMS is used to measure CO_2 emissions, then you must report the relevant information required under WCI.23 for Method 4 Calculation and the following information in this paragraph (a):

Annual quantity of each type of feedstock consumed for ammonia manufacturing (sm^3 of feedstock or kilolitres of feedstock or tonnes of feedstock).

(d) If a CEMS is not used to measure emissions, then you must report the following information:

(1) Whether carbon content for each feedstock is based on reports from the supplier or analysis of carbon content.

(2) If a facility uses gaseous feedstock, the carbon content of the gaseous feedstock(kg C per kg of feedstock).

(3) If a facility uses liquid feedstock, the carbon content of the liquid feedstock, for month n, (kg C per kilolitre of feedstock).

(4) If a facility uses solid feedstock, the carbon content of the solid feedstock, for month n, (kg C per kg of feedstock).

(5) Annual CO_2 emissions associated with the waste recycle stream (tonnes)

(6) Carbon content of the waste recycle stream (kg C per kg of waste recycle stream).

(7) Volume of the waste recycle stream (sm^3)

(e) Annual urea production (tonnes)

§ WCI.83 Calculating GHG emissions

You must calculate and report the annual process CO_2 emissions from each ammonia manufacturing process unit using the procedures in either paragraph (a) or (b) of this section.

(a) Calculate and report under this subpart the process CO_2 emissions by operating and maintaining CEMS according to the Tier 4 Calculation Methodology specified in WCI.23 and all associated requirements for Tier 4 in WCI.20 (General Stationary Fuel Combustion Sources).

(b) Calculate and report under this subpart process CO_2 emissions using the procedures in paragraphs (b)(1) through (b)(6) of this section for gaseous feedstock, liquid feedstock, or solid feedstock, as applicable.

(1) Gaseous feedstock. You must calculate the CO_2 process emissions from gaseous feedstock according to Equation 80-1 of this section:

$$CO_{2,G,k} = \left(\sum_{n=1}^{12} 3.664 * Fdstk_{n,k} * CC_n * \frac{MW}{MVC}\right) * 0.001 \qquad \text{(Eq. 80-1)}$$

Where:

$CO_{2,G,k}$	=	Annual CO2 emissions arising from feedstock consumption (tonnes).
$Fdstk_{n,k}$	=	Volume of the gaseous' feedstock used in month n (sm3 of feedstock).
CC_n	=	Carbon content of the gaseous feedstock, for month n, (kg C per kg of feedstock), determined according to WCI.84(c).
MW	=	Molecular weight of the gaseous feedstock (kg/kg-mole).
MVC	=	Molar volume conversion factor (24.1 sm3 per kg-mole at standard conditions).
3.664	=	Ratio of molecular weights, CO2 to carbon.
0.001	=	Conversion factor from kg to tonnes.
k	=	Processing unit.
n	=	Number of month

(2) Liquid feedstock. You must calculate, from each ammonia manufacturing unit, the CO_2 process emissions from liquid feedstock according to Equation 80-2 of this section:

$$CO_{2,L,k} = \left(\sum_{n=1}^{12} 3.664 * Fdstk_{n,k} * CC_n\right) * 0.001 \qquad \text{(Eq. 80-2)}$$

Where:

$CO_{2,L,k}$	=	Annual CO2 emissions arising from feedstock consumption (tonnes).
$Fdstk_{n,k}$	=	Volume of the liquid feedstock used in month n (kilolitres of feedstock).

CC_n	=	Carbon content of the liquid feedstock, for month n, (kg of C/kilolitre of feedstock) determined according to WCI.84(c).
3.664	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to tonnes.
k	=	Processing unit.
n	=	Number of month

(3) Solid feedstock. You must calculate, from each ammonia manufacturing unit, the CO_2 process emissions from solid feedstock according to Equation 80-3 of this section:

$$CO_{2,S,k} = (\sum_{n=1}^{12} 3.664 * Fdstk_{n,k} * CC_n) * 0.001 \qquad \text{(Eq. 80-3)}$$

Where:

$CO_{2,S,k}$	=	Annual CO_2 emissions arising from feedstock consumption (tonnes).
$Fdstk_{n,k}$	=	Mass of the solid feedstock used in month n (kg of feedstock).
CC_n	=	Carbon content of the solid feedstock, for month n, (kg C per kg of feedstock), determined according to WCI.84(c).
3.664	=	Ratio of molecular weights, CO2 to carbon.
0.001	=	Conversion factor from kg to tonnes.
k	=	Processing unit.
n	=	Number of month.

(4) You must calculate the annual process CO_2 emissions from each ammonia processing unit k at your facility summing emissions, as applicable from Equation 80-1, 80-2, and 80-3 of this section using Equation 80-4.

$$E_{CO2_k} = CO_{2,G} + CO_{2,S} + CO_{2,L} \qquad \text{(Eq. 80-4)}$$

Where:

E_{CO2k}	=	Annual CO_2 emissions from each ammonia processing unit k (tonnes).
k	=	Processing unit.

(5) You must determine the combined CO2 emissions from all ammonia processing units at your facility using Equation 80-5 of this section.

$$CO_2 = \sum_{k=1}^{n} E_{CO2_k} \qquad \text{(Eq. 80-5)}$$

Where:

CO_2	=	Annual combined CO_2 emissions from all ammonia processing units (tonnes).
E_{CO2k}	=	Annual CO_2 emissions from each ammonia processing unit (tonnes).
k	=	Processing unit.

n = Total number of ammonia processing units.

(6) If applicable, ammonia manufacturing facilities that utilize the waste recycle stream as a fuel must calculate emissions associated with the waste stream for each ammonia process unit according to Equation 80-6 of this section:

$$CO_2 = \left(\sum_{n=1}^{12} 3.664 * RecycleStream_n * CC_n * \frac{MW}{MVC}\right) * 0.001 \qquad \text{(Eq. 80-6)}$$

Where:

CO2 = Annual CO_2 contained in waste recycle stream (tonnes).

$RecycleStream_n$ = Volume of the waste recycle stream in month n (sm3).

CC_n = Carbon content of the waste recycle stream, for month n, (kg C per kg of waste recycle stream) determined according to WCI.84(f).

MW = Molecular weight of the waste recycle stream (kg/kg-mole).

MVC = Molar volume conversion factor (24.1 sm3 per kg-mole at standard conditions).

3.664 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to tonnes.

n = Number of month

(c) If GHG emissions from an ammonia manufacturing unit are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with the Tier 4 Calculation Methodology in WCI.23 (General Stationary Fuel Combustion Sources), then the calculation methodology in paragraph (b) of this section shall not be used to calculate process emissions. The owner or operator shall report under this subpart the combined stack emissions according to the Tier 4 Calculation Methodology in WCI.23 and all associated requirements for Methods 4 in WCI.23.

§ WCI.84 Monitoring and QA/QC Requirements

(a) You must continuously measure the quantity of gaseous or liquid feedstock consumed using a flow meter. The quantity of solid feedstock consumed can be obtained from company records and aggregated on a monthly basis.

(b) You must document the procedures used to ensure the accuracy of the estimates of feedstock consumption.

(c) You must determine monthly carbon contents and the average molecular weight of each feedstock consumed from reports from your supplier. As an alternative to using supplier information on carbon contents, you can also collect a sample of each feedstock on a monthly basis and analyze the carbon content and molecular weight of the fuel using any of the following methods listed in paragraphs (c)(1) through (c)(8) of this section, as applicable.

(1) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see regulation).

(2) ASTM D1946-90 (Reapproved 2006) Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see regulation).

(3) ASTM D2502-04 (Reapproved 2002) Standard Test Method for Estimation of Mean Relative Molecular Mass of Petroleum Oils from Viscosity Measurements (incorporated by reference, see regulation).

(4) ASTM D2503-92 (Reapproved 2007) Standard Test Method for Relative Molecular Mass (Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure (incorporated by reference, see regulation).

(5) ASTM D3238-95 (Reapproved 2005) Standard Test Method for Calculation of Carbon Distribution and Structural Group Analysis of Petroleum Oils by the n-d-M Method (incorporated by reference, see regulation).

(6) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, regulation).

(7) ASTM D3176-89 (Reapproved 2002) Standard Practice for Ultimate Analysis of Coal and Coke (incorporated by reference, see regulation).

(8) ASTM D5373-08 Standard Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see regulation).

(d) Calibrate all oil and gas flow meters (except for gas billing meters) and perform oil tank measurements according to the monitoring and QA/QC requirements for Method 3 in WCI.25.

(e) For quality assurance and quality control of the supplier data, on an annual basis, you must measure the carbon contents of a representative sample of the feedstocks consumed using the appropriate ASTM Method as listed in paragraphs (c)(1) through (c)(8) of this section.

(f) Facilities must continuously measure the quantity of waste gas recycled using a flow meter, as applicable. You must determine the carbon content and the molecular weight of the waste recycle stream by collecting a sample of each waste recycle stream on a monthly basis and analyzing the carbon content using the appropriate ASTM Method as listed in paragraphs (c)(1) through (c)(8) of this section.

(g) If CO_2 from ammonia production is used to produce urea at the same facility, you must determine the quantity of urea produced using methods or plant instruments used for accounting purposes (such as sales records). You must document the procedures used to ensure the accuracy of the estimates of urea produced.

§ WCI.85 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever the monitoring and quality assurance procedures in WCI.84 cannot be followed (e.g., if a meter malfunctions during unit operation), a substitute data value for the missing parameter shall be used in the calculations following paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing data on monthly carbon contents of feedstock or the waste recycle stream, the substitute data value shall be the arithmetic average of the quality-assured values of that carbon content in the month preceding and the month immediately following the missing data incident. If no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon content obtained in the month after the missing data period.

(b) For missing feedstock supply rates or waste recycle stream used to determine monthly feedstock consumption or monthly waste recycle stream quantity, you must determine the best available estimate(s) of the parameter(s), based on all available process data.

§ WCI.90 CEMENT MANUFACTURING

§ WCI.91 Source Category Definition

Cement manufacturing is comprised of all processes that are used to manufacture Portland, natural, masonry, pozzolanic, or other hydraulic cements.

§ WCI.92 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2, CH_4, and N_2O in metric tons.

(b) Annual CO_2 process emissions from calcination (metric tons) and the following information:

(1) Monthly plant specific clinker emission factors (metric tons CO_2/metric tons clinker).

(A) Monthly quantities of clinker produced (metric tons).

(B) Monthly total calcium content of clinker, expressed as calcium oxide (CaO) (weight fraction, tonne CaO/tonne clinker).

(C) Monthly total magnesium content of clinker, expressed as magnesium oxide (MgO) (weight fraction, tonne CaO/tonne clinker).

(D) Monthly non-calcined calcium oxide content of clinker, expressed as CaO (weight fraction, tonne CaO/tonne clinker).

(E) Monthly non-calcined magnesium oxide content of clinker, expressed as MgO (weight fraction, tonne MgO/tonne clinker).

(F) Monthly quantity of non-carbonate raw materials entering the kiln (metric tons).

(2) Quarterly cement kiln dust (CKD) emission factor (metric ton CO_2/metric ton CKD not recycled back to the kiln).

(A) Quarterly quantity of CKD not recycled back to the kiln (metric tons).

(c) CO_2 process emissions from organic carbon oxidation (metric tons) and the following information:

(1) Amount of raw material consumed in the report year (metric tons).

(2) Organic carbon content of raw material (wt. fraction).

(d) CO_2, CH_4, and N_2O emissions from fuel combustion in all kilns combined, following the calculation methods and reporting requirements specified in WCI.93(c) (metric tons).

(e) CO_2, CH_4, and N_2O emissions from all other fuel combustion units combined (kilns excluded), following the calculation methods and reporting requirements specified in WCI.20 (metric tons).

(f) If a continuous emissions monitor is used to measure CO_2 emissions from kilns, then the requirements of paragraphs (b) and (c) of this section do not apply for CO_2. Cement plants that measure CO_2 emissions using CEMS shall report fuel usage by fuel type for kilns.

(g) Operators of cement plants shall also comply with the reporting requirements for any other applicable source category listed by regulation, including but not limited to the following:

(1) Coal fuel storage as specified in WCI.100.

(2) Electricity generating as specified in WCI.40.

(3) Cogeneration systems as specified in WCI.42(f).

(h) Number of times missing data procedures were used to determine clinker production, non-calcined calcium oxide, magnesium oxide content of clinker, CKD not recycled, non-calcined calcium oxide, magnesium oxide content of CKD, organic carbon content, and raw material consumption.

§ WCI.93 Calculation of Greenhouse Gas Emissions From Kilns

(a) Determine CO_2 emissions as specified under either paragraph (a)(1) or (a)(2) of this section.

(1) Calculate the total process and combustion CO_2 emissions from all the kilns using a continuous emissions monitoring system (CEMS) as specified in WCI.23(d) and combustion CO_2 emissions from all the kilns using the calculation methodologies specified in paragraph (c) of this section.

(2) Calculate the sum of CO_2 process emissions from kilns and CO_2 fuel combustion emissions from kilns using the calculation methodologies specified in paragraph (b) and (c) of this section.

(b) Process CO_2 Emissions Calculation Methodology. Calculate total CO_2 process emissions as the sum of emissions from calcination, using the method specified in paragraph (b)(1) of this section; and from organic carbon oxidation, using the method specified in paragraph (b)(2) of this section (Equation 90-1).

$$E_{CO2\text{-}P} = E_{CO2\text{-}C} + E_{CO2\text{-}F} \qquad \textbf{Equation 90-1}$$

Where:

$E_{CO2\text{-}P}$ = Annual process CO_2 emissions, tonne/year.
$E_{CO2\text{-}C}$ = Annual process CO_2 emissions from calcination, tonne/year.
$E_{CO2\text{-}F}$ = Annual process CO_2 emissions from feed oxidation, tonne/year.

(1) Calcination Emissions. Calculate CO_2 process emissions from calcination using Equation 90-2 and a plant-specific clinker emission factor and a plant-specific cement kiln dust (CKD) emission factor as specified in this section.

$$E_{CO2-C} = \sum_{m=1}^{12}\left[Q_{cli,m} \times EF_{cli,m}\right] + \sum_{q}^{4}\left[Q_{CKD,q} \times EF_{CKD,q}\right] \qquad \textbf{Equation 90-2}$$

Where:

E_{CO2-C} = Annual process CO_2 emissions from calcination, metric tons.
$Q_{Cli,m}$ = Quantity of clinker produced in month m, metric tons.
$EF_{Cli,m}$ = CO_2 emission factor for clinker produced in month m, computed as specified in paragraph (b)(1)(A) of this section, metric tons CO_2/metric ton clinker.
$Q_{CKD,q}$ = Quantity CKD not recycled to the kiln in quarter q, metric tons.
$EF_{CKD,q}$ = CO_2 emission factor for CKD not recycled to the kiln in quarter q, computed as specified in paragraph (b)(1)(B) of this section, metric ton CO_2/metric ton CKD.

(A) Clinker Emission Factor. Calculate a plant-specific clinker emission factor (EF_{Cli}) for each month based on monthly measurements of the weight fractions of calcium (as CaO) and magnesium (as MgO) content in the clinker and in the non-carbonate raw materials entering the kiln, using Equation 90-3

$$EF_{Cli} = (CaO_{Cli} - CaO_f) \times 0.785 + (MgO_{Cli} - MgO_f) \times 1.092$$ **Equation 90-3**

EF_{Cli} = Monthly CO_2 emission factor for clinker, tonne CO_2/tonne clinker
CaO_{Cli} = Monthly total calcium content of clinker expressed as calcium oxide, tonne CaO/tonne clinker..
CaO_f = Monthly non-calcined calcium oxide content of clinker, tonne CaO/tonne clinker.
MgO_{Cli} = Monthly total magnesium content of clinker expressed as magnesium oxide, tonne MgO/tonne clinker.
MgO_f = Monthly non-calcined magnesium oxide content of clinker, tonne MgO/tonne clinker.
0.785 = Ratio of molecular weights of CO_2 to CaO
1.092 = Ratio of molecular weights of CO_2 to MgO

(B) CKD Emission Factor. If CKD is generated and not recycled back to the kiln, then calculate a plant-specific CKD emission factor based on quarterly sampling. The CKD emission factor shall be calculated using Equation 90-4.

$$EF_{CKD} = (CaO_{CKD} - CaO_f) \times 0.785 + (MgO_{ckd} - MgO_f) \times 1.092$$

Equation 90-4

Where:

EF_{CKD} = Quarterly CO_2 emission factor for CKD not recycled to the kiln, metric ton CO_2/metric ton CKD.

CaO_{CKD} = Quarterly total calcium oxide content of CKD, tonne CaO/tonne CKD.

CaO_f = Quarterly non-calcined calcium oxide content of CKD, tonne CaO/tonne CKD.

MgO_{CKD} = Quarterly total magnesium oxide content of CKD, tonne MgO/tonne CKD.

MgO_f = Quarterly non-calcined magnesium oxide content of CKD, tonne MgO/tonne CKD.

0.785 = Ratio of molecular weights of CO_2 to CaO

1.092 = Ratio of molecular weights of CO_2 to MgO

(2) Organic Carbon Oxidation Emissions. Calculate CO_2 process emissions from the total organic content in raw materials by using Equation 90-5.

$$E_{CO_2-F} = TOC_{RM} \times RM \times 3.664 \qquad \textbf{Equation 90-5}$$

Where:

$E_{CO2-F\backslash}$ = Annual process CO_2 emissions from raw material oxidation, metric tons.
TOC_{RM} = Total organic carbon content in raw material (wt. fraction), measured using the method in WCI.94(b) or using a default of 0.002 (0.2%).
RM = Amount of raw material consumed (metric tons/yr).
3.664 = The CO_2 to carbon molar ratio.

(c) Fuel Combustion Emissions in Kilns. Calculate CO_2, CH_4, and N_2O emissions from stationary fuel combustion following the calculation methods specified in WCI.20. Cement plants that combust pure biomass-derived fuels and combust fossil fuels only during periods of start-up, shut-down, or malfunction may report CO_2 emissions from fossil fuels using the emission factor methodology in WCI.23(a). "Pure" means that the biomass-derived fuels account for 97 percent of the total amount of carbon in the fuels burned.

§ WCI.94 Sampling, Analysis, and Measurement Requirements

(a) Determine the plant-specific weight fractions of total calcium (as CaO) and total magnesium (as MgO) in clinker and in non-carbonate raw material entering the kiln using ASTM C114-09 Determine the weight fraction of carbonate CO_2 in the CKD and the weight fraction of carbonate CO_2 in the raw material using ASTM C114-07. The monitoring must be conducted monthly from clinker, non-carbonate raw material, and CKD samples drawn from bulk storage.

(b) If not using the default value of 0.002 for TOC_{RM} in Equation 90-5, the total organic carbon contents of raw materials must be determined annually using ASTM Method C114-09 a similar industry standard practice or approved method. The analysis must be conducted on sample material drawn from bulk raw material storage for each category of raw material.

(c) The quantity of clinker produced must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

(d) The quantity of CKD not recycled back to the kiln must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

(e) The quantity of raw materials consumed (i.e. limestone, sand, shale, iron oxide, alumina, and non-carbonate raw material) must be determined by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

§ WCI.95 Procedures for Estimating Missing Data

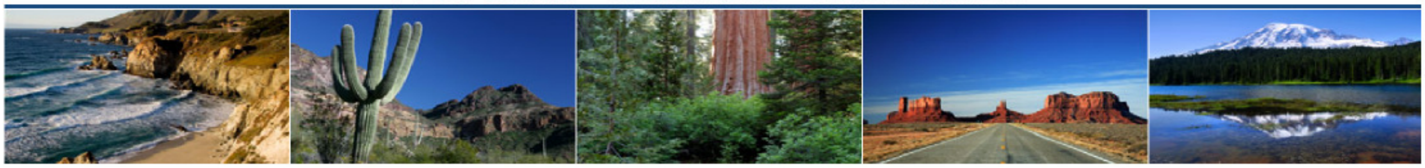
A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations. The owner or operator must document and keep records of the procedures used for all such estimates.

(a) If the CEMS approach is used to determine combined process and combustion CO_2 emissions, the missing data procedures in WCI.20 apply.

(b) For CO_2 process emissions from cement manufacturing facilities calculated according to WCI.93(b), if data on the carbonate content (of clinker or CKD), noncalcined content (of clinker or CKD) or the annual organic carbon content of raw materials are missing, facilities must undertake a new analysis.

(c) For each missing value of monthly clinker production, the substitute data value must be the best available estimate of the monthly clinker production based on information used for accounting purposes, or use the maximum tons per day capacity of the system and the number of days per month.

(d) For each missing value of monthly raw material consumption, the substitute data value must be the best available estimate of the monthly raw material consumption based on information used for accounting purposes (such as purchase records), or use the maximum tons per day raw material throughput of the kiln and the number of days per month.



§ WCI.100 COAL STORAGE

§ WCI.101 Source Category Definition

Coal storage piles are located at any facilities that combust coal. Coal storage piles release fugitive CH_4 emissions. Within natural coal deposits, CH_4 is either trapped under pressure within porous void spaces or adsorbed to the coal. Coal mining, post-mining activities, and coal-handling activities release pressurized CH_4 to the atmosphere; adsorbed CH_4 is also released until the CH_4 in the coal reaches equilibrium with the surrounding atmospheric conditions.

§ WCI.102 Greenhouse Gas Reporting Requirements

The emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

(1) Total CH_4 emissions.

(b) Annual coal purchases (tons for U.S.; metric tons for Canada).

(c) Source of coal purchases:

(1) Coal basin.

(2) State/province.

(3) Coal mine type (surface or underground).

§ WCI.103 Calculation of CH_4 Emissions

Note that this methodology for calculation of methane emissions uses emission factors for post-mining operations including all processes occurring after mining at the coal deposit and prior to combustion (e.g., preparation, handling, processing, transportation, storage, etc.) even though coal storage piles are only a subset of the overall post-mining operations. This follows the approach in the Climate Action Reserve (formerly the California Climate Action Registry) reporting protocol, attributing all post-mining fugitive methane emissions to the facility combusting the coal, which is ultimately responsible for the coal having been processed and delivered to the facility.

Calculate fugitive CH_4 emissions from coal storage piles as specified under paragraph (a), (b), or (c) of this section.

(a) For coal purchased from U.S. sources, calculate fugitive CH_4 emissions using Equation 100-1 (English) and Table 100-1, or Equation 100-1 (Metric) and Table 100-2.

(b) For coal purchased from Canadian sources, calculate fugitive CH_4 emissions using Equation 100-1 (Metric) and Table 100-3.

(c) For coal purchased from non-U.S. and non-Canadian sources, owners or operators should use either WCI.103(a) or WCI.103(b), whichever is the most applicable. This chosen approach is subject to approval by the regulator.

$$CH_4 = \sum_i (PC_i \times EF_i) \times 0.04228 \ / \ 2{,}204.6$$ **Equation 100-1 (English Units)**

Where:

CH_4	=	Fugitive emissions from coal storage piles for each coal category *i* (metric tons CH_4 per year);
PC_i	=	Purchased coal for each coal category *i* (tons per year);
EF_i	=	Default CH_4 emission factor for each coal category *i* specified by location and mine type that coal originated from, provided in Table 100-1 (scf CH_4 per ton of coal);
0.04228	=	Methane conversion factor to convert scf to lbs;
2,204.6	=	Factor to convert lbs to metric tons.

$$CH_4 = \sum_i (PC_i \times EF_i) \times 0.6772 \ / \ 1{,}000$$ **Equation 100-1 (Metric Units)**

Where:

CH_4	=	Fugitive emissions from coal storage piles for each coal category *i*, (metric tons CH_4 per year);
PC_i	=	Purchased coal for each coal category *i* (metric tons per year);
EF_i	=	Default CH_4 emission factor for each coal category *i* specified by location and mine type that coal originated from, provided in Table 100-2 or Table 100-3 (m^3 CH_4 per metric ton of coal);
0.6772	=	Methane conversion factor to convert m^3 to kg;
1,000	=	Factor to convert kg to metric tons.

§ WCI.104 Sampling, Analysis, and Measurement Requirements

(a) Coal Purchase Monitoring Requirements.

Facilities may determine the quantity of coal purchased either using records provided by the coal supplier(s) or monitoring coal purchase quantities using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

§ WCI.105 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraph (a) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing feedstock and production values, the substitute data value shall be the best available estimate of the parameter, based on all available process data. You must document and retain records of the procedures used for all such estimates.

Source: *Management of Methane Emissions from Coal Mines: Environmental, Engineering, Economic and Institutional Implications of Options*. Prepared by Brian G. King, Neill and Gunter (Nova Scotia) Limited, Darmouth, Nova Scotia for Environment Canada. Contract Number K2031-3-7062. March 1994. This document is cited by Environment Canada in the NIR 1990-2007 (Final Submission, April 2009), , but post-mining emission factors are not provided, so they were developed for WCI purposes by Province. Surface emission factors were derived from Table 3.1 (Coal production statistics [Column A] and post-mining emissions [Column F]). Underground emission factors were derived from Table 3.2 (Coal production statistics and post-mining emissions).

§ WCI.130 HYDROGEN PRODUCTION

§ WCI.131 Source Category Definition

A hydrogen production process produces hydrogen gas by steam hydrocarbon reforming, partial oxidation of hydrocarbons, or other transformation of hydrocarbon feedstock. The hydrogen produced may be either transferred offsite or used onsite at petrochemical, ammonia production, refineries, and other plants.

§ WCI.132 Greenhouse Gas Reporting Requirements

For each facility, the annual emissions report must contain the following information:

(a) Process CO_2 Emissions. The CO_2 process emissions from the hydrogen production process.

(b) Feedstock Consumption (if estimating emissions using mass balance approach in WCI.133(b)). Annual feedstock consumption by feedstock type (including petroleum coke) reported in units of million standard cubic feet for gases, gallons for liquids, short tons for non-biomass solids, and bone dry short tons for biomass-derived solid fuels.

(c) Production. Annual hydrogen produced (metric tons).

(d) Stationary Combustion Units. Report CO_2, N_2O, and CH_4 emissions as specified in WCI.20.

(e) Unconverted feedstock. Report the amount of carbon in unconverted feedstock for which GHG emissions are calculated and reported by your facility using other calculation methods provided in this regulation. For example, carbon in waste diverted to a fuel system or flare, where the CO_2 and CH_4 emissions are calculated and reported using other methods provided in this regulation. (metric tons CO_2e/year).

§ WCI.133 Calculation of Greenhouse Gas Emissions

The owner or operator shall calculate and report CO_2 process emissions using the methods in paragraphs (a) or (b) of this section.

(a) Continuous Emission Monitoring Systems. The owner or operator may calculate CO_2 process emissions using CEMS. The owner or operator must comply with the requirements in section WCI.20.

(b) Feedstock Material Balance. The owner or operator may calculate CO_2 process emissions using the following method.

(1) Gaseous fuel and feedstock. You must calculate the annual CO_2 process emissions from gaseous fuel and feedstock according to Equation 130-1 of this section:

$$CO_2 = (\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n * \frac{MW}{MVC}) * 0.001 \qquad \textbf{Equation 130-1}$$

Where:

CO_2	=	Annual CO_2 process emissions arising from fuel and feedstock consumption (metric tons/yr).
$Fdstk_n$	=	Volume of the gaseous fuel and feedstock used in month n (m^3 at standard conditions of 20°C and 1 atmosphere) of fuel and feedstock).
CC_n	=	Weighted average carbon content of the gaseous fuel and feedstock, from the results of one or more analyses for month n for natural gas or from daily analysis for gasseous feedstocks other than natural gas ((kg carbon per kg of fuel and feedstock).
MW	=	Molecular weight of the gaseous fuel and feedstock (kg/kg-mole).
MVC	=	Molar volume conversion factor (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere).
k	=	Months in the year.
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(2) Liquid fuel and feedstock. You must calculate the annual CO_2 process emissions from liquid fuel and feedstock according to Equation 130-2 of this section:

$$CO_2 = (\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n) * 0.001 \qquad \textbf{Equation 130-2}$$

Where:

CO_2	=	Annual CO_2 emissions arising from fuel and feedstock consumption (metric tons/yr).
$Fdstk_n$	=	Volume of the liquid fuel and feedstock used in month n (m^3 of fuel and feedstock).
CC_n	=	Weighted Average carbon content of the liquid fuel and feedstock, from the results of daily analyses for month n (kg carbon per m^3 of fuel and feedstock).
k	=	Months in the year.
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(3) Solid fuel and feedstock. You must calculate the annual CO_2 process emissions from solid fuel and feedstock according to Equation 130-3 of this section:

$$CO_2 = \sum_{n=1}^{k} \frac{44}{12} * (Fdstk_n * CC_n) * 0.001 \qquad \textbf{Equation 130-3}$$

Where:

CO_2	=	Annual CO_2 emissions from fuel and feedstock consumption in metric tons per year month ((metric tons/yr).
$Fdstk_n$	=	Mass of solid fuel and feedstock used in month n (kg of fuel and feedstock).
CC_n	=	Weighted average carbon content of the solid fuel and feedstock, from the results of daily analyses for month n (kg carbon per kg of fuel and feedstock).
k	=	Months in the year.
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(c) If GHG emissions from a hydrogen production process unit are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with WCI.20, then the calculation methodology in paragraph (b) of this section shall not be used to calculate process emissions. The owner or operator shall report the combined stack emissions according to the CEMS methodology in WCI.20.

§ WCI.134 Sampling, Analysis, and Measurement Requirements

(a) Owners or operators using CEMS to estimate CO_2 emissions shall comply with the monitoring requirements in section WCI.20.

(b) Owners or operators using the methods in section WCI.133 (b) or paragraph (c) of this section shall perform the following monitoring:

(1) The owner or operator shall measure the feedstock consumption rate daily Weighted average carbon contents shall be established from the results of daily sampling for month n. For fuels other than gaseous fuels, daily samples may be combined to generate a monthly composite sample for carbon analysis.

(2) The owner or operator shall collect samples of each feedstock consumed and analyze each sample for carbon content using the methods specified in WCI.25(c). For natural gas feedstock not mixed with another feedstock prior to consumption, samples shall be collected and analyzed once per month. For all other feedstocks, samples shall be collected and analyzed daily. The samples shall be collected from a location in the feedstock handling system that provides samples representative of the feedstock consumed in the hydrogen production process.

(3) Owners or operators shall measure the hydrogen produced daily.

(4) Owners or operators shall measure the CO_2 and CO collected daily.

(c) You must use the following methods, as applicable, to determine the carbon content of the feedstocks:

(1) ASTM D2013–07 Standard Practice of Preparing Coal Samples for Analysis.

(2) ASTM D2234/D2234M–07 Standard Practice for Collection of a Gross Sample of Coal.

(3) ASTM D2597–94 (Reapproved 2004) Standard Test Method for Analysis of Demethanized Hydrocarbon Liquid Mixtures Containing Nitrogen and Carbon Dioxide by Gas Chromatography.

(4) ASTM D3176–89 (Reapproved 2002), Standard Practice for Ultimate Analysis of Coal and Coke.

(5) ASTM D4057–06 Standard Practice for Manual Sampling of Petroleum and Petroleum Products.

(6) ASTM D4177–95 (Reapproved 2005) Standard Practice for Automatic Sampling of Petroleum and Petroleum Products.

(7) ASTM D6609–08 Standard Guide for Part-Stream Sampling of Coal.

(8) ASTM D6883–04 Standard Practice for Manual Sampling of Stationary Coal from Railroad Cars, Barges, Trucks, or Stockpiles.

(9) ASTM D7430–08ae1 Standard Practice for Mechanical Sampling of Coal.

(10) ASTM UOP539–97 Refinery Gas Analysis by Gas Chromatography.

(11) GPA 2261–00 Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography.

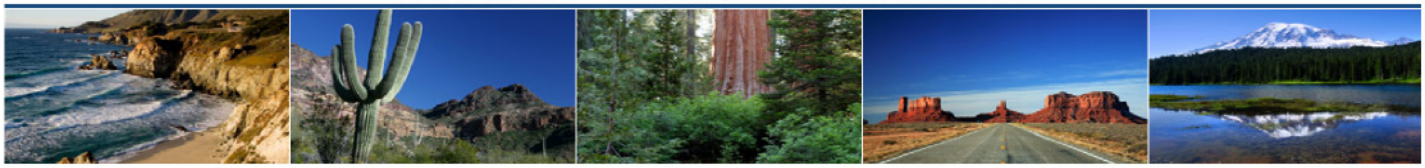
§ WCI.135 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation), a substitute data value for the missing parameter must be used in the calculations as specified in paragraphs (a), (b), and (c) of this section:

(a) For each missing value of the monthly fuel and feedstock consumption, the substitute data value must be the best available estimate of the fuel and feedstock consumption, based on all available process data (e.g., hydrogen production, electrical load, and operating hours). You must document and keep records of the procedures used for all such estimates.

(b) For each missing value of the carbon content or molecular weight of the fuel and feedstock, the substitute data value must be the arithmetic average of the quality-assured values of carbon contents or molecular weight of the fuel and feedstock immediately preceding and immediately following the missing data incident. If no quality-assured data on carbon contents or molecular weight of the fuel and feedstock are available prior to the missing data incident, the substitute data value must be the first quality-assured value for carbon contents or molecular weight of the fuel and feedstock obtained after the missing data period. You must document and keep records of the procedures used for all such estimates.

(c) For missing CEMS data, you must use the missing data procedures in WCI.20.



§ WCI.140 GLASS PRODUCTION

§ WCI.141 Source Category Definition

A glass manufacturing facility manufactures flat glass, container glass, pressed and blown glass, or wool fiberglass by melting a mixture of raw materials to produce molten glass and form the molten glass into sheets, containers, fibers, or other shapes. A glass manufacturing facility uses one or more glass melting furnaces to produce glass. A glass melting furnace that is an experimental furnace or a research and development process unit is not subject to this subpart.

§ WCI.142 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation the annual emissions data report shall include the following information:

(a) Total CO_2 process emissions from all glass melting furnaces.

(b) Total CO_2, CH_4 and N_2O combustion emissions from all glass melting furnaces. You must calculate and report these emissions under WCI.20 (General Stationary Fuel Combustion Sources) by following the requirements of WCI.20.

(c) Total CO_2, CH_4, and N_2O emissions from all stationary fuel combustion units other than glass melting furnaces. You must report these emissions under WCI.23 (General Stationary Fuel Combustion Sources) by following the requirements of WCI.20.

(d) If a CEMS is used to measure CO_2 emissions, then you must report under this method the relevant information required under WCI.23(d) for the Calculation Methodology 4 and the following information:

Annual quantity of glass produced (tonnes).

(e) If a CEMS is not used to determine CO_2 emissions from glass melting furnaces, and process CO_2 emissions are calculated according to the procedures specified in WCI.143(b), then you must report the following information:

(1) Annual quantity of each carbonate-based raw material charged (tonnes)for all furnaces combined.

(2) Annual quantity of glass produced (tonnes) from all furnaces combined.

(3) Total number of glass melting furnaces.

(f) The number of times in the reporting year that missing data procedures were followed to measure monthly quantities of carbonate-based raw materials or mass fraction of the carbonate-based minerals for each glass melting furnace

§ WCI.143 Calculation of GHG Emissions

You must calculate the annual process CO_2 emissions from each glass melting furnace using the procedure in paragraphs (a) and (b) of this section.

(a) For each glass melting furnace that meets the conditions specified in WCI.23(e)(4), you must calculate under this source the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the method 4 calculation methodology specified in WCI.23(d) and all associated requirements in WCI.20 (General Stationary Fuel Combustion Sources).

(b) For each glass melting furnace that is not subject to the requirements in paragraph (a) of this section, use either the procedure in paragraph (b)(1) of this section or the procedure in paragraphs (b)(2) through (b)(7) of this section, except as specified in paragraph (c) of this section.

(1) Calculate the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Calculation Methodology 4 specified in WCI.23(d) (General Stationary Fuel Combustion Sources).

(2) Calculate the process and combustion CO_2 emissions separately using the procedures specified in paragraphs (b)(2)(i) through (b)(2)(vi) of this section.

(i) For each carbonate-based raw material charged to the furnace, obtain from the supplier of the raw material the carbonate-based mineral mass fraction.

(ii) Determine the quantity of each carbonate-based raw material charged to the furnace.

(iii) Apply the appropriate emission factor for each carbonate-based raw material charged to the furnace, as shown in Table 140-1 to this subpart.

(iv) Use Equation 140-1 of this section to calculate process mass emissions of CO2 for each furnace:

$$E_{CO2} = \sum_{i=1}^{n} \left(M_i \times MF_i \times EF_i \times F_i \right) \qquad \text{(Eq. 140-1)}$$

Where:

ECO_2	=	Process emissions of CO_2 from the furnace (tonnes).
n	=	Number of carbonate-based raw materials charged to furnace.
MF_i	=	Annual average mass fraction of carbonate-based mineral i in carbonate-based raw material i (weight fraction).
M_i	=	Annual amount of carbonate-based raw material i charged to furnace (tonnes).
EF_i	=	Emission factor for carbonate-based mineral i (tonnes CO_2 per tonne carbonate-based mineral as shown in Table 140-1.
Fi	=	Fraction of calcination achieved for carbonate-based mineral i, 1.0 for completed calcination (weight fraction).

(v) You must calculate and report the total process CO2 emissions from glass melting furnaces at the facility using Equation 140-2 of this section:

$$CO_2 = \sum_{i=1}^{k} E_{CO_2 i} \qquad \text{(Eq. 140-2)}$$

Where:

CO_2 = Annual process CO_2 emissions from glass manufacturing facility (tonnes).

E_{CO2i} = Annual CO_2 emissions from glass melting furnace i (tonnes).

k = Number of glass melting furnaces.

(vi) Calculate and report under WCI.20 (General Stationary Fuel Combustion Sources) the combustion CO_2 emissions in the glass furnace according to the applicable requirements in WCI.20.

§ WCI.144 Sampling, Analysis, and Measurement Requirements

(a) You must measure annual amounts of carbonate-based raw materials charged to each glass melting furnace from monthly measurements using plant instruments used for accounting purposes, such as calibrated scales or weigh hoppers. Total annual mass charged to glass melting furnaces at the facility shall be compared to records of raw material purchases for the year.

(b) You must measure carbonate-based mineral mass fractions at least annually to verify the mass fraction data provided by the supplier of the raw material; such measurements shall be based on sampling and chemical analysis conducted by a certified laboratory using ASTM D3682-01 (Reapproved 2006) Standard Test Method for Major and Minor Elements in Combustion Residues from Coal Utilization Processes (incorporated by reference, see regulation).

(c) You must determine the annual average mass fraction for the carbonate-based mineral in each carbonate-based raw material by calculating an arithmetic average of the monthly data obtained from raw material suppliers or sampling and chemical analysis.

(d) As an alternative to data provided by the raw material supplier, a value of 1.0 can be used for the monthly mass fraction (MF_i) of carbonate-based mineral i in Equation 140-1 of this section.

(e) You must determine on an annual basis the calcination fraction for each carbonate consumed based on sampling and chemical analysis using an industry consensus standard. This chemical analysis must be conducted using an x-ray fluorescence test or other enhanced testing method published by an industry consensus standards organization (e.g., ASTM, ASME, API, etc.).

§ WCI.145 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., carbonate raw materials consumed, etc.). If the monitoring and quality assurance procedures in WCI.144 cannot be followed and data is missing, you must use the most appropriate of the missing data procedures in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such missing value estimates.

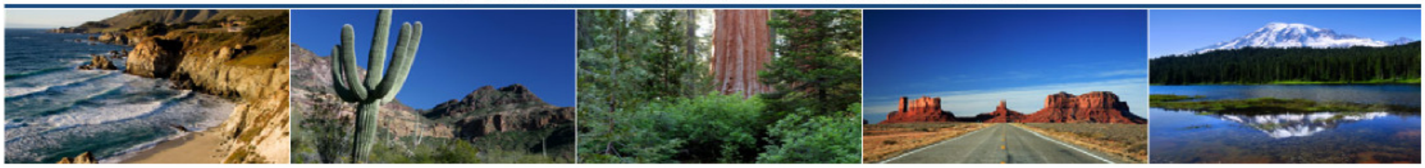
(a) For missing data on the monthly amounts of carbonate-based raw materials charged to any glass melting furnace use the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes, such as purchase records.

(b) For missing data on the mass fractions of carbonate-based minerals in the carbonate-based raw materials assume that the mass fraction of each carbonate based mineral is 1.0.

Table 140-1 —CO_2 Emission Factors for Carbonate-Based Minerals

Carbonate-Based Raw Material – Mineral	CO2 Emission Factor[a]
Limestone – CaCO3	0.43971
Dolomite – CaMg(CO3)2	0.47732
Sodium carbonate/soda ash – Na2CO3	0.41492

[a] Emission factors in units of tonnes of CO2 emitted per tonne of carbonate-based mineral charged to the furnace.



§ WCI.150 IRON AND STEEL MANUFACTURING

§ WCI.151 Source Category Definition

Iron and steel manufacturing comprises five categories: taconite iron ore processing, primary facilities that produce both iron and steel, secondary steelmaking facilities, iron production facilities, and offsite production of metallurgical coke. These processes may occur together in an "integrated" facility or they may occur in separate offsite facilities.

§ WCI.152 Greenhouse Gas Reporting Requirements

In addition to the information required by WCI.3, the annual emissions data report shall contain the following information:

(a) Annual process CO_2 emissions (metric tons) for the following processes:

- (1) Taconite indurating furnace
- (2) Basic oxygen furnace (BOF)
- (3) Coke making operation
- (4) Sinter process
- (5) Electric arc furnace (EAF)
- (6) Argon-oxygen decarburization vessel
- (7) Direct reduction furnace
- (8) Blast furnace

(b) Annual production/usage quantities (metric tons) for the following processes:

- (1) Taconite indurating furnace – fired pellets produced on-site
- (2) BOF – steel produced on-site
- (3) Coke making operation – coke produced and coal charged
- (4) Sinter process – sinter produced
- (5) EAF – steel produced on-site
- (6) Argon-oxygen decarburization vessel – molten steel charged
- (7) Direct reduction furnace – iron produced
- (8) Blast furnace – iron produced

(c) CO_2, N_2O, and CH_4 emissions, not accounted for elsewhere in §WCI.150, from stationary combustion units as specified in §WCI.20. Report these emissions from stationary combustion for each of the following devices:

(1) Taconite indurating furnace

(2) BOF

(3) Coke making operation (coke oven batteries)

(4) Sinter process (sintering furnace)

(5) EAF

(6) Argon-oxygen decarburization vessel

(7) Direct reduction furnace

(8) Blast furnace

(9) Any other stoves, boiler, process heaters, reheat furnaces and other combustion sources.

§ WCI.153 Calculation of CO_2 Emissions

(a) Process CO_2 emissions. Determine process CO_2 emissions as specified under either paragraph (1) or (2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Calculation methodologies specified in paragraph (b) of this section.

[CEMS and mass balance approach are based on IPCC Tier 3 methods.)

(b) Process CO_2 Emissions Calculation Methodology. Calculate CO_2 process emissions for each taconite indurating furnace, basic oxygen furnace, non-recovery coke oven battery, sinter process, EAF, argon-oxygen decarburization vessel, blast furnace, and direct reduction furnace using the following mass balance approaches specified in paragraphs (b)(1) through (b)(8). Specific process inputs or outputs that contribute less than 1 percent of the total mass of carbon into or out of the process do not have to be included in the paragraphs (b)(1) through (b)(8) mass balances.

(1) Calculate taconite indurating furnace CO_2 emissions using Equation 150-1:

$$E_T = [(T \times C_T) - (P \times C_P) - (R \times C_R)] \times 3.664$$ **Equation 150-1**

Where:

E_T	=	Annual CO_2 emissions from taconite indurating furnace (metric tons);
T	=	Annual mass of greenball (taconite) pellets fed to furnace (metric tons);
C_T	=	Carbon content of greenball (taconite) pellets (metric tons C/metric tons taconite pellets);
P	=	Annual mass of fired pellets producted by the furnace (metric tons);
C_P	=	Carbon content of fired pellets (metric tons C/metric tons fired pellets);

R	=	Annual mass of air pollution control residue collected (metric tons);
C_R	=	Carbon content of air pollution control residue (metric tons C/metric tons residue);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

(2) Calculate basic oxygen process furnace CO_2 emissions using Equation 150-2:

$$E_{BOF} = [(I \times C_I) + (SC \times C_{SC}) + (FL \times C_{FL}) + (CAR \times C_{CAR}) - (ST \times C_{ST}) - (SL \times C_{SL}) - (R \times C_R)] \times 3.664$$

Equation 150-2

Where:

E_{BOF}	=	Annual CO_2 emissions from basic oxygen furnaces (metric tons);
I	=	Annual mass of molten iron charged to furnace (metric tons);
C_I	=	Carbon content of molten iron (metric tons C/metric tons molten iron);
SC	=	Annual mass of ferrous scrap charged to furnace (metric tons);
C_{SC}	=	Carbon content of ferrous scrap (metric tons C/metric tons ferrous scrap);
FL	=	Annual mass for flux materials (e.g., limestone, dolomite, etc.) charged to furnace (metric tons);
C_{FL}	=	Carbon content of flux materials (metric tons C/metric tons flux material);
CAR	=	Annual mass of carbonaceous material (e.g., coal, coke, etc.) charged to furnace (metric tons);
C_{CAR}	=	Carbon content of carbonaceous material (metric tons C/metric tons carbonaceous material);
ST	=	Annual mass of molten raw steel produced by furnace (metric tons);
C_{ST}	=	Carbon content of steel (metric tons C/metric tons steel);
SL	=	Annual mass of slag produced by furnace (metric tons);
C_{SL}	=	Carbon content of slag (metric tons C/metric tons slag);
R	=	Annual mass of air pollution control residue collected (metric tons);
C_R	=	Carbon content of air pollution control residue (metric tons C/metric tons residue);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

(3) Calculate coke oven battery CO_2 emissions using Equation 150-3:

$$E_{coke} = [(CC \times C_{CC}) - (CO \times C_{CO}) - (BY \times C_{BY}) - (R \times C_R) - (COG \times C_{COG})] \times 3.664$$

Equation 150-3

Where:

E_{coke}	=	Annual CO_2 emissions from coke production (metric tons);
CC	=	Annual mass of coking coal charged to battery (metric tons);

C_{CC}	=	Carbon content of coking coal (metric tons C/metric tons coking coal);
CO	=	Annual mass of coke produced (metric tons);
C_{CO}	=	Carbon content of coke (metric tons C/metric tons coke);
BY	=	Annual mass of by-product from by-product coke oven battery (metric tons);
C_{BY}	=	Carbon content of by-product (metric tons C/metric tons by-product);
R	=	Quantity of air pollution control residue collected (metric tons);
C_R	=	Carbon content of air pollution control residue (metric tons C/metric tons residue);
COG	=	Annual mass of coke oven gas transferred off site (metric tons);
C_{COG}	=	Carbon content of coke oven gas transferred off site (metric tons C/metric tons coke oven gas);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

(4) Calculate sinter process CO_2 emissions using Equation 150-4:

$$E_{sinter} = [(CAR \times C_{CAR}) + (FE \times C_{FE}) - (S \times C_S) - (R \times C_R)] \times 3.664$$

Equation 150-4

Where:

E_{sinter}	=	Annual CO_2 emissions from sinter process (metric tons);
CAR	=	Annual mass of carbonaceous material (e.g., coal, coke, etc.) charged to furnace (metric tons);
C_{CAR}	=	Carbon content of carbonaceous material (metric tons C/metric tons carbonaceous material);
FE	=	Annual mass of sinter feed material (metric tons);
C_{FE}	=	Carbon content of sinter feed material (metric tons C/metric tons sinter feed material);
S	=	Annual mass of sinter produced (metric tons);
C_S	=	Carbon content of sinter produced (metric tons C/metric tons sinter);
R	=	Quantity of air pollution control residue collected (metric tons);
C_R	=	Carbon content of air pollution control residue (metric tons C/metric tons residue);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

(5) Calculate electric arc furnace (EAF) CO_2 emissions using Equation 150-5:

$$E_{EAF} = [(I \times C_I) + (SC \times C_{SC}) + (FL \times C_{FL}) + (EL \times C_{EL}) + (CAR \times C_{CAR}) - (ST \times C_{ST}) - (SL \times C_{SL}) - (R \times C_R)] \times 3.664$$

Equation 150-5

Where:

E_{EAF}	=	Annual CO_2 emissions from EAF (metric tons);
I	=	Annual mass of direct reduced iron (if any) charged to furnace (metric tons);

C_I	=	Carbon content of direct reduced iron (metric tons C/metric tons direct reduced iron);
SC	=	Annual mass of ferrous scrap charged to furnace (metric tons);
C_{SC}	=	Carbon content of ferrous scrap (metric tons C/metric tons ferrous scrap);
FL	=	Annual mass for flux materials (e.g., limestone, dolomite, etc.) charged to furnace (metric tons);
C_{FL}	=	Carbon content of flux materials (metric tons C/metric tons flux material);
EL	=	Annual mass for carbon electrodes consumed (metric tons);
C_{EL}	=	Carbon content of carbon electrodes (metric tons C/metric tons carbon electrode);
CAR	=	Annual mass of carbonaceous material (e.g., coal, coke, etc.) charged to furnace (metric tons);
C_{CAR}	=	Carbon content of carbonaceous material (metric tons C/metric tons carbonaceous material);
ST	=	Annual mass of molten raw steel produced by furnace (metric tons);
C_{ST}	=	Carbon content of steel (metric tons C/metric tons steel);
SL	=	Annual mass of slag produced by furnace (metric tons);
C_{SL}	=	Carbon content of slag (metric tons C/metric tons slag);
R	=	Annual mass of air pollution control residue collected (metric tons);
C_R	=	Carbon content of air pollution control residue (metric tons C/metric tons residue);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

(6) Calculate argon-oxygen decarburization vessel CO_2 emissions using Equation 150-6:

$$E_{AOD} = \left[Steel \times \left(C_{in} - C_{out}\right) - \left(R \times C_R\right)\right] \times 3.664$$ **Equation 150-6**

Where:

E_{AOD}	=	Annual CO_2 emissions from argon-oxygen decarburization vessels (metric tons);
Steel	=	Annual mass of molten steel charged to vessel (metric tons);
C_{in}	=	Carbon content of molten steel before decarburization (metric tons C/metric tons molten steel);
C_{out}	=	Carbon content of molten steel after decarburization (metric tons C/metric tons molten steel);
R	=	Annual mass of air pollution control residue collected (metric tons);
C_R	=	Carbon content of air pollution control residue (metric tons C/metric tons residue);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

(7) Calculate direct reduction furnace CO_2 emissions using Equation 150-7:

$$E_{DR} = \left[\left(Ore \times C_{Ore}\right) + \sum\left(CAR \times C_{CAR}\right) + \sum\left(OT \times C_{OT}\right) - \left(I \times C_I\right) - \left(NM \times C_{NM}\right) - \left(R \times C_R\right)\right] \times 3.664$$

Equation 150-7

Where:

E_{DR} = Annual CO_2 emissions from direct reduction furnace (metric tons);
Ore = Annual mass of iron ore or iron ore pellets fed to the furnace (metric tons);
C_{Ore} = Carbon content of iron ore or iron ore pellets (metric tons C/metric tons iron ore or iron ore pellets);
CAR = Annual mass of non-fuel carbonaceous materials (e.g., coal, coke, by-products, etc.) charged to furnace (metric tons);
C_{CAR} = Carbon content of non-fuel carbonaceous materials (metric tons C/metric tons non-fuel carbonaceous material);
OT = Annual mass of other materials charged to furnace (metric tons);
C_{OT} = Carbon content of other materials (metric tons C/metric tons other materials);
I = Annual mass of iron produced (metric tons);
C_I = Carbon content of iron (metric tons C/metric tons iron);
NM = Annual mass for non-metallic materials produced (metric tons);
C_{NM} = Carbon content of non-metallic materials (metric tons C/metric tons non-metallic minerals);
R = Annual mass of air pollution control residue collected (metric tons);
C_R = Carbon content of air pollution control residue (metric tons C/metric tons residue);
3.664 = Conversion factor from metric tons of C to metric tons of CO_2.

(8) Calculate blast furnace CO_2 emissions using Equation 150-8:

$$E_{BF} = \left[(Ore \times C_{Ore}) + \sum (CAR \times C_{CAR}) + \sum (F \times C_F) + \sum (OT \times C_{OT}) - (I \times C_I) - (NM \times C_{NM}) - (BG \times C_{BG}) - (R \times C_R) \right] \times 3.664$$

Equation 150-8

Where:

E_{BF} = Annual CO_2 emissions from blast furnace (metric tons);
Ore = Annual mass of iron ore or iron ore pellets fed to the furnace (metric tons);
C_{Ore} = Carbon content of iron ore or iron ore pellets (metric tons C/metric tons iron ore or iron ore pellets);
CAR = Annual mass of non-fuel carbonaceous materials (e.g., coal, coke, by-products, etc.) charged to furnace (metric tons);
C_{CAR} = Carbon content of non-fuel carbonaceous materials (metric tons C/metric tons non-fuel carbonaceous material);
F = Annual mass for flux materials (e.g., limestone, dolomite, etc.) charged to furnace (metric tons);
C_F = Carbon content of flux materials (metric tons C/metric tons flux material);
OT = Annual mass of other materials charged to furnace (metric tons);
C_{OT} = Carbon content of other materials (metric tons C/metric tons other materials);
I = Annual mass of iron produced (metric tons);
C_I = Carbon content of iron (metric tons C/metric tons iron);
NM = Annual mass for non-metallic materials produced (metric tons);

C_{NM} = Carbon content of non-metallic materials (metric tons C/metric tons non-metallic minerals);
BG = Annual mass for blast furnace gas transferred off-site (metric tons);
C_{BG} = Carbon content of blast furnace gas (metric tons C/metric tons blast furnace gas);
R = Annual mass of air pollution control residue collected (metric tons);
C_R = Carbon content of air pollution control residue (metric tons C/metric tons residue);
3.664 = Conversion factor from metric tons of C to metric tons of CO_2.

(9) Calculate total CO_2 emissions using Equation 150-9:

$$E_{CO2} = E_T + E_{BOF} + E_{coke} + E_{sinter} + E_{EAF} + E_{AOD} + E_{DR} + E_{BF}$$ **Equation 150-9**

Where:

E_{CO2} = Total CO_2 emissions (metric tons);
E_T = Emissions from taconite indurating furnace (metric tons);
E_{BOF} = Emissions from basic oxygen furnace (BOF) (metric tons);
E_{coke} = Emissions from coke production (metric tons);
E_{sinter} = Emissions from sinter production (metric tons);
E_{EAF} = Emissions from electric arc furnace (EAF) (metric tons);
E_{AOD} = Emissions from argon-oxygen decarburization vessels (metric tons);
E_{DR} = Emissions from direct reduction furnace (metric tons);
E_{BF} = Emissions from blast furnace (metric tons);

§ WCI.154 Calculation of CH_4 Emissions

(a) Process CH_4 emissions. Determine process CH_4 emissions as specified under either paragraph (1) or paragraph (2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Site-specific emission factors.

§ WCI.155 Sampling, Analysis, and Measurement Requirements

The annual mass of each material used in the §WCI.153 mass balance methodologies shall be determined using plant instruments used for accounting purposes, including either direct measurement of the quantity of material used in the process or by calculations using process operating information.

The average carbon content of each material used shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For iron ore, taconite pellets, and other iron-bearing materials, use ASTM E1915-07a "Standard Test Methods for Analysis of Metal Bearing Ores and Related Materials by Combustion Infrared-Absorption Spectrometry".

(2) For iron and ferrous scrap, use ASTM E1019-08 "Standard Test Methods for Determination of Carbon, Sulphur, Nitrogen, and Oxygen in Steel, Iron, Nickel, and Cobalt Alloys by Various Combustion and Fusion Techniques".

(3) For coal, coke, and other carbonaceous materials (e.g., electrodes, etc.), use ASTM D5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal" or ASTM D5142 -09 Standard Test Methods for Proximate Analysis of the Analysis Sample of Coal and Coke by Instrumental Procedures, for petroleum liquid based fuels and liquid waste-derived fuels.

(4) For steel, use one of the methods described in subparagraph (i) through (iv):

(i) ASM CS-104 UNS No. G10460 "Carbon Steel of Medium Carbon Content".

(ii) ISO/TR 15349-1: 1998 "Unalloyed steel – Determination of low carbon content, Part 1: Infrared absorption method after combustion in an electric resistance furnace (by peak separation) (1998-10-15) – First Edition".

(iii) ISO/TR 15349-3: 1998 "Unalloyed steel – Determination of low carbon content, Part 3: Infrared absorption method after combustion in an electric resistance furnace (with preheating) (1998-10-15) – First Edition".

(iv) ASTM E415-08 "Standard Test Method for Atomic Emission Vacuum Spectrometric Analysis of Carbon and Low-Alloy Steel".

(5) For flux (i.e., limestone or dolomite) and slag, use ASTM C25-06 "Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime".

(6) For fuels, determine carbon content and molecular weight (if applicable) using the applicable methods listed in §WCI.20.

(7) For steel production by-products (e.g., blast furnace gas, coke oven gas, coal tar, light oil, sinter off gas, slag dust, etc.), use an online instrument that determines carbon content to within 5%.

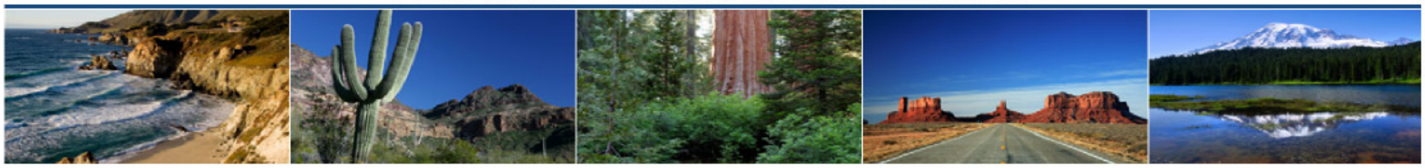
(b) Obtain carbon content from material vendor or supplier.

§ WCI.156 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever the monitoring and quality assurance procedures in WCI.84 cannot be followed (e.g., if a meter malfunctions during unit operation), a substitute data value for the missing parameter shall be used in the calculations following paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing data on monthly carbon contents of feedstock or the waste recycle stream, the substitute data value shall be the arithmetic average of the quality-assured values of that carbon content in the month preceding and the month immediately following the missing data incident. If no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon content obtained in the month after the missing data period.

(b) For missing feedstock supply rates or waste recycle stream used to determine monthly feedstock consumption or monthly waste recycle stream quantity, you must determine the best available estimate(s) of the parameter(s), based on all available process data.



§ WCI.160 LEAD PRODUCTION

§ WCI.161 Source Category Definition

The lead production category includes two primary production processes used to produce lead from lead concentrates (i.e., the sintering/smelting process and the direct smelting process). In addition, secondary production or recycling of lead (primarily from scrapped lead acid batteries) is included in the category.

§ WCI.162 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation the annual emissions data report shall contain the following information:

(a) Annual emissions of CO_2 at the facility level (metric tons).

(b) Annual quantities of each material used (metric tons).

(c) Carbon content of each material used (metric tons C/metric ton reducing agent).

(d) Inferred waste-based carbon-containing material emission factor (if waste-based reducing agent quantification method used).

(e) If you use the missing data procedures in WCI.165(b), you must report how the monthly mass of carbon-containing materials with missing data was determined and the number of months the missing data procedures were used.

(f) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit. You must report these emissions under WCI.20 (General Stationary Fuel Combustion Sources), by following the requirements of WCI.20.

§ WCI.163 Calculation of CO_2 Emissions

Calculate total CO_2 emissions as specified under paragraph (a) or (b) of this section.

(a) Determine facility CO_2 emissions using continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(b) Calculate total CO_2 emissions using Equation 160-1. Specific materials that contribute less than 1 percent of the total carbon into the process are being considered to not be included in the calculation using Equation 160-1.

$$E_{Pb} = \sum_{x} (RA_x \times C_x) \times 3.664 \qquad \textbf{Equation 160-1}$$

Where:

E_{Pb}	=	Annual CO_2 emissions from lead production (metric tons);
RA_x	=	Annual quantity of material *x* used (metric tons);
C_x	=	Carbon content of material *x* (metric tons C/metric tons of *x*);
3.664	=	Conversion factor from metric tons of C to metric tons of CO_2.

§ WCI.164 Sampling, Analysis, and Measurement Requirements

The annual mass of each material introduced into the smelting furnace shall be determined by summing the monthly mass for the material determined for each month of the calendar year. The monthly mass may be determined using plant instruments used for accounting purposes, including either direct measurement of the quantity of the material placed in the unit or by calculations using process operating information.

The average carbon content of each material introduced into the smelting furnace shall be determined as specified under paragraph (a), (b), or (c) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For solid carbonaceous reducing agents and carbon electrodes, use ASTM D5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal".

(2) For liquid reducing agents, use one of the methods described in subparagraph (i) through (iv):

(i) ASTM D2502-04 (Reapproved 2002) "Standard Test Method for Estimation of Molecular Weight (Relative Molecular Mass) of Petroleum Oils from Viscosity Measurements".

(ii) ASTM D2503-92 (Reapproved 2002) "Standard Test Method for Relative Molecular Mass (Relative Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure".

(iii) ASTM D3238-95 (Reapproved 2005) "Standard Test Method for Calculation of Carbon Distribution and Structural Group Analysis of Petroleum Oils by the n-d-M Method".

(iv) ASTM D5291-02 (Reapproved 2007) "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants".

(3) For gaseous reducing agents, use one of the methods described in subparagraph (i) or (ii):

(i) ASTM D1945-03 "Standard Test Method for Analysis of Natural Gas by Gas Chromatography".

(ii) ASTM D1946-90 "Standard Practice for Analysis of Reformed Gas by Gas Chromatography".

(4) For waste-based carbon-containing material, determine carbon content by operating the smelting furnace both with and without the waste-reducing agents while keeping the composition of other material introduced constant.

i. To ensure representativeness of waste-based carbon-containing material variability, the specific testing plan (e.g. number of test runs, other process variables to keep constant, timing of runs) for these trials must be approved by the jurisdiction

(b) Obtain carbon content from material vendor or supplier.

§ WCI.165 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations in WCI.163 is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in the paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

a) For each missing data for the carbon content for the smelting furnaces at your facility that estimate annual process CO_2 emissions using the carbon mass balance procedure in WCI.163, 100 percent data availability is required. You must repeat the test for average carbon contents of inputs according to the procedures in WCI.164 if data are missing.

b) For missing records of the monthly mass of carbon-containing materials, the substitute data value must be based on the best available estimate of the mass of the material from all available process data or data used for accounting purposes (such as purchase records).

§ WCI.170 LIME MANUFACTURING

§ WCI.171 Source Category Definition

Lime manufacturing is comprised of all processes that are used to manufacture a lime product (e.g., calcium oxide, high calcium quicklime, calcium hydroxide, hydrated lime, dolomitic quick lime, dolomitic hydrate, or other products) by calcination of limestone or other highly calcareous materials such as dolomite, aragonite, chalk, coral, marble, and shell.

This source category includes all lime manufacturing plants unless the plant is located at a kraft pulp mill, soda pulp mill, sulfite pulp mill, or only processes sludge containing calcium carbonate from water softening processes. The lime manufacturing source category consists of marketed and non-marketed lime manufacturing facilities.

Lime kilns at pulp and paper manufacturing facilities must report emissions under WCI.210 (Pulp and Paper Manufacturing).

§ WCI.172 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2, CH_4, and N_2O in metric tons.

(b) CO_2 process emissions from lime production (metric tons) for all kilns combined and the following information:

(1) For lime production:

(A) The emission factor (kg CO_2/metric ton) for each lime type for each month.

(B) The quantity of each type of lime produced (metric tons) each month.

(C) The calcium oxide (CaO) content (weight fraction) of each lime type for each month.

(D) The magnesium oxide (MgO) content (weight fraction) of each lime type for each month.

(2) For the production of calcined byproducts and wastes:

(A) The emission factor (kg CO_2/metric ton) for each calcined byproduct/waste type for each quarter.

(B) The quantity of each type of calcined byproduct/waste type produced each quarter.

(C) The calcium oxide (CaO) content (weight fraction) of each calcined byproduct/waste type for each quarter.

(D) The magnesium oxide (MgO) content (weight fraction) of each calcined byproduct/waste type for each quarter.

(3) Number of times during the reporting year that missing data procedures were followed to measure lime production.

(c) CO_2, CH_4, and N_2O emissions from fuel combustion in all kilns combined, following the calculation methods and reporting requirements specified in WCI.173(c) (metric tons).

(d) CO_2, CH_4, and N_2O emissions from all other fuel combustion units combined (kilns excluded), following the calculation methods and reporting requirements specified in WCI.20 (metric tons).

(e) If a continuous emissions monitor is used to measure CO_2 emissions from kilns, then the requirements of paragraphs (b) of this section do not apply for CO_2.

(f) Operators of lime plants shall also comply with the reporting requirements for any other applicable source category listed by regulation, including but not limited to the following:

(1) Coal fuel storage as specified in WCI.100.

(2) Electricity generating as specified in WCI.40.

(3) Cogeneration systems as specified in WCI.42(f).

§ WCI.173 Calculation of greenhouse Gas Emissions from Kilns

(a) Determine process CO_2 emissions as specified under either paragraph (a)(1) or (a)(2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Calculate the sum of CO_2 process emissions from kilns and CO_2 fuel combustion emissions from kilns using the calculation methodologies specified in paragraph (b) and (c) of this section**.**

(b) Process CO_2 Emissions Calculation Methodology. Calculate total CO_2 process emissions as the sum of emissions from lime production, using the method specified in paragraph (b)(1) of this section.

(1) CO_2 Process Emissions. Calculate CO_2 emissions from the production of each type of lime using Equation 170-1 and a plant-specific lime emission factor and a plant-specific calcined byproduct/waste emission factor as specified in this section.

$$CO_2 = \sum_{i}^{12} \sum_{j}^{y} \left[QL_{ij} \times EF_{QL_{ij}} \right] + \sum_{k}^{4} \sum_{l}^{z} \left[CBW_{kl} \times EF_{CBW_{kl}} \right] \qquad \textbf{Equation 170-1}$$

Where:

CO_2	=	CO_2 emissions in metric tons/yr.
QL	=	Monthly quantity of lime produced, metric tons.
EF_{QL}	=	Monthly lime emission factor, metric tons CO_2/metric ton lime computed as specified in paragraph (b)(2) of this section.
CBW	=	Monthly quantity of calcined byproduct/waste, including LKD, scrubber sludge and other calcined wastes produced, metric tons.

EF_{CBW}	=	Monthly calcined byproduct/waste emission factor, computed as specified in paragraph (b)(3) of this section.
i	=	Month.
j	=	Lime type.
k	=	Quarter.
l	=	Calcined byproduct/waste type.
y	=	Total number of lime types.
z	=	Total number of calcined byproduct/waste types.

(2) Monthly Lime Emission Factor. Calculate a plant-specific lime emission factor (EF_{QL}) for each type of lime and month based on the percent of measured CaO and MgO content in lime and using Equation 170-2.

$$EF_{QL} = (CaO\ \ content \times Molecular\ \ ratio\ \ of\ CO_2 / CaO) + (MgO\ \ content \times Molecular\ \ ratio\ \ CO_2 / MgO)$$

Equation 170-2

Where:

CaO Content (by weight)	=	Total CaO content of Lime.
Molecular ratio of CO_2/CaO	=	0.785.
MgO Content (by weight)	=	Total MgO content of Lime.
Molecular ratio of CO_2/MgO	=	1.092.

(3) Quarterly Calcined Byproduct/Waste Emission Factor. The calcined byproduct/waste emission factor shall be calculated using Equation 170-3.

$$EF_{CBW} = [(CaO\ \ content) \times Molecular\ \ ratio\ \ of\ \ CO_2 / CaO] + [(MgO\ \ Content) \times Molecular\ \ ratio\ \ of\ \ CO_2 / MgO]$$

Equation 170-3

Where:

EF_{CBW}	=	Calcined byproduct/waste emission factor.
CaO Content (by weight)	=	Total CaO content of calcined byproduct/waste.
Molecular ratio of CO_2/CaO	=	0.785.
MgO Content (by weight)	=	Total MgO content of calcined byproduct/waste.
Molecular ratio of CO_2/MgO	=	1.092.

(c) Fuel Combustion Emissions in Kilns. Calculate CO_2, CH_4, and N_2O emissions from stationary fuel combustion emissions following the calculation methods specified in WCI.20. Operators of lime manufacturing plants that primarily combust biomass-derived fuels and combust fossil fuels only during periods of start-up, shut-down, or malfunction may report CO_2 emissions from fossil fuels using the emission factor methodology in WCI.23(a). "Pure" means that the biomass-derived fuels account for 97 percent of the total amount of carbon in the fuels burned.

§ WCI.174 Sampling, Analysis, and Measurement Requirements

(a) You must determine the chemical composition (percent total CaO and percent total MgO) of each type of lime and each type of calcined byproduct/waste according to paragraph (a)(1) and (a)(2) of this section. Samples for analysis of the calcium oxide and magnesium oxide content of each lime type and each calcined byproduct/waste type should be collected during the same month or quarter as the production data. At least one sample must be collected monthly for each lime type produced during the month and for each calcined byproduct/waste type produced.

(1) ASTM C25-06 Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime.
(2) The National Lime Association's CO_2 Emissions Calculation Protocol for the Lime Industry English Units Version, February 5, 2008 Revision – National Lime Association.

(b) The quantity of lime produced and sold is to be estimated monthly using direct measurements (such as rail and truck scales) of lime sales for each lime type, and adjusted to take into account the difference in beginning- and end-of-period inventories of each lime type. The inventory period shall be annual at a minimum.

(c) The quantity of calcined byproduct/waste sold is to be estimated monthly using direct measurements (such as rail and truck scales) of calcined byproduct/waste sales for each calcined byproduct/waste type, and adjusted to take into account the difference in beginning- and end-of-period inventories of each calcined byproduct/waste type. The inventory period shall be annual at a minimum. The quantity of calcined byproduct/waste not sold is to be determined no less often than annually for each calcined/byproduct waste type using direct measurements (such as rail and truck scales), or a calcined byproduct/waste generation rate (i.e. calcined byproduct produced as a factor of lime production).

(d) Follow the quality assurance/quality control procedures (including documentation) in National Lime Association's CO_2 Emissions Calculation Protocol for the Lime Industry English Units Version, February 5, 2008 Revision – National Lime Association.

§ WCI.175 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., oxide content, quantity of lime products, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For each missing value of the quantity of lime produced (by lime type), and quantity of byproduct/waste produced and sold, the substitute data value shall be the best available estimate based on all available process data or data used for accounting purposes.
(b) For missing values related to the CaO and MgO content, you must conduct a new composition test.

§ WCI.180 CARBONATES USE

§ WCI.181 Source Category Definition

This source category includes any equipment that uses carbonates listed in Table 180-1 in manufacturing processes that emit carbon dioxide. Table 180-1 includes the following carbonates: limestone, dolomite, ankerite, magnesite, siderite, rhodochrosite, or sodium carbonate. Facilities are considered to emit CO_2 if they consume at least 1,800 tonnes per year of carbonates heated to a temperature sufficient to allow the calcination reaction to occur.

This source category does not include equipment that uses carbonates or carbonate containing minerals that are consumed in the production of cement, copper and nickel, electricity generation, ferroalloys, glass, iron and steel, lead, lime, phosphoric acid, pulp and paper, soda ash, sodium bicarbonate, sodium hydroxide, or zinc.

This source category does not include carbonates used in sorbent technology used to control emissions from stationary fuel combustion equipment. Emissions from carbonates used in sorbent technology are reported under WCI.20 (Stationary Fuel Combustion Sources).

§ WCI.182 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation the annual emissions data report for carbonate use shall include the following information at the facility level calculated in accordance this method:

(a) Annual CO_2 emissions from miscellaneous carbonate use (tonnes).

(b) Annual mass of each carbonate type consumed (tonnes).

(c) If you followed the calculation method of WCI.183(a), you must report the following information:

(1) Annual carbonate consumption by carbonate type (tonnes).

(2) Annual calcination fractions used in calculations.

(d) If you followed the calculation method of WCI.183(b), you must report the following information:

(1) Annual carbonate input by carbonate type (tonnes).

(2) Annual carbonate output by carbonate type (tonnes).

(e) Number of times in the reporting year that missing data procedures were followed to measure carbonate consumption, carbonate input or carbonate output (months).

§ WCI.183 Calculating GHG emissions.

You must determine CO_2 process emissions from carbonate use in accordance with the procedures specified in either paragraphs (a) or (b) of this section.

(a) Calculate the process emissions of CO_2 using calcination fractions with Equation 180-1 of this section.

$$E_{CO2} = \sum_{i=1}^{n} (M_i \times EF_i \times F_i)$$

Equation 180-1

Where:

ECO_2 = Annual CO_2 mass emissions from consumption of carbonates (tonnes).

M_i = Annual mass of carbonate type i consumed (tonnes).

EF_i = Emission factor for the carbonate type i, as specified in Table 180-1 to this Subpart, tonnes CO_2/tonne carbonate consumed.

F_i = Fraction calcination achieved for each particular carbonate type i (weight fraction). As an alternative to measuring the calcination fraction, a value of 1.0 can be used.

n = Number of carbonate types.

(b) Calculate the process emissions of CO_2 using actual mass of output carbonates with Equation 180-2 of this section.

$$E_{CO2} = \left[\sum_{k=1}^{m} (M_k \times EF_k) - \sum_{j=1}^{n} (M_j \times EF_j) \right]$$

Equation 180-2

Where:

ECO_2 = Annual CO_2 mass emissions from consumption of carbonates (tonnes).
M_k = Annual mass of input carbonate type k (tonnes).
EF_k = Emission factor for the carbonate type k, as specified in Table 180-1 of this method (tonnes CO_2/tonne carbonate input).
M_j = Annual mass of output carbonate type j (tonnes).
EF_j = Emission factor for the output carbonate type j, as specified in Table 180-1 of this method (tonnes CO_2/tonne carbonate input).
m = Number of input carbonate types.
n = Number of output carbonate types.

§ WCI.184 Monitoring and QA/QC requirements.

(a) The annual mass of carbonate consumed (for Equation 180-1 of this subpart) or carbonate inputs (for Equation 180-2 of this subpart) must be determined annually from monthly measurements using the same plant instruments used for accounting purposes including purchase records or direct measurement, such as weigh hoppers or weigh belt feeders.

(b) The annual mass of carbonate outputs (for Equation 180-2 of this subpart) must be determined annually from monthly measurements using the same plant instruments used for accounting purposes including purchase records or direct measurement, such as weigh hoppers or belt weigh feeders.

(c) If you follow the procedures of WCI.183(a), as an alternative to assuming a calcination fraction of 1.0, you can determine on an annual basis the calcination fraction for each carbonate consumed based on sampling and chemical analysis using a suitable method such as using an x-ray fluorescence standard method or other enhanced industry consensus standard method published by an industry consensus standard organization (e.g., ASTM, ASME, etc.).

§ WCI.185 Procedures for estimating missing data.

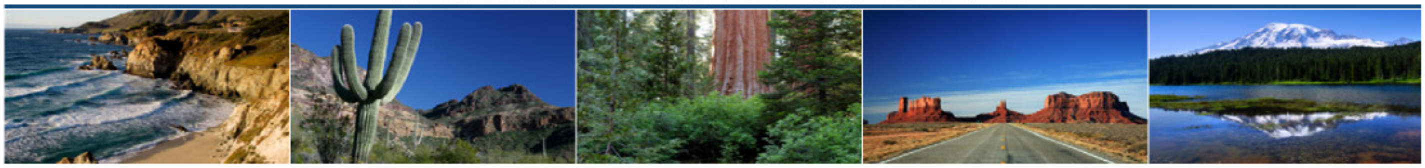
(a) A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraph (b) of this section. You must document and keep records of the procedures used for all such estimates.

(b) For each missing value of monthly carbonate consumed, monthly carbonate output, or monthly carbonate input, the substitute data value must be the best available estimate based on the all available process data or data used for accounting purposes.

§ WCI.186 Data reporting requirements.

Table 180-1 —CO_2 Emission Factors for Common Carbonates

Mineral Name - Carbonate	CO_2 Emission Factor (tonnes CO_2/tonne carbonate)
Limestone - $CaCO_3$	0.43971
Magnesite - $MgCO_3$	0.52197
Dolomite - $CaMg(CO_3)_2$	0.47732
Siderite - $FeCO_3$	0.37987
Ankerite - $Ca(Fe,Mg,Mn)(CO_3)_2$	0.47572
Rhodochrosite - $MnCO_3$	0.38286
Sodium Carbonate/Soda Ash – Na_2CO_3	0.41492
Others	Facility specific factor to be determined through analysis or supplier information



§ WCI.200 PETROLEUM REFINERIES

§ WCI.201 Source Category Definition

(a) A petroleum refinery consists of all processes used to produce gasoline, aromatics, kerosene, distillate fuel oils, residual fuel oils, lubricants, asphalt, or other products through distillation of petroleum or through redistillation, cracking, rearrangement or reforming of unfinished petroleum derivatives.

(b) For the purposes of this subpart, facilities that distill only pipeline transmix (off-spec material created when different specification products mix during pipeline transportation) are not petroleum refineries, regardless of the products produced.

(c) This source category consists of the following sources at petroleum refineries: catalytic cracking units; fluid coking units; delayed coking units; catalytic reforming units; coke calcining units; asphalt blowing operations; blowdown systems; storage tanks; process equipment components (compressors, pumps, valves, pressure relief devices, flanges, and connectors) in gas service; marine vessel, barge, tanker truck, and similar loading operations; flares; sulphur recovery plants; and non-merchant hydrogen plants (i.e., hydrogen plants that are owned or under the direct control of the refinery owner and operator).

§ WCI.202 Greenhouse Gas Reporting Requirements

In addition to the information required by WCI.3, the annual emissions report must contain the following information reported at the facility level:

(a) Catalyst Regeneration. Report CO_2, CH_4, and N_2O emissions.

(b) Process Vents. Report CO_2, N_2O, and CH_4 emissions.

(c) Asphalt Production. Report CO_2 and CH_4 emissions.

(d) Sulphur Recovery. Report CO_2 emissions.

(e) Stationary Combustion Units Other than Flares and Control Devices. Report CO_2, N_2O, and CH_4 emissions as specified in WCI.30 for combustion of refinery fuel gas, still gas, flexigas, or associated gas and WCI.20 for combustion of all other fuels.

(f) Flares and Other Control Devices. Report CO_2, N_2O, and CH_4 emissions.

(g) Above-Ground Storage Tanks. Report CH_4 emissions.

(h) Wastewater Treatment. Report CH_4 and N_2O emissions from anaerobic treatment and CH_4 emissions from oil-water separators.

(i) Equipment Leaks. Report CH_4 emissions.

(j) Feedstock Consumption: Report feedstock consumption by type for all feedstocks which result in GHG emissions in the reporting year (including petroleum coke) in units of cubic meters for gases, kilolitres for liquids, metric tons for non-biomass solids, and bone dry short tons or metric tons for biomass-derived solid fuels.

(k) Fuel Consumption: Report fuel consumption by fuel type consumed in the reporting year in units of cubic meters for gases, kilolitres for liquids, metric tons for non-biomass solids, and bone dry short tons or metric tons for biomass-derived solid fuels.

(l) Coke calcining units. Report CO_2, N_2O, and CH_4 emissions.

(m) Uncontrolled blowdown systems. Report CH_4 emissions.

(n) Loading Operations. Report CH_4 emissions.

(o) Delayed Coking Units. Report CH_4 emissions.

§ WCI.203 Calculation of Greenhouse Gas Emissions

The operator shall calculate GHG emissions using the methods in paragraphs (a) through (i) of this section. If a continuous emissions monitor is used to measure CO_2 emissions from process vents, asphalt production, sulphur recovery, or other control devices then the operator shall calculate the CO_2 emissions from these processes using a continuous emissions monitoring system (CEMS) as specified in WCI.23(d).

(a) Catalyst Regeneration. Operators shall calculate the CO_2, CH_4, and N_2O process emissions resulting from catalyst regeneration using the methods in paragraph (a)(1), (a)(2) and (a)(3), respectively.

(1) For units equipped with CEMS, operators shall calculate CO_2 process emissions resulting from catalyst regeneration using CEMS in accordance with WCI.20. In the absence of CEMS data, the operator shall use the methods in paragraphs (a)(1)(A) through (a)(1)(C).

(A) The operator shall calculate process CO_2 emissions from the continuous regeneration of catalyst material in fluid catalytic cracking units (FCCU) and fluid cokers using Equations 200-1, 200-2, and 200-3.

$$CO_2 = \sum_{i=1}^{n} CR_i \times CF \times 3.664 \times 0.001 \qquad \textbf{Equation 200-1}$$

Where:

CO_2	=	CO_2 emissions (metric tons/yr)
n	=	Number of weeks of operation in the report year (or number of days of operation if equipment is in place to make continuous measurements)
CR_i	=	Weekly coke burn rate in kg/week (or daily average coke burn rate in kg/day if equipment is in place to make continuous measurements)
CF	=	Carbon fraction in coke burned
3.664	=	Ratio of molecular weights, CO_2 to carbon

0.001	=	Conversion factor from kg to metric tons

Either continuously monitor the volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels or calculate the volumetric flow rate of this exhaust gas stream using Equation 200-2 of this section.

$$Q_r = \frac{\left(79 * Q_a + (100 - \%O_{oxy}) * Q_{oxy}\right)}{100 - \%CO_2 - \%CO - \%O_2}$$

Equation 200-2

Where:

Q_r	=	Volumetric flow rate of exhaust gas from regenerator before entering the emission control system (dSm^3/min)
Q_a	=	Volumetric flow rate of air to regenerator, as determined from control room instrumentation (dSm^3/min)
$\%Q_{oxy}$	=	Oxygen concentration in oxygen enriched air stream, percent by volume – dry basis
Q_{oxy}	=	Volumetric flow rate of O_2 enriched air to regenerator as determined from catalytic cracking unit control room instrumentation (dSm^3/min)
$\%CO_2$	=	Carbon dioxide concentration in regenerator exhaust, percent by volume – dry basis
$\%CO$	=	CO concentration in regenerator exhaust, percent by volume – dry basis. When no auxiliary fuel is burned and a continuous CO monitor is not required, assume %CO to be zero
$\%O_2$	=	O_2 concentration in regenerator exhaust, percent by volume – dry basis

Calculate the coke burn rate using Equation 200-3:

$$CR_i = K_1 Q_r \times (\%CO_2 + \%CO) + K_2 Q_a - K_3 Q_r \times \left[\%CO/2 + \%CO_2 + \%O_2\right] + K_3 Q_{oxy} \times (\%O_{oxy})$$

Equation 200-3

Where:

CR_i	=	Weekly coke burn rate in kg/week (or daily coke burn rate in kg/day if equipment is in place to make continuous measurements)
K_1, K_2, K_3	=	Material balance and conversion factors (K_1, K_2, and K_3 from Table 200-1
Q_r	=	Volumetric flow rate of exhaust gas before entering the emission control system (dSm^3/min)
Q_a	=	Volumetric flow rate of air to regenerator as determined from control room instrumentation (dSm^3/min)
$\%CO_2$	=	CO_2 concentration in regenerator exhaust, percent by volume – dry basis

%CO	=	CO concentration in regenerator exhaust, percent by volume – dry basis
$\%O_2$	=	O_2 concentration in regenerator exhaust, percent by volume – dry basis
Q_{oxy}	=	Volumetric flow rate of O_2 enriched air to regenerator as determined from control room instrumentation (dSm^3/min)
$\%O_{oxy}$	=	O_2 concentration in O_2 enriched air stream inlet to regenerator, percent by volume – dry basis

(B) The operator shall calculate process CO_2 emissions resulting from continuous catalyst regeneration in operations other than FCCUs and fluid cokers (e.g. catalytic reforming) using Equation 200-4.

$$CO_2 = CC_{irc} \times (CF_{spent} - CF_{regen}) \times H \times 3.664$$ **Equation 200-4**

Where:

CO_2	=	CO_2 emissions (metric tons/yr)
CC_{irc}	=	Average catalyst regeneration rate (metric tons/hr)
CF_{spent}	=	Weight carbon fraction on spent catalyst
CF_{regen}	=	Weight carbon fraction on regenerated catalyst (default = 0)
H	=	Hours regenerator was operational (hr/yr)
3.664	=	Ratio of molecular weights, CO_2 to carbon

(C) The operator shall calculate process CO_2 emissions resulting from periodic catalyst regeneration using Equations 200-5

$$CO_2 = \sum_{1}^{n} \left[\left(CB_Q \right)_n \times CC \times 3.664 \times 0.001 \right]$$ **Equation 200-5**

Where:

CO_2	=	Annual CO_2 emissions (metric tons/year).
CB_Q	=	Coke burn-off quantity per regeneration cycle from engineering estimates (kg coke/cycle).
n	=	Number of regeneration cycles in the calendar year.
CC	=	Carbon content of coke based on measurement or engineering estimate (kg C per kg coke); default = 0.94.
3.664	=	ratio of molecular weights, CO_2 to carbon
0.001	=	Conversion factor (metric ton/kg).

(2) Calculate CH_4 emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-6 of this section.

$$CH_4 = \left(CO_2 * \frac{EmF_2}{EmF_1} \right)$$ **Equation 200-6**

Where:

CH_4	=	Annual methane emissions from coke burn-off (metric tons CH_4/year).
CO_2	=	Emission rate of CO_2 from coke burn-off calculated in paragraph (a)(1) of this section, as applicable (metric tons/year).
EmF_1	=	Default CO_2 emission factor for petroleum coke of 97 kg CO_2/GJ
EmF_2	=	Default CH_4 emission factor of 2.8 x 10^{-3} kg CH_4/GJ).

(3) Calculate N_2O emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-7 of this section.

$$N_2O = \left(CO_2 * \frac{EmF_3}{EmF_1} \right)$$ **Equation 200-7**

Where:

N_2O	=	Annual nitrous oxide emissions from coke burn-off (mt N_2O/year).
CO_2	=	Emission rate of CO_2 from coke burn-off calculated in paragraphs (a)(1) of this section, as applicable (metric tons/year).
EmF_1	=	Default CO_2 emission factor for petroleum coke of 97 kg CO_2/GJ .
EmF_3	=	Default N_2O emission factor of 5.7 x10^{-4} kg N_2O/GJ.

(b) **Process Vents.** Except for process emissions reported under other requirements of this regulation, the operator shall calculate process emissions of CO_2, CH_4, and N_2O from process vents using Equation 200-8 for each process vent that can be reasonably expected to contain greater than 2 percent by volume CO_2 or greater than 0.5 percent by volume of CH_4 or greater than 0.01 percent by volume (100 parts per million) of N_2O.

$$E_x = \sum_{i=1}^{n} VR_i \times F_{xi} \times (MW_x / MVC) \times VT_i \times 0.001$$ **Equation 200-8**

Where:

E_x	=	Annual emissions of x (metric tons/yr), where x = CO_2, N_2O, or CH_4
VR_i	=	Average volumetric flow rate for venting event i from measurement data, process knowledge or engineering estimates (Sm^3/unit time)

F_{xi} = Molar fraction of x in vent gas stream during event i from measurement data, process knowledge or engineering estimates.
MW_x = Molecular weight of x (kg/kg-mole)
MVC = Molar volume conversion (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere)
VT_i = Time duration of venting event i, in same units of time as VR_i
n = Number of venting events in report year
0.001 = Conversion factor from kg to metric tons

(c) **Asphalt Production**. The operator shall calculate CO_2 and CH_4 process emissions from asphalt blowing activities using either process vent method specified in paragraph (b) or according to the applicable provisions in paragraphs (c)(1) and (c)(2) of this section.

(1) For uncontrolled asphalt blowing operations or asphalt blowing operations controlled by vapor scrubbing, calculate CO_2 and CH_4 emissions using Equations 200-9 and 200-10 of this section, respectively.

$$CO_2 = (Q_{AB} \times EF_{AB.CO2}) \qquad \textbf{Equation 200-9}$$

Where:

CO_2 = Annual CO_2 emissions from uncontrolled asphalt blowing (metric tons CO_2/year).
Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).
$EF_{AB,CO2}$ = Emission factor for CO_2 from uncontrolled asphalt blowing from facility-specific test data (metric tons CO_2/MMbbl asphalt blown); default = 1,100.

$$CH_4 = (Q_{AB} \times EF_{AB,CH4}) \qquad \textbf{Equation 200-10}$$

Where:
CH_4 = Annual methane emissions from uncontrolled asphalt blowing (metric tons CH_4/year).
Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).
$EF_{AB,CH4}$ = Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (metric tons CH_4/MMbbl asphalt blown); default = 580.

(2) For asphalt blowing operations controlled by thermal oxidizer or flare, calculate CO_2 and CH_4 emissions using Equations 200-11 and 200-12 of this section, respectively, provided these emissions are not already included in the flare emissions calculated in paragraph (e) of this section or in the stationary combustion unit emissions required under WCI.20.

$$CO_2 = 0.98 \times (Q_{AB} \times CEF_{AB} \times 3.664) \qquad \textbf{Equation 200-11}$$

Where:

CO_2 = Annual CO_2 emissions from controlled asphalt blowing (metric tons CO_2/year).

0.98	=	Assumed combustion efficiency of thermal oxidizer or flare.
Q_{AB}	=	Quantity of asphalt blown (MMbbl/year).
CEF_{AB}	=	Carbon emission factor from asphalt blowing from facility-specific test data (metric tons C/MMbbl asphalt blown); default = 2,750.
3.664	=	ratio of molecular weights, carbon dioxide to carbon

$$CH_4 = 0.02 \times (Q_{AB} \times EF_{AB,CH4})$$ **Equation 200-12**

Where:

CH_4	=	Annual methane emissions from controlled asphalt blowing (metric tons CH_4/year).
0.02	=	Fraction of methane uncombusted in thermal oxidizer or flare based on assumed 98% combustion efficiency.
Q_{AB}	=	Quantity of asphalt blown (million barrels per year, MMbbl/year).
$EF_{AB,CH4}$	=	Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (metric tons CH_4/MMbbl asphalt blown); default = 580.

(d) **Sulphur Recovery**. The operator shall calculate CO_2 process emissions from sulphur recovery units (SRUs) using Equation 200-13. For the molar fraction (MF) of CO_2 in the sour gas, use either a default factor of 0.20 or a source specific molar fraction value approved by the regulator and derived from source tests conducted at least once per calendar year under the supervision of the regulator.

$$CO_2 = FR \times MW_{CO2} / MVC \times MF \times 0.001$$ **Equation 200-13**

Where:

CO_2	=	Emissions of CO_2 (metric tons/yr)
FR	=	Volumetric flow rate of acid gas to SRU (Sm^3/year)
MW_{CO2}	=	Molecular weight of CO_2 (44 kg/kg-mole)
MVC	=	Molar volume conversion (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere)
MF	=	Molar fraction (%) of CO_2 in sour gas (default MF = 20% expressed as 0.20)
0.001	=	Conversion factor from kg to metric tons

(e) **Flares and Other Control Devices**.

(1) The operator shall calculate and report CO_2, CH_4 and N_2O emissions resulting from the combustion of flare pilot and purge gas using the appropriate method(s) specified in section WCI.20.

(2) The operator shall calculate and report CO_2 emissions resulting from the combustion of hydrocarbons routed to flares for destruction as follows:

(i) Heat value or carbon content measurement. If you have a continuous higher heating value monitor or gas composition monitor on the flare or if you monitor these parameters at least weekly, you must use the measured heat value or carbon content value in calculating the CO_2 emissions from the flare using the applicable methods in paragraphs (e)(2)(i)(A) and (e)(2)(i)(B).

(A) If you monitor gas composition, calculate the CO_2 emissions from the flare using Equation 200-14 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation 200-14 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[3.664 \times (Flare)_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right) \quad \textbf{Equation 200-14}$$

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
n	=	Number of measurement periods. The minimum value for n is 52 (for weekly measurements); the maximum value for n is 366 (for daily measurements during a leap year).
p	=	Measurement period index.
3.664	=	Ratio of molecular weights, carbon dioxide to carbon
$(Flare)_p$	=	Volume of flare gas combusted during measurement period (Sm^3/period). If a mass flow meter is used, measure flare gas flow rate in kg/period and replace the term "$(MW)_p$/MVC" with "1".
$(MW)_p$	=	Average molecular weight of the flare gas combusted during measurement period (kg/kg-mole). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.
MVC	=	Molar volume conversion (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere).
$(CC)_p$	=	Average carbon content of the flare gas combusted during measurement period (kg C per kg flare gas). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.

(B) If you monitor heat content but do not monitor gas composition, calculate the CO_2 emissions from the flare using Equation 200-15 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation 200-15 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \sum_{p=1}^{n} \left[(Flare)_p \times (HHV)_p \times EmF \right]$$ **Equation 200-15**

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
n	=	Number of measurement periods. The minimum value for n is 52 (for weekly measurements); the maximum value for n is 366 (for daily measurements during a leap year).
p	=	Measurement period index.
$(Flare)_p$	=	Volume of flare gas combusted during measurement period (Sm^3/period). If a mass flow meter is used, you must also measure molecular weight and convert the mass flow to a volumetric flow as follows: Flare[m^3] = 0.000001 × Flare[kg] × MVC/$(MW)_p$, where MVC is the molar volume conversion (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere) and $(MW)_p$ is the average molecular weight of the flare gas combusted during measurement period (kg/kg-mole).
$(HHV)_p$	=	Higher heating value for the flare gas combusted during measurement period (GJ per m^3,). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.
EmF	=	Default CO_2 emission factor of 57 kilograms CO_2/GJ (HHV basis).

(ii) Alternative Method for Startup, Shutdown, and Malfunctions. For startup, shutdown, and malfunctions during which you were unable to measure the parameters required by Equations 200-14 and 200-15 of this section, you must determine the quantity of gas discharged to the flare separately for each start-up, shutdown, or malfunction, and calculate the CO_2 emissions as specified in paragraphs (e)(1)(iii)(A) and (e)(1)(iii)(B) of this section.

(A) For periods of start-up, shutdown, or malfunction, use engineering calculations and process knowledge to estimate the carbon content of the flared gas for each start-up, shutdown, or malfunction event.

(B) Calculate the CO_2 emissions using Equation 200-16 of this section.

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[3.664 \times (Flare_{SSM})_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right)$$ **Equation 200-16**

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
n	=	Number of start-up, shutdown, and malfunction events during the reporting year.
p	=	Start-up, shutdown, and malfunction event index.
$(Flare_{SSM})_p$	=	Volume of flare gas combusted during indexed start-up, shutdown, or malfunction event from engineering calculations, (m^3/event).
$(MW)_p$	=	Average molecular weight of the flare gas, from the analysis results or engineering calculations for the event (kg/kg-mole).
MVC	=	Molar volume conversion (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere)
$(CC)_p$	=	Average carbon content of the flare gas, from analysis results or engineering calculations for the event (kg C per kg flare gas).
3.664	=	Ratio of molecular weights, carbon dioxide to carbon

(3) The operator shall calculate and report CH_4 and N_2O emissions resulting from the combustion of hydrocarbons routed to flares for destruction using the methods specified in paragraphs (e)(3)(A) and (e)(3)(B):

(A) Calculate CH_4 using Equation 200-17 of this section.

$$CH_4 = \left(CO_2 \times \frac{EmF_{CH4}}{EmF} \right) + CO_2 \times \frac{0.02}{0.98} \times \frac{16}{44} \times f_{CH4} \qquad \textbf{Equation 200-17}$$

Where:

CH_4	=	Annual methane emissions from flared gas (metric tons CH_4/year).
CO_2	=	Emission rate of CO_2 from flared gas calculated in paragraph (e)(1) and (e)(2) of this section (metric tons/year).
EmF_{CH4}	=	Default CH_4 emission factor for Petroleum Products of 2.8×10^{-3} kg/GJ
EmF	=	Default CO_2 emission factor for flare gas of 57 kilograms CO_2/GJ (HHV basis).
0.02/0.98	=	Correction factor for flare combustion efficiency.
16/44	=	Correction factor ratio of the molecular weight of CH_4 to CO_2
f_{CH4}	=	Weight fraction of carbon in the flare gas prior to combustion that is contributed by methane from measurement values or engineering calculations (kg C in methane in flare gas/kg C in flare gas); default is 0.4.

(B) Calculate N_2O emissions using Equation 200-18 of this section.

$$N_2O = \left(CO_2 \times \frac{EmF_{N2O}}{EmF} \right) \quad \textbf{Equation 200-18}$$

Where:

N_2O = Annual nitrous oxide emissions from flared gas (metric tons N_2O/year).

CO_2 = Emission rate of CO_2 from flared gas calculated in paragraph (b)(1) and (b)(2) of this section (metric tons/year).

EmF_{N2O} = Default N_2O emission factor for Petroleum Products of 5.7×10^{-4} kg/GJ .

EmF = Default CO_2 emission factor for flare gas of 57 kilograms CO_2/GJ (HHV basis).

(4) The operator who uses methods other than flares (e.g. incineration, combustion as a supplemental fuel in heaters or boilers) to destroy low Btu gases (e.g. coker flue gas, gases from vapor recovery systems, casing vents and product storage tanks) shall calculate CO_2 emissions using Equation 200-19. The operator shall determine CC_A and MW_A quarterly using methods specified in WCI.20 and use the annual average values of CC_A and MW_A to calculate CO_2 emissions.

$$CO_2 = GV_A \times CC_A \times MW_A / MVC \times 3.664 \times 0.001 \quad \textbf{Equation 200-19}$$

Where:

CO_2 = CO_2 emissions (metric tons/year)
GV_A = Volume of gas A destroyed annually (m^3/year)
CC_A = Carbon content of gas A (kg C/kg fuel)
MW_A = Molecular weight of gas A
MVC = Molar volume conversion (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere)
3.664 = Ratio of molecular weights, CO_2 to carbon
0.001 = Conversion factor – kg to metric tons

(f) **Storage Tanks.** For storage tanks other than those processing unstabilized crude oil except as provided in paragraph (f)(3) of this section, calculate CH_4 emissions using the applicable methods in paragraphs (f)(1) and (f)(2) of this section.

(1) For storage tanks other than those processing unstabilized crude oil, you must either calculate CH_4 emissions from storage tanks that have a vapor-phase methane concentration of 0.5 volume percent or more using tank-specific methane composition data (from measurement data or product knowledge) and the AP-42 emission estimation methods provided in Section 7.1 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources", including TANKS Model (Version 4.09D) or similar programs, or estimate CH_4 emissions from storage tanks using Equation 200-20 of this section.

$$CH_4 = (0.1 \times Q_{Ref}) \quad \textbf{Equation 200-20}$$

Where:

CH_4	=	Annual methane emissions from storage tanks (metric tons/year).
0.1	=	Default emission factor for storage tanks (metric ton CH_4/MMbbl).
Q_{Ref}	=	Quantity of crude oil plus the quantity of intermediate products received from off site that are processed at the facility (MMbbl/year).

(2) For storage tanks that process unstabilized crude oil, calculate CH_4 emissions from the storage of unstabilized crude oil using either tank-specific methane composition data (from measurement data or product knowledge) and direct measurement of the gas generation rate or by using Equation 200-21 of this section.

$$CH_4 = (995{,}000 \times Q_{un} \times \Delta P) \times MF_{CH4} \times \frac{16}{MVC} \times 0.001 \quad \textbf{Equation 200-21}$$

Where:

CH_4	=	Annual methane emissions from storage tanks (metric tons/year).
Q_{un}	=	Quantity of unstabilized crude oil received at the facility (MMbbl/year).
ΔP	=	Pressure differential from the previous storage pressure to atmospheric pressure (pounds per square inch, psi).
MF_{CH4}	=	Mole fraction of CH_4 in vent gas from the unstabilized crude oil storage tank from facility measurements (kg-mole CH_4/kg-mole gas); use 0.27 as a default if measurement data are not available.
995,000	=	Correlation Equation factor (scf gas per MMbbl per psi)
16	=	Molecular weight of CH_4 (kg/kg-mole).
MVC	=	Molar volume conversion (849.5 scf/kg-mole).
0.001	=	Conversion factor (metric ton/kg).

(3) You do not need to calculate CH_4 emissions from storage tanks that meet any of the following descriptions:

(i) Units permanently attached to conveyances such as trucks, trailers, rail cars, barges, or ships;

(ii) Pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere;
(iii) Bottoms receivers or sumps;
(iv) Vessels storing wastewater; or
(v) Reactor vessels associated with a manufacturing process unit.

(g) **Industrial Wastewater Processing**.

(1) The operator shall calculate CH_4 emissions from anaerobic wastewater treatment (such as anaerobic reactor, digester, or lagoon) using Equation 200-22 or Equation 200-23.

$$CH_4 = Q \times COD_{qave} \times B \times MCF \times 0.001 \qquad \textbf{Equation 200-22}$$

$$CH_4 = Q \times BOD_{5qave} \times B \times MCF \times 0.001 \qquad \textbf{Equation 200-23}$$

Where:

CH_4	=	Emission of methane (metric tons/yr)
Q	=	Volume of wastewater treated (m^3/yr)
COD_{qave}	=	Average of quarterly determinations of chemical oxygen demand of the wastewater (kg/m^3)
BOD_{5qave}	=	Average of quarterly determinations of five-day biochemical oxygen demand of the wastewater (kg/m^3)
B	=	Methane generation capacity (B = 0.25 kg CH_4/kg COD and 0.06 kg CH_4/kg BOD_5)
MCF	=	Methane correction factor for anaerobic decay (0-1.0) from Table 200-2
0.001	=	Conversion factor – kg to metric tons

(2) For anaerobic processes from which biogas is recovered and not emitted, you must adjust the CH_4 emissions calculated in paragraph (g)(1) by the amount of CH_4 collected.

(3) The operator shall calculate N_2O emissions from wastewater treatment using Equation 200-24.

$$N_2O = Q \times N_{qave} \times EF_{N2O} \times 1.571 \times 0.001 \qquad \textbf{Equation 200-24}$$

Where:

N_2O	=	Emissions of N_2O (metric tons/yr)

Q	=	Volume of wastewater treated (m^3/yr)
N_{qave}	=	Average of quarterly determinations of N in effluent (kg N/m^3)
EF_{N2O}	=	Emission factor for N_2O from discharged wastewater (0.005 kg N_2O-N/kg N)
1.571	=	Conversion factor – kg N_2O-N to kg N_2O
0.001	=	Conversion factor – kg to metric tons

(4) **Oil-Water Separators.** The operator shall calculate CH_4 emissions from oil-water separators using Equation 200-25. For the CF_{NMHC} conversion factor, operators shall use either a default factor of 0.6 or species specific conversion factors determined by analysis using a sampling and analysis methodology approved by regulator.

$$CH_4 = EF_{sep} \times V_{water} \times CF_{NMHC} \times 0.001 \qquad \textbf{Equation 200-25}$$

Where:

CH_4	=	Emission of methane (metric tons/yr)
EF_{sep}	=	NMHC (non methane hydrocarbon) emission factor (kg/m^3) from Table 200-3.
V_{water}	=	Volume of waste water treated by the separator (m^3/yr)
CF_{NMHC}	=	NMHC to CH_4 conversion factor
0.001	=	Conversion factor from kg to metric tons

(h) **Equipment leaks**. **C**alculate CH_4 emissions using the method specified in either paragraph (h)(1) or (h)(2) of this section.

(1) Use process-specific methane composition data (from measurement data or process knowledge) and any of the emission estimation procedures provided in the Protocol for Equipment Leak Emissions Estimates (EPA-453/R-95-017, NTIS PB96-175401).

(2) Use Equation 200-26 of this section.

$$CH_4 = (0.4 \times N_{CD} + 0.2 \times N_{PU1} + 0.1 \times N_{PU2} + 4.3 \times N_{H2} + 6 \times N_{FGS}) \qquad \textbf{Equation 200-26}$$

Where:

CH_4	=	Annual methane emissions from equipment leaks (metric tons/year)
N_{CD}	=	Number of atmospheric crude oil distillation columns at the facility.
N_{PU1}	=	Cumulative number of catalytic cracking units, coking units (delayed or fluid), hydrocracking, and full-range distillation columns (including depropanizer and debutanizer distillation columns) at the facility.
N_{PU2}	=	Cumulative number of hydrotreating/hydrorefining units, catalytic reforming units, and visbreaking units at the facility.

N_{H2} = Total number of hydrogen plants at the facility.

N_{FGS} = Total number of fuel gas systems at the facility.

(i) **Coke Calcining.** The operator shall calculate GHG emissions according to the applicable provisions in paragraphs (i)(1) through (i)(3) of this section.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to WCI.20, you must calculate and report CO_2 emissions for coke calcining by following the CEMS Calculation Methodology specified in WCI.20. If the coke calcining unit is not equipped with CEMS must either install a CEMS that complies with the CEMS requirements in WCI.20, or follow the requirements of paragraph (i)(2) of this section.

(2) Calculate the CO_2 emissions from the coke calcining unit using Equation 200-27 of this section.

$$CO_2 = 3.664 \times \left(M_{in} \times CC_{GC} - (M_{out} + M_{dust}) \times CC_{MPC} \right) \quad \textbf{Equation 200-27}$$

Where:

CO_2 = Annual CO_2 emissions (metric tons/year).

M_{in} = Annual mass of green coke fed to the coke calcining unit from facility records (metric tons/year).

CC_{GC} = Average mass fraction carbon content of green coke from facility measurement data (metric ton carbon/metric ton green coke).

M_{out} = Annual mass of marketable petroleum coke produced by the coke calcining unit from facility records (metric tons petroleum coke/year).

M_{dust} = Annual mass of petroleum coke dust collected in the dust collection system of the coke calcining unit from facility records (metric ton petroleum coke dust/year)

CC_{MPC} = Average mass fraction carbon content of marketable petroleum coke produced by the coke calcining unit from facility measurement data (metric ton carbon/metric ton petroleum coke).

3.664 = Ratio of molecular weights, carbon dioxide to carbon

(3) For all coke calcining units, use the CO_2 emissions from the coke calcining unit calculated in paragraphs (i)(1) or (i)(2), as applicable, and calculate CH_4 and N_2O using the following methods:

(i) Calculate CH_4 emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-28 of this section.

$$CH_4 = \left(CO_2 * \frac{EmF_2}{EmF_1} \right)$$ **Equation 200-28**

Where:

CH_4 = Annual methane emissions (metric tons CH_4/year).

CO_2 = Emission rate of CO_2 calculated in paragraphs (i)(1) and (i)(2) of this section, as applicable (metric tons/year).

EmF_1 = Default CO_2 emission factor for petroleum coke (97 kg CO_2/GJ).

EmF_2 = Default CH_4 emission factor of 2.8 x 10^{-3} kg CH_4/GJ).

(ii) Calculate N_2O emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-29 of this section.

$$N_2O = \left(CO_2 * \frac{EmF_3}{EmF_1} \right)$$ **Equation 200-29**

Where:

N_2O = Annual nitrous oxide emissions (metric tons N_2O/year).

CO_2 = Emission rate of CO_2 from paragraphs (i)(1) and (i)(2) of this section, as applicable (metric tons/year).

EmF_1 = Default CO_2 emission factor for petroleum coke (97 kg CO_2/GJ)

EmF_3 = Default N_2O emission factor of 5.7 x 10^{-4} kg N_2O/GJ.

(j) **Uncontrolled Blowdown Systems**. For uncontrolled blowdown systems, you must use the methods for process vents in paragraph (b) of this section.

(k) **Loading Operations**. For crude oil, intermediate, or product loading operations for which the equilibrium vapor-phase concentration of methane is 0.5 volume percent or more, calculate CH_4 emissions from loading operations using product-specific, vapor-phase methane composition data (from measurement data or process knowledge) and the emission estimation procedures provided in Section 5.2 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources." For loading operations in which the equilibrium vapor-phase concentration of methane is less than 0.5 volume percent, you may assume zero methane emissions.

(l) **Delayed coking units.** Calculate the CH_4 emissions from the depressurization of the coking unit vessel (i.e., the "coke drum") to atmosphere using either of the methods provided in paragraphs (l)(1) or (l)(2), provided no water or steam is added to the vessel once it is vented to the atmosphere. You must use the method in paragraph (l)(1) of this section if you add water or steam to the vessel after it is vented to the atmosphere.

(1) Use the process vent method in paragraph (b) of this section and also calculate the CH_4 emissions from the subsequent opening of the vessel for coke cutting operations using Equation 200-30 of this section. If you have coke drums or

vessels of different dimensions, use Equation 200-30 for each set of coke drums or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

$$CH_4 = \left(N \times H \times \frac{(P_{CV} + 101.325)}{101.325} \times f_{void} \times \frac{\pi \times D^2}{4} \times \frac{16}{MVC} \times MF_{CH4} \times 0.001 \right) \quad \textbf{Equation 200-30}$$

Where:

CH_4	=	Annual methane emissions from the delayed coking unit vessel opening (metric tons/year).
N	=	Cumulative number of vessel openings for all delayed coking unit vessels of the same dimensions during the year.
H	=	Height of coking unit vessel (Meters).
P_{CV}	=	Gauge pressure of the coking vessel when opened to the atmosphere prior to coke cutting or, if the alternative method provided in paragraph (l)(2) of this section is used, gauge pressure of the coking vessel when depressurization gases are first routed to the atmosphere (kilopascals)
101.325	=	Assumed atmospheric pressure (kilopascals, kPa)
f_{void}	=	Volumetric void fraction of coking vessel prior to steaming based on engineering judgement (m^3 gas/m^3 of vessel);
D	=	Diameter of coking unit vessel (Meters).
16	=	Molecular weight of CH_4 (kg/kg-mole).
MVC	=	Molar volume conversion (24.06 m^3/ kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere).
MF_{CH4}	=	Average mole fraction of methane in coking vessel gas based on the analysis of at least two samples per year, collected at least four months apart (kg-mole CH_4/kg-mole gas, wet basis);
0.001	=	Conversion factor (metric ton/kg).

(2) Calculate the CH_4 emissions from the depressurization vent and subsequent opening of the vessel for coke cutting operations using Equation 200-18 of this section and the pressure of the coking vessel when the depressurization gases are first routed to the atmosphere. If you have coke drums or vessels of different dimensions, use Equation 200-30 for each set of coke drums or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

§ WCI.204 Sampling, Analysis, and Measurement Requirements

(a) Catalyst Regeneration.

(1) For FCCUs and fluid coking units, the operators shall measure the following parameters:

(A) The daily oxygen concentration in the oxygen enriched air stream inlet to the regenerator.

(B) Continuous measurements of the volumetric flow rate of air and oxygen enriched air entering the regenerator.

(C) Weekly periodic measurements of the CO_2, CO and O_2 concentrations in the regenerator exhaust gas (or continuous measurements if the equipment necessary to make continuous measurements is already in place).

(D) Daily determinations of the carbon content of the coke burned.

(E) The number of days of operation.

(2) For periodic catalyst regeneration, the operators shall measure the following parameters.

(A) The mass of catalyst regenerated in each regeneration cycle.

(B) The weight fraction of carbon on the catalyst prior to and after catalyst regeneration.

(3) For continuous catalyst regeneration in operations other than FCCUs and fluid cokers, the operators shall measure the following parameters.

(A) The hourly catalyst regeneration rate.

(B) The weight fraction of carbon on the catalyst prior to and after catalyst regeneration.

(C) The number of hours of operation.

(b) Process vents. Operators shall measure the following parameters for each process vent.

(1) The vent flow rate for each venting event from measurement data, process knowledge or engineering estimates.

(2) The molar fraction of CO_2, N_2O, and CH_4 in the vent gas stream during each venting event from measurement data, process knowledge or engineering estimates.

(3) The duration of each venting event.

(c) Asphalt Production. Operators shall measure the mass of asphalt blown.

(d) Sulphur Recovery. The operator shall measure the volumetric flow rate of acid gas to the SRU. If using source specific molar fraction value instead of the default factor, the operator shall conduct an annual test of the CO_2 content using methods approved by the Director. The operator shall submit a test plan to the regulator for approval. Once approved, the annual tests shall be conducted in accordance with the approved test plan under the supervision of the Director.

(e) Flares and Other Control Devices. The operator shall measure the following:

(1) If you have a continuous flow monitor on the flare, you must use the measured flow rates when the monitor is operational and the flow rate is within the calibrated range of the measurement device to calculate the flare gas flow. If you do not have a continuous flow monitor on the flare and for periods when the monitor is not

operational or the flow rate is outside the calibrated range of the measurement device, you must use engineering calculations, company records, or similar estimates of volumetric flare gas flow.

(2) If using the method specified in WCI.203(e)(2)(i)(A), monitor the high heat value of the flare gas daily if the flare is already equipped with the necessary measurement devices (at least weekly if not).

(3) If using the method specified in WCI.203(e)(2)(i)(B), monitor the carbon content of the flare gas daily if the flare is already equipped with the necessary measurement devices (at least weekly if not).

(f) Storage Tanks. The operator shall measure the annual throughput of crude oil, naphtha, distillate oil, asphalt, and gas oil for each storage tank using flow meters.

(g) Wastewater Treatment. Operators shall measure the following parameters.

(1) You must collect samples representing wastewater influent to the anaerobic wastewater treatment process, following all preliminary and primary treatment steps (e.g., after grit removal, primary clarification, oil-water separation, dissolved air flotation, or similar solids and oil separation processes). You must collect and analyze samples for COD or BOD_5 concentration once each calendar week.

(2) You must measure the flowrate of wastewater entering anaerobic wastewater treatment process once each calendar week. The flow measurement location must correspond to the location used to collect samples analyzed for COD or BOD_5 concentration.

(3) The quarterly nitrogen content of the wastewater.

(4) Oil-Water Separators. Operators shall measure the daily volume of waste water treated by the oil-water separators .

(h) Coke Calcining. Determine the mass of petroleum coke as required using measurement equipment used for accounting purposes. Determine the carbon content of petroleum coke as using any one of the following methods:

(1) ASTM D3176-89 (Reapproved 2002) Standard Practice for Ultimate Analysis of Coal and Coke.

(2) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants.

(3) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal

§ WCI.205 Procedures for Estimating Missing Data.

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., concentrations, flow rates, fuel heating values, carbon content values). Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For stationary combustion sources, use the missing data procedures in WCI.20.

(b) For each missing value of the heat content, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the "after" value is not obtained by the end of the reporting year, you may use the "before" value for the missing data substitution. If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(c) For missing CO_2, CO, O_2, CH_4, or N_2O concentrations, gas flow rate, and percent moisture, the substitute data values shall be the best available estimate(s) of the parameter(s), based on all available process data (e.g., processing rates, operating hours, etc.). The owner or operator shall document and keep records of the procedures used for all such estimates.

Table 200-1. Coke burn rate material balance and conversion factors

	(kg min)/(hr dSm^3%)	(lb min)/(hr dscf %)
K_1	0.2982	0.0186
K_2	2.0880	0.1303
K_3	0.0994	0.0062

Table 200-2. Default MCF Values for Industrial Wastewater

Type of Treatment and Discharge Pathway or System	Comments	MCF	Range
Untreated			
Sea, river and lake discharge	Rivers with high organic loading may turn anaerobic, however this is not considered here	0.1	0 - 0.2
Treated			
Aerobic treatment plant	Well maintained, some CH_4 may be emitted from settling basins	0	0 – 0.1
Aerobic treatment plant	Not well maintained, overloaded	0.3	0.2 – 0.4
Anaerobic digester for sludge	CH_4 recovery not considered here	0.8	0.8 – 1.0
Anaerobic reactor	CH_4 recovery not considered here	0.8	0.8 – 1.0
Anaerobic shallow lagoon	Depth less than 2 Meters	0.2	0 – 0.3
Anaerobic deep lagoon	Depth more than 2 Meters	0.8	0.8 – 1.0

For CH_4 generation capacity (B) in kg CH_4/kg COD, use default factor of 0.25 kg CH_4/kg COD.

The emission factor for N_2O from discharged wastewater (EF_{N2O}) is 0.005 kg N_2O-N/kg-N.

MCF = methane conversion factor (the fraction of waste treated anaerobically).
COD = chemical oxygen demand (kg COD/m^3).

Table 200-3. Emission Factors for Oil/Water Separators	
Separator Type	**Emission factor (EF_{sep})[a] kg NMHC/m^3 wastewater treated**
Gravity type - uncovered	1.11e-01
Gravity type - covered	3.30e-03
Gravity type – covered and connected to destruction device	0

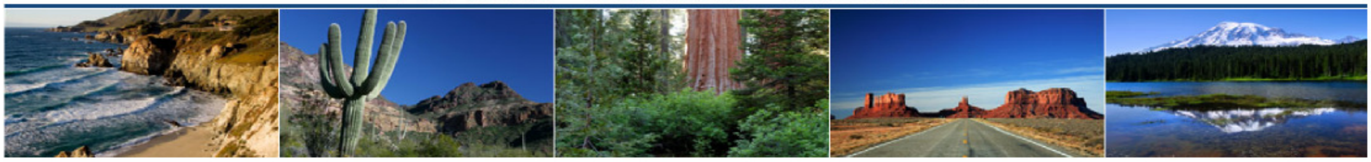
Liquid Density (lb/gal. at 60 ^oF)	8.0925
Antoine's Equation Constants (using K)	A = 75350.06
	B = 9.00346



§ WCI.210 PULP AND PAPER MANUFACTURING

§ WCI.211 Source Category Definition

The pulp and paper manufacturing source category consists of facilities that produce market pulp (i.e., stand-alone pulp facilities), manufacture pulp and paper (i.e., integrated facilities), produce paper products from purchased pulp, produce secondary fiber from recycled paper, convert paper into paperboard products (e.g., containers), or operate coating and laminating processes

§ WCI.212 Greenhouse Gas Reporting Requirements

In addition to the information required by WCI.3, the annual emissions report must contain the following information:

(a) Annual CO_2, biogenic CO_2, CH_4, and N_2O process emissions from all recovery units and kilns combined in metric tons, as specified in WCI.213.

(b) Annual CO_2 emissions from addition of makeup chemicals ($CaCO_3$, Na_2CO_3) in the chemical recovery areas of chemical pulp mills.

(c) CO_2, N_2O, and CH_4 emissions from stationary combustion units in metric tons, as specified in WCI.23.

(d) Annual consumption of carbonate in metric tons.

(e) Annual black liquor production in metric tons.

(f) Annual N_2O, and CH_4 emissions from onsite wastewater treatment plants in metric tons, as specified in WCI.200 (if required by regulation)

§ WCI.213 Calculation of GHG Emissions

Calculate emissions from each unit (i.e., kraft or soda chemical recovery furnace, sulfite chemical recovery combustion unit, stand-alone semichemical recovery combustion unit, or kraft or soda pulp mill lime kiln) as specified under paragraphs (a) through (d) of this section. CH_4 and N_2O emissions must be calculated as the sum of emissions from combustion of fossil fuels and combustion of biomass in spent liquor solids.

(a) Calculate fossil-fuel based CO_2 emissions from direct measurement of fossil fuels consumed and the methodology for stationary combustion sources specified by WCI.20 for the appropriate fuel type. For kraft or soda pulp mill lime kilns, if WCI.20 allows the use of default emission factors, use the default CO_2 emission factors listed in Table 210-1.

(b) Calculate fossil-fuel based CH_4 and N_2O emissions from direct measurement of fossil fuels consumed, default HHV, and default emission factors according to the methodology specified by WCI.20. For kraft or soda pulp mill lime kilns, use the default CH_4 and N_2O emission factors listed in Table 210-1.

(c) Calculate biogenic CO_2 emissions and emissions of CH_4 and N_2O from biomass as specified under subparagraphs (1) through (3).

(1) For kraft or soda chemical recovery furnaces, calculate emissions using Equation 210-1:

$$Emissions = Solids \times HHV \times EF$$

Equation 210-1

Where:

Emissions = Biogenic CO_2 emissions and emissions of CH_4 and N_2O from biomass (spent liquor solids) combustion (metric tons/year).
Solids = Mass of spent liquor solids combusted (metric tons/year).
HHV = Annual high heat value of spent liquor solids (GJ/kg).
EF = Default emission factor for CO_2, CH_4, and N_2O from Table 210-2 (kg/GJ)

(2) For sulfite or stand-alone semichemical chemical recovery combustion units, calculate CO_2 emissions using Equation 210-2:

$$E_{CO2} = 3.664 \times Solids \times CC$$

Equation 210-2

Where:

E_{CO2} = Biogenic CO_2 emissions from spent liquor solids combustion (metric tons/year).
3.664 = Ratio of molecular weights, CO_2 to carbon.
Solids = Mass of spent liquor solids combusted (metric tons/year).
CC = Annual carbon content of spent liquor solids (percent by weight, expressed as a decimal fraction).

(3) For sulfite or stand-alone semichemical chemical recovery combustion units, calculate emissions of CH_4 and N_2O from biomass using Equation 210-1.

(d) For make-up chemical use, calculate CO_2 emissions by using direct or indirect measurement of the quantity of chemicals added and ratios of the molecular weights of CO_2 and make-up chemicals using Equation 210-3:

$$CO_2 = \left(\left[M_{CaCO3} \times \frac{44}{100}\right] + \left[M_{Na2CO3} \times \frac{44}{105.99}\right]\right)$$

Equation 210-3

Where:

CO_2 = CO_2 emissions from make-up chemicals (metric tons/year).
M_{CaCO3} = Make-up quantity of $CaCO_3$ used for reporting year (metric tons/year).
M_{Na2CO3} = Make-up quantity of Na_2CO_3 used for reporting year (metric tons/year).
44 = Molecular weight of CO_2.
100 = Molecular weight of $CaCO_3$.
105.99 = Molecular weight of Na_2CO_3.

§ WCI.214 Monitoring Requirements

At least annually, determine the following fuel properties. If measurements are performed more frequently than annually, then fuel properties must be based on the average of the representative measurements made during the year.

(a) Determine high heat values of black liquor using Technical Association of the Pulp and Paper Industry (TAPPI) T684 om-06 "Gross High Heating Value of Black Liquor".

(b) Determine annual mass of spent liquor solids using one of the methods specified in subparagraph (1) or (2)

(1) Measure mass of annual spent liquor solids using TAPPI T650 om-05 "Solids Content of Black Liquor".

(2) Determine mass of annual spent liquor solids based on records of measurements made with an online measurement system that determines the mass of spent liquor solids fired in a chemical recovery furnace or chemical recovery combustion unit. Measure the quantity of black liquor produced each month.

(c) Determine carbon content using ASTM D5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal".

§ WCI.215 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required sample is not taken), a substitute data value for the missing parameter shall be used in the calculations, according to the requirements of paragraphs (a) through (c) of this section:

a) There are no missing data procedures for measurements of heat content and carbon content of spent pulping liquor. A re-test must be performed if the data from any annual measurements are determined to be invalid.
b) For missing measurements of the mass of spent liquor solids or spent pulping liquor flow rates, use the lesser value of either the maximum mass or fuel flow rate for the combustion unit, or the maximum mass or flow rate that the fuel meter can measure.
c) For the use of makeup chemicals (carbonates), the substitute data value shall be the best available estimate of makeup chemical consumption, based on available data (e.g., past accounting records, production rates). The owner or operator shall document and keep records of the procedures used for all such estimates.

Tables 210-1 and Table 210-2 (Option A)

Canada-specific emission factors for fossil fuel and biomass-based CO_2, CH_4 and N_2O may be supplied by the WCI to replace the U.S. based Tables 210-1 and 210-2 (Option B)

Table 210-1 (Option B-EPA Rule). Kraft Lime Kiln and Calciner Emissions Factors for Fossil Fuel-Based CO_2, CH_4, and N_2O

	Fossil Fuel-Based Emissions Factors (kg/GJ HHV)					
	Kraft Lime Kilns			Kraft Calciners		
Fuel	**CO_2**	**CH_4**	**N_2O**	**CO_2**	**CH_4**	**N_2O**
Residual Oil	72.7	0.0026	0	72.7	0.0026	0.00028
Distillate Oil	69.7			69.7		0.00038

	Biomass-Based Emissions Factors (kg/GJ HHV)		
Wood Furnish	**CO_2[a]**	**CH_4**	**N_2O**
North American Softwood	89.5	0.028	0.0047
North American Hardwood	88.8		
Bagasse	90.5		
Bamboo	88.8		
Straw	90.2		

[a] Includes emissions from both the recovery furnace and pulp mill lime kiln.

§ WCI.220 SODA ASH MANUFACTURING

§ WCI.221 Source Category Definition

A soda ash manufacturing facility is any facility with a manufacturing line that produces soda ash by one of the methods in paragraphs (a) through (c) of this section:

(a) Calcining trona.

(b) Calcining sodium sesquicarbonate.

(c) Using a liquid alkaline feedstock process that directly produces CO_2.

In the context of the soda ash manufacturing sector, “calcining” means the thermal/chemical conversion of the bicarbonate fraction of the feedstock to sodium carbonate.

§ WCI.222 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, each annual report must contain the following information

(a) CO_2 process emissions from the soda ash manufacturing facility.

(b) CO_2, CH_4 and N_2O combustion emissions must be calculated and reported under WCI.20 (General Stationary Combustion) by following the requirements of WCI.20.

(c) If a CEMS is used to measure CO_2 emissions, then you must report under this method the relevant information required under WCI.20.

(d) Annual consumption of trona or liquid alkaline feedstock for each manufacturing line (metric tons).

(e) Annual production of soda ash (metric tons).

(f) Annual quantity of generated CO_2 recycled to carbonation towers (tons), if applicable.

(g) Number of times missing data procedures were used.

§ WCI.223 Calculation of Greenhouse Gas Emissions

Calculate and report the annual process CO_2 emissions from each soda ash manufacturing line using the procedures specified in paragraph (a) or (b) of this section.

(a) For each soda ash manufacturing line that meets the conditions specified in WCI.23(e), calculate and report under this method the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Method 4 Calculation Methodology specified in WCI.23(d) and all associated requirements.

(b) For each soda ash manufacturing line that is not subject to the requirements in paragraph (a) of this section, calculate and report the process CO_2 emissions from the soda ash manufacturing line by using the procedure in either paragraphs (b)(1), (b)(2), or (b)(3) of this section; and the combustion CO_2 emissions using the procedure in paragraph (b)(4) of this section.

(1) Calculate and report under this method the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Method 4 Calculation Methodology specified in WCI.23(d) and all associated requirements for Method 4 in WCI.23(d) (General Stationary Combustion).

(2) Use either Equation 220-1 or Equation 220-2 of this section to calculate annual CO_2 process emissions from each manufacturing line that calcines trona to produce soda ash:

$$E_k = \sum_{n=1}^{12} [(IC_T)_n * (T_t)_n] * \frac{0.097}{1} \quad \text{(Eq. 220-1)}$$

$$E_k = \sum_{n=1}^{12} [(IC_{sa})_n * (T_{sa})_n] * \frac{0.138}{1} \quad \text{(Eq. 220-2)}$$

Where:

E_k	=	Annual CO_2 process emissions from each manufacturing line, k (metric tons).
$(IC_T)_n$	=	Inorganic carbon content (percent by weight, expressed as a decimal fraction) in trona input, from the carbon analysis results for month n. This represents the ratio of trona to trona ore.
$(IC_{sa})_n$	=	Inorganic carbon content(percent by weight, expressed as a decimal fraction) in soda ash output, from the carbon analysis results for month n. This represents the purity of the soda ash produced.
$(T_t)_n$	=	Mass of trona input in month n (metric tons).
$(T_{sa})_n$	=	Mass of soda ash output in month n (metric tons).
0.097/1	=	Ratio of metric ton of CO_2 emitted for each metric ton of trona.
0.138/1	=	Ratio of metric ton of CO_2 emitted for each metric ton of soda ash produced.

(3) Site-specific emission factor method. Use Equations 220-3, 220-4, and 220-5 of this section to determine annual CO_2 process emissions from manufacturing lines that use the liquid alkaline feedstock process to produce soda ash. You must conduct an annual performance test and measure CO_2 emissions and flow rates at all process vents from the mine water stripper/evaporator for each manufacturing line and calculate CO_2 emissions as described in paragraphs (b)(3)(i) through (b)(3)(iv) of this section.

(i) During the performance test, you must measure the process vent flow from each process vent during the test and calculate the average rate for the test period in metric tons per hour.

(ii) Using the test data, you must calculate the hourly CO_2 emission rate using Equation 220-3 of this section:

$$ER_{CO2} = [(C_{co2} * 10000) * 4.16 x 10^{-8} * 44] * (Q * 60) * 0.001 \qquad \text{(Eq. 220-3)}$$

Where:

ER_{CO2} = CO_2 mass emission rate (metric tons/hour).

C_{CO2} = Hourly CO_2 concentration (per cent CO_2) as determined by WCI.224(c).

10000 = Conversion factor from per cent to parts per million

4.16 x 10-8 = Conversion factor from ppm to kg-mole/dsm3 (kg-mole/dsm3/ppm).

44 = kg per kg-mole of carbon dioxide.

Q = Stack gas volumetric flow rate per minute (dsm3 per minute).

60 = Minutes per hour

0.001 = Conversion factor from kg to metric tons (metric tons/kg)

(iii) Using the test data, you must calculate a CO_2 emission factor for the process using Equation 220-4 of this section:

$$EF_{CO2} = \frac{ER_{CO2}}{V_t} \qquad \text{(Eq. 220-4)}$$

Where:

EF_{CO2} = CO_2 emission factor (metric tons CO_2/metric ton of process vent flow from mine water stripper/evaporator).

ER_{CO2} = CO_2 mass emission rate (metric tons/hour).

V_t = Process vent mass flow rate from mine water stripper/evaporator during annual performance test (metric tons/hour).

(iv) Calculate annual CO_2 process emissions from each manufacturing line using Equation 220-5 of this section:

$$E_k = EF_{CO2} * V_a * H \qquad \text{(Eq. 220-5)}$$

Where:

Ek = Annual CO2 process emissions for each manufacturing line, k (metric tons).

EF_{CO2}	=	CO_2 emission factor (metric tons CO_2/metric ton of process vent flow from mine water stripper/evaporator).
V_a	=	Annual process vent mass flow rate from mine water stripper/evaporator (metric tons/hour).
H	=	Annual operating hours for the each manufacturing line.

(4) Calculate and report under WCI.20 (General Stationary Fuel Combustion Sources) the combustion CO_2, CH_4, and N_2O emissions in the soda ash manufacturing line according to the applicable requirements of WCI.20.

§ WCI.224 Sampling, Analysis, and Measurement Requirements

Section WCI.223 provides four different procedures for emission calculations. The appropriate paragraphs (a) through (d) of this section should be used for the procedure chosen.

(a) If you determine your emissions using WCI.223(b)(2) Equation 220-1 of this subpart) you must:

(1) Determine the monthly inorganic carbon content of the trona from a weekly composite analysis for each soda ash manufacturing line, using a modified version of ASTM E359-00(Reapproved 2005)e1, Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate). ASTM E359-00(Reapproved 2005)e1 is designed to measure the total alkalinity in soda ash not in trona. The modified method of ASTM E359-00 adjusts the regular ASTM method to express the results in terms of trona. Although ASTM E359-00(Reapproved 2005) uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of trona input produced by each soda ash manufacturing line on a monthly basis using belt scales or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of trona consumed.

(b) If you calculate CO_2 process emissions based on soda ash production (WCI.223(b)(2)Equation 220-2 of this method), you must:

(1) Determine the inorganic carbon content of the soda ash (i.e., soda ash purity) using ASTM E359-00(Reapproved 2005)e1 Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate). Although ASTM E359-00(Reapproved 2005) uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of soda ash produced by each soda ash manufacturing line on a monthly basis using belt scales, by weighing the soda ash at the truck or rail load out points of your facility, or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of soda ash produced.

(c) If you calculate CO_2 emissions using the site-specific emission factor method in WCI.223(b)(3), you must:

(1) Conduct an annual performance test that is based on representative performance (i.e., performance based on normal operating conditions) of the affected process.

(2) Sample the stack gas and conduct three emissions test runs of 1 hour each.

(3) Conduct the stack test using EPA Method 3A at 40 CFR part 60, appendix A-2 to measure the CO2 concentration, Method 2, 2A, 2C, 2D, or 2F at 40 CFR part 60, appendix A-1 or Method 26 at 40 CFR part 60, appendix A-2 to determine the stack gas volumetric flow rate. All QA/QC procedures specified in the reference test methods and any associated performance specifications apply. For each test, the facility must prepare an emission factor determination report that must include the items in paragraphs (c)(3)(i) through (c)(3)(iii) of this section.

   (i) Analysis of samples, determination of emissions, and raw data.

   (ii) All information and data used to derive the emissions factor(s).

   (iii) You must determine the average process vent flow rate from the mine water stripper/evaporator during each test and document how it was determined.

(4) You must also determine the annual vent flow rate from the mine water stripper/evaporator from monthly information using the same plant instruments or procedures used for accounting purposes (i.e., volumetric flow meter).

WCI.225 Procedures for estimating missing data

For the emission calculation methodologies in WCI.223(b)(2)and (b)(3), a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., inorganic carbon content values, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in the paragraphs (a) through (d) of this section. You must document and keep records of the procedures used for all such missing value estimates.

(a) For each missing value of the weekly composite of inorganic carbon content of either soda ash or trona, the substitute data value shall be the arithmetic average of the quality-assured values of inorganic carbon contents from the week immediately preceding and the week immediately following the missing data incident. If no quality-assured data on inorganic carbon contents are available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon contents obtained after the missing data period.

(b) For each missing value of either the monthly soda ash production or the trona consumption, the substitute data value shall be the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes.

(c) For each missing value collected during the performance test (hourly CO_2 concentration, stack gas volumetric flow rate, or average process vent flow from mine water stripper/evaporator during performance test), you must repeat the annual performance test following the calculation and monitoring and QA/QC requirements under WCI.223(b)(3) and WCI.224(c).

(d) For each missing value of the monthly process vent flow rate from mine water stripper/evaporator, the substitute data value shall be the best available estimate(s) of the parameter(s), based on all available process data or the lesser of the maximum capacity of the system or the maximum rate the meter can measure.

§ WCI.230 ELECTRICITY TRANSMISSION (AND EMISSIONS FROM ELECTRICAL EQUIPMENT IN ELECTRICITY GENERATION)

§ WCI.231 Source Category Definition

Sulfur hexafluoride (SF_6) are perflurorocarbons (PFCs) are used as gaseous dielectric mediums for electric power distribution equipment, including transmission and distribution systems, substations, high-voltage circuit breakers, switches, and other electrical equipment. This category includes fugitive emissions from equipment that is located at a facility that the operator is responsible for maintaining in proper working order.

§ WCI.232 Greenhouse Gas Reporting Requirements

For each facility, the emissions data report shall include the following information:

(a) Annual greenhouse gas emissions in metric tons, reported as follows:

(1) Fugitive SF_6 emitted from equipment.

(2) Fugitive PFCs emitted from equipment

§ WCI.233 Calculation of SF_6 Emissions

SF_6 emissions must be calculated using either a mass-balance or direct measurement approach. Section (a) describes the mass balance approach; section (b) describes the direct measurement approach.

(a) Mass Balance Approach.

(1) Calculate the annual SF_6 emissions using a mass balance approach that tracks and systematically accounts for all operator uses of SF_6, as follows. Any quantity of SF_6 that cannot be accounted for is then assumed to have been emitted into the atmosphere.

(2) Calculate the change in inventory of SF_6 in storage using Equation 230-1.

$$\Delta S_{Inv} = S_{Inv-Begin} - S_{Inv-End}$$ **Equation 230-1**

Where:

ΔS_{Inv} = Change in inventory of SF_6 in storage, kilograms ("Storage" includes cylinders, gas carts, and other storage containers, but excludes equipment. Value will be negative if quantity of SF_6 increases during the year);

$S_{Inv-Begin}$ = Quantity of SF_6 in storage at the beginning of the year, kilograms;

$S_{Inv-End}$ = Quantity of SF_6 in storage at the end of the year, kilograms.

(3) Calculate the sum of all SF_6 acquired from other entities during the year either in storage containers or in equipment using Equation 230-2.

Equation 230-2

$$S_{PA} = S_{Cyl} + S_{Equip} + S_{\mathrm{Re}\,cyc-ret}$$

Where:

S_{PA}	=	Sum of all SF_6 acquired from other entities during the year either in storage containers or in equipment, kilograms;
S_{Cyl}	=	Quantity of SF_6 purchased from producers or distributors in cylinders, kilograms;
S_{Equip}	=	Quantity of SF_6 provided by equipment manufacturers with/inside equipment, kilograms;
$S_{Recyc\text{-}ret}$	=	Quantity of SF_6 returned to site after off-site recycling, kilograms.

(4) Calculate the sum of all SF_6 sold or otherwise disbursed during the year either in storage containers or in equipment using Equation 230-3.

$$S_{SD} = S_{Sales} + S_{\mathrm{Re}\,turns} + S_{Destruct} + S_{\mathrm{Re}\,cyc-off}$$

Equation 230-3

Where:

S_{SD}	=	Sum of all SF_6 sold or otherwise disbursed during the year either in storage containers or in equipment, kilograms;
S_{Sales}	=	Quantity of SF_6 sold to other entities (including gas left in equipment that is sold), kilograms;
$S_{Returns}$	=	Quantity of SF_6 returned to suppliers, kilograms;
$S_{Destruct}$	=	Quantity of SF_6 sent to destruction facilities, kilograms;
$S_{Recyc\text{-}off}$	=	Quantity of SF_6 sent off-site for recycling, kilograms.

(5) Calculate the net increase in nameplate capacity of equipment using Equation 230-4.

$$\Delta S_{Cap} = S_{Cap-new} - S_{Cap-retire}$$

Equation 230-4

Where:

ΔS_{Cap}	=	Net increase in total nameplate capacity of equipment using SF_6 in storage, kilograms ("Total nameplate capacity" refers to the full and proper charge of the equipment rather than to the actual charge, which may reflect leakage.);
$S_{Cap\text{-}new}$	=	Total nameplate capacity (proper full charge) of new equipment, kilograms;
$S_{Cap\text{-}retire}$	=	Total nameplate capacity (proper full charge) of retired or sold equipment, kilograms.

(6) Calculate total annual emissions using Equation 230-5.

$$S = \left(\Delta S_{Inv} + S_{PA} - S_{SD} - \Delta S_{Cap}\right) / 1{,}000 \qquad \textbf{Equation 230-5}$$

Where:

S	=	Annual SF_6 emissions, metric tons;
ΔS_{Inv}	=	Change in inventory of SF_6 in storage, kilograms ("Storage" includes cylinders, gas carts, and other storage containers, but excludes equipment. Value will be negative if quantity of SF_6 increases during the year);
S_{PA}	=	Sum of all SF_6 acquired during the year either in storage containers or in equipment, kilograms;
S_{SD}	=	Sum of all SF_6 sold or otherwise disbursed during the year either in storage containers or in equipment, kilograms;
ΔS_{Cap}	=	Net increase in total nameplate capacity of equipment using SF_6 in storage, kilograms ("Total nameplate capacity" refers to the full and proper charge of the equipment rather than to the actual charge, which may reflect leakage.);
1,000	=	Factor to convert kilograms to metric tons.

(b) Direct Measurement Approach.

SF_6 emissions are estimated by directly measuring the mass of SF_6 added to electrical equipment during operation (operation phase) and the amount of SF_6 collected from any decommissioned equipment (decommissioning phase).

In the operation phase, SF_6 added to equipment can be measured using one of two methods: automated mass-flow measurement or weigh-scale measurement. In automated mass-flow measurement, mass-flow meters attached to electrical equipment directly measure the amount of SF_6 added to equipment. In weigh-scale measurement, an SF_6 cylinder is measured before and after its contents are added to electrical equipment, the difference being equal to the SF_6 added to the equipment. Annual SF_6 emissions for both methods are calculated according to Equation 230-6.

$$S_O = \sum_{i}^{N} s_i \qquad \textbf{Equation 230-6}$$

Where:

S_O	=	Annual SF_6 emissions during operation phase, kilograms;
N	=	Number of SF_6 additions in a given year;
s_i	=	SF_6 added to equipment during 'i'th addition, kilograms.

Annual SF_6 emissions during the decommissioning phase are calculated according to Equation 230-7.

$$S_D = \sum_{i}^{N} (NC_i - S_i) \qquad \textbf{Equation 230-7}$$

Where:

S_D = Annual SF_6 emissions during decommissioning phase, kilograms;

N = Number of equipment decommissioned in a given year;

NC_i = Nameplate capacity of 'i'th decommissioned equipment, kilograms;

S_i = SF_6 collected from 'i'th decommissioned equipment, kilograms.

Total annual SF_6 emissions are calculated as the sum of SF_6 emissions from equipment operation and decommissioning, according to Equation 230-8.

Equation 230-8

$$S = \frac{S_O + S_D}{1{,}000}$$

Where:

S = Annual SF_6 emissions during, metric tons;
S_O = Annual SF_6 emissions during operation phase, kilograms;
S_D = Annual SF_6 emissions during decommissioning phase, kilograms.

(c) The methods in either paragraph (a) or (b) of this section shall be used to estimate emissions of PFCs from power transformers, substituting the relevant PFC(s) for SF6 in equation 230-5 or 230-8.

§ WCI.234 Sampling, Analysis, and Measurement Requirements

Calibration of equipment used to measure the mass of SF_6 used for top-ups to electrical equipment must be conducted as specified in paragraphs (a) and (b) of this section.

a) For automated mass-flow measurement, equipment must be calibrated according to regulation.

b) For weigh-scale measurement, equipment must be calibrated every 6 months by weighing objects of pre-determined mass and zeroing the weigh scale accordingly.

§ WCI.235 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Replace missing data, if needed, based on data from equipment with a similar nameplate capacity for SF6 and PFC, and from similar equipment repair, replacement, and maintenance operations.

§ WCI.240 ZINC PRODUCTION

§ WCI.241 Source Category Definition

The zinc production category includes three primary production processes used to produce zinc (i.e., electro-thermic distillation, pyrometallurgical, and electrolytic). In addition, secondary zinc production is also included in this category.

§ WCI.242 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of CO_2 at the facility level (metric tons).

(b) Annual quantities of each carbon-containing input material used (metric tons).

(c) Carbon content of each carbon-containing input material used (metric tons C/metric ton reducing agent).

(d) Inferred waste-based carbon-containing material emission factor (if waste-based reducing agent quantification method used).

(e) If you use the missing data procedures in WCI.245(b), you must report how the monthly mass of carbon-containing materials with missing data was determined and the number of months the missing data procedures were used.

(f) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit. You must report these emissions under WCI.20 (General Stationary Fuel Combustion Sources), by following the requirements of WCI.20.

§ WCI.243 Calculation of CO_2 Emissions

Calculate total CO_2 emissions as specified under paragraph (a) or (b) of this section.

(a) Determine facility CO_2 emissions using continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(b) Calculate total CO_2 emissions using Equation 240-1. Specific materials that contribute less than 1 percent of the total carbon into the process are being considered to not be included in the calculation using Equation 240-1.

$$E_{CO_2} = \sum_i (Q_i \times C_i) \times 3.664 \qquad \textbf{Equation 240-1}$$

Where:

E_{CO2} = Annual CO_2 emissions from carbon-containing materials (metric tons);

Q_i = Annual quantity of carbon-containing material *i* (metric tons);

C_i = Carbon content of carbon-containing material *i* (metric tons C/metric ton process input);

3.664 = Stoichiometric conversion factor from C to CO_2.

§ WCI.244 Sampling, Analysis, and Measurement Requirements

The annual mass of each solid carbon-containing input material consumed shall be determined by summing the monthly mass for the material determined for each month of the calendar year. The monthly mass may be determined using facility instruments, procedures, or records used for accounting purposes, including either direct measurement of the quantity of the material consumed or by calculations using process operating information.

The average carbon content of each material consumed shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For zinc-bearing materials, use ASTM E1941-04 "Standard Test Method for Determination of Carbon in Refractory and Reactive Metals and Their Alloys".
(2) For carbonaceous reducing agents and carbon electrodes, use ASTM D5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal".
(3) For flux materials (i.e., limestone or dolomite), use ASTM C25-06 "Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime".
(4) For waste-based carbon-containing material, determine carbon content by operating the smelting furnace both with and without the waste-reducing agents while keeping the composition of other material introduced constant.
    i. To ensure representativeness of waste-based reducing agent variability, the specific testing plan (e.g. number of test runs, other process variables to keep constant, timing of runs) for these trials must be approved by the jurisdiction

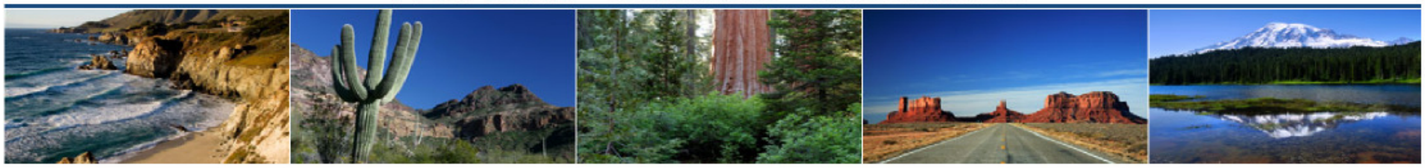
(b) Obtain carbon content from material vendor or supplier.

§ WCI.245 Procedures for Estimating Missing Data

For the carbon input procedure in WCI.243, a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., raw materials carbon content values, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

a) For missing records of the carbon content of inputs for facilities that estimate emissions using the carbon input procedure in WCI.243; 100 percent data availability is required. You must repeat the test for average carbon contents of inputs according to the procedures in WCI.245(b) if data are missing.

b) For missing records of the annual mass of carbon-containing inputs using the carbon input procedure in WCI.243, the substitute data value must be based on the best available estimate of the mass of the input material from all available process data or information used for accounting purposes, such as purchase records.



§ WCI.260 Nickel and Copper Metal Production

§ WCI.261 Source Category Definition

The nickel and copper metal production category includes process-related sources at nickel and copper metal smelting and refining facilities. Metals addressed in other categories (i.e., iron and steel, ferroalloys, aluminum, magnesium, lead, and zinc) are not included in this category.

The nickel and copper metal production category includes three main processes that produce CO_2 emissions: removal of impurities from nickel or copper ore concentrate using carbonate flux reagents (i.e., limestone [$CaCO_3$] or dolomite [$CaCO_3 \cdot MgCO_3$]), the use of other reducing agents to extract metals from their oxides (e.g., metallurgical coke, coal, natural gas, etc.), and the use of material (e.g., coke) for slag cleaning and the consumption of graphite or carbon electrodes in electric arc furnaces. It is important to distinguish between fuels used for combustion and fuels used as reducing agents; only fuels used as reducing agents should be included in the base metal production category. Fuels used for combustion are reported in WCI.020.

§ WCI.262 Greenhouse Gas Reporting Requirements

In addition to the information required by the Reporting Regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of CO_2 at the facility level (metric tons).

(b) Annual quantities of each carbonate flux reagent used (metric tons).

(c) Fractional purity of each carbonate flux reagent used (metric tons carbonate/metric tons raw material).

(d) Annual quantities of other reducing agents used (metric tons).

(e) Carbon content of other reducing agent used or material used for slag cleaning (metric tons C/metric ton reducing agent or material for slag cleaning).

(f) Annual quantity of ore processed (metric tons).

(g) Carbon content of ore processed (metric tons C/metric ton ore).

§ WCI.263 Calculation of CO_2 emissions

Calculate total CO_2 emissions as specified under paragraph (a) through (d) of this section.

(a) Calculate CO_2 emissions from carbonate flux reagents using Equation 260-1.

$$E_{cf} = Q_{ls} \times f_{ls} \times \left(\frac{44}{100}\right) + Q_d \times f_d \times \left(\frac{88}{184}\right)$$ **Equation 260-1**

Where:

E_{cf} = Annual CO_2 emissions from carbonate flux reagents (metric tons);

Q_{ls} = Annual quantity of limestone consumed (metric tons);

f_{ls} = Fractional purity of limestone (metric tons $CaCO_3$/metric tons of raw material);

44/100 = Stoichiometric conversion factor from $CaCO_3$ to CO_2;

Q_d = Annual quantity of dolomite consumed (metric tons);

f_d = Fractional purity of dolomite (metric tons $CaCO_3 \cdot MgCO_3$/metric tons of raw material);

88/184 = Stoichiometric conversion factor from $CaCO_3 \cdot MgCO_3$ to CO_2.

(b) Calculate CO_2 emissions from other reducing agents or material used in slag cleaning using Equation 260-2.

Equation 260-2

Where:

E_{ra} = Annual CO_2 emissions from other reducing agents or material used for slag cleaning (metric tons);

Q_a = Annual quantity of other reducing agents or material used for slag cleaning (metric tons);

C_a = Carbon content of other reducing agents or material used for slag cleaning (metric tons C/metric ton of reducing agent or material used for slag cleaning);

3.664 = Stoichiometric conversion factor from C to CO_2.

(c) Calculate CO_2 emissions from release of carbon from metal ores using Equation 260-3.

$$E_{ore} = Q_{ore} \times C_{ore} \times 3.664$$ **Equation 260-3**

Where:

E_{ore} = Annual process CO_2 emissions from metal ore, tonnes

Q_{ore} = Annual quantity of nickel or copper metal ore consumed (metric tons);

C_{ore} = Carbon content of nickel or copper metal ore (metric tons C/metric ton of nickel or copper ore);

3.664 = Stoichiometric conversion factor from C to CO_2.

(d) Calculate CO_2 emissions from carbon electrode consumption in electric arc furnaces (EAFs) using Equation 260-4.

$$E_{ce} = Q_{ce} \times C_{ce} \times 3.664$$ **Equation 260-4**

Where:

E_{ce}	=	Annual CO_2 emissions from carbon electrode consumption in EAFs (metric tons);
Q_{ce}	=	Quantity of carbon electrodes consumed (metric tons);
C_{ce}	=	Carbon content of carbon electrodes (metric tons C/metric ton carbon electrodes);
3.664	=	Stoichiometric conversion factor from C to CO_2.

§ WCI.264 Sampling, analysis, and measurement requirements

The annual mass of each solid carbon-containing input material consumed shall be determined using facility instruments, procedures, or records used for accounting purposes, including either direct measurement of the quantity of the material consumed or by calculations using process operating information.

The average carbon content of each material consumed shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For coal and coke, use ASTM D5373-08 “Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal and Coke”.

(2) For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291-02 (Reapproved 2007) “Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants”, ultimate analysis of oil or computations based on ASTM D3238-95 (Reapproved 2005) and either ASTM D2502-04 or ASTM D2503-92 (Reapproved 2007).

(3) For gaseous fuels, use ASTM D1945-03 or ASTM D1946-90 (Reapproved 2006).

(4) For carbonate flux reagents (i.e., limestone and dolomite), use ASTM C25-06 “Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime”.

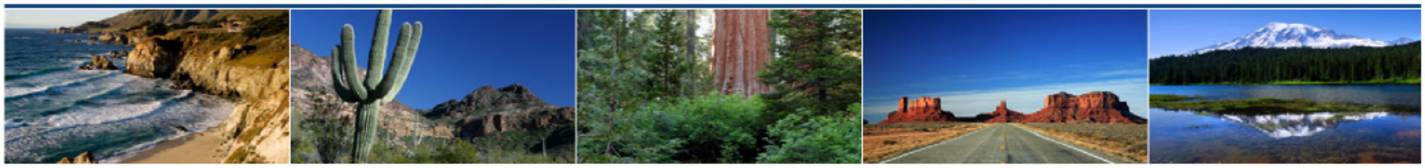
(b) Obtain carbon contents of the material, including carbon electrodes, from the vendor or supplier.

§ WCI.265 Procedures for Estimating Missing Data

For the carbon input procedure in WCI.263, a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., raw materials carbon content values, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing records of the carbon content of inputs for facilities that estimate emissions using the carbon input procedure in WCI.263; 100 percent data availability is required. You must repeat the test for average carbon contents of inputs according to the procedures in WCI.264 if data are missing.

(b) For missing records of the annual mass of carbon-containing inputs using the carbon input procedure in WCI.263, the substitute data value must be based on the best available estimate of the mass of the input material from all available process data or information used for accounting purposes, such as purchase records.



§ WCI.270 FERROALLOY PRODUCTION

§ WCI.271 Source Category Definition

Ferroalloy production consists of any facility that uses pyrometallurgical techniques to produce any of the following metals: ferrochromium, ferromanganese, ferromolybdenum, ferronickel, ferrosilicon, ferrotitanium, ferrotungsten, ferrovanadium, silicomanganese, or silicon metal.

§ WCI.272 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual process CO2 emissions (metric tons) from each electric arc furnace (EAF) used in the production of any ferroalloy listed in §WCI.271.

(b) Annual process CH4 emissions (metric tons) from each electric arc furnace (EAF) used in the production of any ferroalloy listed in Table 270-1 (i.e., ferrosilicon [65%, 75%, or 90%] or silicon metal.

(c) CO2, N2O, and CH4 emissions from stationary combustion units as specified in §WCI.23.

(d) Annual facility ferroalloy product production capacity (metric tons).

(e) Annual production for each ferroalloy product from each EAF (metric tons).

(f) Total number of EAFs at facility used for production of ferroalloy products.

(g) Identification number of each EAF

(h) Annual material quantity for each material included for the calculation of annual process CO2 emissions for each EAF.

(i) Annual average of the carbon content determinations for each material included for the calculation of annual process CO2 emissions for each EAF.

(j) Method used for determination of carbon content for each material reported (e.g., supplier provided information, representative samples analyses, etc.)

(k) If missing data procedures used (§WCI.275), how monthly mass of carbon-containing inputs and output with missing data was determined and the number of months the missing data procedures were used.

§ WCI.273 Calculation of GHG Emissions

(a) Process CO2 emissions. Determine process CO_2 emissions as specified under either paragraph (1) or (2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in §WCI.23(d).

(2) Calculation methodologies specified in paragraph (b) of this section.

(b) Process CO_2 Emissions Calculation Methodology. Calculate electric arc furnace (EAF) CO_2 emissions using the mass balance approach specified in paragraphs (b)(1) and (b)(2). Specific process inputs or outputs that contribute less than 1 percent of the total carbon into or out of the process do not have to be includes in the paragraph (b)(1) and (b)(2) mass balances

(1) Calculate EAF CO_2 emissions using Equation 270-1:

$$E_{EAF} = \left[(RA \times C_{RA}) + (EL \times C_{EL}) + (Ore \times C_{Ore}) + (FL \times C_{FL}) - (PR \times C_{PR}) - (NP \times C_{NP})\right] \times 3.664$$

Equation 270-1

Where:

E_{EAF} = Annual CO_2 emissions from EAF (metric tons);
RA = Annual mass of reducing agent charged or introduced to EAF (metric tons);
C_{RA} = Carbon content of reducing agent (metric tons C/metric tons reducing agent);
EL = Annual mass of carbon electrodes consumed (metric tons);
C_{EL} = Carbon content of carbon electrodes (metric tons C/metric tons carbon electrode);
Ore = Annual mass of ore charged to EAF (metric tons);
C_{Ore} = Carbon content of ore (metric tons C/metric tons carbon electrode);
FL = Annual mass of flux materials charged or introduced to EAF (metric tons);
C_{FL} = Carbon content of flux materials (metric tons C/metric tons flux material);
PR = Annual mass of alloy product tapped from EAF (metric tons);
C_{PR} = Carbon content of alloy product (metric tons C/metric tons alloy product);
NP = Annual mass of outgoing non-product material removed from EAF (metric tons);
C_{NP} = Carbon content of outgoing non-product material (metric tons C/metric tons non-product);
3.664 = Conversion factor from metric tons of C to metric tons of CO_2.

(2) Determine combined annual CO_2 emissions from all EAFs at the facility using Equation 270-2:

$$E_{CO2-Fac} = \sum_{1}^{k} E_{EAF-k}$$ **Equation 270-2**

Where:

$E_{CO2\text{-}Fac}$ = Annual process CO_2 emissions from EAFs at facility used for the production of any ferroalloy listed in listed in §WCI.271 (metric tons).
$E_{EAF\text{-}k}$ = Annual process CO_2 emissions calculated from EAF *k* using Equation 270-1 (metric tons).
k = Total number of EAFs at facility used for the production of any ferroalloy listed in §WCI.271 (metric tons).

(c) Process CH_4 Emissions Calculation Methodology. For any ferroalloy listed in Table 270-1, calculate emissions using procedure specified in paragraphs (c)(1) and (c)(2).

(1) For each EAF, calculate annual CH_4 emissions using Equation 270-3:

$$E_{CH4} = \sum_{1}^{i} \left(M_i \times EF_i \right) \qquad \textbf{Equation 270-3}$$

Where:

E_{CH4} = Annual process CH_4 emissions from an individual EAF (metric tons).
M_i = Annual mass of alloy product *i* produced in the EAF (metric tons).
EF_i = CH_4 emission factor for alloy product *i* from Table 270-1 (metric ton CH_4/ metric ton of alloy product *i*).

(2) Determine combined annual CH_4 emissions from all EAFs at the facility using Equation 270-4:

$$E_{CH4-Fac} = \sum_{1}^{j} E_{CH4-j} \qquad \textbf{Equation 270-4}$$

Where:

$E_{CH4-Fac}$ = Annual process CH_4 emissions from EAFs at facility used for the production of ferroalloys listed in Table 270-1 (metric tons).
E_{CH4-j} = Annual process CH_4 emissions calculated from EAF *j* using Equation 270-3 (metric tons).
j = Total number of EAFs at facility used for the production of ferroalloys listed in Table 270-1.

§ WCI.274 Sampling, Analysis, and Measurement Requirements

The annual mass of each material used in the §WCI.273 mass balance methodologies shall be determined using plant instruments used for accounting purposes, including either direct measurement of the quantity of material used in the process or by calculations using process operating information.

The average carbon content of each material used shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For metal ore and alloy product, use ASTM E1941-04 “Standard Test Method for Determination of Carbon in Refractory and Reactive Metals and Their Alloys”.

(2) For carbonaceous reducing agents and carbon electrodes, use ASTM D5373-08 “Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal”.

(3) For flux materials (e.g., limestone, dolomite, etc.), use ASTM C25-06 “Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime”.

(b) Obtain carbon content from material vendor or supplier.

§ WCI.275 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. Records must be documented and kept of the procedures used for all such estimates.

(a) If CO_2 emissions for EAFs are estimated using the carbon mass balance in §WCI.273(b)(1), 100 percent data availability is required for the carbon content of the input and output materials. The test for average carbon contents according to §WCI.274 must be repeated if data are missing.

(b) For each missing value of monthly mass of carbon-containing inputs and outputs, the substitute data value must be based on the best available estimate of the mass of inputs and outputs from all available process data or data used for accounting purposes.

(c) If CH_4 emissions for EAFs are required to be calculated, the estimate is based on an annual quantity of certain alloy products, so 100 percent data availability is required.

Table 270-1 —Electric Arc Furnace (EAF) CH_4 Emission Factors.

	CH4 Emission Factor (metric ton CH_4 per metric ton product)		
	EAF Operation		
Alloy product produced in EAF	**Batch-Charging**	**Sprinkle-Charging[a]**	**Sprinkle-Charging and >750°C[b]**
Silicon metal	0.0015	0.0012	0.0007
Ferrosilicon 90%	0.0014	0.0011	0.0006
Ferrosilicon 75%	0.0013	0.0010	0.0005
Ferrosilicon 65%	0.0013	0.0010	0.0005

[a] Sprinkle-charging is charging intermittently every minute.

[b] Temperature measured in off-gas channel downstream of the furnace hood.

§ WCI.280 MOBILE EQUIPMENT AT FACILITIES

§ WCI.281 Source Category definition

The mobile equipment at facilities category includes:

(a) Mobile equipment used for the on-site transportation or movement of substances, materials or products, and

(b) Other mobile equipment such as tractors, mobile cranes, log transfer equipment, mining machinery, graders, backhoes and bulldozers, and other industrial equipment,

but does not include an on road vehicle, an aircraft or a marine vessel.

For clarity, an on-road vehicle means a motor vehicle that:

(a) Can exceed a speed of 40 kilometers per hour on a level paved surface, and

(b) Has features customarily associated with safe and practical highway use such as a reverse gear (unless the vehicle is a motorcycle), a differential and safety features required by federal or provincial laws,

but does not include a vehicle that exhibits features that render its use on a highway unsafe, impractical or highly unlikely, such as tracked road contact or inordinate size.

Mobile equipment that is part of normal facility operations that are operated by contractors is also included as it is managed or controlled by the facility.

§ WCI.282 Greenhouse Gas Reporting Requirements

In addition to the information required by the British Columbia Reporting Regulation, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2, CO_2 from biomass, CH_4, and N_2O at the facility level by fuel type (including differentiation of biodiesel and ethanol from conventional fuel types) (metric tons).

(b) Annual and quarterly quantities of fuel used by fuel type (including differentiation of biodiesel and ethanol from conventional fuel types) (litres) from the sum of mobile equipment at the facility.

§ WCI.283 Calculation of CO_2 Emissions

Calculate the annual CO_2 mass emissions from mobile equipment using the procedures in paragraph (a),(b), or (c), as appropriate.

(a) If fossil fuel quantities are measured, calculate total CO_2 emissions using Equation 280-1.

$$E_{i,CO2} = Q_i \times EF_i$$

Equation 280-1

Where:

$E_{i,CO2}$ = Quarterly CO_2 emissions from mobile equipment for fuel *i* (metric tons);

Q_i = Quarterly quantity of fuel *i* used in mobile equipment (litres);

EF_i = Emission factor for the fuel (metric tons CO_2e/litre, required emission factors provided in WCI.020).

(b) If fossil fuel quantities are not measured, use hours of operation for each mobile equipment to calculate total CO_2 emissions using Equations 280-2 and 280-3.

$$E_{i,k,CO2} = (h_{i,k} \times hp_{i,k} \times LF_{i,k} \times BSFC_{i,k}) \times EF_{i,CO2}$$ **Equation 280-2**

$$E_{Total,i,CO2} = \sum_k E_{i,k,CO2}$$ **Equation 280-3**

Where:

$E_{i,k,CO2}$ = Quarterly CO_2 emissions from mobile equipment *k* for fuel *i* (metric tons);

$h_{i,k}$ = Quarterly hours of operation for mobile equipment *k* for fuel *i* (hours);

$hp_{i,k}$ = Rated equipment horsepower for mobile equipment *k* for fuel *i* (horsepower);

$LF_{i,k}$ = Load factor for mobile equipment *k* for fuel *i* (unitless; ranges between 0 and 1);

$BSFC_{i,k}$ = Brake-specific fuel consumption for mobile equipment *k* for fuel *i* (litres/horsepower-hour);

$EF_{i,CO2}$ = Emission factor for fuel *i* (metric tons CO_2e/litre, required emission factors provided in WCI.020);

$E_{Total,i,CO2}$ = Total quarterly CO_2 emissions for fuel *i* (metric tons).

(c) CO_2 Emissions Calculation Methodology for Mixtures of Biomass Fuel and Fossil Fuel. Calculate biomass and non-biomass CO_2 emissions as specified in paragraph (1) of this section.

(1) The owner or operator that combusts fuels or fuel mixtures where there is a mixture of biofuel (i.e. biodiesel and ethanol) and other fuels shall determine the portion of the biofuel used by broad fuel category (i.e. gasoline and diesel) and use the appropriate emission factors for each of the biofuel and the conventional fuel. When reporting emissions, CO_2 from the biomass component of biofuels shall be reported separately from CO_2 from fossil fuels.

§ WCI.284 Calculation of CH_4 and N_2O Emissions

Calculate the annual CH_4 and N_2O mass emissions from mobile equipment using the procedures in paragraph (a) or (b), as appropriate. Annual emissions for each fuel type and GHG are calculated as the sum of the quarterly emissions. Annual emissions are reported by fuel and by GHG.

(a) If fossil fuel quantities are measured, calculate total CH_4 and N_2O emissions using Equation 280-4 and the emission factors provided in WCI.020.

$$E_{i,g} = Q_i \times EF_{i,g} \times \left(\frac{1}{10^6}\right) \qquad \textbf{Equation 280-4}$$

Where:

$E_{i,g}$ = Quarterly emissions of greenhouse gas *g* (CH_4 or N_2O) from mobile equipment for fuel *i* (metric tons);

Q_i = Quarterly quantity of fuel *i* (litres);

$EF_{i,g}$ = Greenhouse gas *g* (CH_4 or N_2O) mobile equipment emission factor for fuel *i* (grams/litre) (required emission factors provided in WCI.020);

$(1/10^6)$ = Conversion factor from grams to metric tons.

(b) If fossil fuel quantities are not measured, use hours of operation for each mobile equipment to calculate total CH_4 or N_2O emissions using Equations 280-5 and 280-6.

$$E_{i,k,g} = \left(h_{i,k} \times hp_{i,k} \times LF_{i,k} \times BSFC_{i,k}\right) \times EF_{i,g} \times \left(\frac{1}{10^6}\right) \qquad \textbf{Equation 280-5}$$

$$E_{Total,i,g} = \sum_k E_{i,k,g} \qquad \textbf{Equation 280-6}$$

Where:

$E_{i,k,g}$ = Quarterly greenhouse gas *g* (CH_4 or N_2O) emissions from mobile equipment *k* for fuel *i* (metric tons);

$h_{i,k}$ = Quarterly hours of operation for mobile equipment *k* for fuel *i* (hours);

$hp_{i,k}$ = Rated equipment horsepower for mobile equipment *k* for fuel *i* (horsepower);

$LF_{i,k}$ = Load factor for mobile equipment *k* for fuel *i* (unitless; ranges between 0 and 1);

$BSFC_{i,k}$ = Brake-specific fuel consumption for mobile equipment *k* for fuel *i* (litres/horsepower-hour);

$EF_{i,g}$ = Emission factor for greenhouse gas *g* (CH_4 or N_2O) for fuel *i* (grams/litre, required emission factors provided in WCI.020);

$(1/10^6)$	=	Conversion factor from grams to metric tons;
$E_{Total,i,g}$	=	Total quarterly emissions greenhouse gas *g* (CH_4 or N_2O) for fuel *i* (metric tons).

§ WCI.285 Sampling, Analysis, and Measurement Requirements

Fuel use and emission factors shall be determined as specified under paragraphs (a),(b) and (c) of this section.

(a) For biofuels, the portion(s) of ethanol or biodiesel from vendor specifications.

(b) For conventional fuels and biofuels, required emission factors listed in WCI.020.

(c) Fuel volumes used shall be determined by vendor receipts, dipstick measurement or other appropriate means on a quarterly basis, starting on January 1 of the calendar year.

§ WCI.300 PETROCHEMICAL MANUFACTURING

§ WCI.301 Source Category Definition

(a) The petrochemical manufacturing source category consists of any facility that manufacturers petrochemicals, including acrylonitrile, carbon black, propylene, ethylene, ethylene dichloride, ethylene oxide, or methanol, from feedstocks derived from petroleum, or petroleum and natural gas liquids.

(b) A process that produces a petrochemical as a byproduct is not part of the petrochemical production source category.

(c) A facility that makes methanol, hydrogen, and/or ammonia from synthesis gas should report under this section if the annual mass of methanol produced exceeds the individual annual mass production levels of both hydrogen recovered as product and ammonia. The facility should report under WCI.130 (Hydrogen Production) if the annual mass of hydrogen recovered as product exceeds the individual annual mass production levels of both methanol and ammonia. The facility should report under WCI.80 (Ammonia Manufacturing) if the annual mass of ammonia produced exceeds the individual annual mass production levels of both hydrogen recovered as product and methanol.

(d) A direct chlorination process that is operated independently of an oxychlorination process to produce ethylene dichloride is not part of the petrochemical production source category.

(e) A process that produces a petrochemical from bio-based feedstock is not part of the petrochemical production source category.

§ WCI.302 Greenhouse Gas Reporting Requirements

In addition to the information required by WCI.3, the annual emissions report must contain the following information:

(a) CO_2, N_2O, and CH_4 emissions from combustion of fuels in the stationary combustion units in metric tons, as specified in WCI.20.

(b) CO_2, N_2O, and CH_4 emissions from flares in metric tons for facilities complying with either WCI.303(a)(2) or WCI.303(c).

(c) CO_2, N_2O, and CH_4 process emissions from vents in metric tons for facilities complying with WCI.303(a)(3).

(d) CO_2, N_2O, and CH_4 process emissions from equipment leaks in metric tons for facilities complying with WCI.303(a)(4).

(e) CO_2 process emissions in metric tons for facilities complying with WCI.303(b).

(f) CO_2, N_2O, and CH_4 process emissions from ethylene production facilities in metric tons for facilities complying with WCI.303(c).

(g) Annual consumption of feedstock by type for all feedstocks that result in GHG emissions in cubic meters for gases and liquids, metric tons for solid fuels.

§ WCI.303 Calculation of GHG Emissions

Calculate GHG emissions using one of the methods in paragraphs (a), (b), or (c):

(a) **Method 1:** Calculate the GHG emissions from petrochemical production processes using the methods specific in paragraphs (a)(1) through (a)(3) of this section.

(1) For flares, calculate CO_2, CH_4 and N_2O emissions using the methods specified in WCI.203(e).

(2) For combustion devices other than flares, calculate CO_2, CH_4 and N_2O emissions resulting from the combustion of fuels and process off-gas as specified in paragraphs (a)(2)(i) through (a)(2)(iii):

(i) Calculate CO_2 emissions from fuels and process off-gas in accordance with the methods in specified in WCI.23.

(ii) Calculate CH_4 and N_2O emissions from combustion of fuels using the applicable methods in WCI.24. Use the appropriate default emission factors for CH_4 and N_2O from Tables 20-2, 20-4, 20-6, and 20-7.

(iii) Calculate CH_4 and N_2O emissions from process off-gas using the applicable method in WCI.24. Use the emission factors of 2.8×10^{-3} kg/GJ for CH_4 and 5.7×10^{-4} kg/GJ for N_2O.

(3) Calculate the emissions from process vents using the method specified in WCI.203(b) for each process vent that can be reasonably expected to contain greater than 2 percent by volume CO_2 or greater than 0.5 percent by volume of CH_4 or greater than 0.01 percent by volume (100 parts per million) of N_2O.

(4) Calculate the emissions from equipment leaks using the method specified in WCI.203(h)(1).

(b) **Method 2:** Calculate the emissions of CO_2 from each process unit, for each calendar month as described in paragraphs (b)(1) through (b)(5) of this section.

(1) For each gaseous and liquid feedstock and product, measure the volume or mass used or produced each calendar month with a flow meter. Alternatively, for liquids, you may calculate the volume used or collected in each month based on measurements of the liquid level in a storage tank at least once per month (and just prior to each change in direction of the level of the liquid). Fuels used for combustion purposes are not considered to be feedstocks. The emissions from the combustion of fuels (other than process off-gas) in stationary combustion units must be calculated in accordance with the methods specified in WCI.23 for CO_2 and the methods specified in WCI.24 for CH_4 and N_2O.

(2) For each solid feedstock and product, measure the mass used or produced each calendar month.

(3) Collect a sample of each feedstock and product at least once per month and determine the carbon content of each sample. Alternatively, you may use the results of analyses conducted by a fuel or feedstock supplier, provided the sampling and analysis is conducted at least once per month. If multiple valid carbon content measurements are made during the monthly measurement period, average them arithmetically.

(4) If you determine that the monthly average concentration of a specific compound in a feedstock or product is greater than 99.5 percent by volume (or mass for liquids and solids), then as an alternative to the sampling and analysis specified in paragraph (b)(3) of this section, you may calculate the carbon content assuming 100 percent of that feedstock or product is the specific compound during periods of normal operation. You must maintain records of any determination made in accordance with this paragraph (b)(4) along with all supporting data, calculations, and other information. This alternative may not be used for products during periods of operation when off-specification product is produced. You must reevaluate determinations made under this paragraph (b)(4) after any process change that affects the feedstock or product composition. You must keep records of the process change and the corresponding composition determinations. If the feedstock or product composition changes so that the average monthly concentration falls below 99.5 percent, you are no longer permitted to use this alternative method.

(5) Calculate the CO_2 mass emissions for each petrochemical process unit using Equations 300-2 through 300-5 of this section.

(i) <u>Gaseous feedstocks and products</u>. Use Equation 300-1 of this section to calculate the net annual carbon input or output from gaseous feedstocks and products. Note that the result will be a negative value if there are no gaseous feedstocks in the process but there are gaseous products.

$$C_g = \sum_{n=1}^{12} [\sum_{i=1}^{j\ or\ k} [(F_{gf})_{i,n} * (CC_{gf})_{i,n} * \frac{(MW_f)_i}{MVC} - (P_{gp})_{i,n} * (CC_{gp})_{i,n} * \frac{(MW_p)_i}{MVC}]]$$

Equation 300-1

Where:

C_g	=	Annual net contribution to calculated emissions from carbon (C) in gaseous materials (kilograms/year, kg/yr).
$(F_{gf})_{i,n}$	=	Volume of gaseous feedstock i introduced in month “n” (m^3).
$(CC_{gf})_{i,n}$	=	Average carbon content of the gaseous feedstock i for month “n” (kg C per kg of feedstock).
$(MW_f)_i$	=	Molecular weight of gaseous feedstock i (kg/kg-mole).
MVC	=	Molar volume conversion factor (24.06 m^3/kg-mole for STP of 20°C and 1 atmosphere, or 23.67 m^3/kg-mole for STP of 15.6°C and 1 atmosphere).
$(P_{gp})_{i,n}$	=	Volume of gaseous product i produced in month “n” (m^3).
$(CC_{gp})_{i,n}$	=	Average carbon content of gaseous product i, including streams containing CO_2 recovered for sale or use in another process, for month “n” (kg C per kg of product).
$(MW_p)_i$	=	Molecular weight of gaseous product i (kg/kg-mole).

j = Number of feedstocks.
k = Number of products.

(ii) Liquid feedstocks and products. Use Equation 300-2 of this section to calculate the net carbon input or output from liquid feedstocks and products. Note that the result will be a negative value if there are no liquid feedstocks in the process but there are liquid products.

$$C_l = \sum_{n=1}^{12} [\sum_{i=1}^{j\ or\ k} [(F_{lf})_{i,n} * (CC_{lf})_{i,n} - (P_{lp})_{i,n} * (CC_{lp})_{i,n}]] \quad \textbf{Equation 300-2}$$

Where:

C_l = Annual net contribution to calculated emissions from carbon in liquid materials, including liquid organic wastes (kg/yr).
$(F_{lf})_{i,n}$ = Volume or mass of liquid feedstock i introduced in month "n" (m^3 of feedstock).
$(CC_{lf})_{i,n}$ = Average carbon content of liquid feedstock i for month "n" (kg C per m^3).
$(P_{lp})_{i,n}$ = Volume or mass of liquid product i produced in month "n" (m^3).
$(CC_{lp})_{i,n}$ = Average carbon content of liquid product i, including organic liquid wastes, for month "n" (kg C per m^3 of product).
j = Number of feedstocks.
k = Number of products.

(iii) Solid feedstocks and products. Use Equation 300-3 of this section to calculate the net annual carbon input or output from solid feedstocks and products. Note that the result will be a negative value if there are no solid feedstocks in the process but there are solid products.

$$C_s = \sum_{n=1}^{12} \left\{ \sum_{i=1}^{j\ or\ k} \left[(F_{sf})_{i,n} * (CC_{sf})_{i,n} - (P_{sp})_{i,n} * (CC_{sp})_{i,n} \right] \right\} \quad \textbf{Equation 300-3}$$

Where:

C_s = Annual net contribution to calculated emissions from carbon in solid materials (kg/yr).
$(F_{sf})_{i,n}$ = Mass of solid feedstock i introduced in month "n" (kg).
$(CC_{sf})_{i,n}$ = Average carbon content of solid feedstock i for month "n" (kg C per kg of feedstock).
$(P_{sp})_{i,n}$ = Mass of solid product i produced in month "n" (kg).
$(CC_{sp})_{i,n}$ = Average carbon content of solid product i in month "n" (kg C per kg of product).
j = Number of feedstocks.
k = Number of products.

(iv) Annual emissions. Use the results from Equations 300-1 through 300-3 of this section, as applicable, in Equation 300-4 of this section to calculate annual CO_2 emissions.

$$CO_2 = 0.001 * 3.664 * (C_g + C_l + C_s)$$ **Equation 300-4**

Where:

CO_2	=	Annual CO_2 mass emissions from process operations and process off-gas combustion (metric tons/year).
0.001	=	Conversion factor from kg to metric tons.
3.664	=	Ratio of molecular weight, carbon dioxide to carbon.

(c) **<u>Method 3:</u>** (Optional combustion methodology for ethylene production processes) For ethylene production processes, calculate CO_2, CH_4, and N_2O emissions as specified in paragraphs (c)(1) and (c)(2):

(1) For each flare, calculate CO_2, CH_4, and N_2O emissions using the methodology for flares specified in WCI.203(e).

(2) For all other combustion units, calculate the CO_2 emissions from combustion of fuel that contains ethylene process off-gas using either calculation methodology 3 or calculation methodogy 4 in WCI.23(c) and (d), respectively. Calculate CH_4 and N_2O emissions using the applicable method in WCI.24 and the emission factors of 2.8×10^{-3} kg/GJ for CH_4 and 5.7×10^{-4} kg/GJ for N_2O. You are not required to use the same calculation method for each stationary combustion unit that burns ethylene process off-gas.

§ WCI.304 Monitoring Requirements

(a) If you calculate emissions using the method specified in WCI.303(a):

(1) **Flares.** You must comply with the monitoring requirements for flares specified in WCI.204(e).

(2) **Process Vents.** You must comply with the monitoring requirements for process vents specified in WCI.204(b).

(b) If you calculate emissions using the method specified in WCI.303(b):

(1) **Feedstock Consumption.** You must measure the feedstock consumption using the same plant instruments used for accounting purposes, such as weigh hoppers, belt weigh feeders, or flow meters.

(2) **Product Production.** You must measure the amount of product produced using the same plant instruments used for accounting purposes, such as weigh hoppers, belt weigh feeders, or flow meters.

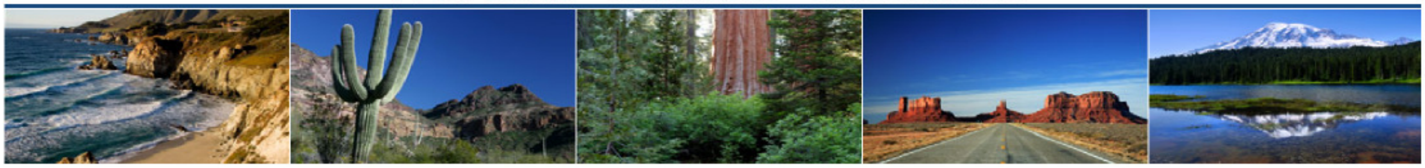
(3) **Carbon Content.** Except as allowed by WCI.303(b)(4), the carbon content of each feedstock and product must be measured at least once per month.

§ WCI.305 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For each missing value of the carbon content and molecular weight, the substitute data value shall be the arithmetic average of the quality assured values of the parameter immediately preceding and immediately following the missing data incident. If no quality assured data are available prior to the missing data incident, the substitute data value shall be the first quality assured data value obtained after the missing data period.

(b) For missing feedstock and production values, the substitute data value shall be the best available estimate of the parameter, based on all available process data. You must document and retain records of the procedures used for all such estimates.



§ WCI.310 NITRIC ACID MANUFACTURING

§ WCI.311 Source Category Definition

A nitric acid production facility uses one or more trains to produce weak nitric acid (30 to 70 percent in strength). A nitric acid train produces weak nitric acid through the catalytic oxidation of ammonia.

§ WCI.312 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation the annual emissions data report shall include the following information at the facility level calculated in accordance this method

(a) You must report facility wide N_2O process emissions as required by this method.

(b) Annual nitric acid production from the nitric acid facility (tonnes, 100 percent acid basis).

(c) You must report under WCI.20 (General Stationary Fuel Combustion Sources) the emissions of CO_2, CH_4, and N_2O from each stationary combustion unit by following the requirements of WCI.20.

§ WCI.313 Calculation of GHG emissions

(a) You must determine annual N_2O process emissions from each nitric acid train according to paragraphs (a)(1) or (a)(2) of this section.

(1) Use a site-specific emission factor and production data according to paragraphs (b) through (h) of this section.

(2) Request Director approval for an alternative method of determining N_2O emissions according to paragraphs.

(b) You must conduct an annual performance test according to paragraphs (b)(1) through (b)(3) of this section.

(1) You must measure N_2O emissions from the absorber tail gas vent for each nitric acid train using the methods specified in WCI.314(b) through (d).

(2) You must conduct the performance test under normal process operating conditions and without using N_2O abatement technology (if applicable).

(3) You must measure the production rate during the performance test and calculate the production rate for the test period in metric tons (100 percent acid basis) per hour.

(c) You must determine an N_2O emissions factor to use in Equation 310-3 of this section according to paragraphs (c)(1) or (c)(2) of this section.

(1) You may request Director approval for an alternative method of determining N_2O concentration according to the procedures in paragraphs (a)(2) of this section. Alternative methods include the use of N_2O CEMs.

(2) Using the results of the performance test in paragraph (b) of this section, you must calculate an average site-specific emission factor for each nitric acid train "t" according to Equation 310-1 of this section:

$$EF_{N2Ot} = \frac{\sum_{1}^{n} \frac{C_{N2O} * 1.14 \times 10^{-7} * Q}{P}}{n} \qquad \text{(Eq. 310-1)}$$

Where:

EF_{N2Ot}	=	Average site-specific N_2O emissions factor for nitric acid train "t" (kg N_2O generated/tonne nitric acid produced, 100 percent acid basis).
C_{N2O}	=	N_2O concentration for each test run during the performance test (ppm N_2O).
1.828×10^{-6}	=	Conversion factor (kg/dsm^3-ppm N_2O).
Q	=	Volumetric flow rate of effluent gas for each test run during the performance test (dsm^3/hr).
P	=	Production rate for each test run during the performance test (tonnes nitric acid produced per hour, 100 percent acid basis).
n	=	Number of test runs.

(d) If applicable, you must determine the destruction efficiency for each N_2O abatement technology according to paragraphs (d)(1), (d)(2), or (d)(3) of this section.

(1) Use the manufacturer's specified destruction efficiency.

(2) Estimate the destruction efficiency through process knowledge. Examples of information that could constitute process knowledge include calculations based on material balances, process stoichiometry, or previous test results provided the results are still relevant to the current vent stream conditions. You must document how process knowledge (if applicable) was used to determine the destruction efficiency.

(3) Calculate the destruction efficiency by conducting an additional performance test on the emissions stream following the N_2O abatement technology.

(e) If applicable, you must determine the abatement factor for each N_2O abatement technology. The abatement factor is calculated for each nitric acid train according to Equation 310-2 of this section.

$$AF_{N\,t} = \frac{P_{a\,t\,Abate}}{P_{a\,t}} \qquad \text{(Eq. 310-2)}$$

Where:

$AF_{N\,t}$	=	Abatement factor of N_2O abatement technology at nitric acid train "t" (fraction of annual production that abatement technology is operating).
$P_{a\,t}$	=	Total annual nitric acid production from nitric acid train "t" (tonne acid produced, 100 percent acid basis).

$P_{a\,t\,Abate}$ = Annual nitric acid production from nitric acid train "t" during which N_2O abatement was used (tonne acid produced, 100 percent acid basis).

(f) You must determine the annual amount of nitric acid produced and the annual amount of nitric acid produced while each N_2O abatement technology is operating from each nitric acid train (100 percent basis).

(g) You must calculate N_2O emissions for each nitric acid train by multiplying the emissions factor (determined in Equation 310-1 of this section) by the annual nitric acid production and accounting for N_2O abatement, according to Equation 310-3 of this section:

$$E_{N_2Ot} = \sum_{N=1}^{z} \frac{EF_{N20t} * P_{a\,t} * (1-(DF_{N\,t} * AF_{N\,t}))}{1000} \qquad \text{(Eq. 310-3)}$$

Where:

E_{N2Ot} = N_2O mass emissions per year for nitric acid train "t" (tonnes).

EF_{N2Ot} = Average site-specific N_2O emissions factor for nitric acid train "t" (kg N_2O generated/tonne acid produced, 100 percent acid basis).

$P_{a\,t}$ = Annual nitric acid production from the train "t" (tonne acid produced, 100 percent acid basis).

$DF_{N\,t}$ = Destruction efficiency of N_2O abatement technology N that is used on nitric acid train "t" (percent of N_2O removed from air stream).

$AF_{N\,t}$ = Abatement factor of N_2O abatement technology for nitric acid train "t" (fraction of annual production that abatement technology is operating).

1000 = Conversion factor (kg/tonne).

z = Number of different N_2O abatement technologies.

(h) You must determine the annual nitric acid production emissions combined from all nitric acid trains at your facility using Equation 310-4 of this section:

$$N_2O = \sum_{t=1}^{m} E_{N2Ot} \qquad \text{(Eq. 310-4)}$$

Where:

N_2O = Annual process N_2O emissions from nitric acid production facility (tonnes)

E_{N2Ot} = N_2O mass emissions per year for nitric acid train "t" (tonnes).

m = Number of nitric acid trains.

§ WCI.314 Sampling, Analysis, and Measurement Requirements

(a) You must conduct a new performance test and calculate a new site-specific emissions factor according to a test plan as specified in paragraphs (a)(1) through (a)(3) of this section.

(1) Conduct the performance test annually.

(2) Conduct the performance test when your nitric acid production process is changed, specifically when abatement equipment is installed.

(3) If you requested Director approval for an alternative method of determining N_2O concentration under WCI.313(a)(2), you must conduct the performance test if your request has not been approved by the Director within 150 days of the end of the reporting year in which it was submitted.

(b) You must measure the N_2O concentration during the performance test using one of the methods in paragraphs (b)(1) through (b)(3) of this section.

(1) EPA Method 320 at 40 CFR part 63, appendix A, Measurement of Vapor Phase Organic and Inorganic Emissions by Extractive Fourier Transform Infrared (FTIR) Spectroscopy.

(2) ASTM D6348-03 Standard Test Method for Determination of Gaseous Compounds by Extractive Direct Interface Fourier Transform Infrared (FTIR) Spectroscopy.

(3) An equivalent method, with Director approval.

(c) You must determine the production rate(s) (100 percent basis) from each nitric acid train during the performance test according to paragraphs (c)(1) or (c)(2) of this section.

(1) Direct measurement of production and concentration (such as using flow meters, weigh scales, for production and concentration measurements).

(2) Existing plant procedures used for accounting purposes (i.e. dedicated tank-level and acid concentration measurements).

(d) You must conduct all performance tests in conjunction with the applicable methods approved by the Director. For each test, the facility must prepare an emission factor determination report that must include the items in paragraphs (d)(1) through (d)(3) of this section.

(1) Analysis of samples, determination of emissions, and raw data.

(2) All information and data used to derive the emissions factor(s).

(3) The production rate during each test and how it was determined.

(e) You must determine the monthly nitric acid production and the monthly nitric acid production during which N_2O abatement technology is operating from each nitric acid train according to the methods in paragraphs (c)(1) or (c)(2) of this section.

(f) You must determine the annual nitric acid production and the annual nitric acid production during which N_2O abatement technology is operating for each train by summing the respective monthly nitric acid production quantities.

§ WCI.315 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section.

(a) For each missing value of nitric acid production, the substitute data shall be the best available estimate based on all available process data or data used for accounting purposes (such as sales records).

(b) For missing values related to the performance test, including emission factors, production rate, and N_2O concentration, you must conduct a new performance test according to the procedures in WCI.314 (a) through (d).

§ WCI.340 PHOSPHORIC ACID PRODUCTION

§ WCI.341 Source Category Definition

The phosphoric acid production source category consists of facilities that use a wet-process phosphoric acid process line to produce phosphoric acid by reacting phosphate rock with acid.

§ WCI.342 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual CO_2 process emissions from all wet-process phosphoric acid production lines, as specified in WCI.343 (metric tons).

(b) CO_2, N_2O, and CH_4 emissions from stationary combustion units, as specified in WCI.23 (metric tons).

(c) Annual phosphoric acid production (metric tons).

(d) Annual phosphoric acid permitted production capacity (metric tons).

(e) Annual arithmetic average percent inorganic carbon in phosphate rock from monthly records (%).

(f) Annual phosphate rock consumption from monthly records (metric tons).

(g) Number of times missing data procedures were used to estimate phosphate rock consumption (months) and inorganic carbon contents of the phosphate rock (month).

§ WCI.343 Calculation of CO_2 Emissions

(a) Calculate CO_2 process emissions using Equation 340-1 and the measured inorganic carbon content and feedstock input of the phosphate rock.

$$CO_2 = \sum_{i=1}^{12} \frac{FS_i \times CF_i \times 3.664}{c} \qquad \textbf{Equation 340-1}$$

Where:

CO_2 = Annual carbon dioxide emitted (metric tons/year).
FS_i = Feedstock consumption in month *i* (metric tons/month).
CF_i = Carbonate content of feedstock (kg C/metric ton feedstock) for month *i*.
3.664 = Ratio of molecular weights, CO_2 to carbon.
c = Conversion factor (1,000 kg/metric ton).

§ WCI.344 Sampling, Analysis, and Measurement Requirements

The monthly mass of phosphate rock consumed shall be determined using either existing plant procedures that are used for accounting purposes (such as sales records) or data from existing monitoring equipment that is used to measure total mass flow of phosphorus-bearing feed.

The monthly inorganic carbon content shall be obtained as specified under paragraphs (a) and (b) of this section.

(a) Obtain a monthly grab sample of phosphate rock directly from the rock being fed to the process line according to the following requirements:

(1) Follow the applicable standard method in "Phosphate Mining States Methods Used and Adopted by the Association of Fertilizer and Phosphate Chemists AFPC Manual 10th Edition 2009 – Version 1.9".

(2) If phosphate rock is obtained from more than one origin in a month, a sample must be obtained from each origin of rock or a composite representative sample must be obtained.

(b) Determine the inorganic carbon content of each monthly grab sample of phosphate rock (consumed in the production of phosphoric acid) using the applicable standard method in "Phosphate Mining States Methods Used and Adopted by the Association of Fertilizer and Phosphate Chemists AFPC Manual 10th Edition 2009 – Version 1.9".

§ WCI.345 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. Records must be documented and kept of the procedures used for all such estimates.

(a) A substitute data value must be determined by calculated the arithmetic average of the quality-assured values of inorganic carbon contents of phosphate rock of origin *i* from samples immediately preceding and immediately following the missing data incident. If no quality-assured data on inorganic carbon contents of phosphate rock of origin *i* are available prior to the missing data incident, then the substitute data value shall be the first quality-assured value of inorganic carbon contents for phosphate rock of origin *i* obtained after the missing data period.

(b) For each missing value of monthly mass consumption of phosphate rock (by origin), the substitute data value shall be the best available estimate based on all available process data or data used for accounting purposes.

Western Climate Initiative

Proposed Harmonization of Essential Requirements for Mandatory Reporting (ERs) in Canadian Jurisdictions with the WCI ERs and the U.S. EPA GHG Reporting Program

Stakeholder Conference Call

September 27, 2010

Background

- Final WCI Essential Requirements – July 2009
- Final U.S. EPA Mandatory Reporting Rule (“EPA Rule”) – September 2009
- U.S. facilities emitting >25,000 tonne CO_{2e} are subject to both programs (WCI has a 10,000 tonne threshold)
- Proposed harmonized ERs for U.S. jurisdictions – May 2010
  - Format is the same as EPA Rule
  - Final harmonized ERs expected Fall 2010

Proposed Harmonized ERs for Canadian Jurisdictions

- Released September 8, 2010
- Maintain consistency across all WCI jurisdictions
- Follow same format as original WCI ERs
- Allow review and input by stakeholders

Canadian Harmonization Principles

- Same level of reporting accuracy as U.S. facilities
- Quantification methods sufficient for GHG reporting under cap-and-trade program
- Suitable for use in Canada
  - Metric units
  - Canadian emission factors
- Facilitate harmonization with Environment Canada CEPA Section 46 (or future regulatory) reporting

Canadian Harmonization Approach

- Revise existing WCI ERs to conform with harmonized ERs for U.S. jurisdictions
  - Made content in WCI ERs “methodologically consistent” with ERs for U.S. jurisdictions
    - Harmonized ERs for US jurisdictions follow markup of EPA Rule
    - Harmonized ERs for Canadian jurisdictions keep WCI ER format
- Assure harmonization with Environment Canada’s reporting programs
- Require fewer data elements to be reported in Canadian jurisdictions due to 3rd party verification
- Add missing data procedures following EPA Rule
- Identify sources subject to “reporting only”

Sources Subject to Reporting Only

- Electricity Generation (WCI.20) – fugitive HFC emissions from cooling
- Coal Storage (WCI.100)
- Petroleum Refineries (WCI.200)
  - GHG emissions from asphalt blowing
  - CH_4 emissions from equipment leaks and storage tanks
  - CH_4 emissions from crude oil, intermediate, and product loading operations
- Mobile Equipment at Facilities (WCI.280)

On-Going Canadian Harmonization

- Natural Gas Transmission and Distribution (WCI.350)
- Petroleum and Natural Gas Production and Gas Processing (WCI.360)
- Underground Coal Mines (WCI.250)
- Magnesium Production (WCI.290)

- Electricity Imports (WCI.060) being reviewed by WCI Electricity Committee
- Other recently released EPA methods will be reviewed by WCI Reporting Committee (e.g. Carbon Dioxide Injection and Geologic Sequestration)

Western Climate Initiative

Questions?

Significant Changes to WCI ERs for Canadian Jurisdictions

- Table in documentation itemizes changes by source category
- Next few slides summarize the most significant changes, in addition to missing data procedures and reporting-only requirements
  - New, expanded sampling, analysis, and measurement requirements
  - Different sampling frequency
  - Different quantification method (or tier)
  - Changes for biomass combustion

Significant Changes – General Stationary Combustion (WCI.20)

- Several changes to harmonize with EPA Rule Subpart C:
  - Exemption for portable equipment, emergency generators and flares, etc.
- Must report annual weighted carbon content (CC) and high heat value (HHV)
- Very large combustion sources must either measure fuel CC or install CEMS, if:
  - >250 million BTU/hour heat input
  - Operated >1,000 hours/year
  - Excluding units that only use fuels in Table 20-1a
- Clarifications on:
  - Methods based on type of fuels
  - Sampling frequencies, requirements
  - Biogenic emissions from mixtures

Significant Changes – GSC (WCI.20) – Cont.

Parameter[a]	Fuel Type and Applicable CO_2 Quantification Method						
	Natural Gas	Fuels in Table 20-1a (e.g., distillates, LPG)	Coal	Solid Biomass	MSW	Other Fuels (e.g., liquid fuels, gas derived from fossil fuels, biogas)	Units ≥ 250 mmBTU/hr
Method 1	✔	✔					
Method 2	✔	✔		✔[b]			
Method 3	✔	✔	✔	✔	✔[b]	✔	✔[c]
Method 4	✔	✔	✔	✔	✔	✔	✔[c]

[a] Method 1 = Emission factors

Method 2 = HHV testing

Method 3 = Carbon content

Method 4 = CEMS

[b] Applies to steam and default factor (method 2) or efficiency testing (method 3)

[c] Except for natural gas, biomass and fuels in Table 20-1a

Significant Changes – Petroleum Refineries (WCI.200) and Refinery Fuel Gas (WCI.30)

- Added flexibility in methods for some sources
  - Flares
  - Startup and shutdown conditions and malfunctions
  - Process vents
- Modified existing and added new methods based on EPA Rule Subpart Y
  - Sources for which GHG emissions must be estimated (also added to definitions)
  - CH_4 and N_2O for some activities
  - Storage tanks
  - Industrial waste water
  - Equipment leaks
  - Emissions from combustion of refinery fuel gas (RFG)

Significant Changes – Iron and Steel (WCI.150)

- More specific breakdown of methods for upstream process-by-process approach
  - Coke oven batteries (COB)
  - Blast furnace
  - Basic oxygen furnace (BOF)
  - Electric arc furnace (EAF)
  - Others (sinter, direct reduction furnace, taconite, argon oxygen decarburization)
- Coke oven gas and blast furnace gas now reported upstream instead of at combustion unit
- All process and combustion emissions reported in the same method

Significant Changes – Petrochemical Manufacturing (WCI.300)

- Clarified and expanded definition of facility
- Changed methods refer to petroleum refinery methods (WCI.200)
  - Flares, equipment leaks, process vents
  - Continues to use GSC (WCI.20) for non-flare combustion sources
- Added new optional methods
  - To be consistent with EPA Subpart Y
  - Mass balance for gaseous, liquid, and solid feedstock(s) and products

Significant Changes – Cont.

- Cement Manufacturing (WCI.90)
  - Additional Reporting
    - Monthly emission factors
    - Organic carbon oxidation emissions
  - Adopted USEPA equations
  - Removed requirement for plant-specific clinker kiln dust (CKD)
- Lime Manufacturing (WCI.170)
  - Changed reporting for byproducts and waste from monthly to quarterly
  - Change byproduct sampling from quarterly to monthly
  - Added reporting for other combustion sources even when CEMS are used

Significant Changes – Cont.

- Adipic Acid (WCI.50) and Nitric Acid (WCI.310) Manufacturing
  - Added option to use continuous monitors with recording of monthly results
  - More specific monitoring requirements
- Hydrogen Production (WCI.130)
  - Added requirement to report amount of carbon in unconverted feedstock
  - Modified equations to separate calculations for liquid, gaseous, and solid fuels and feedstocks
- Pulp and Paper Manufacturing (WCI.210)
  - Changed to use methods in GSC (WCI.20) for fossil-fuel combustion
  - Added method based on HHV of spent liquor solids for biogenic emissions
  - Added method for estimating CO_2 from make-up chemical use

Significant Changes – Cont.

- Copper and Nickel Production (WCI.260)
  - Entirely new section based on method developed by Environment Canada
  - Clarified sampling frequency for CC
- Lead Manufacturing (WCI.160)
  - Added reporting for inferred waste-based carbon-containing material emission factor
  - Clarified sampling frequency for CC and methods
- Zinc Manufacturing (WCI.240)
  - Added requirement for CC of input materials if missing data procedures used
  - Clarified equation variables

Significant Changes – Cont.

- Primary Aluminum Manufacturing (WCI.70)
  - Added some reporting requirements to be consistent with EPA Subpart F
  - Changed from daily to monthly production data reporting when estimating CF_4 and C_2F_6 emissions
- Soda Ash Manufacturing (WCI.220)
  - Added more options for estimating emissions when CEMS not used
  - Expanded sampling, analysis, and measurement requirements
- Mobile Equipment at Facilities (WCI.280)
  - Entirely new section based on method developed by British Columbia
  - CO_2 calculations based on either fuel quantities and emission factors, or hours of operation, horsepower, load factor, and fuel economy

New WCI ERs Based on EPA Rule

- Ammonia Manufacturing (WCI.80) – based on Subpart G
- HCFC-22 Production (WCI.120) – based on Subpart O
- Glass Production (WCI.140) – based on Subpart N
- Carbonates Use (WCI.180) – based on Subpart U
- Electricity Transmission (WCI.230) – based on Subpart DD and existing methodology used in Canada
- Ferroalloy Production (WCI.270) – based on Subpart K
- Phosphoric Acid Production (WCI.340) – based on Subpart Z

Next Steps

Who?	What?	When? (2010)
Stakeholders	Submit comments on proposed Canadian harmonization package #1	Oct. 12
WCI	Finalize Canadian harmonization package #1	To be determined
WCI	Propose Canadian harmonization package #2 (magnesium, oil and gas, transmission and distribution, underground coal mines)	Early Oct.
Stakeholders	Submit comments on proposed Canadian harmonization package #2	To be determined
WCI	Finalize Canadian harmonization package #2	End of Nov.

Western Climate Initiative

WCI Regional Program Design

WCI Stakeholder Meeting
Montréal, QC
September 15, 2010

Program Design Overview

- Program Design released July 27, 2010
  http://westernclimateinitiative.org/the-wci-cap-and-trade-program/program-design
- Comprehensive strategy to reduce greenhouse gases and spur a clean-energy economy
  - Reduce emissions to 15% below 2005 levels by 2020
- Culmination of two years of work since WCI released initial design recommendations in 2008
- WCI Partners include *Arizona, British Columbia, California, Manitoba, Montana, New Mexico, Ontario, Oregon, Québec, Utah, and Washington*

Program Design Overview

- Based on extensive analysis and stakeholder consultation
- Includes an emissions cap and other core policies that are affordable, gradual, and support economic growth. The program:
  - Uses a market-based approach to cap most emissions
  - Encourages reductions throughout the economy
  - Expands energy efficiency programs
  - Encourages additional renewable energy sources
  - Tackles transportation emissions

Program Design Overview

- Economically- and geographically-broad cap covers nearly 90% of the region's emissions, providing flexibility to achieve least-cost emission reductions
- Provides a roadmap to inform Partners in their development of implementing regulations
- Jurisdictions with caps beginning in 2012 will include most of the region's emissions
  - The WCI program accommodates jurisdictions with alternative schedules

Program Benefits

- Reduces costly impacts that climate change will have on water resources, natural ecosystems, air quality, and environment-dependent industries like agriculture and tourism
- Provides incentives for clean-energy technologies
- Creates green jobs
- Increases energy security
- Protects public health

Document Organization

- Design Summary
  - Program highlights
  - Summary of major policy recommendations (see following slides)
- Supporting Documentation
  - Issue-specific recommendations and papers
- Detailed Design
  - Operational components

Major Policy Recommendations / Findings

- Relying on high-quality emissions data
  - State reporting rules being harmonized with EPA requirements, where they are adequate for C&T purposes
  - Working with federal governments on 1-window reporting
- Setting program emission limits
  - Annual allowance budgets decline linearly from emissions expected in first year of program (2012 for some sources, 2015 for others) to the 2020 reduction goal for each Partner
  - Use of offsets and allowances from other systems limited to 49% of the total reductions expected from the program
  - Early reduction allowances are optional

Major Policy Recommendations / Findings

- Enhancing flexibility and managing costs
  - Three cost containment mechanisms are being considered as options for Partners, in addition to the standard mechanisms included in the 2008 Design Recommendations (banking, offsets, broad scope, etc.)
  - Strategic allowance reserve
  - Contingent allowance reserve
  - Use of issued allowances with future vintages

Major Policy Recommendations / Findings

- Maintaining competitiveness and preventing emissions leakage (industries other than power)
  - Could be accomplished through the free distribution of allowances to industries with a high risk of leakage
  - Distribution in such cases should be standardized (e.g., through the use of common output-based benchmarks)
- Addressing electricity sector issues
  - Imports and leakage
  - RECs will have no compliance role
  - Allowance set-asides are an option for Partners who want to maintain the GHG reduction value of voluntary RE

Major Policy Recommendations / Findings

- Designing for high-quality offsets
  - Recommendations for WCI offset project criteria and other offset essential elements finalized in June
  - Recommendations under development for the process of approving offset projects and issuing offset credits
- Designing fair and transparent allowance auctions
  - Program Design contains several recommendations, closely aligned with RGGI auction design
  - Work is in progress to finalize recommendations on the remaining auction design elements
  - These are enumerated in the Program Design

Major Policy Recommendations / Findings

- Ensuring a well-functioning allowance market
  - Several recommendations were finalized in a separate update released in July, including recommendations on the treatment of offsets, participation by and registration of intermediaries, the role of derivatives and OTC transactions, reporting requirements, and public disclosure
  - Recommendations have yet to be issued on holding limits, market oversight, and centralized reporting of OTC derivative contracts

Major Policy Recommendations / Findings

- Linking programs
  - Prior to linking, WCI jurisdictions will have the opportunity to review each jurisdiction's program to assess its consistency with the Program Design
  - Distinctions made between unilateral linking, bilateral linking, and accepting offsets that are not part of a C&T program

Major Policy Recommendations / Findings

- Coordinating program administration
  - Three areas are highlighted in the Program Design, which the WCI Partners continue to investigate
  - Establishment and maintenance of an allowance tracking system
  - Compliance, verification, and enforcement (e.g., provisions for technical and compliance assistance, and a common requirement to surrender three additional compliance instruments for each excess tonne)
  - Regional administrative organization

Next Steps

- Complete outstanding WCI program design issues
- Put in place administrative systems and infrastructure
- Continue advancing core policies and programs
- Work closely with federal governments and other regional organizations to promote national and international action and ensure coordination

Western Climate Initiative

Le Programme Détaillé de la WCI

Réunion des détenteurs d’enjeux
Montréal, Québec
15 Septembre 2010

Vue d'ensemble

- Le Programme Détaillé de plafond/échanges de la WCI a été publié le 27 Juillet 2010
  http://westernclimateinitiative.org/the-wci-cap-and-trade-program/program-design
- Stratégie complète pour réduire les émissions de GES et pour promouvoir les énergies propres
  - Réduire les émissions de 15% par rapport à 2015 en 2020
- Deux années de travail depuis la publication du Modèle Recommandé en 2008
- Les partenaires de la WCI sont: AZ, BC, CA, MB, MT, NM, ON, OR, QC, UT et WA

Vue d'ensemble

- Le Programme Détaillé est fondé sur des analyses approfondies et sur la consultation des détenteurs d'enjeux
- Le Programme Détaillé inclut un plafond d'émission et d'autres politiques qui sont abordables, graduelles et soutiennent la croissance de l'économie :

  approche marché, réductions réparties dans toute l'économie, efficacité énergétique, énergies renouvelables, secteur des transports

    - uti

Vue d’ensemble

- Les émissions couvertes par le programme de la WCI représentent 90% des émissions de la région
- Le programme sert de guide aux partenaires dans l’élaboration de leur réglementation
- Les juridictions qui vont mettre en oeuvre le programme en 2012 couvrent la majorité des émissions de la WCI
- Le programme de la WCI est conçu de façon à permettre l’arrivée d’autres juridictions dans le programme

Les avantages du programme

- Réduction des impacts des changements climatiques sur les ressources en eau, les écosystèmes naturels, la qualité de l'air, les industries dépendantes de l'environnement comme l'agriculture et le tourisme
- Favorise le développement des technologies énergétiques propres
- Création d'emplois verts
- Accroître notre sécurité énergétique
- Impact positif sur la santé publique

Les composantes du document

- Sommaire du Programme
  - Les faits saillants du programme
  - Sommaire des pricipales politiques recommandées
- La Documentation
  - Les documents produits par les groupes de travail de la WCI qui ont servi à l'élaboration des recommandations
- Programme Détaillé
  - Les composantes opérationnelles
    - » Semblable à un réglement modèle

Les principales recommandations

- Programme fondé sur des données d'émission de grande qualité
  - **États-Unis** : Harmonisation des règlements de déclaration des États avec les exigences de l'EPA
  - **Canada** : Travail avec le gouvernement fédéral pour une déclaration unique
- Quantité totale d'émissions permises
  - Les budgets de droits d'émission vont décroître de façon linéaire à partir de la mise en place du programme (2012 pour certains secteurs et 2015 pourd'autres) jusqu'à l'atteinte de la cible de réduction en 2020
  - L'utilisation de CC ou de droits d'émission provenant d'autres programmes reconnus est limitée à 49% de la réduction totale
  - L'octroi de droits d'émission pour des réductions hâtives est optionnel

Les principales recommandations

- Permettre la flexibilité et le contrôle des prix
  - Trois mécanismes de contrôle des prix sont présentement considérés par les juridictions, en addition aux mécanismes déjà prévus dans le Modèle Recommandé de 2008 (mise en banque, les crédits compensatoires, une couverture étendue, etc.)
  - Une réserve de droits d'émission stratégique
  - Une réserve de droits d'émission pour les imprévus
  - L'utilisation lors de la période de conformité de droits d'émission futurs déjà détenus

Les principales recommandations

- Maintenir la compétitivité des entreprises et prévenir les fuites
  - Pourrait être accompli au moyen d'une distribution gratuite des droits d'émission aux entreprises qui pourraient faire l'objet de fuites
  - Cette distribution devra être standardisée, c'est-à-dire en utilisant une base de production commune (output-based benchmarks)
- Le secteur de la production d'électricité
  - Importation et fuite (voir la présentation du 8 septembre)
  - Les Certificats d'Énergie Renouvelable (REC) ne pourront être utilisés lors de la période de conformité
  - La mise de coté de droits d'émission est une option qui peut être utilisée par les juridictions qui voudraient maintenir la valeur des réductions qui proviennent de la production d'énergie renouvelable volontaire

Les principales recommandations

- Des crédits compensatoires (CC) de grande qualité
  - Les recommandations entourant les critères pour développer les CC de la WCI et les autres éléments essentiels sont terminées depuis juin 2010
  - Les recommandations entourant le processus d'approbation des CC et leur création sont présentement en élaboration
- Une vente à l'enchère transparente et équitable
  - Le Programme Détaillé comporte plusieurs recommandations qui sont semblables au processus de vente à l'enchère du RGGI
  - Finaliser les recommandations sur les éléments restants à développer
  - Celles-ci sont énumérées dans le Programme Détaillé

Les principales recommandations

- Assurer un marché efficace des droits d'émission
  - Plusieurs recommandations ont été finalisées dans une mise à jour publiée en juillet, incluant des recommandations sur le traitement des CC, les participants et l'enregistrement des intermédiaires , le rôle des dérivés et des transactions de gré à gré, les exigences de déclaration, et la divulgation d'information au public
  - Les recommandations suivantes seront finalisées:

    la limite de possession, la supervision du marché et la déclaration des transactions de gré à gré de dérivés à un organisme central

Les principales recommandations

- Les liens entre les programmes
  - Avant de créer des liens entre les programmes, les partenaires de la WCI auront l'opportunité de réviser les programmes des autres partenaires pour s'assurer qu'ils sont conformes au Programme Détaillé
  - Des distinction seront faites entre un lien unilatéral, un lien bilatéral et l'acceptation de CC qui ne font pas partie d'un programme de plafonds/échanges.

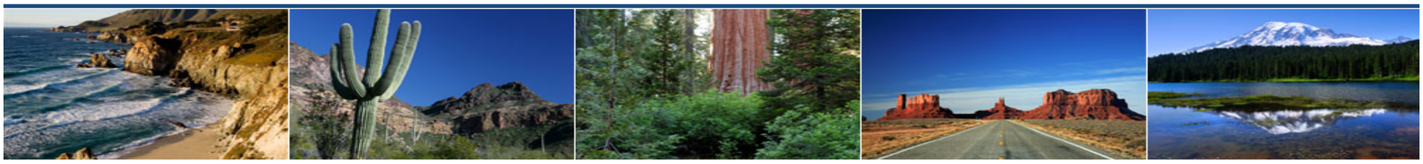
Les principales recommandations

- Coordonner l’administration du programme
  - Trois priorités du Programme Détaillé sur lesquels les partenaires vont continuer de travailler :
  - La création et l’entretien d’un système de suivi des droits d’émission
  - La conformité, la vérification et l’observance (la fourniture d’assistance technique et l’exigence de remettre trois droits d’émission pour chacune des tonnes de GES émises en trop lors de la période de conformité)
  - La création d’une organisation administrative régionale

Prochaines étapes

- Résoudre les problèmes complexes soulevés dans le Programme Détaillé de la WCI
- Mettre en place le système administratif et l'infrastructure
- Poursuivre le développement des politiques et programmes
- Travailler en étroite collaboration avec les autorités fédérales et les autres organisations régionales afin de promouvoir des actions nationales et internationales et d'assurer leur coordination

Western Climate Initiative



Second Harmonization Package -

Harmonization of Essential Requirements for Mandatory Reporting in Canadian Jurisdictions with the WCI Essential Requirements for Mandatory Reporting and the EPA Greenhouse Gas Reporting Program

October 29, 2010

1 Second Harmonization Package 2

2 Other Changes to the Proposal 2

3 Stakeholder Comments 3

1 Second Harmonization Package

On September 8, 2010, the WCI proposed the "Harmonization of Essential Requirements for Mandatory Reporting in Canadian Jurisdictions with the WCI Essential Requirements for Mandatory Reporting and the EPA Greenhouse Gas Reporting Program" (the 'ERs'). This second WCI harmonization package builds upon the previous package and proposes methods for electronics manufacturing, underground coal mining, magnesium production, natural gas transmission and distribution, and petroleum and natural gas systems. The specific language for the changes is set forth in the Appendices. Unlike for the first harmonization package no summary of changes is presented as all methods are being newly proposed by the WCI for use in Canada.

Methods for the first three sectors (magnesium, electronics and underground coal) were developed using the U.S. EPA's final or proposed Part 98 Subparts as a base, and then converted into the WCI Canadian format. For the latter two sectors (petroleum and natural gas systems, and natural gas transmission and distribution), the EPA's proposed Subpart W and the June 7, 2010 "WCI Comments and Recommendations for the Proposed Mandatory Reporting of Greenhouse Gas Emissions from Petroleum and Natural Gas Operations" were together used as a base upon which sampling, analysis and measurement requirements, definitions, and emission factors appropriate for use in Canada were incorporated. Some consequential changes to WCI.20 (general stationary combustion) are being contemplated as a result of this process. The format of the harmonized Canadian ERs follows the original WCI format, a format that had already been used in guidance documents and regulations in several Canadian WCI jurisdictions.

The proposed WCI ERs are methodologically consistent with those of the U.S. EPA (or as proposed by the WCI) but are appropriate for use in the Canadian jurisdictions. At such a point when the U.S. EPA finalizes Subpart W, the WCI will develop cap and trade quality requirements for sources covered by Subpart W for use in U.S. jurisdictions. This may mean modifications will be required to the current proposed Canadian language covering the same sources. No evaluation has yet been conducted with respect to "reporting only" sources within the scope of the methods in the second harmonization package.

2 Future Changes to the Proposal

Further EPA rule revisions, such as conforming changes to Subpart A (General provisions) and Subpart H (cement), have been or are expected to be finalized to go into effect later this year. As a result, some consequential modifications to the proposed ERs in the first harmonization package may be required. In addition, stakeholder comments received on the first harmonization package are currently under review, and may result in changes to those proposed Canadian ERs.

3 Stakeholder Comments

This section to be completed after the public consultation period is over.

APPENDICES

§ WCI.110 MAGNESIUM PRODUCTION

§ WCI.111 Source Category Definition

Electronics manufacturing facilities include, but are not limited to, facilities that manufacture semiconductors, liquid crystal displays (LCDs), micro-electro-mechanical systems (MEMS), and photovoltaic cells (PV). The electronics source category consists of any of the processes listed in paragraphs (a) through (f) of this section that are located at electronics manufacturing facilities.

(a) Processes in which the etching process uses plasma-generated fluorine atoms and other reactive fluorine-containing fragments, which chemically react with exposed thin-films (e.g., dielectric, metals) and silicon to selectively remove portions of material.

(b) Processes in which chambers used for depositing thin films are cleaned periodically using plasma-generated fluorine atoms and other reactive fluorine-containing fragments from fluorinated and other gases.

(c) Processes in which wafers are cleaned using plasma-generated fluorine atoms or other reactive fluorine-containing fragments to remove residual material from wafer surfaces.

(d) Processes in which some fluorinated compounds can be transformed in the plasma processes into different fluorinated compounds which are then exhausted, unless abated, into the atmosphere.

(e) Processes in which the chemical vapor deposition process or other manufacturing processes use N_2O.

(f) Processes in which fluorinated GHGs are used as heat transfer fluids to cool process equipment, control temperature during device testing, and solder semiconductor devices to circuit boards.

§ WCI.112 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of N_2O and fluorinated GHGs. The fluorinated GHGs that are emitted from electronics production processes include, but are not limited to, those listed in Table 110-1 of this subpart. The process that must be reported include: fluorinated GHGs from plasma etching, fluorinated GHGs from chamber cleaning, fluorinated GHGs from wafer cleaning, N_2O from chemical vapor deposition and other manufacturing processes, and fluorinated GHGs from heat transfer fluid use.

(b) CO_2, N_2O, and CH_4 emissions from stationary combustion units as specified in §WCI.23.

(c) The method of emissions calculation used in §WCI.113.

(d) Production in terms of substrate surface area (e.g., silicon, PV-cell, LCD).

(e) Emission factors used for process utilization and by-product formation rates and the source for each factor for each fluorinated GHG and N_2O.

(f) Where process categories for semiconductor facilities as defined in §WCI.113(a)(1)(i) through (a)(1)(iii) are not used, descriptions of individual processes or process categories used to estimate emissions.

(g) For each fluorinated GHG and N_2O, annual gas consumed during the reporting year and facility-wide gas-specific heel-factors used.

(h) The apportioning factors for each process category (i.e., fractions of each gas fed into each individual process or process category used to calculate fluorinated GHG and N_2O emissions) and a description of the engineering model used for apportioning gas usage per §WCI.114(b). If the method used to develop the apportioning factors permits the development of facility-wide consumption estimates that are independent of the estimates calculated in Equation 110-6 of this subpart (e.g., that are based on wafer passes for each individual process or process category), report the independent facility-wide consumption estimate for each fluorinated GHG and N_2O.

(i) Fraction of each gas fed into each process type that is fed into tools with abatement systems.

(j) Description of all abatement systems through which fluorinated GHGs or N_2O flow at the facility, including the number of devices of each manufacturer, model numbers, manufacturers guaranteed destruction or removal efficiencies, if any, and record of destruction or removal efficiency measurements over its in-use life. The inventory of abatement systems shall also include a description of the associated tools and/or processes for which these systems treat exhaust.

(k) For each abatement system through which fluorinated GHGs or N_2O flow at the facility, for which controlled emissions are reported, the following:

(1) Certification that each abatement system used at the facility is installed, maintained, and operated in accordance with manufacturers' specifications.

(2) The uptime and the calculations to determine uptime for that reporting year.

(3) The default destruction or removalefficiency value or properly measured destruction or removal efficiencies for each abatement system used in that reporting year to reflect controlled emissions.

(4) There the default destruction or removal efficiency value is used to report controlled emissions, certification that the abatement systems for which controlled emissions are being reported are specifically designed for fluorinated GHG and N_2O abatement.

(5) Where properly measured destruction or removal efficiencies or class averages of destruction or removal efficiencies are used to report controlled emissions, the following:

(i) A description of the class including the abatement system manufacturer and model number, and the fluorinated GHG and N_2O in the process effluent stream;
(ii) The total number of systems in that class for the reporting year.
(iii) The total number of systems for which destruction or removal efficiency was measured in that class for the reporting year.

(iv) A description of the calculation used to determine the class average, including all inputs of the calculation.

(v) A description of method of randomly selecting class members for testing.

(l) For heat transfer fluid emissions, inputs in the mass-balance equation, Equation 110-8 of this subpart for each fluorinated GHG.

(m) Example calculations for fluorinated GHG, N_2O, and heat transfer fluid emissions.

§ WCI.113 Calculation of GHG Emissions

(a) For each fluorinated GHG and each process type used at the facility (i.e., plasma etching, chamber cleaning, or wafer cleaning) as appropriate, calculate annual facility-level emissions using Equations 110-1 and 110-2 of this section and according to the procedures in paragraph (a)(1), (a)(2), or (a)(3) of this section.

$$processtypeE_i = \sum_{j=1}^{N} E_{ij} \qquad \textbf{Equation 110-1}$$

Where:

$processtypeE_i$	=	Annual emissions of input gas *i* from the processes type (metric tons);
E_{ij}	=	Annual emissions of input gas *i* from individual process *j* or process category *j* (metric tons); and
N	=	Total number of individual processes *j* or process categories *j*, which depend on the electronics manufacturing facility and emission calculation methodology.

$$processtypeBE_k = \sum_{j=1}^{N}\sum_{i} BE_{kij} \qquad \textbf{Equation 110-2}$$

Where:

$processtypeBE_k$	=	Annual emissions of by-product gas *k* from the processes type (metric tons);
BE_{kij}	=	Annual emissions of by-product *k* formed from input gas *i* during individual process *j* or process category *j* (metric tons); and
N	=	Total number of individual processes *j* or process categories *j*, which depend on the electronics manufacturing facility and emission calculation methodology.

(1) Semiconductor facilities that fabricate devices on wafers measuring 300 mm or less in diameter shall calculate annual facility-level emissions of each fluorinated GHG used at a facility for each fluorinated GHG-using process type, either from all individual processes at that facility in accordance with §WCI.114(c), or from process categories as defined in this paragraph (a)(1).

(i) All etching process categories for which annual fluorinated GHG emissions shall be calculated are defined in this paragraph (a)(1)(i).

(A) Oxide etch means any process using fluorinated GHG reagents to selectively remove SiO_2, SiO_x-based or fully organic-based thin-film material that has been deposited on a wafer during semiconductor device manufacturing.

(B) Nitride etch means any process using fluorinated GHG reagents to selectively remove SiN, SiON, Si_3N_4, SiC, SiCO, SiCN, etc. (represented by the general chemical formula, $Si_wO_xN_yX_z$ where w, x, y and z are zero or integers and X can be some other element such as carbon) that has been deposited on a wafer during semiconductor manufacturing.

(C) Silicon etch also often called polysilicon etch means any process using fluorinated GHG reagents to selectively remove silicon during semiconductor manufacturing.

(D) Metal etch means any process using fluorinated GHG reagents associated with removing metal films (such as aluminum or tungsten) that have been deposited on a wafer during semiconductor manufacturing.

(ii) All chamber cleaning processcategories for which annual fluorinated GHG emissions shall be calculated are defined in this paragraph (a)(1)(ii).

(A) In situ plasma means cleaning thin-film production chambers, after processing one or more wafers, with a fluorinated GHG cleaning reagent that is dissociated into its cleaning constituents by a plasma generated inside the chamber where the film was produced.

(B) Remote plasma system means cleaning thin-film production chambers, after processing one or more wafers, with a fluorinated GHG cleaning reagent dissociated by a remotely located (e.g., upstream) plasma source.

(C) In situ thermal means cleaning thin-film production chambers, after processing one or more wafers, with a fluorinated GHG cleaning reagent that is thermally dissociated into its cleaning constituents inside the chamber where the thin-film (or thin films) was (were) produced.

(iii) All wafer cleaning process categories for which annual fluorinated GHG emissions shall be calculated are defined in this paragraph (a)(1)(iii) .

(A) Bevel cleaning means any process using fluorinated GHG reagents with plasma to clean the edges of wafers during semiconductor manufacture.

(B) Ashing means any process using fluorinated GHG reagents with plasma to remove photoresist materials during wafer manufacture.

(2) Semiconductor facilities that fabricate devices on wafers measuring greater than 300 mm in diameter shall calculate annual facility-level emissions of each fluorinated GHG used at a facility for all individual processes at that facility in accordance with §WCI.114(c).

(3) All other electronics facilities shall calculate annual facility-level emissions of each fluorinated GHG used at a facility for each process type, including etching and chemical vapor deposition chamber cleaning.

(b) For each fluorinated GHG and each individual process, process category, or process type used at the facility as appropriate, calculate annual facility-level emissions using Equations 110-3 and 110-4 of this section, and according to the procedures in either paragraph (b)(1), (b)(2), or (b)(3) of this section.

$$E_{ij} = C_{ij}(1 - U_{ij})(1 - a_{ij} \times d_{kj}) \times 0.001$$

Equation 110-3

Where:

E_{ij}	=	Annual emissions of input gas *i* from individual process, process category, or process type *j* (metric tons);
C_{ij}	=	Amount of input gas *i* consumed in individual process, process category, or process type *j*, as calculated in Equation 110-6 (kg) of this section and apportioned pursuant to §WCI.114(b);
U_{ij}	=	Process utilization for input gas *i* during individual process, process category, or process type *j*;
a_{ij}	=	Fraction of input gas *i* used in individual process, process category, or process type *j* with abatement systems;
d_{ij}	=	Fraction of input gas *i* destroyed in abatement systems connected to individual process, process category, or process type *j*, accounting for uptime as specified in §WCI.114(e)(2). This is zero unless the facility adheres to requirements in §WCI.114(e); and
0.001	=	Conversion factor from kg to metric tons.

$$BE_{ijk} = B_{ijk} \times C_{ij} \times (1 - a_{ij} \times d_{kj}) \times 0.001$$

Equation 110-4

Where:

BE_{ijk}	=	Annual emissions of by-product *k* formed from input gas *i* during individual process, process category, or process type *j* (metric tons);
B_{ijk}	=	Amount of gas *k* created as a by-product per amount of input gas *i* (kg) consumed in individual process, process category, or process type *j* (kg);
C_{ij}	=	Amount of input gas *i* consumed in individual process, process category, or process type *j*, as calculated in Equation 110-6 (kg) of this section and apportioned pursuant to §WCI.114(b);
a_{ij}	=	Fraction of input gas *i* used in individual process, process category, or process type *j* with abatement systems;
d_{kj}	=	Fraction of by-product gas k destroyed in abatement systems connected to individual process, process category, or process type j, accounting for uptime as specified in §WCI.114(e)(2). This is zero unless the facility adheres to requirements in §WCI.114(e); and
0.001	=	Conversion factor from kg to metric tons.

(1) Semiconductor facilities that fabricate devices on wafers measuring 300 mm or less in diameter shall use the procedures in either paragraph (b)(1)(i) or (b)(1)(ii) of this section.

(i) Except as provided in paragraph (b)(1)(ii), use default process category emission factors for process utilization and by-product formation rates shown in Tables 110-2, 110-3, and 110-4 of this subpart as appropriate.

(ii) Recipe-specific measurements may be used instead of the process category default factors provided that the methods in §WCI.114(c) are followed.

(2) Semiconductor facilities that fabricate devices on wafers measuring greater than 300 mm in diameter shall use recipe-specific measurements and follow methods in §WCI.114(c) to calculate emissions from each fluorinated GHG-using process type. Equations 110-1 through 110-4 shall be used to calculate fluorinated GHG emissions from all fluorinated GHG-using process recipes.

(3) All other electronics facilities shall use the default process type-specific emission factors for process utilization and by-product formation rates shown in Tables 110-5, 110-6, and 110-7 of this subpart for MEMS, LCD, and PV manufacturing, respectively.

(c) Calculate annual facility-level N_2O emissions from electronics manufacturing processes, using Equation 110-5 of this section and the methods in this paragraph (c).

(1) Use a factor for N_2O utilization for chemical vapor deposition processes pursuant to either paragraph (c)(1)(i) or (c)(1)(ii) of this section.

(i) Develop a facility-specific N_2O utilization factor averaged over all N_2O-using recipes used for chemical vapor deposition processes in accordance with §WCI.114(d).

(ii) If a facility-specific N_2O utilization factor for chemical vapor deposition processes is not available, a value of 20 percent must be used as the default utilization factor for N_2O from chemical vapor deposition processes.

(2) Use a factor for N_2O utilization for other manufacturing processes pursuant to either paragraph (c)(2)(i) or (c)(2)(ii) of this section.

(i) Develop a facility-specific N_2O utilization factor averaged over all N_2O-using recipes used for manufacturing processes other than chemical vapor deposition processes in accordance with §WCI.114(d).

(ii) If a facility-specific N_2O utilization factor for manufacturing processes other than chemical vapor deposition is not available, a value of 0 percent must be used as a default utilization factor for N_2O from manufacturing processes other than chemical vapor deposition.

(3) If a facility employs abatement systems and wishes to quantify and document N2O emission reductions due to these systems, it must adhere to the requirements in §WCI.114(e).

(4) Calculate annual facility-level N2O emissions for all processes at the facility using Equation 110-5 of this section.

$$E(N_2O) = \sum_j C_{N_2O,j}\left(1 - U_{N_2O,j}\right)\left(1 - a_{N_2O,j} \times d_{N_2O,j}\right) \times 0.001$$

Equation 110-5

Where:

$E(N_2O)$	=	Annual emissions of N_2O (metric tons/year);
$C_{N2O,j}$	=	Amount of N_2O consumed for N_2O-using process *j*, as calculated in Equation 110-6 of this section and apportioned to N_2O-using process *j* (kg);
$U_{N2O,j}$	=	Process utilization for N_2O-using process *j*;
$a_{N2O,j}$	=	Fraction of N_2O used in N_2O-using process *j* with abatement systems;
$d_{N2O,j}$	=	Fraction of N_2O for N_2O-using process *j* destroyed by abatement systems connected to process *j*, accounting for uptime as specified in §WCI.114(e)(2). This is zero unless the facility adheres to requirements in §WCI.114(e); and
0.001	=	Conversion factor from kg to metric tons.

(d) Calculate gas consumption for each fluorinated GHG and N_2O used at the facility using facility-wide gas-specific heel factors, as determined in §WCI.114(a), and using Equation 110-6 of this section.

$$C_i = \left(I_{Bi} - I_{Ei} + A_i - D_i\right) \times 0.001$$

Equation 110-6

Where:

C_i	=	Annual consumption of input gas *i* (metric tons/year);
I_{Bi}	=	Inventory of input gas *i* stored in cylinders or other containers at the beginning of the year, including heels (kg);
I_{Ej}	=	Inventory of input gas *i* stored in cylinders or other containers at the end of the year, including heels (kg);
A_i	=	Acquisitions of gas *i* during the year through purchases or other transactions, including heels in cylinders or other containers returned to the electronics manufacturing facility (kg);
D_i	=	Disbursements under exceptional circumstances of gas *i* through sales or other transactions during the year, including heels in cylinders or other containers returned by the electronics manufacturing facility to the chemical supplier, calculated using Equation 110-7 of this section (kg); and
0.001	=	Conversion factor from kg to metric tons.

(e) Calculate disbursements of gas *i* using Equation 110-7 of this section.

$$D_i = h_i \times N_i \times F_i + X_i$$

Equation 110-7

Where:

D_i	=	Disbursements of gas *i* through sales or other transactions during the year, including heels in cylinders or other containers returned by the electronics manufacturing facility to the gas distributor (kg);
h_i	=	Facility-wide gas-specific heel factor for input gas *i* (%), as determined in §98.94(b) of this subpart;
N_i	=	Number of cylinders or other containers returned to the gas distributor containing the standard heel of gas *i*;
F_i	=	Full capacity of cylinders or other containers containing gas *i* (kg); and
X_i	=	Disbursements under exceptional circumstances of gas *i* through sales or other transactions during the year. These include returns of containers whose contents have been weighed due to an exceptional circumstance as specified in §WCI.114(a)(5) of this subpart (kg).

(f) For facilities that use fluorinated heat transfer fluids, you shall report the annual emissions of fluorinated GHG heat transfer fluids using the mass balance approach described in Equation 110-8 of this section.

$$E_i = \rho_i\left(I_{ib} + P_i - N_i + R_i - I_{ie} - D_i\right)\times 0.001$$

Equation 110-8

Where:

E_i	=	Emissions of fluorinated GHG heat transfer fluid *i*, (metric tons/year);
ρ_i	=	Density of fluorinated heat transfer fluid *i* (kg/liter);
I_{ib}	=	Inventory of fluorinated heat transfer fluid *i* (in containers, not equipment) at the beginning of the reporting year (liters). The inventory at the beginning of the reporting year must be the same as the inventory at the end of the previous reporting year;
P_i	=	Acquisitions of fluorinated heat transfer fluid *i* during the current reporting year (liters). Includes amounts purchased from chemical suppliers, amounts purchased from equipment suppliers with or inside of equipment, and amounts returned to the facility after off-site recycling;
N_i	=	Total nameplate capacity (full and proper charge) of equipment that uses fluorinated heat transfer fluid *i* and that is newly installed during the reporting year (liters);
R_i	=	Total nameplate capacity (full and proper charge) of equipment that uses fluorinated heat transfer fluid *i* and that is removed from service during the current reporting year (liters);
I_{ie}	=	Inventory of fluorinated heat transfer fluid *i* (in containers, not equipment) at the end of current reporting year (liters);
D_i	=	Disbursements of fluorinated heat transfer fluid *i* during the current reporting year (liters). Includes amounts returned to chemical suppliers, sold with or inside of equipment, and sent off site for verifiable recycling or destruction. Disbursements should include only amounts that are properly stored and transported so as to prevent emissions in transit; and
0.001	=	Conversion factor from kg to metric tons.

§ WCI.114 Sampling, Analysis, and Measurement Requirements

(a) For purposes of Equation 110-6 of this section, you must estimate facility-wide gas-specific heel factors for each cylinder/container type for each gas used according to the procedures in paragraphs (a)(1) through (a)(6) of this section.

(1) Base the facility-wide gas-specific heel factors on the residual weight or pressure of a gas cylinder/container that the facility uses to change out that cylinder/container for each cylinder/container type for each gas used.

(2) The residual weight or pressure used for §WCI.114(a)(1) shall be determined by monitoring the mass or the pressure of your cylinders/containers. If monitoring the pressure, convert the pressure to mass using the ideal gas law, as displayed in Equation 110-9 of this section, with an appropriately selected *Z* value.

$$pV = ZnRT \qquad \textbf{Equation 110-9}$$

Where:

p	=	Absolute pressure of the gas (Pa);
V	=	Volume of the gas (m^3);
Z	=	Compressibility factor;
n	=	Amount of substance of the gas (moles);
R	=	Gas constant (8.314 Joule/Kelvin mole); and
T	=	Absolute temperature (K).

(3) Use the facility-wide gas-specific cylinder/container residual mass, determined from §WCI.114(a)(1) and (a)(2), to calculate the unused gas for each container, which when expressed as fraction of the initial mass in the cylinder/container is the heel factor.

(4) The initial mass used to calculate the facility-wide gas-specific heel factor may be based on the weight of the gas provided in the gas supplier documents; however, the facilities remain responsible for the accuracy of these masses and weights under this subpart.

(5) In the exceptional circumstance that a cylinder/container is changed at a residual mass or pressure that differs by more than 20 percent from the facility-wide gas-specific determined values, that cylinder shall be weighed, or the pressure of that cylinder shall be measured with a pressure gauge, in place of using a heel factor.

(6) Recalculate facility-wide gas-specific heel factors applied at the facility in the event that the residual weight or pressure of the gas cylinder/container that the facility uses to change out that cylinder/container differs by more than 1 percentage point from that used to calculate the previous gas-specific heel factor.

(b) Semiconductor facilities shall apportion fluorinated GHG consumption by process category, as defined in §WCI.113(a)(1)(i) through (a)(1)(iii), or by individual process using a facility-specific engineering model based on wafer passes.

(c) If factors for fluorinated GHG process utilization and by-product formation rates are used other than the defaults provided in Tables 110-2 through 110-4 of this subpart, the factors must have been measured using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006). Factors for fluorinated GHG process utilization and by-product formation rates measured by manufacturing equipment suppliers may be used if the conditions in paragraphs (c)(1) and (c)(2) of this section are met.

(1) The manufacturing equipment supplier has measured the GHG emission factors for process utilization and by-product formation rates using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006).

(2) The conditions under which the measurements were made are representative of the facility's fluorinated GHG emitting processes.

(d) If N_2O utilization factors other than those defaults provided in §WCI.113(c)(1)(ii) or (c)(2)(ii) are used, factors that have been measured using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006) must be used. Utilization factors measured by manufacturing equipment suppliers may be used if the conditions in paragraphs (d)(1) and (d)(2) of this section are met.

(1) The manufacturing equipment supplier has measured the N_2O utilization factors using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006).

(2) The conditions under which the measurements were made are representative of the facility's N_2O emitting processes.

(e) If the facility employs abatement systems and wishes to reflect emission reductions due to these systems in appropriate calculations in §WCI.113, the facility must adhere to the procedures in paragraphs (e)(1) and (e)(2) of this section. If the facility uses the default destruction or removal efficiency of 60 percent, the facility must adhere to procedures in paragraph (e)(3) of this section. If the facility uses either a properly measured destruction or removal efficiency, or a class average of properly measured destruction or removal efficiencies during a reporting year, the facility must adhere to procedures in paragraph (e)(4) of this section.

(1) The facility must certify and document that the systems are properly installed, operated, and maintained according to manufacturers' specifications by adhering to the procedures in paragraphs (e)(1)(i) and (e)(1)(ii) of this section.

(i) Proper installation must be verified by certifying the systems are installed in accordance with the manufacturers' specifications.

(ii) Proper operation and maintenance must be verified by certifying the systems are operated and maintained in accordance with the manufacturers' specifications.

(2) The facility must take into account and report the uptime of abatement systems when using destruction or removal efficiencies to reflect emission reductions. Abatement system uptime is expressed as the sum of an abatement system's operational productive, standby, and engineering times divided by the total operations time of its associated manufacturing tool(s) as referenced in SEMI Standard E-10-0340 "Specification for Definition and Measurement of Equipment Reliability, Availability, and Maintainability" (2004).

(3) To report controlled emissions using the default destruction or removal efficiency, the facility must certify and document that the abatement systems at the facility for which it is reporting controlled emissions are specifically designed for fluorinated GHG and N_2O abatement and you shall use a default destruction or removal efficiency of 60 percent for those abatement systems.

(4) If the facility does not use the default destruction or removal efficiency value to report controlled emissions, the facility must use either a properly measured destruction or removal efficiency, or a class average of properly measured destruction or removal efficiencies during a reporting year, determined in accordance with procedures in paragraphs (e)(4)(i) through (e)(4)(v) of this section.

(i) Destruction or removal efficiencies must be properly measured in accordance with EPA's "Protocol for Measuring Destruction or Removal Efficiency of Fluorinated Greenhouse Gas Abatement Equipment in Electronics Manufacturing" (March 2010).

(ii) A facility must annually select and properly measure the destruction or removal efficiency for a random sample of abatement systems to include in a random sampling abatement system testing program (RSASTP) in accordance with procedures in paragraphs (f)(3)(ii)(A) and (f)(3)(ii)(B) of this section.

(A) Each reporting year a random sample of three or 20 percent of installed abatement systems, whichever is greater, for each abatement system class shall be tested. In instances where 20 percent of the total number of abatement systems in each class does not equate to a whole number, the number of systems to be tested shall be determined by rounding up to the nearest integer.

(B) The facility must select the random sample each reporting year for the RSASTP without repetition of systems in the sample, until all systems in each class are properly measured in a 5-year period.

(iii) If a facility has measured the destruction or removal efficiency of a particular abatement system during the previous two-year period, the facility shall calculate emissions from that system using the destruction or removal efficiency most recently measured for that particular system.

(iv) If an individual abatement system has not yet undergone proper destruction or removal efficiency testing during the previous two-year period, the facility may apply a simple average of the properly measured destruction or removal efficiencies for all systems of that class, in accordance with the RSASTP. The facility shall maintain or exceed the RSASTP schedule and regime if it wishes to apply class average destruction or removal efficiency factors to abatement systems that have not been properly measured as per the RSASTP.

(v) In instances where redundant abatement systems are used, the facility may account for the total abatement system uptime calculated for a specific exhaust stream during the reporting year.

(f) Facilities must adhere to the QA/QC procedures of this paragraph when estimating fluorinated GHG and N_2O emissions from all electronics manufacturing processes:

(1) Facilities must follow the QA/QC procedures in the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006) when estimating facility-specific, recipe-specific fluorinated GHG and N2O utilization and by-product formation rates.

(2) Facilities must follow the QA/QC procedures in EPA's "Protocol for Measuring Destruction or Removal Efficiency of Fluorinated Greenhouse Gas Abatement Equipment in Electronics Manufacturing" (March 2010) when estimating abatement systems destruction or removal efficiency.

(3) Facilities must certify that gas consumption is tracked to a high degree of precision as part of normal facility operations ensuring that the inventory at the beginning of the reporting is the same as the inventory at the end of the previous year.

(g) Facilities must adhere to the QA/QC procedures of this paragraph when estimating fluorinated GHG emissions from heat transfer fluid use and annual gas consumption for each fluorinated GHG and N_2O used at the facility:

(1) Facilities must review all inputs to Equations 110-6 and 110-8 of this section to ensure that all inputs and outputs to the facility's system are accounted for.

(2) Facilities must not enter negative inputs into the mass balance Equations 110-6 and 110-8 of this section and shall ensure that no negative emissions are calculated.

(3) Facilities must ensure that the beginning of year inventory matches the end of year inventory from the previous year.

(h) All instruments (e.g., mass spectrometers and fourier transform infrared measuring systems) used to determine the concentration of fluorinated GHG and N_2O in process streams shall be calibrated just prior to destruction or removal efficiency, gas utilization, or by-product formation measurement through analysis of certified standards with known concentrations of the same chemicals in the same ranges (fractions by mass) as the process samples. Calibration gases prepared from a high-concentration certified standard using a gas dilution system that meets the requirements specified in Method 205, 40 CFR part 51, Appendix M may also be used.

(i) All flowmeters, weigh scales, pressure gauges, and thermometers used to measure quantities that are monitored under this section or used in calculations under §WCI.113 shall have an accuracy and precision of one percent of full scale or better.

§ WCI.115 Missing Data Procedures

(a) Except as provided in paragraph §WCI.115(b), a complete record of all measured parameters used in the fluorinated GHG and N_2O emissions calculations in §WCI.113 and§WCI.114 is required.

(b) If a facility uses heat transfer fluids and is missing data for one or more of the parameters in Equation 110-8 of this subpart, the facility must estimate heat transfer fluid emissions using the arithmetic average of the emission rates for the year immediately preceding the period of missing data and the months immediately following the period of missing data. Alternatively, you may estimate missing information using records from the heat transfer fluid supplier. The facility must document the method used and values estimated for all missing data values.

Table 110-1. Examples of Fluorinated GHGs Used by the Electronics Industry

Product Type	Fluorinated GHGs used during manufacturing
Electronics	CF_4, C_2F_6, C_3F_8, c-C_4F_8, c-C_4F_8O, C_4F_6, C_5F_8, CHF_3, CH_2F_2, NF_3, SF6,and HTFs [CF_3-(O-CF(CF_3)-CF_2)$_n$-(O-CF2)$_m$-O-CF_3, C_nF_{2n+2}, C_nF_{2n+1}(O)C_mF_{2m+1}, $C_nF_{2n}O$, (C_nF2$_{n+1}$)$_3$N].

This proposed WCI Essential Requirement would be for use in WCI Canadian jurisdictions. At such a point when the U.S. EPA finalizes Subpart W, the WCI will develop cap and trade quality requirements for sources covered by Subpart W for use in U.S. jurisdictions. This may mean modifications will be required to the current proposed Canadian language covering the same sources.

§ WCI.250 UNDERGROUND COAL MINES

§ WCI.251 Source Category Definition

The underground coal mine source category consists of active underground coal mines, and any underground mines under development that have operational pre-mining degasification systems. An underground coal mine is a mine at which coal is produced by tunneling into the earth to the coalbed, which is then mined with underground mining equipment such as cutting machines and continuous, longwall, and shortwall mining machines, and transported to the surface.

(a) Underground coal mines are categorized as active if any one of the following five conditions apply:

  (1) Mine development is underway.

  (2) Coal has been produced within the last 90 days.

  (3) Mine personnel are present in the mine workings.

  (4) Mine ventilation fans are operative.

  (5) The mine operates on an intermittent basis.

(b) The underground coal mine source category includes the following:

  (1) Each ventilation well or shaft, including both those wells and shafts where gas is emitted and those where gas is sold, used onsite, or otherwise destroyed (including by flaring).

  (2) Each degasification system well or shaft, including degasification systems deployed before, during, or after mining operations are conducted in a mine area. This includes both those wells and shafts where gas is emitted, and those where gas is sold, used onsite, or otherwise destroyed (including by flaring).

(c) The underground coal mine source category does not include abandoned or closed mines, surface coal mines, or post-coal mining activities (i.e., storage or transportation of coal).

§ WCI.252 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Quarterly CH_4 destruction at all ventilation and degasification system destruction devices or point of offsite transport (metric tons CH_4).

(b) Quarterly CH_4 emissions (net) from all ventilation and degasification systems (metric tons CH_4).

(c) Quarterly CO_2 emissions from onsite destruction of coal mine gas CH_4, where the gas is not a fuel input for energy generation or use (e.g., flaring) (metric tons CO_2).

§ WCI.253 Calculation of GHG Emissions

(a) For each ventilation shaft, vent hole, or centralized point into which CH_4 from multiple shafts and/or vent holes are collected, calculate the quarterly CH_4 liberated from the ventilation system using Equation 250-1 of this section. Measure CH_4 content, flow rate, temperature, pressure, and moisture content of the gas using the procedures outlined in §WCI.254.

$$CH_{4V} = n \times \left(V \times MCF \times \frac{C}{100\%} \times 0.6775 \times \frac{288.71K}{T} \times \frac{P}{1\ atm} \times 1{,}440 \right)$$

Equation 250-1

Where:

CH_{4V}	=	Quarterly CH_4 liberated from a ventilation monitoring point (metric tons CH_4);
V	=	Daily volumetric flow rate for the quarter (cubic meters) based on sampling or a flow rate meter. If a flow rate meter is used and the meter automatically corrects for temperature and pressure, replace "288.71K/T × P/1 atm" with "1";
MCF	=	Moisture correction factor for the measurement period, volumetric basis;
	=	1 when V and C are measured on a dry basis or if both are measured on a wet basis.
	=	1 - $(f_{H2O})_n$ when V is measured on a wet basis and C is measured on a dry basis.
	=	$1/[1-(f_{H2O})]$ when V is measured on a dry basis and C is measured on a wet basis.
(f_{H2O})	=	Moisture content of the CH_4 emitted during the measurement period, volumetric basis (cubic meter water per cubic meter emitted gas);
C	=	Daily CH_4 concentration of ventilation gas for the quarter (%, wet basis);
n	=	Number of days in the quarter where active ventilation of mining operations is taking place at the monitoring point;
0.6775	=	Density of CH_4 at 288.71 K (15.56 °C) and 1 atm (kg/m^3);
288.71K	=	288.71 Kelvin;
T	=	Temperature at which flow is measured (K) for the quarter;
P	=	Pressure at which flow is measured (atm); and
1,440	=	Conversion factor (min/day).

(1) Unless required to be modified to meet existing regulatory inspection schedules, the quarterly periods are:

(i) January 1 – March 31.

(ii) April 1 – June 30.

(iii) July 1 – September 30.

(iv) October 1 – December 31.

(2) Daily values of V, MCF, C, T, and P must be based on measurements taken at least once each quarter with no fewer than 6 weeks between measurements. If measurements are taken more frequently than once per quarter, then use the average value for all measurements taken. If continuous measurements are taken, then use the average value over the time period of continuous monitoring.

(3) If a facility has more than one monitoring point, the facility must calculate total CH4 liberated from ventilation systems ($CH_{4VTotal}$) as the sum of the CH_4 from all ventilation monitoring points in the mine, as follows in Equation 250-2:

$$CH_{4VTotal} = \sum_{i=1}^{m} \left(CH_{4V}\right)_i$$

Equation 250-2

Where:

$CH_{4VTotal}$ = Total quarterly CH_4 liberated from ventilation systems (metric tons CH_4);
CH_{4V} = Quarterly CH_4 liberated from each ventilation monitoring point (metric tons CH_4 and
m = Number of ventilation monitoring points.

(b) For each monitoring point in the degasification system (this could be at each degasification well and/or vent hole, or at more centralized points into which CH_4 from multiple wells and/or vent holes are collected), calculate the weekly CH_4 liberated from the mine using CH_4 measured weekly or more frequently (including by CEMS) according to §WCI.254(c), CH_4 content, flow rate, temperature, pressure, and moisture content, and Equation 250-3 of this section.

$$CH_{4D} = \sum_{i=1}^{n} \left(V_i \times MCF_i \times \frac{C_i}{100\%} \times 0.6775 \times \frac{288.71K}{T_i} \times \frac{P_i}{1\,atm} \times 1{,}440 \right)$$

Equation 250-3

Where:

CH_{4D} = Weekly CH_4 liberated from a monitoring point (metric tons CH_4);
V_i = Daily measured total volumetric flow rate for the days in the week when the degasification system is in operation at that monitoring point, based on sampling or a flow rate meter (cubic meters). If a flow rate meter is used and the meter automatically corrects for temperature and pressure, replace"288.71K/T × P/1 atm" with "1";
MCF_i = Moisture correction factor for the measurement period, volumetric basis;
= 1 when V_i and C_i are measured on a dry basis or if both are measured on a wet basis.
= $1-(f_{H2O})_i$ when V_i is measured on a wet basis and C_i is measured on a dry basis.
= $1/[1-(f_{H2O})_i]$ when V_i is measured on a dry basis and C_i is measured on a wet basis.

$(f_{H2O})_i$	=	Moisture content of the CH_4 emitted during the measurement period, volumetric basis (cubic meter water per cubic meter emitted gas);
C_i	=	Daily CH_4 concentration of gas for the days in the week when the degasification system is in operation at that monitoring point (%, wet basis);
n	=	Number of days in the week that the system is operational at that measurement point.
0.6775	=	Density of CH_4 at 288.71 K (15.56 ℃) and 1 atm (kg/m^3);
288.71K	=	288.71 Kelvin;
T_i	=	Daily temperature at which flow is measured (K);
P_i	=	Daily pressure at which flow is measured (atm); and
1,440	=	Conversion factor (min/day).

(1) Daily values for V, MCF, C, T, and P must be based on measurements taken at least once each calendar week with at least 3 days between measurements. If measurements are taken more frequently than once per week, then use the average value for all measurements taken that week. If continuous measurements are taken, then use the average values over the time period of continuous monitoring when the continuous monitoring equipment is properly functioning.

(2) Quarterly total CH4 liberated from degasification systems for the mine should be determined as the sum of CH4 liberated determined at each of the monitoring points in the mine, summed over the number of weeks in the quarter, as follows in Equation 250-4:

$$CH_{4DTotal} = \sum_{i=1}^{m} \sum_{j=1}^{w} \left(CH_{4D}\right)_{i,j}$$

Equation 250-4

Where: :

$CH_{4DTotal}$	=	Quarterly CH_4 liberated from all degasification monitoring points (metric tons CH_4);
CH_{4D}	=	Weekly CH_4 liberated from a degasification monitoring point (metric tons CH_4);
m	=	Number of monitoring points; and
w	=	Number of weeks in the quarter during which the degasification system is operated.

(c) If gas from degasification system wells or ventilation shafts is sold, used onsite, or otherwise destroyed (including by flaring), calculate the quarterly CH_4 destroyed for each destruction device and each point of offsite transport to a destruction device, using Equation 250-5 of this section. You must measure CH_4 content and flow rate according to the provisions in §WCI.254.

$$CH_{4Destroyed} = CH_4 \times DE$$

Equation 250-5

Where:

$CH_{4Destroyed}$ = Quarterly CH_4 destroyed (metric tons);
CH_4 = Quarterly CH_4 routed to the destruction device or offsite transfer point (metric tons); and
DE = Destruction efficiency (lesser of manufacturer's specified destruction efficiency and 0.99). If the gas is transported off-site for destruction, use DE = 1.

(d) Calculate total CH_4 destroyed as the sum of the methane destroyed at all destruction devices (onsite and offsite), using Equation 250-6 of this section.

$$CH_{4DestroyedTotal} = \sum_{i=1}^{d} \left(CH_{4Destroyed}\right)_d$$

Equation 250-6

Where:

$CH_{4DestroyedTotal}$ = Quarterly total CH_4 destroyed at the mine (metric tons CH_4);
$CH_{4Destroyed}$ = Quarterly CH_4 destroyed from each destruction device or offsite transfer point; and
d = Number of onsite destruction devices and points of offsite transport.

(e) Calculate the quarterly measured net CH4 emissions to the atmosphere using Equation 250-7 of this section.

$$CH_{emitted\ (net)} = CH_{4VTotal} + CH_{4DTotal} - CH_{4DestroyedTotal}$$

Equation 250-7

Where:

$CH_{4emitted\ (net)}$ = Quarterly CH_4 emissions from the mine (metric tons).
$CH_{4VTotal}$ = Quarterly sum of the CH_4 liberated from all mine ventilation monitoring points (CH_{4V}), calculated using Equation 250-2 of this section (metric tons).
$CH_{4DTotal}$ = Quarterly sum of the CH_4 liberated from all mine degasification monitoring points (CH_{4D}), calculated using Equation 250-4 of this section (metric tons).
$CH_{4DestroyedTotal}$ = Quarterly sum of the measured CH_4 destroyed from all mine ventilation and degasification systems, calculated using Equation 250-6 of this section (metric tons).

(f) For the methane collected from degasification and/or ventilation systems that is destroyed on site and is not a fuel input for energy generation or use (those emissions are monitored and reported under §WCI.20), estimate the CO_2 emissions using Equation 250-8 of this section.

$$CO_2 = CH_{4\,Destroyed\ on\ site} \times \left(\frac{44}{16}\right)$$

Equation 250-8

Where:

CO_2	=	Total quarterly CO_2 emissions from CH_4 destruction (metric tons);
$CH_{4Destroyedonsite}$	=	Quarterly sum of the CH_4 destroyed, calculated as the sum of CH_4 destroyed for each onsite, non-energy use, as calculated individually in Equation 250-5 of this section (metric tons); and
44/16	=	Ratio of molecular weights of CO_2 to CH_4.

§ WCI.254 Sampling, Analysis, and Measurement Requirements

Emissions may be estimated by monitoring as specified under paragraphs (a) through (g).

(a) For CH_4 liberated from ventilation systems, CH_4 must be monitored from each ventilation well and shaft, from a centralized monitoring point, or from a combination of the two options. Operators are allowed flexibility for aggregating emissions from more than one ventilation well or shaft, as long as emissions from all are addressed, and the methodology for calculating total emissions documented. Monitor using one of the following options:

(1) Collect quarterly or more frequent grab samples (with no fewer than 6 weeks between measurements) and make quarterly measurements of flow rate, temperature, and pressure. The sampling and measurements must be made at the same locations as MSHA inspection samples are taken, and should be taken when the mine is operating under normal conditions. Follow MSHA sampling procedures as set forth in the MSHA Handbook "General Coal Mine Inspection Procedures and Inspection Tracking System Handbook Number PH–08–V–1", January 1, 2008 or appropriate equivalent in Canada. Record the date of sampling, airflow, temperature, and pressure measured, the hand-held methane and oxygen readings (percent), the bottle number of samples collected, and the location of the measurement or collection.

(2) Obtain results of the quarterly (or more frequent) testing performed by appropriate equivalent to MSHA in Canada (if any).

(3) Monitor emissions through the use of one or more continuous emission monitoring systems (CEMS). If operators use CEMS as the basis for emissions reporting, they must provide documentation on the process for using data obtained from their CEMS to estimate emissions from their mine ventilation systems.

(b) For CH_4 liberated at degasification systems, CH_4 must be monitored from each well and gob gas vent hole, from a centralized monitoring point, or from a combination of the two options. Operators are allowed flexibility for aggregating emissions from more than one well or gob gas vent hole, as long as emissions from all are addressed, and the methodology for calculating total emissions documented. Monitor both gas volume and methane concentration by one of the following two options:

(1) Monitor emissions through the use of one or more continuous emissions monitoring systems (CEMS).

(2) Collect weekly (once each calendar week, with at least three days between measurements) or more frequent samples, for all degasification wells and gob gas vent holes. Determine weekly or more frequent flow rates and methane composition from these degasification wells and gob gas vent holes. Methane composition should be determined either by submitting samples to a lab for analysis, or from the use of methanometers at the degasification well site. Follow the sampling protocols for sampling of methane emissions from ventilation shafts, as described in §WCI.254(a)(1).

(c) Monitoring must adhere to one of the following standards:

(1) ASTM D1945–03 "Standard Test Method for Analysis of Natural Gas by Gas Chromatography"

(2) ASTM D1946–90 (Reapproved 2006) "Standard Practice for Analysis of Reformed Gas by Gas Chromatography"

(3) ASTM D4891–89 (Reapproved 2006) "Standard Test Method for Heating Value of Gases in Natural Gas Range by Stoichiometric Combustion"

(4) ASTM UOP539–97 "Refinery Gas Analysis by Gas Chromatography"

(d) All fuel flow meters, gas composition monitors, and heating value monitors that are used to provide data for the GHG emissions calculations shall be calibrated prior to the first reporting year, using the applicable methods specified in paragraphs (d)(1) through (7) of this section. Alternatively, calibration procedures specified by the flow meter manufacturer may be used. Fuel flow meters, gas composition monitors, and heating value monitors shall be recalibrated either annually or at the minimum frequency specified by the manufacturer, whichever is more frequent. For fuel, flare, or sour gas flow meters, the operator shall operate, maintain, and calibrate the flow meter using any of the following test methods or follow the procedures specified by the flow meter manufacturer. Flow meters must meet the accuracy requirements specified by regulation in the jurisdiction.

(1) ASME MFC–3M–2004 "Measurement of Fluid Flow in Pipes Using Orifice, Nozzle, and Venturi"

(2) ASME MFC–4M–1986 (Reaffirmed 1997) "Measurement of Gas Flow by Turbine Meters"

(3) ASME MFC–6M–1998 "Measurement of Fluid Flow in Pipes Using Vortex Flowmeters"

(4) ASME MFC–7M–1987 (Reaffirmed 1992) "Measurement of Gas Flow by Means of Critical Flow Venturi Nozzles"

(5) ASME MFC–11M–2006 "Measurement of Fluid Flow by Means of Coriolis Mass Flowmeters"

(6) ASME MFC–14M–2003 "Measurement of Fluid Flow Using Small Bore Precision Orifice Meters"

(7) ASME MFC–18M–2001 "Measurement of Fluid Flow using Variable Area Meters"

(e) For CH_4 destruction, CH_4 must be monitored at each onsite destruction device and each point of offsite transport for combustion using continuous monitors of gas routed to the device or point of offsite transport.

(f) All temperature and pressure monitors must be calibrated using the procedures and frequencies specified by the manufacturer.

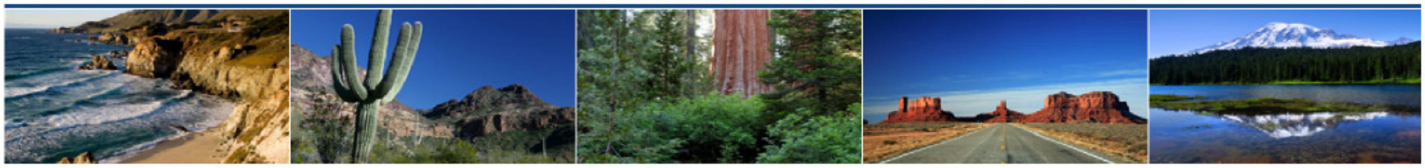
(g) If applicable, the owner or operator shall document the procedures used to ensure the accuracy of gas flow rate, gas composition, temperature, and pressure measurements. These

(h) procedures include, but are not limited to, calibration of fuel flow meters, and other measurement devices. The estimated accuracy of measurements, and the technical basis for the estimated accuracy shall be recorded.

§ WCI.255 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations, in accordance with the following.

For each missing value of CH_4 concentration, flow rate, temperature, and pressure for ventilation and degasification systems, the substitute data value shall be the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.



§ WCI.290 MAGNESIUM PRODUCTION

§ WCI.291 Source Category Definition

Magnesium production and processing source category consists of any process in which magnesium metal is produced through smelting (including electrolytic smelting), refining, or remelting operations or in which molten magnesium is used in alloying, casting, drawing, extruding, forming, or rolling operations.

Two important sector-specific definitions are the following:

(a) *Cover gas* means SF_6, HFC–134a, fluorinated ketone (FK 5–1–12) or other gas used to protect the surface of molten magnesium from rapid oxidation and burning in the presence of air. The molten magnesium may be the surface of a casting or ingot production operation or the surface of a crucible of molten magnesium that feeds a casting operation.

(b) *Carrier gas* means the gas with which cover gas is mixed to transport and dilute the cover gas thus maximizing its efficient use. Carrier gases typically include CO_2, N_2, and/or dry air.

§ WCI.292 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of the following gases in metric tons per year resulting from their use as cover gases or carrier gases in magnesium production or processing:

   (1) Sulfur hexafluoride (SF_6).

   (2) HFC–134a.

   (3) FK 5–1–12 (a fluorinated ketone).

   (4) Carbon dioxide (CO_2).

   (5) Any other GHGs (as defined by regulation).

(b) CO_2, N_2O, and CH_4 emissions from stationary combustion units as specified in §WCI.23.

(c) Types of production processes at the facility (e.g., primary, secondary, die casting, etc.).

(d) Amount of magnesium produced or processed in metric tons for each process type, including the output of primary and secondary magnesium production processes and the input to magnesium casting processes.

(e) For any missing data, the length of time the data were missing for each cover gas or carrier gas, the method used to estimate emissions in their absence, and the quantity of emissions thereby estimated.

(f) If applicable, an explanation of any change greater than 30 percent in the facility's cover gas usage rate (e.g., installation of new melt protection technology or leak discovered in the cover gas delivery system that resulted in increased emissions).

(g) Description of any new melt protection technologies adopted to account for reduced or increased GHG emissions in any given year.

§ WCI.293 Calculation of GHG Emissions

(a) Calculate the mass of each GHG emitted from magnesium production or processing over the calendar year using either Equation 290-1 or Equation 290-2 of this section, as appropriate. Both of these equations equate emissions of cover gases or carrier gases to consumption of cover gases or carrier gases.

(1) To estimate emissions of cover gases or carrier gases by monitoring changes in container masses and inventories, emissions of each cover gas or carrier gas shall be estimated using Equation 290-1 of this section:

$$E_x = \left(I_{B,x} - I_{E,x} + A_x - D_x\right) \times 0.001$$

Equation 290-1

Where:

E_x	=	Emissions of each cover gas or carrier gas *x* over the reporting year (metric tons);
$I_{B,x}$	=	Inventory of each cover gas or carrier gas *x* stored in cylinders or other containers at the beginning of the year, including heels (kg);
$I_{E,x}$	=	Inventory of each cover gas or carrier gas *x* stored in cylinders or other containers at the end of the year, including heels (kg);
A_x	=	Acquisitions of each cover gas or carrier gas *x* during the year through purchases or other transactions, including heels in cylinders or other containers returned to the magnesium production or processing facility (kg);.
D_x	=	Disbursements of each cover gas or carrier gas *x* to sources and locations outside the facility through sales or other transactions during the year, including heels in cylinders or other containers returned by the magnesium production or processing facility to the gas supplier (kg);
0.001	=	Conversion factor from kg to metric tons; and
x	=	Each cover gas or carrier gas that is a GHG.

(2) To estimate emissions of cover gases or carrier gases by monitoring changes in the masses of individual containers as their contents are used, emissions of each cover gas or carrier gas shall be estimated using Equation 290-2 of this section:

$$E_x = \sum_{p=1}^{n} Q_p \times 0.001$$

Equation 290-2

Where:

E_x = Emissions of each cover gas or carrier gas *x* over the reporting year (metric tons);
Q_p = Mass of the cover or carrier gas consumed (kg) over the container-use period *p* as estimated using Equation 290-3;
n = Number of container-use periods in the year;
= Inventory of each cover gas or carrier gas *x* stored in cylinders or other containers at the beginning of the year, including heels (kg);
0.001 = Conversion factor from kg to metric tons; and
x = Each cover gas or carrier gas that is a GHG.

(b) For purposes of Equation 290-2 of this section, the mass of the cover gas used over the period *p* for an individual container shall be estimated by using Equation 290-3 of this section:

$$Q_p = M_B - M_E$$

Equation 290-3

Where: :

Q_p = Mass of the cover or carrier gas consumed (kg) over the container-use period *p* (e.g., one month, etc.);
M_B = Mass of the container's contents (kg) at the beginning of period *p*; and
M_E = Mass of the container's contents (kg) at the end of period *p*.

(c) If a facility has mass flow controllers (MFC) and the capacity to track and record MFC measurements to estimate total gas usage, the mass of each cover or carrier gas monitored may be used as the mass of cover or carrier gas consumed (Q_p), in kg for period *p* in Equation 290-2 of this section.

§ WCI.294 Sampling, Analysis, and Measurement Requirements

Emissions (consumption) of cover gases and carrier gases may be estimated by monitoring as specified under paragraphs (a) through (c). Emissions must be estimated at least annually.

(a) Monitor the changes in container weights and inventories using Equation 290-1 of this subpart as follows:

(1) All quantities required by Equation 290-1 of this subpart must be measured using scales or load cells with an accuracy of 1 percent of full scale or better, accounting for the tare weights of the containers.

(2) Gas masses or weights provided by the gas supplier (e.g., for the contents of containers containing new gas or for the heels remaining in containers returned to the gas supplier) if the supplier provides documentation verifying that accuracy standards are met. However, the facility remains responsible for the accuracy of these masses or weights under this subpart.

(b) Monitor the changes in individual container weights as the contents of each container are used using Equations 290-2 and 290-3 of this subpart. The container identities and masses must be monitored and recorded as follows:

(1) Track the identities and masses of containers leaving and entering storage with check-out and check-in sheets and procedures. The masses of cylinders returning to storage shall be measured immediately before the cylinders are put back into storage.

(2) All the quantities required by Equations 290-2 and 290-3 of this subpart must be measured using scales or load cells with an accuracy of 1 percent of full scale or better, accounting for the tare weights of the containers.

(3) Gas masses or weights provided by the gas supplier (e.g., for the contents of cylinders containing new gas or for the heels remaining in cylinders returned to the gas supplier) if the supplier provides documentation verifying that accuracy standards are met. However, the facility remains responsible for the accuracy of these masses or weights under this subpart.

(c) Monitoring the mass flow of the pure cover gas or carrier gas into the gas distribution system. When estimating emissions by monitoring the mass flow of the pure cover gas or carrier gas into the gas distribution system, gas flow meters, or mass flow controllers, with an accuracy of 1 percent of full scale or better must be used.

All flow meters, scales, and load cells used to measure quantities that are to be reported under this subpart shall be calibrated using calibration procedures specified by the flow meter, scale, or load cell manufacturer. Calibration shall be performed prior to the first reporting year. After the initial calibration, recalibration shall be performed at the minimum frequency specified by the manufacturer.

§ WCI.295 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. Records must be documented and kept of the procedures used for all such estimates.

(a) A complete record of all measured parameters used in the GHG emission calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter will be used in the calculations as specified in paragraph (b) of this section.

(b) Replace missing data on the emissions of cover or carrier gases by multiplying magnesium production during the missing data period by the average cover or carrier gas usage rate from the most recent period when operating conditions were similar to those for the period for which the data are missing. Calculate the usage rate for each cover or carrier gas using Equation 290-4 of this section:

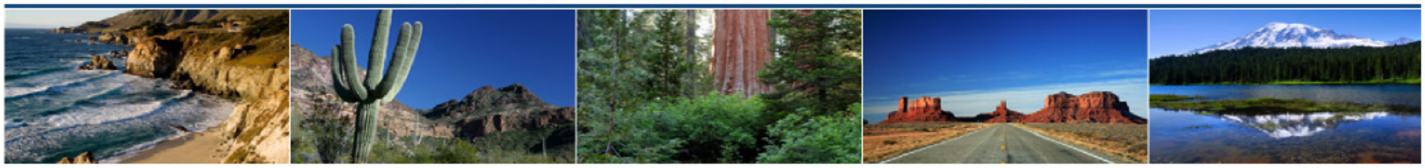
$$R_x = \left(\frac{C_x}{Mg}\right) \times 0.001$$

Equation 290-4

Where:

R_x	=	Usage rate of a particular cover gas or carrier gas *x* over the period of comparable operation (metric tons gas/metric ton Mg);
C_x	=	Consumption of a particular cover gas or carrier gas *x* over the period of comparable operation (kg);
Mg	=	Magnesium produced or fed into the process over the period of comparable operation (metric tons);
0.001	=	Conversion factor from kg to metric tons; and
x	=	Each cover gas or carrier gas that is a GHG.

(c) If the precise before and after weights are not available, it should be assumed that the container was emptied in the process (i.e., quantity purchased should be used, less heel).



This proposed WCI Essential Requirement would be for use in WCI Canadian jurisdictions. When the U.S. EPA finalizes Subpart W, the WCI will develop cap and trade quality requirements for sources covered by Subpart W for use in U.S. jurisdictions. This may mean modifications will be required to the current proposed Canadian language covering the same sources.

§ WCI.350 NATURAL GAS TRANSMISSION AND DISTRIBUTION

§ WCI.351 Source Category Definition

This source category consists of the following:

(a) Onshore natural gas transmission compression. Onshore natural gas transmission compression means any fixed combination of compressors that move natural gas at elevated pressure from production fields or natural gas processing facilities, in transmission pipelines, to natural gas distribution pipelines, or into storage. In addition, transmission compressor station includes equipment for liquids separation, natural gas dehydration, and tanks for the storage of water and hydrocarbon liquids.

(b) Underground natural gas storage. Underground natural gas storage means subsurface storage, including but not limited to, depleted gas or oil reservoirs and salt dome caverns utilized for storing natural gas that has been transferred from its original location for the primary purpose of load balancing (the process of equalizing the receipt and delivery of natural gas); natural gas underground storage processes and operations (including, but not limited to, compression, dehydration and flow measurement); and all the wellheads connected to the compression units located at the facility.

(c) Liquefied natural gas (LNG) storage. LNG storage means onshore LNG storage vessels located above ground, equipment for liquefying natural gas, compressors to capture and re-liquefy boil-off-gas, re-condensers, and vaporization units for re-gasification of the liquefied natural gas.

(d) LNG import and export equipment. LNG import equipment means all onshore or offshore equipment that receives imported LNG via ocean transport, stores LNG, re-gasifies LNG, and delivers re-gasified natural gas to a natural gas transmission or distribution system. LNG export equipment means all onshore or offshore equipment that receives natural gas, liquefies natural gas, stores LNG, and transfers the LNG via ocean transportation to any location, including locations in the United States.

(e) Natural gas distribution. Natural gas distribution consists of all natural gas equipment downstream of the station yard inlet shut-off valves of natural gas transmission pipelines at stations where pressure reduction and/or measuring and/or odorizing first occurs for eventual delivery of natural gas to consumers, or as otherwise separated from natural gas transmission by provincial or federal laws or regulations.

(f) Natural gas transmission pipelines. Natural gas transmission pipelines means a high pressure pipeline (and associated equipment) transporting sellable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering, regulating stations where the natural gas is typically odorized before delivery to customers, or as otherwise separated from natural gas transmission by provincial or federal laws or regulations.

§ WCI.352 Greenhouse Gas Reporting Requirements

Where greenhouse gases are not emitted from a specific emission source identified in paragraphs (a) to (g) then the reported emissions for the specific source shall be reported as zero.

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) CO_2 and CH_4 emissions from each industry source, including those in paragraph (b) through (g) of this section. In addition, N_2O emissions from flares and stationary combustion equipment identified for each industry source, including those specified in paragraph (b) through (g) of this section.

(b) For onshore natural gas transmission compression, report emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressor rod packing.

(ii) Centrifugal compressor wet seal degassing.

(iii) Blowdown vent stacks.

(iv) Natural gas pneumatic high bleed devices.

(v) Natural gas pneumatic low bleed device venting.

(vi) Other venting emission sources.*

(2) Fugitive emissions from connectors, block valves, control valves, compressor blowdown valves, pressure relief valves, orifice meters, other meters, regulators, open ended lines, reciprocating compressor rod packing and other fugitive emission sources.*

(3) Flares.

(4) Stationary combustion sources combusting field gas; stationary combustion sources combusting fuels other than field gas must report under WCI.20 (General Stationary Combustion Sources).

(c) For underground natural gas storage, report emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressor rod packing.

(ii) Centrifugal compressor wet seal degassing.

(iii) Natural gas pneumatic high bleed devices.

(iv) Natural gas pneumatic low bleed devices.

(v) Other venting emission sources.*

(2) Fugitive emissions from connectors, block valves, control valves, compressor blowdown valves, pressure relief valves, orifice meters, other meters, regulators, open ended lines and other fugitive emission sources.*

(3) Flares.

(4) Stationary combustion sources combusting field gas; stationary combustion sources combusting fuels other than field gas must report under WCI.20 (General Stationary Combustion Sources).

(d) For LNG storage, report emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressor rod packing.

(ii) Centrifugal compressor wet seal degassing.

(iii) Other venting emission sources.*

(2) Fugitive emissions from valves; pump seals; connectors; vapor recovery compressors, reciprocating compressor rod packing, centrifugal compressor dry seals and other fugitive sources.*

(3) Flares.

(4) Stationary combustion sources combusting field gas; stationary combustion sources combusting fuels other than field gas must report under WCI.20 (General Stationary Combustion Sources).

(e) LNG import and export equipment, report emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressor rod packing.

(ii) Centrifugal compressor wet seal degassing.

(iii) Blowdown vent stacks.

(iv) Other venting emission sources.*

(2) Fugitive emissions from valves, pump seals, connectors, vapor recovery compressors, centrifugal compressor dry seals reciprocating compressor rod packing and other fugitive sources.*

(3) Flares.

(4) Stationary combustion sources combusting field gas; stationary combustion sources combusting fuels other than field gas must report under WCI.20 (General Stationary Combustion Sources).

(f) For natural gas distribution, report emissions from the following sources:

(1) Above ground meter regulators and gate station fugitive emissions from connectors, block valves, control valves, pressure relief valves, orifice meters, other meters, regulators, farm taps, and open ended lines.

(2) Below ground meter regulators and vault fugitives.

(3) Pipeline fugitives.

(4) Service line fugitives.

(5) Stationary combustion sources combusting field gas; stationary combustion sources combusting fuels other than field gas must report under WCI.20 (General Stationary Combustion Sources).

(6) Other venting emission sources.*

(7) Other fugitive emission sources.*

(g) For natural gas transmission pipelines

(1) Above ground meter regulators and gate station fugitive emissions from connectors, block valves, control valves, pressure relief valves, orifice meters, other meters, regulators, farm taps, and open ended lines.

(2) Below ground meter regulators and vault fugitives.

(3) Pipeline fugitives.

(4) Other venting emission sources.*

(5) Other fugitive emission sources.*

(h) Facility and company-specific emission factors used in place of Tables 350-1 to 350-5

(i) Report activity data for each aggregated source type as follows:

(1) Count of natural gas pneumatic high bleed devices.

(2) Count of natural gas pneumatic low bleed devices.

(3) Count of natural gas driven pneumatic pumps.

(4) For each dehydrator unit report the following:

(i) Glycol dehydrators:

(A) The number of glycol dehydrators operated

(ii) Desiccant dehydrators:

(A) The number of desiccant dehydrators operated.

(5) For each compressor blowdown vent stack report the following for each compressor:

(i) Type of compressor whether reciprocating or centrifugal.
(ii) Compressor capacity in horse powers.
(iv) Number of blowdowns per year.

(6) For fugitive emissions sources using emission factors for estimating emissions report the following:

(i) Component count for each fugitive emissions source.

(j) Report emissions separately for portable equipment for the following source types (aggregate emissions by source type:

(1) Dehydrators, compressors, electrical generators, steam boilers, and heaters.

** other venting emission or other fugitive sources not specificially listed are not required to be reported if a source type is reasonably estimated to be below 0.5% of total operation emissions.*

*** where a quantification method is not provided for a specific source (such as for other venting and other fugitive sources, best practices must be used to estimate emissions*

§ WCI.353 Calculation of Greenhouse Gas Emissions

If greenhouse gases are not emitted from one or more of the following emission sources, the reporter will not need to calculate emissions from the emission source(s) in question and reported emissions for the emission source(s) will be zero.

(a) Natural gas pneumatic high bleed device venting and natural gas driven pneumatic pump venting.

(1) Calculate emissions from a natural gas pneumatic high bleed flow control device venting and natural gas driven pneumatic pump venting as follows:

(i) Estimate gas consumption for all high bleed natural gas powered devices and pneumatic pumps using a statistically defensible emission factor that is reviewed every three to five years.

(ii) Calculate CH_4 and CO_2 emissions from high bleed pneumatic devices and pumps using Equation 350-1 of this section.

$$E_{GHGi} = V_{NG} * M_i * MW_i / MVC * 0.001 \qquad \text{Equation 350-1}$$

Where:

E_{GHGi}	=	emissions of GHG i (i = CH_4 or CO_2) in metric tons
V_{NG}	=	volume of natural gas consumed by metered high bleed pneumatic devices and pumps (m^3/year)
M_i	=	mole fraction of CH_4 or CO_2 in natural gas supply
MW_i	=	molecular weight of GHG_i
MVC	=	molar volume conversion factor
0.001	=	conversion factor – kg to metric tons

(2) If in 2011 the statistically defensible emission factor is not available use the following method to estimate emissions from high bleed devices and natural gas driven pneumatic pumps that are not equipped with meters must be calculated using the following methods.

(i) For high bleed devices, calculate vented emissions using manufacturer data.

(A) Obtain from the manufacturer specific pneumatic device model natural gas bleed rate during normal operation.

(B) Calculate the natural gas emissions for each continuous bleed device using Equation 350-2 of this section.

$$E_{s,n} = B_s * T \qquad \text{Equation 350-2}$$

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions, in m^3.

B_s = Natural gas driven pneumatic device bleed rate volume at standard conditions in m^3 per minute, as provided by the manufacturer.

T = Amount of time in minutes that the pneumatic device has been operational through the reporting period.

(C) If manufacturer data for a specific device is not available, then use data for a similar device model, size and operational characteristics (or published default values) to estimate emissions.

(ii) Calculate emissions from natural gas driven pneumatic pump venting as follows:

(A) Obtain from the manufacturer specific pump model natural gas emission (or manufacturer "gas consumption") per unit volume of liquid circulation rate at pump speeds and operating pressures.

(B) Maintain a log of the amount of liquid pumped annually from individual pumps.

(C) Calculate the natural gas emissions for each pump using Equation 350-3 of this section.

$$E_{s,n} = F_s * V \qquad \text{Equation 350-3}$$

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions in m^3 per year.

F_s = Natural gas driven pneumatic pump gas emission in "emission per volume of liquid pumped at operating pressure" in m^3/liter at standard conditions, as provided by the manufacturer.

V = Volume of liquid pumped annually in liters/year.

(D) If manufacturer data for a specific pump in Equation 350-3 is not available, then use data for a similar pump model, size and operational characteristics (or published default values) to estimate emissions.

(iii) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section.

(b) <u>Natural gas pneumatic low bleed device venting</u>. Calculate emissions from natural gas pneumatic low continuous bleed device venting using Equation 350-4 of this section.

$$Mass_{s,i} = Count * EF * GHG_i * Conv_i * 24*365 \qquad \text{Equation 350-4}$$

Where:

$Mass_{s,i}$ = Annual total mass GHG emissions in metric tons per year at standard conditions from all natural gas pneumatic low bleed device venting, for GHG_i.

Count = Total number of natural gas pneumatic low bleed devices.

EF = Population emission factors for natural gas pneumatic low bleed device venting listed in Tables 350-1 and 350-2 of this section for onshore natural gas transmission and underground natural gas storage facilities, respectively.

GHG_i = 1.

$Conv_i$ = Conversion from m^3 to metric tons CO_2e; 0.01427 for CH_4, and 0.001832 for CO_2 at stp off 15 degrees celsius and 1 atmostphere

24 * 365 = Conversion to yearly emissions estimate.

(c) Blowdown vent stacks. Calculate blowdown vent stack emissions as follows:

(1) Calculate the total volume (including, but not limited to, pipelines, compressor case or cylinders, manifolds, suction and discharge bottles and vessels) between isolation valves.

(2) Retain logs of the number of blowdowns for each equipment type.

(3) Calculate the total annual venting emissions using Equation 350-5 of this section:

$$E_{a,n} = N * V_v \qquad \text{Equation 350-5}$$

Where:

$E_{a,n}$ = Annual natural gas venting emissions at ambient conditions from blowdowns in m^3.

N = Number of blowdowns for the equipment in reporting year.

V_v = Total volume of blowdown equipment chambers (including, but not limited to, pipelines, compressors and vessels) between isolation valves in m^3.

(4) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (i) of this section.

(5) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section.

(6) Blowdowns that are directed to flares use the WCI.353(d) Flare stacks calculation method rather than WCI.353(c) Blowdown vent stacks calculation method.

(d) Flare stacks. Calculate emissions from a flare stack as follows:

(1) If you have a continuous flow measurement device on the flare, you must use the measured flow volumes to calculate the flare gas emissions. If you do not have a continuous flow measurement device on the flare, you can install a flow measuring device on the flare or use engineering calculations, company records, or similar estimates of volumetric flare gas flow.

(2) If you have a continuous gas composition analyzer on gas to the flare, you must use these compositions in calculating emissions. If you do not have a continuous gas composition analyzer on gas to the flare, you must use the appropriate gas compositions for each stream of hydrocarbons going to the flare as follows:

(i) When the stream going to flare is natural gas, use the GHG mole percent in feed natural gas for all streams upstream of the de-methanizer and GHG mole percent in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead for onshore natural gas processing facilities.

(ii) When the stream going to the flare is a hydrocarbon product stream, such as ethane or butane, then use a representative composition from the source for the stream.

(3) Determine flare combustion efficiency from manufacturer. If not available, assume that flare combustion efficiency is 98 percent.

(4) Calculate GHG volumetric emissions at actual conditions using Equations 350-6, 350-7, 350-8, and 350-9 of this section.

$$E_{a,CH4} = V_a * (1-\eta) * X_{CH4} \quad \text{Equation 350-6}$$

$$E_{a,CO2}(non-combustion) = V_a * X_{CO2} \quad \text{Equation 350-7}$$

$$E_{a,CO2}(combusted) = \sum_j \eta * V_a * Y_j * R_j \quad \text{Equation 350-8}$$

$$E_{a,CO2}(total) = E_{a,CO2}(combusted) + E_{a,CO2}(un-combusted) \quad \text{Equation 350-9}$$

Where:

$E_{a,CH4}$	=	Contribution of annual uncombusted CH_4 emissions from flare stack in m^3, under ambient conditions.
$E_{a,CO2}$ (non-combusted)	=	Contribution of annual CO_2 emissions from CO_2 in the inlet gas passing through the flare, in m^3, under ambient conditions.

$E_{a,CO2}$ (combusted)	=	Contribution of annual emissions from combustion from flare stack in m^3, under ambient conditions
$E_{a,I}$ (total)	=	Total annual emissions from flare stack in m^3, under ambient conditions
V_a	=	Volume of natural gas sent to flare in m^3, during the year.
η	=	Percent of natural gas combusted by flare (default is 98 percent).
X_i	=	Concentration of GHG *i* in gas to the flare.
Y_j	=	Concentration of natural gas hydrocarbon constituents *j* (such as methane, ethane, propane, butane, and pentanes plus).
R_j	=	Number of carbon atoms in the natural gas hydrocarbon constituent *j*; 1 for methane, 2 for ethane, 3 for propane, 4 for butane, and 5 for pentanes plus).

(5) Calculate GHG volumetric emissions at standard conditions using calculations in paragraph (i) of this section.

(6) Calculate both CH_4 and CO_2 mass emissions from volumetric CH_4 and CO_2 emissions using calculation in paragraph (k) of this section.

(7) Calculate N_2O emissions using the emission factors for Gas Flares listed in Table 350-6 of this section.

(8) This emissions source excludes any emissions calculated under other emissions sources in this section.

(e) Centrifugal compressor wet seal degassing vents. Calculate emissions from centrifugal compressor wet seal degassing vents as follows:

(1) For each centrifugal compressor determine the volume of vapors from wet seal oil degassing tank sent to an atmospheric vent or flare using a temporary or permanent flow measurement meter such as, but not limited to, a vane anemometer according to methods set forth in WCI.354(b).

(2) Estimate annual emissions using meter flow measurement using Equation 350-10 of this section.

$$E_{a,i} = MT * T * M_i * (1 - B) \qquad \text{Equation 350-10}$$

Where:

$E_{a,i}$ = Annual GHG i (either CH_4 or CO_2) volumetric emissions at ambient conditions.

MT = Meter reading of gas emissions per unit time.

T = Total time the compressor associated with the wet seal(s) is operational in the reporting year.

M_i = Mole percent of GHG i in the degassing vent gas; use the appropriate gas compositions in paragraph (j)(2) of this section.

B = Percentage of centrifugal compressor wet seal degassing vent gas sent to vapor recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapor recovery system and the amount of vent gas that is directed to the fuel gas system.

(3) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using paragraph (i) of this section.

(4) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (k) of this section.

(5) Calculate emissions from degassing vent vapors to flares as follows:

(i) Use the degassing vent vapor volume and gas composition as determined in paragraphs (e)(1) through (3) of this section.

(ii) Use the calculation methodology of flare stacks in paragraph (d) of this section to determine degassing vent vapor emissions from the flare.

(f) Reciprocating compressor rod packing venting. Calculate annual CH_4 and CO_2 emissions from each reciprocating compressor rod packing venting as follows:

(1) Estimate annual emissions using a meter flow measurement using Equation 350-11 of this section.

$$E_{a,i} = MT * T * M_i \qquad \text{Equation 350-11}$$

Where:

$E_{a,i}$ = Annual GHG i (either CH_4 or CO_2) volumetric emissions at ambient conditions.

MT = Meter volumetric reading of gas emissions per unit time, under ambient conditions.

T = Total time the compressor associated with the venting is operational in the reporting year.

M_i = Mole percent of GHG i in the vent gas; use the appropriate gas compositions in paragraph (j)(2) of this section.

(2) If the rod packing case is connected to an open ended vent line then use one of the following two methods to calculate emissions**.**

(i) Measure emissions from all vents (including (as a singular case) emissions manifolded to common vents) including rod packing, unit isolation valves, and blowdown valves using bagging according to methods set forth in WCI.354(c).

(ii) Use a temporary meter such as, but not limited to, a vane anemometer or a permanent meter such as, but not limited to, an orifice meter to measure emissions from all vents (including (as a singular case) emissions manifolded to a common vent) including rod packing vents, unit isolation valves, and blowdown valves according to methods set forth in WCI.354(b).

(3) If the rod packing case is not equipped with a vent line use the following method to estimate emissions:

(i) You must use the methods described in WCI.354(a) to conduct a progressive sample leak detection of fugitive emissions from the packing case into an open distance piece, or from the compressor crank case breather cap or vent with a closed distance piece.

(ii) Measure emissions using a high flow sampler, or calibrated bag, or appropriate meter according to methods set forth in WCI.354(d).

(4) Conduct one measurement for each compressor in each of the operational modes that occurs during a reporting period:

(i) Operating.

(ii) Standby pressurized.

(iii) Not operating, depressurized.

(5) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using calculations in paragraph (i) of this section.

(6) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in paragraphs (j) and (k) of this section.

(g) <u>Leak detection and leaker emission factors</u>. The methods described in WCI.354(a) must be used to conduct a progressive sample leak detection of fugitive emissions from all sources listed in WCI.352(b)(2), (c)(2), (d)(2), (e)(2), (f)(1) and (g)(1). If fugitive emissions are detected for sources listed in this paragraph, calculate emissions using Equation 350-18 of this section for each source with fugitive emissions.

$$E_{s,i} = Count * EF * GHG_i * T \qquad \text{Equation 350-12}$$

Where:

$E_{s,i}$ = Annual total volumetric GHG emissions at standard conditions from each fugitive source.

Count = Total number of this type of emission source found to be leaking.

EF	=	Leaker emission factor for specific sources listed in Table 350-1 through Table 350-5 of this section.
GHG_i	=	the concentration of CO_2 in the feed natural gas or 1 for CH_4.
T	=	Total time the specific source associated with the fugitive emission was leaking in the reporting year, in hours.

(1) Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions using calculations in paragraph (k) of this section.

(2) Onshore natural gas transmission compression facilities shall use the appropriate default leaker emission factors listed in Table 350-1 of this section for fugitive emissions detected from connectors; block valves; control valves; compressor blowdown valves; pressure relief valves; orifice meters; other meters; regulators; and open ended lines.

(3) Underground natural gas storage facilities for storage stations shall use the appropriate default leaker emission factors listed in Table 350-2 of this section for fugitive emissions detected from connectors; block valves; control valves; compressor blowdown valves; pressure relief valves; orifice meters; other meters; regulators; and open ended lines.

(4) LNG storage facilities shall use the appropriate default leaker emission factors listed in Table 350-3 of this section for fugitive emissions detected from valves; pump seals; connectors; and other.

(5) LNG import and export facilities shall use the appropriate default leaker emission factors listed in Table 350-4 of this section for fugitive emissions detected from valves; pump seals; connectors; and other.

(6) Natural gas distribution facilities for above ground meter regulator and gate stations shall use the appropriate default leaker emission factors listed in Table 350-5 of this section for fugitive emissions detected from connectors; block valves; control valves; pressure relief valves; orifice meters; other meters; regulators; and open ended lines.

(h) Population count and emission factors. This paragraph applies to emissions sources listed in WCI.352(b)(1)(v), (c)(i)(iv), (c)(2), (d)(2), (e)(2), (f)(2), (f)(3), (f)(4), g(2) and g(3) on streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas content less than 10 percent CH_4 plus CO_2 by weight do not need to be reported. Calculate emissions from all sources listed in this paragraph using Equation 350-13 of this section.

$$E_{s,i} = Count * EF * GHG_i * T \qquad \text{Equation 350-13}$$

Where:

$E_{s,I}$	=	Annual total volumetric GHG emissions at standard conditions from each fugitive source.

Count = Total number of this type of emission source at the facility.

EF = Population emission factor for specific sources listed in Table 350-1 through Table 350-5 of this section.

GHG_i = GHG_i equals the concentration of CO_2 in produced natural gas or feed natural gas and 1 for CH_4.

T = Total time the specific source associated with the fugitive emission was operational in the reporting year, in hours.

(1) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (k) of this section.

(2) Underground natural gas storage facilities for storage wellheads shall use the appropriate default population emission factors listed in Table 350-2 of this section for fugitive emissions from connectors; valves; pressure relief valves; and open ended lines.

(3) LNG storage facilities shall use the appropriate default population emission factors listed in Table 350-3 of this section for fugitive emissions from vapor recovery compressors.

(4) LNG import and export facilities shall use the appropriate default population emission factor listed in Table 350-4of this section for fugitive emissions from vapor recovery compressors.

(5) Natural gas distribution facilities shall use the appropriate default population emission factors listed in Table 350-5 of this section for fugitive emissions from below grade M&R stations; gathering pipelines; mains; and services.

(i) Volumetric emissions. Calculate volumetric emissions at standard conditions as specified in paragraphs (i)(1) or (2) of this section.

(1) Calculate natural gas volumetric emissions at standard conditions by converting ambient temperature and pressure of natural gas emissions to standard temperature and pressure (15 degrees celsius and 1 atmophere (101.325 kPA)) natural gas using Equation 350-14 of this section.

$$E_{s,n} = \frac{E_{a,n} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 350-14

Where:

$E_{s,n}$ = Natural gas volumetric emissions at standard temperature and pressure (STP) conditions.

$E_{a,n}$ = Natural gas volumetric emissions at ambient conditions.

T_s = Temperature at standard conditions. (^oC).

T_a = Temperature at actual emission conditions. (^oC).

P_s = Absolute pressure at standard conditions (kPa).

P_a = Absolute pressure at ambient conditions (kPa).

(2) Calculate GHG volumetric emissions at standard conditions by converting ambient temperature and pressure of GHG emissions to standard temperature and pressure using Equation 350-15 this section.

$$E_{s,i} = \frac{E_{a,i} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 350-15

Where:

$E_{s,i}$ = GHG i volumetric emissions at standard temperature and pressure (STP) conditions.

$E_{a,i}$ = GHG i volumetric emissions at actual conditions.

T_s = Temperature at standard conditions. (^oC).

T_a = Temperature at actual emission conditions. (^oC).

P_s = Absolute pressure at standard conditions (kPa).

P_a = Absolute pressure at ambient conditions (kPa).

(j) GHG volumetric emissions. Calculate GHG volumetric emissions at standard conditions as specified in paragraphs (j)(1) and (2) of this section.

(1) Estimate CH_4 and CO_2 emissions from natural gas emissions using Equation 350-16 of this section.

$$E_{s,i} = E_{s,n} * M_i$$

Equation 350-16

Where:

$E_{s,i}$ = GHG i (either CH_4 or CO_2) volumetric emissions at standard conditions.

$E_{s,n}$ = Natural gas volumetric emissions at standard conditions.

M_i = Mole percent of GHG i in the natural gas.

(2) For Equation 350-16 of this section, the mole percent, M_i, shall be the annual average mole percent for each facility, as specified in paragraphs (j)(2)(i) through (vii) of this section.

(i) GHG mole percent in transmission pipeline natural gas that passes through the facility for onshore natural gas transmission compression facilities.

(ii) GHG mole percent in natural gas stored in underground natural gas storage facilities.

(iii) GHG mole percent in natural gas stored in LNG storage facilities.

(iv) GHG mole percent in natural gas stored in LNG import and export facilities.

(v) GHG mole percent in local distribution pipeline natural gas that passes through the facility for natural gas distribution facilities.

(k) GHG mass emissions. Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions by converting the GHG volumetric emissions into mass emissions using Equation 350-17 of this section.

$$Mass_{s,i} = E_{s,i} * \rho_i * GWP * 10^{-3}$$ Equation 350-17

Where:

$Mass_{s,i}$ = GHG i (either CH_4 or CO_2) mass emissions at standard conditions in metric tons CO_2e.

$E_{s,i}$ = GHG i (either CH_4 or CO_2) volumetric emissions at standard conditions, in m^3.

ρ_i = Density of GHG i, 1.871 kg/m^3 for CO_2 and 0.681 kg/m^3 for CH_4 at stp off 15 degrees celsius and 1 atmosphere.

GWP = Global warming potential, 1 for CO_2 and 21 for CH_4.

(l) Other vented or fugitive emissions

All vented or fugitive emissions not covered by quantification methods in WCI.353 must be calculated by methodologies consistent with those here or as presented in the Canadian Gas Association Methodology Manual.

§ WCI.354 Sampling, Analysis, and Measurement Requirements

Instruments used for sampling, analysis and measurement must be operated and calibrated according to legislative, manufacturer's, or other written specifications or requirements. All sampling, analysis and measurement must be conducted only by, or under the direct supervision of individuals with demonstrated understanding and experience in the application (and principles related) of the specific sampling, analysis and measurement technique in use.

(a) If a documented leak detection or integrity management standard or requirement that is required by legislation or regulation such as CSA Z662-07 Oil & Gas Pipeline Systems or the [CGA reference for fugitive emissions], the documented standard or requirement must be followed – including service schedules for different components - with reporting as required for input to the calculation methods herein.

If there is no such legal requirement, then progressive sampling is required using one of the methods outlined below in combination with best industry practices for use of the method– including service schedules for different components - to determine the count of leaks (and time leaking) required in WCI.363(o) and (n)(3)(i), as applicable. Progressive sampling means establishing a statistically valid baseline sample of leaks under normal operating conditions for the 2011 and 2012 calendar years, with subsequent sampling determined based random or spot sampling, modeling or measurement of leaks under normal operating conditions. A minimum of 18 months and a maximum of 36 months is allowed between surveys. This interval is determined based on whether there are indications of leaks. If a leak found and immediately repaired, the existing schedule may be maintained.

Leak detection for fugitive emissions must be performed for all identified equipment in operation or on standby mode during a reporting period.

(1) Optical gas imaging instrument. Use an optical gas imaging instrument for fugitive emissions detection in accordance with 40 CFR part 60, subpart A, §60.18 (i)(1) and (2) *Alternative work practice for monitoring equipment leaks* (or per relevant standard in Canada). In addition, the optical gas imaging instrument must be operated to image the source types required by this proposed reporting rule in accordance with the instrument manufacturer's operating parameters. The optical gas imaging instrument must comply with the following requirements:

(i) Provide the operator with an image of the potential leak points for each piece of equipment at both the detection sensitivity level and within the distance used in the daily instrument check described in the relevant best practices. The detection sensitivity level depends upon the frequency at which leak monitoring is to be performed.

(ii) Provide a date and time stamp for video records of every monitoring event.

(2) Bubble tests

(3) Portable organic vapour analyzer. Use a portable organic vapour analyzer in accordance with US EPA Method 21 or as outlined in the [CGA reference for fugitive emissions] or the CAPP Best Management Practices for Fugitive Emissions

(4) Other methods as outlined in the [CGA reference for fugitive emissions] or the CAPP Best Management Practices for Fugitive Emisisons may be used as necessary for operational circumstances

(b) All flow meters, composition analyzers and pressure gauges that are used to provide data for the GHG emissions calculations shall use measurement methods, maintenance practices, and calibration methods, prior to the first reporting year and in each subsequent reporting year using an appropriate standard method published by a consensus standards organization such as, but not limited to, Canadian Standards Association (CSA), Canadian Gas Association, Canadian Energy Pipeline Association (CEPA), ASTM International, American National Standards Institute (ANSI) and manufacturer's standards. If a consensus based standard is not available, you must use manufacturer instructions to calibrate the meters, analyzers, and pressure gauges.

(c) Use calibrated bags (also known as vent bags) only where the emissions are at near-atmospheric pressures such that it is safe to handle and can capture all the emissions, below the maximum temperature specified by the vent bag manufacturer, and the entire emissions volume can be encompassed for measurement.

(1) Hold the bag in place enclosing the emissions source to capture the entire emissions and record the time required for completely filling the bag. If the bag inflates in less than one second, assume one second inflation time.

(2) Perform three measurements of the time required to fill the bag, report the emissions as the average of the three readings.

(3) Estimate natural gas volumetric emissions at standard conditions using calculations in WCI.353(i).

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.353(j) and (k).

(d) Use a high volume sampler to measure emissions within the capacity of the instrument.

(1) A technician following (and competent to follow) manufacturer instructions shall conduct measurements, including equipment manufacturer operating procedures and measurement methodologies relevant to using a high volume sampler, including, but not limited to, positioning the instrument for complete capture of the fugitive emissions without creating backpressure on the source.

(2) If the high volume sampler, along with all attachments available from the manufacturer, is not able to capture all the emissions from the source then you shall use anti-static wraps or other aids to capture all emissions without violating operating requirements as provided in the instrument manufacturer's manual.

(3) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.353(j) and (k).

(4) Calibrate the instrument at 2.5 percent methane with 97.5 percent air and 100 percent CH_4 by using calibrated gas samples and by following manufacturer's instructions for calibration.

(Proposed to be added as WCI.025(g) – general stationary combustion)
Measurement and Metering Act of Canada standards (or other appropriate standards if the Measurement and Metering Act is not applicable) are deemed to be sufficient rigor for the sampling, analysis and measurement for the combustion of pipeline quality natural gas (including for derivation of standard gas composition) for facilities covered by WCI.350 – Natural Gas Transmission and Distribution. If a required meter is not covered by the Measurement and Metering Act, it must exist and meet the requirements of the applicable greenhouse gas reporting regulation for the jurisdiction.

§ WCI.355 Procedures for Estimating Missing Data

A complete record of all estimated and/or measured parameters used in the GHG emissions calculations is required. If data are lost or an error occurs during annual emissions estimation or measurements, you must repeat the estimation or measurement activity for those sources as soon as possible, including in the subsequent reporting year if missing data are not discovered until after December 31 of the reporting year, until valid data for reporting is obtained. Data developed and/or collected in a subsequent reporting year to substitute for missing data cannot be used for that subsequent year's emissions estimation. Where missing data procedures are used for the previous year, at least 30 days must separate emissions estimation or measurements for the previous year and emissions estimation or meausrements for the current year of data collection.

Directions on the use of Tables 350-1 to 350-5

(1) Starting with [2012] calendar year emissions, for each component listed in the Tables 350-1 to 350-5

(i) If facility specific emission factors for a component type are available they must be used

(ii) If facility specific emissions factors for a component type are not available, n operator must use company specific emission factors

(iii) If a specific component type cannot be safely or reasonably accessed to develop valid facility or company-specific emission factors, estimates in the default Tables 350-1 to 350-5 may be used. Similarly, equipment or facilities that have low utilization (e.g. some booster stations) may continue to use the default tables.

(iv) If a facility-specific emission factor has been used in a previous reporting year, it must continue to be used until updated. If a company-specific emission factor has been used in a previous reporting year, it must continue to be used until updated or a facility-specific emission factor is used in its place.

(v) Any changes from facility-specific factors to company-specific or table factors, or from company specific factors to the defaults in Tables 350-1 to 350-5 must be approved by the jurisdiction and substantiated by proof that the new approach is more accurate for the facility or facilities in question.

(vi) Documentation on the method used to update the emission factors, input data and sampling used, and the like must be kept by the operator and provided to the jurisdiction or verifier upon request.

(2) For 2011 calendar year emissions,

(i) An operator may use the default factors specified below, company or facility-specific emissions factors (if such emission factors are available). If the default factors in Tables 350-1 to 350-5 are used, an explanation as to why company or facility specific emission factors are cannot be used must be provided to the jurisdiction.

(3) All emission factors must be developed using Canadian Gas Association standard methods, or other methods if Canadian Gas Association methods are not available. Facility and company-specific emission factors must be updated at a minimum on a three year cycle, with the first update to the original facility and company-specific emission factors for the 2015 reporting period, at the latest.

(4) Updated emission factors can only be incorporated for reporting purposes at the start of a reporting period and not during a calendar year.

(5) The default emission factors provided in Tables 350-1 to 350-5 below are industry average emission factors for Canada as of the 2010 calendar year. The factors will be updated every 3-5 years based on new data, methods and statistically valid samples of the entire industry and developed in collaboration with industry groups.

[Except where noted, the following emission factors are from the CGA Methodology Manual version (2007). As the emission factors are updated by the CGA from time to time, the intention is to update the emission factors here]

§ WCI.356 Definitions

Blowdown vent stack emissions mean natural gas released due to maintenance and/or blowdown operations including but not limited to compressor blowdown and emergency shut-down (ESD) system testing.

Calibrated bag means a flexible, non-elastic, anti-static bag of a calibrated volume that can be affixed to a emitting source such that the emissions inflate the bag to its calibrated volume.

Centrifugal compressor means any equipment that increases the pressure of a process natural gas by centrifugal action, employing rotating movement of the driven shaft.

Centrifugal compressor dry seals mean a series of rings around the compressor shaft where it exits the compressor case that operates mechanically under the opposing forces to prevent natural gas from escaping to the atmosphere.

Centrifugal compressor dry seals emissions mean natural gas released from a dry seal vent pipe and/or the seal face around the rotating shaft where it exits one or both ends of the compressor case.

Centrifugal compressor wet seal degassing venting emissions means emissions that occur when the high-pressure oil barriers for centrifugal compressors are depressurized to release absorbed natural gas. High-pressure oil is used as a barrier against escaping gas in centrifugal compressor shafts. Very little gas escapes through the oil barrier, but under high pressure, considerably more gas is absorbed by the oil. The seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated. The separated gas is commonly vented to the atmosphere.

Component, for the purposes of WCI.350 and WCI.360 only, means but is not limited to each metal to metal joint or seal of non-welded connection separated by a compression gasket, screwed thread (with or without thread sealing compound), metal to metal compression, or fluid barrier through which natural gas or liquid can escape to the atmosphere.

Compressor means any machine for raising the pressure of a natural gas by drawing in low pressure natural gas and discharging significantly higher pressure natural gas.

Flare combustion means unburned hydrocarbons including CH_4, CO_2, N_2O emissions resulting from the incomplete combustion of gas in flares.

Flare combustion efficiency means the fraction of natural gas, on a volume or mole basis, that is combusted at the flare burner tip.

Fugitive emissions means the same as defined in the relevant greenhouse gas reporting regulation.

Fugitive emissions detection means the process of identifying emissions from equipment, components, and other point sources.

Gas conditions mean the actual temperature, volume, and pressure of a gas sample.

High-Bleed Pneumatic Devices are automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate in excess of six standard cubic feet per hour.

Liquefied natural gas (LNG) means natural gas (primarily methane) that has been liquefied by reducing its temperature to -162 degrees Celsius at atmospheric pressure.

LNG boiloff gas means natural gas in the gaseous phase that vents from LNG storage tanks due to ambient heat leakage through the tank insulation and heat energy dissipated in the LNG by internal pumps.

Low-Bleed Pneumatic Devices mean automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate equal to or less than six standard cubic feet per hour.

Natural gas driven pneumatic pump means a pump that uses pressurized natural gas to move a piston or diaphragm, which pumps liquids on the opposite side of the piston or diaphragm.

Operating pressure means the containment pressure that characterizes the normal state of gas or liquid inside a particular process, pipeline, vessel or tank.

Pipeline quality natural gas means natural gas having a high heat value equal to or greater than 36.1 MJ/m3 or less than 40.98 MJ/m3, and which is at least ninety percent methane by volume, and which is less than five percent carbon dioxide by volume.

Portable means the same as defined in WCI.27 and WCI.361(a)(2)

Pump means a device used to raise pressure, drive, or increase flow of liquid streams in closed or open conduits.

Pump seals means any seal on a pump drive shaft used to keep methane and/or carbon dioxide containing light liquids from escaping the inside of a pump case to the atmosphere.

Pump seal emissions means hydrocarbon gas released from the seal face between the pump internal chamber and the atmosphere.

Reciprocating compressor means a piece of equipment that increases the pressure of a process natural gas by positive displacement, employing linear movement of a shaft driving a piston in a cylinder.

Reciprocating compressor rod packing means a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of compressed natural gas that escapes to the atmosphere.

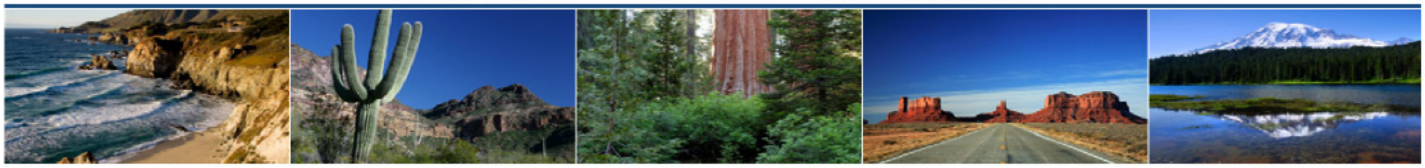
Re-condenser means heat exchangers that cool compressed boil-off gas to a temperature that will condense natural gas to a liquid.

Reservoir means a porous and permeable underground natural formation containing significant quantities of hydrocarbon liquids and/o r gases. A reservoir is characterized by a single natural pressure system.

Vapor recovery system means any equipment located at the source of potential gas emissions to the atmosphere or to a flare, that is composed of piping, connections, and, if necessary, flow-inducing devices, and that is used for routing the gas back into the process as a product and/or fuel.

Vaporization unit means a process unit that performs controlled heat input to vaporize LNG to supply transmission and distribution pipelines or consumers with natural gas.

Vented emissions means the same as defined in the relevant greenhouse gas reporting regulation, including but not limited to process designed flow to the atmosphere through seals or vent pipes, equipment blowdown for maintenance, and direct venting of gas used to power equipment (such as pneumatic devices).



This proposed WCI Essential Requirement would be for use in WCI Canadian jurisdictions. When the U.S. EPA finalizes Subpart W, the WCI will develop cap and trade quality requirements for sources covered by Subpart W for use in U.S. jurisdictions. This may mean modifications will be required to the current proposed Canadian language covering the same sources.

§WCI.360 PETROLEUM AND NATURAL GAS PRODUCTION AND GAS PROCESSING

§ WCI.361 Source Category Definition

(a) This source category consists of the following:

(1) Offshore petroleum and natural gas production. Offshore petroleum and natural gas production is any platform structure, affixed temporarily or permanently to offshore submerged lands, that houses equipment to extract hydrocarbons from the ocean or lake floor and that transfers such hydrocarbons to storage, transport vessels, or onshore. In addition, offshore production includes secondary platform structures and storage tanks associated with the platform structure.

(2) Onshore petroleum and natural gas production. Onshore petroleum and natural gas production equipment means all structures associated with wells (including but not limited to compressors, generators, or storage facilities), piping (including but not limited to flowlines or intra-facility gathering lines), and portable non-self-propelled equipment (including but not limited to well drilling and completion equipment, workover equipment, gravity separation equipment, auxiliary non-transportation-related equipment, and leased, rented or contracted equipment) used in the production, extraction, recovery, lifting, stabilization, separation or treating of petroleum and/or natural gas (including condensate). This also includes associated storage or measurement and all systems engaged in gathering produced gas from multiple wells, all EOR operations using CO_2, and all petroleum and natural gas production located on islands, artificial islands or structures connected by a causeway to land, an island, or artificial island.

(3) Onshore natural gas processing. Natural gas processing plants are designed to separate and recover natural gas liquids (NGLs) or other non-methane gases and liquids from a stream of produced natural gas to meet onshore natural gas transmission pipeline quality specifications through equipment performing one or more of the following processes: oil and condensate removal, water removal, separation of natural gas liquids, sulfur and carbon dioxide removal, fractionation of NGLs, or other processes, and also the capture of CO_2 separated from natural gas streams for delivery outside the facility. In addition, field gathering and/or boosting stations that gather and process natural gas from multiple wellheads, and compress and transport natural gas (including but not limited to flowlines or intra-facility gathering lines or compressors) as feed to the natural gas processing plants may be considered a part of the processing plant if emissions are not

calculated under onshore petroleum and natural gas production. Gathering and boosting stations that send the natural gas to an onshore natural gas transmission compression facility, or natural gas distribution facility, or to an end user are also considered within onshore natural gas processing for the purposes of emissions calculation. All residue gas compression equipment operated by a processing plant, whether inside or outside the processing plant fence, are considered part of the natural gas processing plant.

(b) This source category does not include natural gas transmission and distribution (i.e., onshore natural gas transmission compression, underground natural gas storage, liquefied natural gas (LNG) storage, LNG import and export equipment, and natural gas distribution). These are included in §WCI.350 (Natural Gas Transmission and Distribution).

§ WCI.362 Greenhouse Gas Reporting Requirements

Where greenhouse gases are not emitted from a specific emission source identified in paragraphs (a) to (g) then the reported emissions for the specific source shall be reported as zero.

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) CO_2 and CH_4 (and N_2O, if applicable) emissions (in metric tonnes) from each industry segment specified in paragraph (b) through (d) of this section. Onshore and offshore petroleum and natural gas production facilities must report emissions for the province.

(b) For offshore petroleum and natural gas production, report emissions from all "stationary fugitive" and "stationary vented" sources identified in the Minerals Management Service (MMS) Gulfwide Offshore Activity Data System (GOADS) study (2005 Gulfwide Emission Inventory Study MMS 2007-067). *[WCI.363(p), reserved]*

(c) For onshore petroleum and natural gas production, report emissions from the following source types:

(1) Natural gas pneumatic high bleed device venting. *[WCI.363(a)]*

(2) Natural gas driven pneumatic pump venting. *[WCI.363(a)]*

(3) Natural gas pneumatic low bleed device venting. *[WCI.363(b)]*

(4) Acid gas removal venting and incineration *[WCI.363(c)]*

(5) Dehydrator vent stacks. *[WCI.363(d)]*

(6) Well venting for liquids unloading. *[WCI.363(e)]*

(7) Gas well venting during conventional or unconventional well completions, except where vent gas is sent to a flare. *[WCI.363(f)]*

(8) Gas well venting during conventional well workovers, except where vent gas is sent to a flare. *[WCI.363(f)]*

(9) Blowdown vent stacks. *[WCI.363(g)]*

(10) Storage tanks. *[WCI.363(h)]*

(11) Well testing venting and flaring. *[WCI.363(i)]*

(12) Associated gas venting and flaring. *[WCI.363(j)]*

(13) Centrifugal compressor wet seal degassing venting. *[WCI.363(l)]*

(14) Reciprocating compressor rod packing venting. *[WCI.363(m)]*

(15) Fugitive emissions from reciprocating compressor rod packing. *[WCI.363(m)]*

(16) Gathering pipeline fugitives. *[WCI.363(o)]*

(17) Fugitive emissions from valves, connectors, open ended lines, pressure relief valves, compressor starter gas vents, pumps, flanges, and other fugitive sources* (such as instruments, loading arms, pressure relief valves, stuffing boxes, compressor seals, dump lever arms, and breather caps for crude services). *[WCI.363(o) or best practices if specific methods not identified]*

(18) EOR injection pump blowdown. *[WCI.363(t)]*

(19) Hydrocarbon liquids dissolved CO_2 from flashing. *[WCI.363(u)]*

(20) Produced water dissolved CO_2. *[WCI.363(v)]*

(21) Coal bed methane produced water emissions. *[WCI.363(v)]*

(22) Other venting emission sources* *[best practices]*

(d) For onshore natural gas processing, report emissions from the following sources:

(1) Acid gas removal venting or incineration. *[WCI.363(c)]*

(2) Dehydrator vent stacks. *[WCI.363(d)]*

(3) Blowdown vent stacks. *[WCI.363(g)]*

(4) Storage tanks. *[WCI.363(h)]*

(5) Flare stacks. *[WCI.363(k)]*

(6) Centrifugal compressor wet seal degassing venting. *[WCI.363(l)]*

(7) Reciprocating compressor rod packing venting. *[WCI.363(m)]*

(8) Fugitive emissions from reciprocating compressor rod packing. *[WCI.363(m)]*

(9) Gathering pipeline fugitives. *[WCI.363(o)]*

(10) Fugitive emissions from: valves, connectors, open ended lines, pressure relief valves, meters, centrifugal compressor dry and wet seals and other fugitive sources* *[WCI.363(n) or best practices if specific methods not identified]*

(11) Other venting emission sources**[best practices]*

(e) CO_2, CH_4, and N_2O emissions from each flare. *[including WCI.363(k)]*

(f) CO_2, CH_4, and N_2O from each stationary fuel combustion source type combusting field gas *[WCI.363(w)]* and fuels other than field gas. Stationary combustion sources that combust fuels other than field gas must report under §WCI.20 (General Stationary Combustion Sources).

(g) CO_2, CH_4, and N_2O from each portable equipment combustion source type combusting field gas *[WCI.363(w)]* and fuels other than field gas. Portable equipment combustion sources that combust fuels other than field gas must report under §WCI.20 (General Stationary Combustion Sources).

(h) Facility and company-specific emission factors used in place of Tables 360-1 to 360-2

(i) Report activity data for each aggregated source type as follows (for each individual facility or aggregate of facilities reported):

(1) Count of natural gas pneumatic high bleed devices.

(2) Count of natural gas pneumatic low bleed devices.

(3) Count of natural gas driven pneumatic pumps.

(4) For each dehydrator unit report the following:
(i) Glycol dehydrators:

(A) The number of glycol dehydrators operated.
(ii) Desiccant dehydrators:
(A) The number of desiccant dehydrators operated.

(5) Count of wells vented to the atmosphere for liquids unloading

(6) Count of wells venting during well completions:
(i) Number of conventional completions.
(ii) Number of completions employing hydraulic fracturing.

(7) Count of wells venting during well workovers:
(i) number of conventional well workovers involving well venting to the atmosphere.
(ii) number of unconventional well workovers involving well venting to the atmosphere.

(8) For each compressor blowdown vent stack report the following for each compressor:
   (i) Type of compressor whether reciprocating or centrifugal.
   (ii) Compressor capacity in horse powers.
   (iii) Number of blowdowns per year.

(9) Count of wells tested in the reporting period.

(10) Count of wells venting or flaring associated natural gas in the reporting period.

(11) Count of wells being unloaded for liquids in the reporting year.

(12) Count of wells completed (worked over) in the reporting year

(13) For fugitive emissions sources where emission factors are used for estimating emissions, report the following:
   (i) Component count for each fugitive emissions source.

(j) Report emissions separately for portable equipment for the following source types (aggregated by source type):

(1) dehydrators, compressors, electrical generators, steam boilers, and heaters.

** other venting emission or other fugitive sources not specifically listed are not required to be reported if a source type is reasonably estimated to be below 0.5% of total operation emissions.*

*** where a quantification method is not provided for a specific source (such as for other venting and other fugitive sources, best practices must be used to estimate emissions*

§ WCI.363 Calculating GHG Emissions

Zero emissions shall be reported for a given emission source where a quantification method is not applicable to the reporting operation's activities, or the greenhouse gas calculation equates to zero emissions.

(a) <u>Natural gas pneumatic high bleed device venting and natural gas driven pneumatic pump venting.</u> Calculate emissions from a natural gas pneumatic high bleed flow control device venting and natural gas drived pneumatic pump venting as follows:

(1) Calculate vented emissions from a natural gas pneumatic high bleed control devices or pneumatic pump as follows:
   (i) Measure gas consumption for all high bleed natural gas powered devices and pneumatic pumps using a meter or meters that meet accuracy requirements specified by relevant oil and gas metering requirements in the jurisdiction (even if a meter is not prescribed for this circumstance in the relevant requirements). In Year 1, reporters are required to meter gas consumption for at least 50% of all high bleed devices and pneumatic pumps. Metering of gas consumption for all high bleed

devices and pneumatic pumps is required in Year 2. Common meters may be used where possible.
[timing of meter installation with relation to planned downtime and statistically relevant samples are being considered]

(ii) Calculate CH_4 and CO_2 emissions from high bleed pneumatic devices and pumps using Equation 360-1.

$$E_{GHGi} = V_{NG} \times M_i \times \left(\frac{MW_i}{MVC} \right) \times 0.001 \qquad \textbf{Equation 360-1}$$

Where:

E_{GHGi}	=	emissions of GHG *i* (CH_4 or CO_2) (metric tons)
V_{NG}	=	volume of natural gas consumed by metered high bleed pneumatic devices and pumps (m^3/year).
M_i	=	mole fraction of CH_4 or CO_2 in natural gas supply.
MW_i	=	molecular weight of GHG *i*.
MVC	=	molar volume conversion factor.
0.001	=	conversion factor from kg to metric tons.

(2) In Year 1, emissions from high bleed devices and natural gas driven pneumatic pumps that are not equipped with meters must be calculated using the following methods.

(i) For high bleed devices, calculate vented emissions using manufacturer data.

(A) Obtain from the manufacturer specific pneumatic device model natural gas bleed rate during normal operation.

(B) Calculate the natural gas emissions for each continuous bleed device using Equation 360-2.

$$E_{s,n} = B_s \times T \qquad \textbf{Equation 360-2}$$

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions (m^3).
B_s = Natural gas driven pneumatic device bleed rate volume at standard conditions, as provided by the manufacturer (m^3 per minute).
T = Amount of time that the pneumatic device has been operational through the reporting period (minutes).

(C) If manufacturer data for a specific device is not available, then use data for a similar device model, size and operational characteristics to estimate emissions.

(ii) Calculate emissions from natural gas driven pneumatic pump venting as follows:

(A) Obtain from the manufacturer specific pump model natural gas emission (or manufacturer "gas consumption") per unit volume of liquid circulation rate at pump speeds and operating pressures.

(B) Maintain a log of the amount of liquid pumped annually from individual pumps.

(C) Calculate the natural gas emissions for each pump using Equation 360-3.

$$E_{s,n} = F_s \times V \qquad \textbf{Equation 360-3}$$

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions (m^3/year).
F_s = Natural gas driven pneumatic pump gas emission in "emission per volume of liquid pumped at operating pressure" at standard conditions, as provided by the manufacturer (m^3/liter).
V = Volume of liquid pumped annually (liters/year).

(D) If manufacturer data for a specific pump in Equation 360-3 is not available, then use data for a similar pump model, size and operational characteristics to estimate emissions.

(iii) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(b) Natural gas pneumatic low bleed device venting. Calculate emissions from natural gas pneumatic low continuous bleed device venting using Equation 360-4.

$$Mass_{s,i} = Count \times EF \times GHG_i \times Conv_i \times 24 \times 365$$

Equation 360-4

Where:

$Mass_{s,i}$	=	Annual total mass GHG emissions at standard conditions from all natural gas pneumatic low bleed device venting, for GHG i (metric tons/year).
Count	=	Total number of natural gas pneumatic low bleed devices.
EF	=	Population emission factors for natural gas pneumatic low bleed device venting listed in Table 360-1.
GHG_i	=	Concentration of GHG i (CH_4 or CO_2), in produced natural gas.
$Conv_i$	=	Conversion from m^3 to metric tons CO2e for GHG i; (0.01427 for CH_4, and 0.001832 for CO_2).
24 × 365	=	Conversion to yearly emissions estimate.

(c) Acid gas removal (AGR) venting or incineration process. Except for AGRs where the acid gases are re-injected into the oil/gas field, calculate CO_2 emissions only (not CH_4) for AGR (including but not limited to processes such as amine, membrane, molecular sieve or other absorbents and adsorbents) using Equation 360-5.

$$Mass_{a,CO2} = (V_1 \times \%Vol_1) - (V_2 \times \%Vol_2)$$

Equation 360-5

Where:

$E_{a,CO2}$	=	Annual volumetric CO_2 emissions at ambient condition (m^3/year).
V_1	=	Metered total annual volume of natural gas flow into AGR unit at ambient condition (m^3/year).
$\%Vol_1$	=	Volume weighted CO_2 content of natural gas into the AGR unit.
V_2	=	Metered total annual volume of natural gas flow out of the AGR unit at ambient condition (m^3/year).
$\%Vol_2$	=	Volume weighted CO_2 content of natural gas out of the AGR unit.

(1) If a continuous gas analyzer is installed, then the continuous gas analyzer results must be used. If continuous gas analyzer is not available, monthly gas samples must be taken to determine $\%Vol_1$ and $\%Vol_2$ according to methods set forth in WCI.364(b).

(2) Calculate CO_2 volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(3) Mass CO_2 emissions shall be calculated from volumetric CO_2 emissions using calculations in paragraphs (r) and (s) of this section.

(d) Dehydrator vent stacks. For dehydrator vent stacks without vapor recovery or thermal control devices, calculate annual mass CH_4 and CO_2 emissions at standard temperature and pressure (STP) conditions using a simulation software package of similar accuracy to GRI-GLYCalc Version 4.0 .

(1) A minimum of the following parameters must be used for characterizing emissions from dehydrators:
   (i) Feed natural gas flow rate.
   (ii) Feed natural gas water content.
   (iii) Outlet natural gas water content.
   (iv) Absorbent circulation pump type (natural gas pneumatic/air pneumatic/electric).
   (v) Absorbent circulation rate.
   (vi) Absorbent type: including, but not limited to, triethylene glycol (TEG), diethylene glycol (DEG) or ethylene glycol (EG).
   (vii) Use of stripping natural gas.
   (viii) Use of flash tank separator (and disposition of recovered gas).
   (ix) Hours operated.
   (x) Wet natural gas temperature, pressure, and composition.

(2) Calculate annual emissions from dehydrator vent stacks to flares or regenerator fire-box/fire tubes as follows:
   (i) Use the dehydrator vent stack volume and gas composition as determined in paragraph (d)(1) of this section.
   (ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine dehydrator vent stack emissions from the flare or regenerator combustion gas vent.

(3) Dehydrators that use desiccant shall calculate emissions from the amount of gas vented from the vessel every time it is depressurized for the desiccant refilling process using Equation 360-6.

$$E_{s,n} = \left(\frac{H \times D^2 \times \pi \times P_2 \times \%G \times 365}{4 \times P_1 \times T} \right)$$

Equation 360-6

Where:

$E_{s,n}$	=	Annual natural gas emissions at standard conditions.
H	=	Height of the dehydrator vessel (m^3).
D	=	Inside diameter of the vessel (m^3).
P_1	=	Atmospheric pressure (kPa).
P_2	=	Pressure of the gas (kPa).
π	=	pi (3.14).
%G	=	Percent of packed vessel volume that is gas.
365	=	Conversion from days to years.
T	=	Time between refilling (days).

(i) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(e) Well venting for liquids unloading.

(1) The emissions for well venting for liquids unloading shall be determined using the following calculation methodology:

Calculate emissions from each well venting for liquids unloading using Equation 360-7.

$$E_{s,n} = \left(\left[7.854 \times 10^{-5}\right] \times CD^2 \times WD \times \left[\frac{SP}{101.325}\right] \times V \right) + \left(SFR \times HR\right)$$

Equation 360-7

Where:

$E_{s,n}$	=	Annual natural gas emissions at standard conditions, in m^3/year.
7.854×10^{-5}	=	$(\pi/4)/(10000)$
CD	=	Casing diameter (cm).
WD	=	Well depth (m).
SP	=	Shut-in pressure (kPa-gage).
V	=	Number of vents per year.
SFR	=	Sales flow rate of gas well (m^3/hr).
HR	=	Hours that the well was left open to the atmosphere during unloading.

Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(f) Gas well venting during conventional or unconventional well completions and workovers. Calculate emissions from gas conventional or uncoventional (from hydraulic fracturing) well venting during well completions and workovers for each gas well using Equation 360-8. Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (r) of this section. Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

$$E_{a,n} = T \times FR$$

Equation 360-8

Where:

$E_{a,n}$	=	Annual natural gas vented emissions at ambient conditions (m^3).
T	=	Cumulative amount of time in hours of well venting during the year.
FR	=	Flow rate under ambient conditions, as required in paragraph (f)(1) of this section (m^3/hr).

(1) The flow rate for gas well venting during well completions and workovers from hydraulic fracturing shall be determined using either of the calculation methodologies described in this paragraph (f)(1). The same calculation methodology must be used for the entire volume for the reporting year.

(i) Calculation Methodology 1. For each well completion and each well workover, a recording flow meter shall be installed on the vent line during each well unloading event according to methods set forth in WCI.364(b). The average flow rate in cubic feet per minute of venting is calculated for each well completion and each well workover.

(ii) Calculation Methodology 2. For each well completion and each well workover, record the pressures measured before and after the well choke according to methods set forth in WCI.364(b). The average flow rate in cubic feet per minute of venting across the choke is calculated for each well completion and each well workover.

(iii) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(iv) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(2) Calculate annual emissions from gas well venting during well completions and workovers to flares as follows:

(i) Use the gas well venting volume during well completions and workovers as determined in paragraph (f)(1) of this section.

(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine gas well venting during well completions and workovers emissions from the flare.

(f.1) Gas well venting during conventional well completions and workovers.

Reserved *[paragraph (f) indicated to be appropriate for use in Canada for conventional gas wells]*

(g) Blowdown vent stacks. Calculate blowdown vent stack emissions as follows:

(1) Calculate the total volume (including, but not limited to, pipelines, compressor case or cylinders, manifolds, suction and discharge bottles and vessels) between isolation valves.

(2) Retain logs of the number of blowdowns for each equipment type.

(3) Calculate the total annual venting emissions using Equation 360-10:

$$E_{a,n} = N \times V_v$$

Equation 360-10

Where:

$E_{a,n}$	=	Annual natural gas venting emissions at ambient conditions from blowdowns (m^3).
N	=	Number of blowdowns for the equipment in reporting year.
V_v	=	Total volume of blowdown equipment chambers (including, but not limited to, pipelines, compressors and vessels) between isolation valves (m^3).

(4) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(5) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(h) Onshore production and processing storage tanks. For emissions from atmospheric pressure storage tanks receiving produced liquids from onshore petroleum and natural gas production faciliites (including stationary liquid storage not owned or operated by the reporter) and onshore natural gas processing facilities, calculate annual CH_4 and CO_2 emissions as specified in paragraphs (h)(1) or (h)(2). For atmospheric storage tanks vented to flares, use the calculation methodology for flare stacks in paragraph (k) of this section. Storage tanks equipped with vapor recovery units (VRU) are exempt from the requirements of this paragraph.

(1) CH_4 and CO2 emissions at storage tank batteries where the oil production rate is 10 barrels per day or greater shall be calculated using Equation 360-11

.

$$E_{GHGi} = GOR \times PR \times \left(\frac{1}{MVC}\right) \times MW_g \times MF_i \times 0.001$$

Equation 360-11

Where:

E_{GHGi}	=	Annual emissions of greenhouse gas *i* (CO_2 or CH_4) (metric tons/year).
GOR	=	Gas Oil Ratio (m^3/bbl).
PR	=	oil production rate (bbl/measurement period).
MVC	=	molar volume conversion.
MW_g	=	molecular weight of the gas (kg/kg-mole).
MF_i	=	mass fraction of greenhouse gas *i* (CO_2 or CH_4) in gas (kg *i* /kg gas).
0.001	=	conversion factor (metric tons/kg).

(2) Methane and carbon dioxide emissions at storage tank batteries where the oil production rate is less than 10 barrels per day shall calculate methane emissions the using the latest

software package for E&P Tank. A minimum of the following parameters must be used to characterize emissions from liquid transfer to atmospheric pressure storage tanks.

(i) Separator oil composition.
(ii) Separator temperature.
(iii) Separator pressure.
(iv) Sales oil API gravity.
(v) Sales oil production rate.
(vi) Sales oil Reid vapor pressure.
(vii) Ambient air temperature.
(viii) Ambient air pressure.

(i) Well testing venting and flaring. Calculate well testing venting and flaring emissions as follows:

(1) Determine the gas to oil ratio (GOR) of the hydrocarbon production from each well tested.

(2) Estimate venting emissions using Equation 360-12.

$$E_{a,n} = GOR \times FR \times D$$

Equation 360-12

Where:

$E_{a,n}$	=	Annual volumetric natural gas emissions from well testing ambient conditions (m^3).
GOR	=	Gas to oil ratio (m^3 of gas per barrel of oil); oil here defined as hydrocarbon liquids produced of all API gravities.
FR	=	Flow rate in barrels of oil per day for the well being tested.
D	=	Number of days during the year the well is tested.

(3) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(4) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(5) Calculate emissions from well testing to flares as follows:

(i) Use the well testing emissions volume and gas composition as determined in paragraphs (i)(1) through (3) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine well testing emissions from the flare.

(j) Associated gas venting and flaring. Calculate associated gas venting and flaring emissions as follows:

(1) Determine the GOR ratio of the hydrocarbon production from each well whose associated natural gas is vented or flared.

(2) Estimate venting emissions using the Equation 360-13.

$$E_{a,n} = GOR \times V$$

Equation 360-13

Where:

$E_{a,n}$	=	Annual volumetric natural gas emissions from associated gas venting under ambient conditions (m^3).
GOR	=	Gas to oil ratio (m^3 of gas per barrel of oil); oil here defined as hydrocarbon liquids produced of all API gravities.
V	=	Total volume of oil produced in barrels in the reporting year.

(3) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(4) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(5) Calculate emissions from associated natural gas to flares as follows:
  (i) Use the associated natural gas volume and gas composition as determined in paragraph (j)(1) through (3) of this section.
  (ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine associated gas emissions from the flare.

(k) Flare stacks. Calculate emissions from a flare stack as follows:

(1) If there is a continuous flow measurement device on the flare, measured flow volumes must be used to calculate the flare gas emissions. If there is not a continuous flow measurement device on the flare, a flow measuring device can be installed on the flare or engineering calculations, company records, or similar estimates of volumetric flare gas flow can be used.

(2) If there is a continuous gas composition analyzer on the gas to the flare, these compositions must be used in calculating emissions. If there is not a continuous gas composition analyzer on the gas to the flare, the appropriate gas compositions for each stream of hydrocarbons going to the flare must be used as follows:
  (i) When the stream going to flare is natural gas, use the GHG mole percent in feed natural gas for all streams upstream of the de-methanizer and GHG mole percent in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead for onshore natural gas processing facilities.

(ii) When the stream going to the flare is a hydrocarbon product stream, such as ethane or butane, then use a representative composition from the source for the stream.

(3) Determine flare combustion efficiency from manufacturer. If not available, assume that flare combustion efficiency is 98 percent.

(4) Calculate GHG volumetric emissions at actual conditions using Equations 360-14a, 360-14b, 360-15, and 360-16.

$$E_{a,CH4} = V_a \times (1-\eta) \times X_{CH4}$$

Equation 360-14a

$$E_{a,CO2}(noncombusted) = V_a \times X_{CO2}$$

Equation 360-14b

$$E_{a,CO2}(combusted) = \sum_j \eta \times V_a \times Y_j \times R_j$$

Equation 360-15

$$E_{a,CO2}(total) = E_{a,CO2}(noncombusted) + E_{a,CO2}(combusted)$$

Equation 360-16

Where:

$E_{a,CH4}$	=	Contribution of annual uncombusted CH_4 emissions from flare stack under ambient conditions (m^3).
$E_{a,CO2}$ (noncombusted)	=	Contribution of annual CO_2 emissions from CO_2 in the inlet gas passing through the flare uncombusted under ambient conditions (m^3).
$E_{a,CO2}$ (combusted)	=	Contribution of annual CO_2 emissions from combustion from flare stack under ambient conditions (m^3)
$E_{a,I}$ (total)	=	Total annual emissions from flare stack under ambient conditions (m^3)
V_a	=	Volume of natural gas sent to flare during the year (m^3).
η	=	Percent of natural gas combusted by flare (default is 98 percent).
X_i	=	Concentration of GHG i in gas to the flare.
Y_j	=	Concentration of natural gas hydrocarbon constituents j (i.e., methane, ethane, propane, butane, and pentanes plus).
R_j	=	Number of carbon atoms in the natural gas hydrocarbon constituent j (i.e., 1 for methane, 2 for ethane, 3 for propane, 4 for butane, and 5 for pentanes plus).

(5) Calculate GHG volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(6) Calculate both CH_4 and CO_2 mass emissions from volumetric CH_4 and CO_2 emissions using calculation in paragraph (s) of this section.

(7) Calculate N_2O emissions using the emission factors for Gas Flaring listed in Table 360-3.

(8) This emissions source excludes any emissions calculated under other emissions sources in WCI.363.

(l) Centrifugal compressor wet seal degassing vents. Calculate emissions from centrifugal compressor wet seal degassing vents as follows:

(1) For each centrifugal compressor determine the volume of vapors from wet seal oil degassing tank sent to an atmospheric vent or flare using a temporary or permanent flow measurement meter such as, but not limited to, a vane anemometer according to methods set forth in WCI.364(b).

(2) Estimate annual emissions using meter flow measurement using Equation 360-17.

$$E_{a,i} = MT \times T \times M_i \times (1 - B)$$

.

Equation 360-17

Where:

$E_{a,i}$	=	Annual volumetric emissions of GHG i (either CH_4 or CO_2) at ambient conditions.
MT	=	Meter reading of gas emissions per unit time.
T	=	Total time the compressor associated with the wet seal(s) is operational in the reporting year.
M_i	=	Mole percent of GHG i in the degassing vent gas; use the appropriate gas compositions in paragraph (r)(2) of this section.
B	=	Percentage of centrifugal compressor wet seal degassing vent gas sent to vapor recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapor recovery system and the amount of vent gas that is directed to the fuel gas system.

(3) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using paragraph (q) of this section.

(4) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (s) of this section.

(5) Calculate emissions from degassing vent vapors to flares as follows:
  (i) Use the degassing vent vapor volume and gas composition as determined in paragraphs (l)(1) through (3) of this section.
  (ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine degassing vent vapor emissions from the flare.

(m) Reciprocating compressor rod packing venting. Calculate annual CH_4 and CO_2 emissions from each reciprocating compressor rod packing venting as follows:

(1) Estimate annual emissions using a meter flow measurement using Equation 360-18.

$$E_{a,i} = MT \times T \times M_i$$

Equation 360-18

Where:

$E_{a,i}$	=	Annual volumetric emissions of GHG i (either CH_4 or CO_2) at ambient conditions.
MT	=	Meter volumetric reading of gas emissions per unit time, under ambient conditions.
T	=	Total time the compressor associated with the venting is operational in the reporting year.
M_i	=	Mole percent of GHG i in the vent gas; use the appropriate gas compositions in paragraph (r)(2) of this section.

(2) If the rod packing case is connected to an open ended vent line then use one of the following two methods to calculate emissions.
  (i) Measure emissions from all vents (including emissions manifolded to common vents) including rod packing, unit isolation valves, and blowdown valves using bagging according to methods set forth in WCI.364(c).
  (ii) Use a temporary meter such as, but not limited to, a vane anemometer or a permanent meter such as, but not limited to, an orifice meter to measure emissions from all vents (including emissions manifolded to a common vent) including rod packing vents, unit isolation valves, and blowdown valves according to methods set forth in WCI.364(b).

(3) If the rod packing case is not equipped with a vent line use the following method to estimate emissions:
  (i) Use the methods described in WCI.364(a) to conduct a progressive sample leak detection of fugitive emissions from the packing case into an open distance piece, or from the compressor crank case breather cap or vent with a closed distance piece.
  (ii) Measure emissions using a high flow sampler, or calibrated bag, or appropriate meter according to methods set forth in WCI.364(d).

(4) Conduct one measurement for each compressor in each of the operational modes that occurs during a reporting period:
  (i) Operating.
  (ii) Standby pressurized.
  (iii) Not operating, depressurized.

(5) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(6) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in paragraphs (r) and (s) of this section.

(n) Leak detection and leaker emission factors. The methods described in WCI.364(a) must be used to conduct a progressive sample leak detection of fugitive emissions from all sources listed in §WCI.362(d)(10). If fugitive emissions are detected for sources listed in this paragraph, calculate emissions using Equation 360-19 for each source with fugitive emissions.

$$E_{s,i} = Count \times EF \times GHG_i \times T$$

Equation 360-19

Where:

$E_{s,i}$	=	Annual total volumetric GHG emissions at standard conditions from each fugitive source.
Count	=	Total number of this type of emission source found to be leaking.
EF	=	Leaker emission factor for specific sources listed in Table 360-1 or Table 360-2.
GHG_i	=	For onshore natural gas processing facilities, concentration of GHG i, CH_4 or CO_2, in the total hydrocarbon of the feed natural gas.
T	=	Total time the specific source associated with the fugitive emission was leaking in the reporting year, in hours.

(1) Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions using calculations in paragraph (s) of this section.

(2) Onshore natural gas processing facilities shall use the appropriate default leaker emission factors listed in Table 360-2 for fugitive emissions detected from valves; connectors; open ended lines; pressure relief valves; meters; and centrifugal compressor dry seals.

(o) Population count and emission factors. This paragraph applies to emissions sources listed in §WCI.362(c)(2), (c)(16), (c)(17), (c)(21), and (d)(9) on streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas content less than 10 percent CH_4 plus CO_2 by weight do not need to be reported. Calculate emissions from all sources listed in this paragraph using Equation 360-20.

$$E_{s,i} = Count \times EF \times GHG_i \times T$$

Equation 360-20

Where:

$E_{s,i}$	=	Annual total volumetric GHG emissions at standard conditions from each fugitive source.
Count	=	Total number of this type of emission source at the facility.
EF	=	Population emission factor for specific sources listed in Table 360-1 or Table 360-2.
GHG_i	=	for onshore petroleum and natural gas production facilities and onshore natural gas processing facilities, concentration of GHG i, CH_4 or CO_2, in produced natural gas or feed natural gas.
T	=	Total time the specific source associated with the fugitive emission was operational in the reporting year, in hours.

(1) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (s) of this section.

(2) Onshore petroleum and natural gas production facilities shall use the appropriate default population emission factors listed in Table 360-1 for fugitive emissions from valves; connectors; open ended lines; pressure relief valves; compressor starter gas vent; pump; flanges; other; and CBM well water production. Where facilities conduct EOR operations the emissions factor listed in Table 360-1 shall be used to estimate all streams of gases, including recycle CO_2 stream. In cases where the stream is almost all CO_2, the emissions factors in Table 360-1 shall be assumed to be for CO_2 instead of natural gas.

(3) Onshore natural gas processing facilities shall use the appropriate default population emission factor listed in Table 360-2 for fugitive emissions from gathering pipelines.

(p) Offshore petroleum and natural gas production facilities in both provincial and federal waters.
[reserved]

(q) Volumetric emissions. Calculate volumetric emissions at standard conditions as specified in paragraphs (q)(1) or (2).

(1) Calculate natural gas volumetric emissions at standard conditions by converting ambient temperature and pressure of natural gas emissions to standard temperature and

pressure (15 degrees Celsius and 1 atmosphere in Canada) natural gas using Equation 360-21.

$$E_{s,n} = \frac{E_{a,n} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 360-21

Where:

$E_{s,n}$	=	Natural gas volumetric emissions at standard temperature and pressure (STP) conditions.
$E_{a,n}$	=	Natural gas volumetric emissions at ambient conditions.
T_s	=	Temperature at standard conditions (^{o}C).
T_a	=	Temperature at actual emission conditions (^{o}C).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at ambient conditions (kPa).

(2) Calculate GHG volumetric emissions at standard conditions by converting ambient temperature and pressure of GHG emissions to standard temperature and pressure using Equation 360-22.

$$E_{s,i} = \frac{E_{a,i} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 360-21

Where:

$E_{s,i}$	=	GHG i volumetric emissions at standard temperature and pressure (STP) conditions.
$E_{a,i}$	=	GHG i volumetric emissions at actual conditions.
T_s	=	Temperature at standard conditions (^{o}C).
T_a	=	Temperature at actual emission conditions (^{o}C).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at ambient conditions (kPa).

(r) GHG volumetric emissions. Calculate GHG volumetric emissions at standard conditions as specified in paragraphs (r)(1) and (2).

(1) Estimate CH_4 and CO_2 emissions from natural gas emissions using Equation 360-23.

$$E_{s,i} = E_{s,n} \times M_i$$

Equation 360-23

Where:

$E_{s,i}$ = GHG i (CH_4 or CO_2) volumetric emissions at standard conditions.
$E_{s,n}$ = Natural gas volumetric emissions at standard conditions.
M_i = Mole percent of GHG i in the natural gas.

(2) For Equation 360-23 of this section, the mole percent, M_i, shall be the annual average mole percent for each facility, as specified in paragraphs (r)(2)(i) and (ii) of this section.

(i) GHG mole percent in produced natural gas for onshore petroleum and natural gas production facilities. If you have a continuous gas composition analyzer for produced natural gas, you must use these values in calculating emissions. If you do not have a continuous gas composition analyzer, then the known composition for the company or operator for the specific field must be used as taken according to methods set forth in WCI.364(b).

(ii) GHG mole percent in feed natural gas for all emissions sources upstream of the de-methanizer and GHG mole percent in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead for onshore natural gas processing facilities. If you have a continuous gas composition analyzer on feed natural gas, you must use these values in calculating emissions. If you do not have a continuous gas composition analyzer, then the known composition for the company or operator for the specific field must be used as taken according to methods set forth in WCI.364(b).

(s) <u>GHG mass emissions</u>. Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions by converting the GHG volumetric emissions into mass emissions using Equation 360-24.

$$Mass_{s,i} = E_{s,i} \times \rho_i \times GWP_i \times 10^{-3}$$

Equation 360-24

Where:
$Mass_{s,i}$ = GHG i (CH_4 or CO_2) mass emissions at standard conditions (metric tons CO_2e).
$E_{s,i}$ = GHG i (CH_4 or CO_2) volumetric emissions at standard conditions (m^3).
ρ_i = Density of GHG i, (1.871 kg/m^3 for CO_2 and 0.681 kg/m^3 for CH_4).
GWP_i = Global warming potential of GHG i (1 for CO_2 and 21 for CH_4).

(t) <u>EOR injection pump blowdown</u>. Calculate pump blowdown emissions as follows:

(1) Calculate the total volume in cubic meters (including, but not limited to, pipelines, compressors and vessels) between isolation valves.

(2) Retain logs of the number of blowdowns per reporting period.

(3) Calculate the total annual venting emissions using Equation 360-25.

$$Mass_{c,i} = N \times V_v \times R_c \times GHG_i \times 10^{-3}$$

Equation 360-25

Where:

$Mass_{c,i}$	=	Annual EOR injection gas venting emissions at critical conditions "c" from blowdowns (metric tons).
N	=	Number of blowdowns for the equipment in reporting year.
V_v	=	Total volume of blowdown equipment chambers (including, but not limited to, pipelines, compressors, manifolds and vessels) between isolation valves (m^3).
R_c	=	Density of critical phase EOR injection gas in kg/m^3. Use an appropriate standard method published by a consensus-based standards organization to determine density of super critical EOR injection gas.
GHG_i	=	Mass fraction of GHG_i in critical phase injection gas.

(u) Hydrocarbon liquids dissolved CO_2. Calculate dissolved CO_2 in hydrocarbon liquids as follows:

(1) Determine the amount of CO_2 retained in hydrocarbon liquids after flashing in tankage at STP conditions. Quarterly samples must be taken according to methods set forth in WCI.364(b) to determine retention of CO_2 in hydrocarbon liquids immediately downstream of the storage tank. Use the average of the quarterly analysis for the reporting period.

(2) Estimate emissions using Equation 360-26.

$$Mass_{s,CO2} = S_{hl} \times V_{hl}$$

Equation 360-26

Where:

$Mass_{s,CO2}$	=	Annual CO_2 emissions from CO_2 retained in hydrocarbon liquids beyond tankage (metric tons).
S_{hl}	=	Amount of CO_2 retained in hydrocarbon liquids under standard conditions (metric tons per barrel).
V_{hl}	=	Total volume of hydrocarbon liquids produced (barrels per year).

(v) Produced water dissolved CO_2. Calculate dissolved CO_2 in produced water that is not re-injected as follows:

(1) Determine the amount of CO_2 retained in produced water at STP conditions. Quarterly samples must be taken according to methods set forth in WCI.364(b) to determine retention of CO_2 in produced water immediately downstream of the separator where

hydrocarbon liquids and produced water are separated. Use the average of the quarterly analysis for the reporting period.

(2) Estimate emissions using the Equation 360-27.

$$Mass_{s,CO2} = S_{pw} \times V_{pw}$$

Equation 360-27

Where:

$Mass_{s, CO2}$	=	Annual CO_2 emissions from CO_2 retained in produced water beyond tankage (metric tons).
S_{pw}	=	Amount of CO_2 retained in produced water under standard conditions (metric tons per barrel).
V_{pw}	=	Total volume of produced water produced (barrels per year).

(3) EOR operations that route produced water from separation directly to re-injection into the hydrocarbon reservoir in a closed loop system without any leakage to the atmosphere are exempt from paragraph (v) of this section.

(w) Field gas combustion. For combustion units that combust field gas, you must comply with following requirements:

(1) Measure the higher heating value of the field gas annually.

(2) If the measured higher heating value is equal to or greater than 36,1 MJ/m^3 and less than 40.98 MJ/m^3, then calculate the CO_2, CH_4, and N_2O emissions using the methods in WCI.20 (General Stationary Combustion Sources) following the methods required for pipeline quality natural gas.

(3) If the measured higher heating value is less than 36,1 MJ/m^3 or greater than 40.98 MJ/m^3, then calculate the CO_2, CH_4, and N_2O emissions using either the Tier 3 or Tier 4 methodology in WCI.20 (General Stationary Combustion Sources). Sampling, analysis and measurement requirements (including for gas composition) required for WCI.360 in WCI.025(f) applies in place of those indicated for Equation 20-7.

§ WCI.364 Sampling, Analysis, and Measurement Requirements

Instruments used for sampling, analysis and measurement must be operated and calibrated according to legislative, manufacturer's, or other written specifications or requirements. All sampling, analysis and measurement must be conducted only by, or under the direct supervision of individuals with demonstrated understanding and experience in the application (and principles related) of the specific sampling, analysis and measurement technique in use.

(a) If a documented leak detection or integrity management standard or requirement that is required by legislation orregulation such as CSA Z662-07 Oil & Gas Pipeline Systems or the CAPP Best Management Practices for Fugitive Emisisons, the documented standard or requirement must be followed – including service schedules for different components - with reporting as required for input to the calculation methods herein.

If there is no such legal requirement, then progressive sampling is required using one of the methods outlined below in combination with best industry practices for use of the method– including service schedules for different components - to determine the count of leaks (and time leaking) required in WCI.363(o) and (n)(3)(i), as applicable. Progressive sampling means establishing a statistically valid baseline sample of leaks under normal operating conditions for the 2011 and 2012 calendar years, with subsequent sampling determined based random or spot sampling modelling or measurement of leaks under normal operating conditions. A minimum of 18 months and a maximum of 36 months is allowed between surveys. This interval is determined based on whether there are indications of leaks. If a leak found and immediately repaired, the existing schedule may be maintained.

Leak detection for fugitive emissions must be performed for all identified equipment in operation or on standby mode during a reporting period.

(1) Optical gas imaging instrument. Use an optical gas imaging instrument for fugitive emissions detection in accordance with 40 CFR part 60, subpart A, §60.18 (i)(1) and (2) *Alternative work practice for monitoring equipment leaks* (or per relevant standard in Canada). In addition, the optical gas imaging instrument must be operated to image the source types required by this proposed reporting rule in accordance with the instrument manufacturer's operating parameters. The optical gas imaging instrument must comply with the following requirements:

(i) Provide the operator with an image of the potential leak points for each piece of equipment at both the detection sensitivity level and within the distance used in the daily instrument check described in the relevant best practices. The detection sensitivity level depends upon the frequency at which leak monitoring is to be performed.

(ii) Provide a date and time stamp for video records of every monitoring event.

(2) Bubble tests

(3) Portable organic vapour analyzer. Use a portable organic vapour analyzer in accordance with US EPA Method 21 or as outlined in the CAPP Best Management Practices for Fugitive Emisisons

(4) Other methods as outlined in the CAPP Best Management Practices for Fugitive Emisisons may be used as necessary for operational circumstances

(b) All flow meters, composition analyzers and pressure gauges that are used to provide data for the GHG emissions calculations shall use measurement methods, maintenance practices, and calibration methods, prior to the first reporting year and in each subsequent reporting year using an appropriate standard method published by a consensus standards organization such as, but not limited to, ASTM International, Canadian Standards Assocation (CSA), American National Standards Institute (ANSI), the relevant provincial or national oil and gas regulator, Measurement Canada, Canadian Association of Petroleum Producers (CAPP) and American Petroleum Institute (API). If a consensus based standard is not available, manufacturer instructions must be used to calibrate the meters, analyzers, and pressure gauges.

(c) Use calibrated bags (also known as vent bags) only where the emissions are at near-atmospheric pressures such that it is safe to handle and can capture all the emissions, below the maximum temperature specified by the vent bag manufacturer, and the entire emissions volume can be encompassed for measurement.

(1) Hold the bag in place enclosing the emissions source to capture the entire emissions and record the time required for completely filling the bag. If the bag inflates in less than one second, assume one second inflation time.

(2) Perform three measurements of the time required to fill the bag, report the emissions as the average of the three readings.

(3) Estimate natural gas volumetric emissions at standard conditions using calculations in WCI.363(r).

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.363(r) and (s).

(d) Use a high volume sampler to measure emissions within the capacity of the instrument.

(1) A technician following manufacturer instructions shall conduct measurements, including equipment manufacturer operating procedures and measurement methodologies relevant to using a high volume sampler, including, but not limited to, positioning the instrument for complete capture of the fugitive emissions without creating backpressure on the source.

(2) If the high volume sampler, along with all attachments available from the manufacturer, is not able to capture all the emissions from the source, then anti-static wraps or other aids must be used to capture all emissions without violating operating requirements as provided in the instrument manufacturer's manual.

(3) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.363(r) and (s).

(4) Calibrate the instrument at 2.5 percent methane with 97.5 percent air and 100 percent CH_4 by using calibrated gas samples and by following manufacturer's instructions for calibration.

(e) Onshore Production and Processing Storage Tanks.

(1) A pressurized sample of produced liquids shall be collected from the separator at a location upstream of the storage tank. This point would typically be at the final separation device before produced oil transitions from separator outlet pressure to atmospheric pressure and enters a production storage tank. This may require the installation of a sampling valve at the appropriate location. Sampling protocol specific to the collection of separator liquid can be found in the following publications:
   (i) Appendix C Sampling Protocol section (page 33) of the *E&P TANK Version 2.0 User's Manual*.
   (ii) Wyoming Department of Environmental Quality Air Quality Division guidance document *Oil and Gas Production Facilities, Chapter 6, Section 2 Permitting Guidance (revised August 2001), Appendix D Sampling and Analysis of Hydrocarbon Liquids and Natural Gas.*
   (iii) Gas Processors Association (GPA) Standard 2174-93, *Obtaining Liquid Hydrocarbon Samples for Analysis by Gas Chromatography*.

(2) The sample collection pressure shall be determined at the time of collection and again prior to processing in the laboratory to insure that sample integrity has been maintained. Liquid temperature should also be determined and recorded at the time of collection.

(3) Sampling and laboratory based determination of GOR shall be conducted at prescribed intervals and at a time when operational parameters of the storage tank battery are representative and consistent with normal operating conditions. Sampling shall be annual for oil production rates between 11 and 100 barrels/day, semi-annual for oil production rates between 101 and 500 barrels/day, and quarterly for oil production rates greater than 500 barrels/day.

(4) An additional sample shall be collected and analyzed if:
   (i) The oil production rate at the storage tank battery changes more than 20 percent for time periods in excess of one week (e.g., in cases where a well or wells feeding the storage tank battery stop or start production).
   (ii) The separator operating pressures change by more than 10 percent.

(5) The volume (barrels) of liquid produced during the sampling interval shall be determined using a calibrated liquid meter or industry standard method to an accuracy of ±5%.

[proposed to be added as WCI.025(f) – General Stationary Combustion]
For field gas combustion or general stationary combustion of natural gas within facilities covered by WCI.360, legislative or regulatory requirements, such as those required by the Petroleum and Natural Gas Act of British Columbia are sufficient for the points of measurement that are metered. For British Columbia, combustion sources specifically covered by the Petroleum and Natural Gas Act are to be calculated in the manner prescribed by the Act, its regulations, guidelines and policies. Combustion sources not covered by the Act must be metered according to the following sampling and measurement requirements.

(1) *For combustion emission sources where meters are not required by legislation or regulation a calculated shrinkage value is sufficient but must be assigned using engineering estimation techniques to the various sources, if required for reporting.*

(2) *For field or pipeline quality natural gas combustion emission sources where metering is not required by law or regulation and shrinkage is not calculated, engineering estimation techniques that consolidate to common meter points such as that at the input to a processing plant used for financial purposes are sufficient. As required, fuel use must be allocated (using equipment specifications, operating hours, and flow rates) to specific emission sources.*

(3) *For upstream sources, a meter is required at each installation or at a point where fuel use can allocated to multiple combustion sources such that the aggregated of all combustion sources are metered.*

All combustion estimates must be calculated in such a manner that ensures that fugitive, flaring and venting emissions as calculated under WCI.360 are uniquely reported and that no double-counting of emissions in one or more categories occurs.

Carbon content and molecular weight of the field gas determined annually by a company or operator for a specific field for operational and regulatory purposes must be used as inputs to Equation 20-7 When this is data is not available, the generic emission factors provided in Table 360-4 (to be developed) must be used by a company or operator for the specific field in question.

[proposed to be added to WCI.025(b)(1)]

For facilities that are covered by WCI.360 (Petroleum and Natural Gas Production and Gas Processing) but are less than 10,000 tonnes in individual size, an operator may calculate fuel consumption for propane and diesel without correcting for the difference in inventory at the beginning and end of the year.

§ WCI.365 *Procedures for Estimating Missing Data*

A complete record of all estimated and/or measured parameters used in the GHG emissions calculations is required. If data are lost or an error occurs during annual emissions estimation or measurements, you must repeat the estimation or measurement activity for those sources as soon as possible, including in the subsequent reporting year if missing data are not discovered until after December 31 of the reporting year, until valid data for reporting is obtained. Data developed and/or collected in a subsequent reporting year to substitute for missing data cannot be used for that subsequent year's emissions estimation. Where missing data procedures are used for the previous year, at least 30 days must separate emissions estimation or measurements for the previous year and emissions estimation or meausrements for the current year of data collection.

§ WCI.366 Definitions

Absorbent circulation pump means a pump commonly powered by natural gas pressure that circulates the absorbent liquid between the absorbent regenerator and natural gas contactor.

Acid Gas means hydrogen sulfide ($H2S$) and carbon dioxide ($CO2$) contaminants that are separated from sour natural gas by an acid gas removal.

Acid Gas Removal unit (AGR) means a process unit that separates hydrogen sulfide and/or carbon dioxide from sour natural gas using liquid or solid absorbents or membrane separators.

Acid gas removal vent stack emissions mean the acid gas separated from the acid gas absorbing medium (e.g., an amine solution) and released with methane and other light hydrocarbons to the atmosphere or a flare.

Air injected flare means a flare in which air is blown into the base of a flare stack to induce complete combustion of low Btu natural gas (i.e., high non-combustible component content).

Blowdown vent stack emissions mean natural gas released due to maintenance and/or blowdown operations including but not limited to compressor blowdown and emergency shut-down (ESD) system testing.

Calibrated bag means a flexible, non-elastic, anti-static bag of a calibrated volume that can be affixed to a emitting source such that the emissions inflate the bag to its calibrated volume.

Centrifugal compressor means any equipment that increases the pressure of a process natural gas by centrifugal action, employing rotating movement of the driven shaft.

Centrifugal compressor dry seals mean a series of rings around the compressor shaft where it exits the compressor case that operates mechanically under the opposing forces to prevent natural gas from escaping to the atmosphere.

Centrifugal compressor dry seals emissions mean natural gas released from a dry seal vent pipe and/or the seal face around the rotating shaft where it exits one or both ends of the compressor case.

Centrifugal compressor wet seal degassing venting emissions means emissions that occur when the high-pressure oil barriers for centrifugal compressors are depressurized to release absorbed natural gas. High-pressure oil is used as a barrier against escaping gas in centrifugal compressor shafts. Very little gas escapes through the oil barrier, but under high pressure, considerably more gas is absorbed by the oil. The seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated. The separated gas is commonly vented to the atmosphere.

Coal Bed Methane (CBM) means natural gas which is extracted from underground coal deposits or "beds."

Component, for the purposes of WCI.350 and WCI.360 only, means but is not limited to each metal to metal joint or seal of non-welded connection separated by a compression gasket, screwed thread (with or without thread sealing compound), metal to metal compression, or fluid barrier through which natural gas or liquid can escape to the atmosphere.

Compressor means any machine for raising the pressure of a natural gas by drawing in low pressure natural gas and discharging significantly higher pressure natural gas.

Condensate means hydrocarbon and other liquid separated from natural gas that condenses due to changes in the temperature, pressure, or both, and remains liquid at storage conditions, includes both water and hydrocarbon liquids.

Dehydrator means a device in which a liquid absorbent (including but not limited to desiccant, ethylene glycol, diethylene glycol, or triethylene glycol) directly contacts a natural gas stream to absorb water vapor.

Dehydrator vent stack emissions means natural gas released from a natural gas dehydrator system absorbent (typically glycol) reboiler or regenerator, including stripping natural gas and motive natural gas used in absorbent circulation pumps. De-methanizer means the natural gas processing unit that separates methane rich residue gas from the heavier hydrocarbons (e.g., ethane, propane, butane, pentane-plus) in feed natural gas stream).

Desiccant means a material used in solid-bed dehydrators to remove water from raw natural gas by adsorption. Desiccants include activated alumina, palletized calcium chloride, lithium chloride and granular silica gel material. Wet natural gas is passed through a bed of the granular or pelletized solid adsorbent in these dehydrators. As the wet gas contacts the surface of the particles of desiccant material, water is adsorbed on the surface of these desiccant particles. Passing through the entire desiccant bed, almost all of the water is adsorbed onto the desiccant material, leaving the dry gas to exit the contactor.

E&P Tank means the most current version of an exploration and production field tank emissions equilibrium program that estimates flashing, working and standing losses of hydrocarbons, including methane, from produced crude oil and gas condensate. Equal or successors to E&P Tank Version 2.0 for Windows Software. Copyright (C) 1996-1999 by The American Petroleum Institute and The Gas Research Institute.

Engineering estimation, for the purposes of WCI.350 and WCI.360, means an estimate of emissions based on engineering principles applied to measured and/or approximated physical parameters such as dimensions of containment, actual pressures, actual temperatures, and compositions.

Enhanced Oil Recovery (EOR) means the use of certain methods such as water flooding or gas injection into existing wells to increase the recovery of crude oil from a reservoir. In the context of this rule, EOR applies to injection of critical phase carbon dioxide into a crude oil reservoir to enhance the recovery of oil.

Field means the surface area underlaid or appearing to be underlaid by one or more pools, and the subsurface regions vertically beneath that surface area;

Flare combustion means unburned hydrocarbons including CH4, CO2, N2O emissions resulting from the incomplete combustion of gas in flares.

Flare combustion efficiency means the fraction of natural gas, on a volume or mole basis, that is combusted at the flare burner tip.

Fugitive emissions means the same as defined in the relevant greenhouse gas reporting regulation

Fugitive emissions detection means the process of identifying emissions from equipment, components, and other point sources.

Gas conditions mean the actual temperature, volume, and pressure of a gas sample.

Gas gathering/booster stations mean centralized stations where produced natural gas from individual wells is co-mingled, compressed for transport to processing plants, transmission and distribution systems, and other gathering/booster stations which co-mingle gas from multiple production gathering/booster stations. Such stations may include gas dehydration, gravity separation of liquids (both hydrocarbon and water), pipeline pig launchers and receivers, and gas powered pneumatic devices.

Gas to oil ratio (GOR) means the ratio of the volume of gas at standard temperature and pressure that is produced from a volume of oil when depressurized to standard temperature and pressure.

High-Bleed Pneumatic Devices are automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate in excess of six standard cubic feet per hour.

Liquefied natural gas (LNG) means natural gas (primarily methane) that has been liquefied by reducing its temperature to -260 degrees Fahrenheit at atmospheric pressure.

LNG boiloff gas means natural gas in the gaseous phase that vents from LNG storage tanks due to ambient heat leakage through the tank insulation and heat energy dissipated in the LNG by internal pumps.

Low-Bleed Pneumatic Devices mean automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate equal to or less than six standard cubic feet per hour.

Natural gas driven pneumatic pump means a pump that uses pressurized natural gas to move a piston or diaphragm, which pumps liquids on the opposite side of the piston or diaphragm.

Offshore means seaward of the terrestrial borders of the Canada, including waters subject to the ebb and flow of the tide, as well as adjacent bays, lakes or other normally standing waters, and extending to the outer boundaries of the jurisdiction and control of Canada.

Operating pressure means the containment pressure that characterizes the normal state of gas or liquid inside a particular process, pipeline, vessel or tank.

Portable means the same as defined in WCI.27 and WCI.361(a)(2)

Pump means a device used to raise pressure, drive, or increase flow of liquid streams in closed or open conduits.

Pump seals means any seal on a pump drive shaft used to keep methane and/or carbon dioxide containing light liquids from escaping the inside of a pump case to the atmosphere.

Pump seal emissions means hydrocarbon gas released from the seal face between the pump internal chamber and the atmosphere.

Reciprocating compressor means a piece of equipment that increases the pressure of a process natural gas by positive displacement, employing linear movement of a shaft driving a piston in a cylinder.

Reciprocating compressor rod packing means a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of compressed natural gas that escapes to the atmosphere.

Re-condenser means heat exchangers that cool compressed boil-off gas to a temperature that will condense natural gas to a liquid.

Reservoir means a porous and permeable underground natural formation containing significant quantities of hydrocarbon liquids and/o r gases. A reservoir is characterized by a single natural pressure system.

Sales oil means produced crude oil or condensate measured at the production lease automatic custody transfer (LACT) meter or custody transfer meter tank gauge.

Sour natural gas means natural gas that contains significant concentrations of hydrogen sulfide and/or carbon dioxide that exceed the concentrations specified for commercially saleable natural gas delivered from transmission and distribution pipelines.

Sweet Gas is natural gas with low concentrations of hydrogen sulfide (H_2S) and/or carbon dioxide (CO_2) that does not require (or has already had) acid gas treatment to meet pipeline corrosion-prevention specifications for transmission and distribution.

Transmission pipeline means high pressure cross country pipeline transporting sellable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering, regulating stations where the natural gas is typically odorized before delivery to customers.

Turbine meter means a flow meter in which a gas or liquid flow rate through the calibrated tube spins a turbine from which the spin rate is detected and calibrated to measure the fluid flow rate.

Vapor recovery system means any equipment located at the source of potential gas emissions to the atmosphere or to a flare, that is composed of piping, connections, and, if necessary, flow-inducing devices, and that is used for routing the gas back into the process as a product and/or fuel.

Vaporization unit means a process unit that performs controlled heat input to vaporize LNG to supply transmission and distribution pipelines or consumers with natural gas.

Vented emissions means means the same as defined in the relevant greenhouse gas reporting regulation, including but not limited to process designed flow to the atmosphere through seals or vent pipes, equipment blowdown for maintenance, and direct venting of gas used to power equipment (such as pneumatic devices).

Well completions means a process that allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and test the reservoir flow characteristics. This process includes high-rate back-flow of injected water and sand used to fracture and prop-open fractures in low permeability gas reservoirs.

Well workover means the performance of one or more of a variety of remedial operations on producing oil and gas wells to try to increase production. This process also includes high-rate back-flow of injected water and sand used to re-fracture and prop-open new fractures in existing low permeability gas reservoirs.

Wellhead means the piping, casing, tubing and connected valves protruding above the Earth's surface for an oil and/or natural gas well. The wellhead ends where the flow line connects to a wellhead valve.

Wet natural gas means natural gas in which water vapor exceeds the concentration specified for commercially saleable natural gas delivered from transmission and distribution pipelines. This input stream to a natural gas dehydrator is referred to as "wet gas".

Directions on the use of Tables 360-1 to 360-2

(1) Starting with [2012] calendar year emissions, for each component listed in the Tables 360-1 to 360-2:

(i) If facility specific emission factors for a component type are available they must be used.

(ii) If facility specific emissions factors for a component type are not available, an operator must use company specific emission factors.

(iii) If a specific component type cannot be safely or reasonably accessed to develop valid facility or company-specific emission factors, estimates in the default tables 360-1 to 360-2 may be used. Similarly, equipment or facilities that have low utilization (e.g. some booster stations) may continue to use the default tables.

(iv) If a facility-specific emission factor has been used in a previous reporting year, it must continue to be used until updated. If a company-specific emission factor has been used in a previous reporting year, it must continue to be used until updated or a facility-specific emission factor is used in its place.

(v) Any changes from facility-specific factors to company-specific or the defaults in Tables 360-1 to 360-2, or from company specific factors to the defaults in Tables 360-1 to 360-2 must be approved by the jurisdiction and substantiated by evidence that the new approach is more accurate for the facility or facilities in question.

(vi) Documentation on the method used to update the emission factors, input data, sampling methodology and other relevant information must be kept by the operator and provided to the jurisdiction or verifier upon request.

(2) For 2011 calendar year emissions:

(i) An operator may use the default factors specified below, company or facility-specific emissions factors (if such emission factors are available). If the default factors in Tables 360-1 to 360-2 are used, an explanation as to why company or facility specific emission factors are cannot be used must be provided to the jurisdiction.

(3) All emission factors must be developed using Canadian Association of Petroleum Producer of Canadian Gas Association standard methods, or other methods if Canadian Association of Petroleum Producer or Canadian Gas Association methods are not available. Facility and company-specific emission factors must be updated at a minimum on a three year cycle, with the first update to the original facility and company-specific emission factors for the 2015 reporting period, at the latest.

(4) All emission factors must be developed using Canadian Association of Petroleum Producer of Canadian Gas Association standard methods, or other methods if Canadian Association of Petroleum Producer or Canadian Gas Association methods are not

available. Facility and company-specific emission factors must be updated at a minimum on a three year cycle, with the first update to the original facility and company-specific emission factors for the 2015 reporting period, at the latest.

(5) Updated emission factors can only be incorporated for reporting purposes at the start of a reporting period and not during a calendar year.

(6) The default emission factors provided in Tables 360-1 to 360-2 below are published emission factors for Canada as of the 2010 calendar year. The factors will be updated every 3-5 years based on new data, methods and statistically valid samples of the entire industry and developed in collaboration with industry groups.

Important note on Tables 360-1 and 360-2

Specific stakeholder comment is sought on two alternatives being considered for the provision of default emission factors for use in WCI.363(b),(n) and (o). The first approach would use existing equations 360-4, 360-19 and 360-20 in combination with the structure provided in Tables 360-1 and 360-2, below (as converted to metric units) and data processed from Tables 6-21 and 6-22 (below) from API Compendium of GHG Emission Methodologies for the Oil and Gas Industry, August 2009 (http://www.api.org/ehs/climate/new/upload/2009_GHG_COMPENDIUM.pdf).

The second approach would use the data in Tables 6-21 and 6-22, but instead keep the data in the published version, obviating the need to first convert the total hydrocarbon content factors to a volume of methane basis. As the emission factors are updated by CAPP or the API from time to time, the intention would be to update the emission factors here as well. The second approach would necessitate modifying Equations 360-4,-19 and -20 per the following example:

*Es,i,j =sum(Count * EF * Xj) * t /1000*

Where:
Es,i = Annual emissions at standard conditions for each source
Count = number of components of type i
EF = population emission factor for component type i [kg/source/h]
X = mass fraction of CH4 in stream j
t = hours per year [hours]

TABLE 360-1 –DEFAULT WHOLE GAS EMISSION FACTORS FOR ONSHORE PRODUCTION

Onshore production	Emission Factor (scf/hour/component)
Population Emission Factors - All Components, Gas Service	
Valve	0.08
Connector	0.01
Open-ended Line	0.04
Pressure Relief Valve	0.17
Low-Bleed Pneumatic Device Vents	2.75
Gathering Pipelines[1]	2.81
CBM Well Water Production[2]	0.11
Population Emission Factors - All Components, Light Crude Service[3]	
Valve	0.04
Connector	0.01
Open-ended Line	0.04
Pump	0.01
Other[5]	0.24
Population Emission Factors - All Components, Heavy Crude Service[4]	
Valve	0.001
Flange	0.001
Connector (other)	0.0004
Open-ended Line	0.01
Other[5]	0.003

[1] Emission Factor is in units of "scf/hour/mile"

[2] Emission Factor is in units of "scf methane/gallon", in this case the operating factor is "gallons/year" and do not multiply by methane content

[3] Hydrocarbon liquids greater than or equal to 20˚API are considered "light crude"

[4] Hydrocarbon liquids less than 20˚API are considered "heavy crude"

[5] ”Others” category includes instruments, loading arms, pressure relief valves, stuffing boxes, compressor seals, dump lever arms, and vents.

TABLE 360-2 –DEFAULT TOTAL HYDROCARBON EMISSION FACTORS FOR PROCESSING

Processing	Before De-methanizer Emission Factor (scf/hour/component)	After De-methanizer Emission Factor (scf/hour/component)
Leaker Emission Factors - Reciprocating Compressor Components, Gas Service		
Valve	15.88	18.09
Connector	4.31	9.10
Open-ended Line	17.90	10.29
Pressure Relief Valve	2.01	30.46
Meter	0.02	48.29
Leaker Emission Factors - Centrifugal Compressor Components, Gas Service		
Valve	0.67	2.51
Connector	2.33	3.14
Open-ended Line	17.90	16.17
Dry Seal	105	105
Leaker Emission Factors - Other Components, Gas Service		
Valve		6.42
Connector		5.71
Open-ended Line		11.27
Pressure Relief Valve		2.01
Meter		2.93
Population Emission Factors - Other Components, Gas Service		
Gathering Pipelines[1]		2.81

[1] Emission Factor is in units of "scf/hour/mile"

TABLE 360-3 –DEFAULT NITROUS OXIDE EMISSION FACTORS FOR GAS FLARING

Gas Flaring	Emission Factor (metric tons/MMscf gas production or receipts)
Population Emission Factors - Gas Flaring	
Gas Production	5.90E-07
Sweet Gas Processing	7.10E-07
Sour Gas Processing	1.50E-06
Conventional Oil Production[1]	1.00E-04
Heavy Oil Production[2]	7.30E-05

[1] Emission Factor is in units of "metric tons/barrel conventional oil production"

[2] Emission Factor is in units of "metric tons/barrel heavy oil production"

Western Climate Initiative

Second Harmonization Package

Proposed Harmonization of Essential Requirements for Mandatory Reporting (ERs) in Canadian Jurisdictions with the WCI ERs and the U.S. EPA GHG Reporting Program

Stakeholder Conference Call

November 8, 2010

Background

- Final WCI Essential Requirements – July 2009
- Final U.S. EPA Mandatory Reporting Rule ("EPA Rule") – September 2009
- U.S. facilities emitting >25,000 tonne CO_{2e} are subject to both programs (WCI has a 10,000 tonne threshold)
- Proposed harmonized ERs for U.S. jurisdictions – May 2010
  - Format is the same as EPA Rule
  - Final harmonized ERs expected Fall 2010

Proposed Harmonized ERs for Canadian Jurisdictions

- First Harmonization Package released September 8, 2010
- Maintain consistency across all WCI jurisdictions
- Follow same format as original WCI ERs
- Stakeholder comments and EPA modifications are currently being reviewed

- Second Harmonization Package released October 29, 2010

Canadian Harmonization Principles

- Same level of reporting accuracy as U.S. facilities
- Quantification methods sufficient for GHG reporting under cap-and-trade program
- Suitable for use in Canada
  - Metric units
  - Canadian emission factors
- Facilitate harmonization with Environment Canada CEPA Section 46 (or future regulatory) reporting

Canadian Harmonization Approach

- Revise existing WCI ERs to conform with harmonized ERs for U.S. jurisdictions
  - Made content in WCI ERs "methodologically consistent" with ERs for U.S. jurisdictions
    - Harmonized ERs for US jurisdictions follow markup of EPA Rule
    - Harmonized ERs for Canadian jurisdictions keep WCI ER format
- Assure harmonization with Environment Canada's reporting programs
- Require fewer data elements to be reported in Canadian jurisdictions due to 3rd party verification
- Add missing data procedures following EPA Rule
- Identify sources subject to "reporting only"

Sources Subject to Reporting Only

- Under review for sources within the second harmonization package

On-Going Canadian Harmonization

- Second Harmonization Package includes:
  - Electronics Manufacturing (WCI. 110)
  - Underground Coal Mines (WCI.250)
  - Magnesium Production (WCI.290)
  - Natural Gas Transmission and Distribution (WCI.350)
  - Petroleum and Natural Gas Production and Gas Processing (WCI.360)
- First Harmonization Package stakeholder comments are currently being reviewed
- Other recently released EPA methods will be reviewed by WCI Reporting Committee (e.g. Carbon Dioxide Injection and Geologic Sequestration)

Western Climate Initiative

Questions?

Significant Changes to WCI ERs for Canadian Jurisdictions

- New sources for the WCI
- Methods are based on proposed or final EPA Subparts and Canada-specific circumstances
- Next few slides summarize the most significant items for each method
- All methods
  - incorporate missing data procedures
  - reduce amount of data to be reported (from EPA) due to third party verification

Significant Changes – General Stationary Combustion (WCI.20)

- Consequential changes to incorporate sampling, analysis and measurement for Petroleum and Natural Gas Systems, and Natural Gas Transmission and Distribution
  - *Measurement and Metering Act of Canada* for T&D
  - Existing legislation and regulation for upstream sources (e.g. *Petroleum and Natural Gas Act of B.C.*)
  - Use of known field gas composition in place of specific sampling and measurement
  - Inventory adjustment not required for propane and diesel for smaller upstream sources.

Electronics Manufacturing, Underground Coal Mines and Magnesium Production

- Electronics Manufacturing (WCI.110) based on final EPA Subpart I
- Underground Coal Mines (WCI.250) based on final EPA Subpart FF
  - Reduced disaggregation of data reporting
  - Allowed for use of Canadian standards
- Magnesium Production (WCI.290) based on final EPA Subpart T

Significant Items – Natural Gas Transmission and Distribution (WCI.350)

- Based on **proposed** EPA Subpart W, WCI submission to the EPA and Canada-specific circumstances
- Definitions modified for use in Canada
- Incorporated Canadian Gas Association emission factors. Phase in of company/facility-specific emission factors.
- Expanded equipment for leak detection and incorporates progressive sampling

Significant Items – Petroleum and Natural Gas Systems (WCI.360)

- Based on **proposed** EPA Subpart W, WCI submission to the EPA and Canada-specific circumstances
- Definitions modified for use in Canada
- Incorporates method for field gas combustion
- Merged conventional and unconventional completions/workovers
- Deferred methods for offshore oil and gas
- Bracketed text on metering of high bleed pneumatics/pumps
- Expanded leak detection equipment, incorporates progressive sampling
- Suggested CAPP/API emission factors. Phase in of company/facility-specific emission factors.

Next Steps

Who?	What?	When? (2010)
Stakeholders	Submit comments on proposed Canadian harmonization package #2	Nov. 24
WCI	Finalize Canadian harmonization package #1	late Nov.
WCI	Finalize Canadian harmonization package #2	Early Dec.

WCI.8 Verification WCI.8-1

1 Introduction

On July 16, 2009, The WCI published the Final Essential Requirements for Mandatory Reporting (the “ERs”) to be implemented by the WCI Partner jurisdictions. On September 22, 2009, U.S. EPA adopted its final Mandatory Reporting Rule (the “EPA rule”) for greenhouse gas emissions. Many U.S. facilities in the WCI region will be subject to both reporting programs. Specifically, most facilities with emissions of CO_2e greater than or equal to 25,000 metric tons per year in WCI states will be subject to both programs.

The WCI Partners were concerned that the existence of two different reporting systems in a WCI state could result in the imposition of duplicative or conflicting reporting obligations on facilities subject to both programs. Unless steps were taken to reconcile the WCI ERs with the EPA rule, a facility in a WCI state and with CO_2e emissions of 25,000 metric tons per year or greater could be required to prepare and submit two reports containing different data values in different formats to two jurisdictions.

In order to avoid the imposition of this burden on reporting facilities, the Partners directed the WCI Reporting Committee to develop amended ERs that are harmonized with the EPA rule.

Both the EPA rule and the WCI ERs require the filing of initial reports for the 2010 reporting year by Spring 2011 (March 31, 2011, and April 1, 2011, respectively). The goal of the Reporting Committee is to issue amended ERs in time for implementation in the 2011 reporting year. The adoption and implementation of interim measures to harmonize existing reporting requirements with the EPA rule has been left to the discretion of individual WCI jurisdictions.

This document and its Appendices explain the WCI’s approach to harmonizing the ERs and the EPA rule in U.S. jurisdictions (the “harmonized ERs”). As explained below, the WCI also has proposed amended ERs that are methodologically consistent with the harmonized ERs but appropriate for use in the Canadian Partner jurisdictions.

On May 28, 2010, the WCI made this document available for stakeholder review and comment. The stakeholder comment period closed on June 28, 2010. A summary of the comments received and WCI’s response is set forth in section 5 below. Changes made to the harmonized ERs other than as a result of stakeholder comments are summarized in section 6 below.

2 Harmonization Principles

2.1 For U.S. Jurisdictions

In developing harmonized ERs for use in U.S. jurisdictions, the WCI Reporting Committee adhered to the following principles:

1. A U.S. facility should be able to comply with both the MRR and a WCI jurisdiction's reporting requirements by following a single set of monitoring, recordkeeping and reporting requirements.

2. The quantification methods included in the harmonized ERs must be sufficiently reliable and accurate to be employed in a greenhouse gas (GHG) cap-and-trade program.

The most straightforward way to follow the first principle would be to adopt the EPA rule without change. Unfortunately, it is not possible to do so and also adhere to the second principle. As EPA has acknowledged, the EPA rule, unlike the WCI ERs, has not been specifically designed to meet the needs of a cap-and-trade program:

> A key difference between the Federal mandatory GHG reporting rule and the RGGI and WCI programs is that the Federal mandatory GHG rule is solely a reporting requirement. It does not in any way regulate GHG emissions or require any emissions reductions.

74 Fed. Reg. 16448, 16460 (2009); see also 74 Fed. Reg. 56260, 56369 (2009) (EPA rule designed to gather data needed to "inform future climate change policies").

Fortunately, in nearly all cases where the Reporting Committee determined that a modification to the EPA rule was necessary for implementation of a cap-and-trade program or to achieve other WCI objectives, the modification could be implemented without requiring any alteration to the EPA program. For example, Subpart C of EPA's general stationary combustion rule establishes essentially the same four-tiered approach as section WCI.20 of the ERs. In some cases, WCI.20 requires the use of a higher tier than the EPA rule. Because the EPA rule generally *allows* the use of higher tier for any facility, however, a facility may use the methodology required by WCI.20 and still submit a report conforming to the EPA rule.

In a few cases, the Reporting Committee identified additional data elements that the EPA rule does not require but that WCI jurisdictions will need for cap-and-trade or other purposes.[1] In order to avoid imposing a requirement to file a supplemental report addressing these data elements, the Reporting Committee has been working with EPA and the National Data Exchange to secure changes to the EPA GHG reporting schema that will allow submission of reports containing these data elements directly to EPA. In addition, EPA has indicated that it may be possible to make adjustments to the online reporting tool it is developing for the federal GHG reporting program to accommodate state and regional reporting requirements.

[1] For example, gathering data related to cogeneration.

WCI intends to follow the same principles with regard to future additions or amendments to the EPA rule, such as the recently re-proposed Subpart W for the oil and gas industry, and the recently proposed revisions to Subpart A and several source category subparts (prepublication version posted on EPA web site July 20, 2010). WCI will review each proposed revision to assess its suitability for cap-and-trade before incorporating it into the harmonized ERs.

2.2 For Canadian Jurisdictions

In developing harmonized ERs for use in Canadian jurisdictions that modify the existing ERs, the WCI Reporting Committee is adhering to the following principles:

1. A Canadian facility should apply the same functions, equations, sampling protocols and measurement criteria as U.S. facilities subject to the U.S. version of the harmonized ERs. This means that the harmonized ERs will achieve the same level of reporting accuracy for Canadian and U.S. facilities, but the U.S. version may require more data elements to be reported to harmonize with the EPA rule.

2. The quantification methods included in the harmonized ERs must remain sufficiently reliable and accurate to be employed in a greenhouse gas (GHG) cap-and-trade program.

3. The WCI reporting system must remain suitable for use in Canadian jurisdictions. For example, it must allow reporting in metric as well as English units and must where necessary include Canada-specific emission factors.

4. The harmonized ERs should facilitate harmonization with Canadian federal reporting. Some Canadian jurisdictions are working with Environment Canada to develop a one-window reporting tool for provincial and national GHG reporting requirements.

3 Harmonization Approach

3.1 For U.S. Jurisdictions

The WCI proposes to achieve harmonization in U.S. jurisdictions by adopting incorporation-by-reference rules that modify the EPA rule in a manner consistent with the harmonization principles set forth in section 2.1. The new WCI ERs for U.S. jurisdictions, which are attached to this document as appendices, therefore take the form of a markup of the EPA rule. The partners anticipate that each U.S. Partner will adopt an incorporation-by-reference rule consistent with this markup.

The WCI chose this approach for U.S. jurisdictions, rather than attempting to amend the existing WCI ERs to achieve harmonization, for the following reasons:

- Although the WCI ERs and EPA rule for the most part follow similar approaches to GHG quantification, they vary widely in organization and formatting and in the details of the monitoring, recordkeeping and reporting requirements imposed. It would therefore be extraordinarily difficult to amend the ERs to conform to the EPA rule without inadvertently introducing inconsistencies between the two programs. Any inconsistency would subject U.S. facilities to the risk of noncompliance with one program or the other.

- An incorporation-by-reference rule will make it much easier for a facility subject to both WCI and EPA requirements to assure itself that it is complying with both programs.

3.2 For Canadian Jurisdictions

For the Canadian jurisdictions, the key requirement is that the WCI reporting system as a whole require the use of comparable methodologies and produce comparable results for facilities of the same type, so that a “ton is a ton” in both the U.S. and Canada. For Canadian jurisdictions it is not nearly as important to avoid small differences between the ERs and the EPA rule as it is for the U.S. jurisdictions, where differences create a risk of inadvertent non-compliance.

Canadian Partners have invested substantial resources in developing regulations to implement the existing WCI ERs. In addition, the provinces face technical and legal issues with the incorporation by reference of the EPA rule that do not apply to the states. The WCI therefore has proposed amendments to the existing WCI ERs to assure that they conform in substance with the U.S. version of the harmonized ERs as well as the interest provinces have in harmonizing their reporting programs with Environment Canada’s.

3.3 Verification

Consistent with the Design Recommendations for the WCI Regional Cap-and-Trade Program, the harmonized ERs will continue to require third party verification of emission reports by entities and facilities included in the cap. A version of the verification rule, WCI.8, revised to cross reference the U.S. version of the harmonized ERs is included as an appendix.

Because the EPA rule does not require third-party verification, it generally requires reporting of substantially more data than the existing WCI ERs. In the absence of third-party verification, EPA must require the submission of sufficient data to enable the agency to implement its own audit program. In order to assure consistency with the first harmonization principle—allowing compliance with both programs through preparation of a single report—the WCI markup of the EPA rule does not attempt to reduce the amount of data required in a report for U.S. jurisdictions.

The amount of data to be reported for Canadian jurisdictions will be modified to reflect that third party verification is required for emissions reports at a certain threshold of emissions, so less data is required to be reported to the Canadian jurisdictions as compared to that which is required to be reported to the EPA for their internal verification.

3.4 Missing Data Procedures

The EPA rule includes procedures in each subpart for replacing missing data resulting from monitoring failures. With the exception of methodologies for facilities subject to 40 C.F.R. Part 75 (the acid rain program), these missing data procedures do not appear to be sufficiently rigorous to support a cap-and-trade system. There is no limitation on the amount of data that may be missing, and replacement methods appear to be both inadequate (for example, many use only one or two available data points) and inequitable (for example, Part 75 power plants have to apply punitive methods, while other facilities do not).

In order to move forward with a harmonization proposal in time to allow implementation for the 2011 reporting year, the proposed harmonized ERs retain the EPA missing data procedures. Before implementation of the cap-and-trade program, however, the WCI intends to revisit this issue. The WCI is investigating how the EPA missing data procedures can be modified to be more consistent with the needs of a cap-and-trade program while adhering to the harmonization principles in section 2.1 and intends to propose and implement the necessary modifications in time for the 2012 reporting year.

As a partial measure to address the possibility of gaming, the harmonized ERs include a provision making it clear that the use of a missing data procedure does not excuse a facility's failure to follow the monitoring requirements of the rule.

4 Summary of Changes to EPA Rule

The following table summarizes the changes to the EPA rule that the WCI is proposing to implement in WCI jurisdictions. The specific language for the changes is set forth in the Appendices.

The table also identifies potential differences in approach that may be employed by the Canadian WCI jurisdictions.

§	Change to EPA Rule	Rationale
Subpart A—General Provisions		
98.1	Added new (c) substituting jurisdiction for EPA and EPA administrator throughout rule.	Clarifies who is responsible for administering the incorporated-by-reference version of the EPA rule. Since the EPA rule does not provide for delegation, EPA will remain responsible for administering the original 40 C.F.R. Part 98 requirements.
98.1 and passim[2]	Added new (d) providing for identification of data that will be reported for informational purposes only, will not be subject to cap and trade and will not be counted towards the threshold for verification. Added "reporting only" label to certain EPA subparts and specific quantification methods.	Not all quantification methods specified by the harmonized ERs are suitable for a cap-and-trade system. The "reporting only" label provides notice to stakeholders on WCI's current view on which emissions should not be subject to the cap-and-trade program.
98.1	Added new (e) to authorize a WCI jurisdiction to allow submission of a report to EPA to meet the requirements of the harmonized ERs.	As discussed above, WCI is working with EPA to allow reporting entities to use EPA's system to meet the requirements of both the EPA rule and the harmonized ERs.

[2] Occurring in various places.

§	Change to EPA Rule	Rationale
98.2 passim	Changed threshold for reporting from 25,000 metric tons to 10,000 metric tons.	Consistent with WCI design recommendation for reporting. EPA has indicated that it may be able to accommodate reports by facilities with emissions below the EPA rule threshold.
98.2(a)(3)(iii)	Changed heat input threshold for fuel combustion units from 30 mmBtu/hr to 12 mmBtu/hr.	The 30 mmBtu/hr threshold is designed to provide facilities whose only regulated GHG source is fuel combustion an easy method for determining whether they are above the 25,000 metric tons emission threshold. For WCI's 10,000 metric tons threshold, the equivalent heat input threshold is 12 mmBtu/hr.
98.2(b)(2)	Added exclusions from the applicability determination for certain emissions from the combustion of biomass.	Consistent with WCI Design Recommendations and existing WCI.1(b)(2).
98.2(i)	Modified to change threshold for off-ramp to 10,000, rather than 25,000, metric tons per year and to establish additional off-ramp for facilities required to report to WCI jurisdiction but not EPA (i.e. emissions between 10,000 and 25,000 metric tons per year) that subsequently fall below 10,000- metric-tons-per-year threshold.	Consistent with existing WCI.1(e)(2).

§	Change to EPA Rule	Rationale
98.3(g), 98.3(g)(5)(iv)	Added requirement to submit records within 20 days of a request from a WCI jurisdiction.	Failure of EPA rule to specify a time period for responding may make enforcement difficult. Modified from 10-day response time in existing WCI.4(b) in response to stakeholder comments.
98.3(h)	Added a new (2) requiring facilities subject to WCI but not EPA reporting requirements to submit correction only if cumulative errors exceed 5 % of total CO2e emissions.	Consistent with WCI.2(f). This change cannot be applied to facilities subject to the EPA rule, since EPA requires the correction of any errors.
98.3(i)(6)	Added requirement to obtain jurisdictional approval of monitoring plan provisions that allow postponement of measurement device calibrations.	See Section 5.2.2.
98.3	Added a method for calculating weighted averages as new (j).	In some cases, the harmonized ERs require more frequent sampling than the EPA rule. This subsection provides a method for reducing the data obtained from the additional samples to fit the EPA reporting system, and produces more accurate emissions estimates.
98.3	Added new (k) requiring a jurisdiction's approval before a facility may switch from a CEMS to a mass- or fuel-based monitoring method or vice versa.	This provision is designed to prevent facilities from using changes in monitoring methods to create an artificial reduction in GHG emissions.

§	Change to EPA Rule	Rationale
98.3	Added a modified version of the de minimis provision in WCI.2(d) as new (l). Instead of allowing the use of any alternative method approved by the verifier, as in the current ERs, the modified version requires the use of a method permitted by 40 C.F.R. Part 98 for the facility. So, for example, a facility subject to verification could use Tiers 1 or 2, rather than Tier 3, for up to 3 percent of its combustion emissions.	The EPA rule does not include a de minimis provision. Allowing U.S. facilities to employ methods that are not specified by the EPA rule therefore would be inconsistent with harmonization. In some cases, however, the harmonized ERs require the use of a higher tier than would otherwise be required by the EPA rule. In these cases, it is consistent with harmonization to allow the use of the lower tier for emissions determined to be de minimis.
98.3	Added new (m) to make it clear the missing data procedures included in the EPA rule (and therefore the harmonized ERs) do not excuse facilities from possible enforcement action for failure to conduct the monitoring required by the rule.	See section 3.4.
Subpart C—General Stationary Combustion		
98.32(b), 98.33(f)	Added requirement to report fugitive HFC emissions from cooling units.	Consistent with existing WCI.42(h) and WCI.42(d).
98.33(a)(2)(iii)	Limit availability of Equation C-2c (ratio of heat input to steam method) to municipal solid waste and solid biomass, rather than allowing its use for any other solid fuel listed in Table C-1.	Consistent with existing WCI.23(b)(2).

§	Change to EPA Rule	Rationale
98.33(a) (4)(iv)	Require CEMS installed after beginning of first reporting year subject to rule to include a CO2 monitor, rather than an oxygen monitor.	Although it may make sense not to require the retrofit of grandfathered CEMS with a CO2 monitor, there is no reason for newly installed CEMS not to include such a monitor. See also discussion in Section 5.3.2.
98.33(b) (1)	For any fuel with a variable HHV and carbon content, limit use of Tier 1 (default emission factors and HHV) to units that are both (1) below both EPA's 250 mmBtu/hr heat input threshold and (2) located at facilities that are not subject to verification (i.e., emissions < 25,000 metric tons/yr). Fuels with standard HHVs and carbon contents that may use Tier 1 in accordance with the EPA rule are listed in new Table C-1a.	See Section 5.3.1.
98.33(b)(1)(iii)	Allow the use of Tier 1 for a biomass fuel only when the fuel has been determined by the jurisdiction not to be subject to a compliance obligation.	Tier 1 is not sufficiently accurate for the combustion of fuels subject to a cap-and-trade program. EPA's approach of allowing Tier 1 for *all* biomass fuels is therefore not suitable for WCI jurisdictions.
98.33(b) (2)	Limit use of Tier 2 (default emission factors and measured HHV) to units that are both (1) below both EPA's 250 mmBtu/hr heat input threshold and (2) located at facilities that are not subject to verification (i.e., emissions < 25,000 metric tons/yr), except for facilities that burn pipeline quality natural gas or distillate fuel oil.	Consistent with existing WCI.23(e)(2).

§	Change to EPA Rule	Rationale
98.33(b)(3)	Require the use of Tier 3 (measured carbon content) for all units at a facility subject to verification (i.e. emissions > 25,000 metric tons/yr), except for certain listed fuels with standardized and uniform composition. Require Tier 3 for the combustion of *all* fuels that are not listed in Table C-1, not just for unlisted fuels that provide 10% or more of a unit's annual heat input.	Revised from existing WCI.23(e)(3) to allow Tier 1 or Tier 2 for certain fuels where uniformity of composition gives high accuracy for Tier 1. Exempting unlisted fuels that provide less than 10 % of a unit's heat input could result in a significant gap in a facility's reported emissions. Corrected markup to reflect this intent.
98.33(c)	Add new (6) to allow an operator use a source-specific emission factor to calculate CH4 and N2O emissions.	Consistent with existing WCI.24(d). Since this is optional, it does not conflict with harmonization principle 1.
98.33(e)(2)	Require the use of 98.33(e)(3) for the combustion of any fossil fuel/biomass mixture containing an undeterminable quantity of fossil fuels, not just MSW.	The method specified in 98.33(e)(2) assumes that the amount of fossil fuel in a fossil fuel/biomass mixture can be determined and that a mass balance approach is therefore possible. Its use therefore must be limited to fuels where the amount of fossil fuel in a mixture can in fact be determined. Other mixtures must as a practical matter be subject to 98.33(e)(3).
98.34(b)(3)(ii)(E)	Require installation of equipment necessary to perform daily sampling and analysis of carbon content and molecular weight for refinery fuel gas by beginning of first reporting year subject to harmonized ERs.	Consistent with existing WCI.34.

§	Change to EPA Rule	Rationale
98.36(b), (d)	Added provisions requiring reporting of nameplate capacity and net power generated for EGUs and cogeneration data, as well as certain fuel data if not reported under 40 C.F.R. Part 75.	Consistent with existing WCI.40.
98.36(e)(3), (e)(4)	Changed time to respond to requests for data needed for verification from 30 to 20 days.	Consistent with new requirement in 98.3(g). See above.
Subpart D—Electricity Generation		
98.46	Corrected cross-reference.	Clarification.
Subpart E—Adipic Acid Production		
No change.		
Subpart F—Aluminum Production		
98.64(a)	Changed to require re-measurement of smelter-specific slope coefficients every 36 months, rather than every 10 years. Inserted additional conditions that would trigger the obligation to re-measure the coefficients before the expiration of the 36-month period.	Consistent with WCI.74(b).
98.64(a), (d)	Changed to require the use of smelter-specific measurements rather than the default values specified in table F-1.	Consistent with WCI.74.
98.64(b)	Changed minimum measurement frequency from annually to monthly for all parameters.	Consistent with WCI.74(a).
Subpart G—Ammonia Production		
No change.		

§	Change to EPA Rule	Rationale
Subpart H—Cement Production		
No change to EPA rule for U.S. jurisdictions. Unlike the EPA rule, existing WCI.090 allows emissions to be calculated on a facility-wide basis. The harmonized ERs for U.S. jurisdictions will retain the EPA requirement to calculate emissions for each kiln in order to assure harmonization. Canadian jurisdictions, however, may continue to allow facility-based calculations.		
Subpart K—Feroalloy Production		
No change.		
Subpart N—Glass Production		
Passim	Changed to apply to batch as well as continuous processes.	Consistent with draft WCI method. This change may require facilities not subject to the EPA rule to report but should not result in a facility subject to both the WCI and EPA programs being subject to inconsistent reporting obligations.
Subpart O—HCFC-22 Production and HFC-23 Destruction		
No change.		
Subpart P—Hydrogen Production		
98.160(a)	Changed to apply subpart to production of hydrogen for use on site as well as hydrogen sold as a product.	Consistent with WCI.131. This change may require facilities not subject to the EPA rule to report but should not result in a facility subject to both the WCI and EPA programs being subject to inconsistent reporting obligations.
98.163(b), 98.164(b)(2)-(4)	Require daily, rather than monthly or weekly, analysis of carbon feedstocks other than natural gas. As an alternative, allow analysis of a composite of up to 30 weighted samples.	Consistent with WCI.134(b)(1). Higher frequency sampling is required to ensure accuracy adequate for a cap-and-trade program. See also Section 5.2.6.

<table>
<tr><th>§</th><th>Change to EPA Rule</th><th>Rationale</th></tr>
<tr><td>98.166(b)</td><td>Added (7) requiring reporting of carbon in unconverted feedstock for which GHG emissions are calculated and reported by the facility using other methods.</td><td>In order to avoid possible double counting of emissions, WCI.133, Equation 130-1 allows subtraction of carbon “accounted for elsewhere” from the amount of feedstock, before calculation of the mass balance. EPA’s equations P-1, P-2 and P-3 do not allow for such a deduction. The equations themselves cannot be modified in the harmonized ERs, because that would require reporting different emissions to EPA and a U.S. WCI jurisdiction. The harmonized ERs therefore provide for the reporting of carbon accounted for elsewhere in bulk, which can then be subtracted from a facility’s total emissions by the WCI data system.</td></tr>
<tr><td colspan="3">Subpart Q—Iron and Steel Production</td></tr>
<tr><td colspan="3">No change to EPA rule for U.S. jurisdictions.

The EPA rule requires the reporting of CO2 from the combustion of coke oven gases at the point of combustion under Subpart C. Existing WCI.153 requires the reporting of emissions attributable to coke oven gases and blast furnace gases at the point of generation using a mass balance method. U.S. jurisdictions will employ the EPA method in order to assure harmonization. Canadian jurisdictions may continue to employ existing WCI.153. It is anticipated that the methods will produce substantially similar results.

Jurisdictions also may choose not to allow the use of the site-specific emission factor method established by 98.173(b)(2) for process emissions.</td></tr>
<tr><td colspan="3">Subpart R—Lead Production</td></tr>
<tr><td colspan="3">No change.</td></tr>
<tr><td colspan="3">Subpart S—Lime Production</td></tr>
<tr><td colspan="3">No change.</td></tr>
</table>

§	Change to EPA Rule	Rationale
Subpart V—Nitric Acid Production		
No change.		
Subpart X—Petrochemical Production		
No change.		
Subpart Y—Petroleum Refineries		
98.253(b)(1)(iii) 98.256(e)(8)	Amended to allow use of alternative equation Y-3 for flare emissions only during periods of startup, shutdown or malfunction.	The more accurate methods specified in equations Y-1 and Y-2 should be used for periods of normal operations.
98.253(c)(2) 98.256(f)(9)	Require calculation of emissions from catalytic cracking units that do not use CEMS and have rated capacities less than 10,000 barrels per stream day using this method (no less than hourly monitoring of O2, CO2 and CO), rather than 98.173(c)(3), which is deleted.	The EPA TSD for this sector states that the method specified in 98.173(c)(3) for units that do not have the necessary monitors is highly uncertain.
98.253(h), (l), (m), (n)	Identified as reporting only.	WCI does not believe the methods specified in these sections are sufficiently accurate to support a cap-and-trade program.
98.253(i)	Rather than allowing the use of default factors in Equation Y-18 for CO2 emissions from delayed coking units, require (1) the volumetric void fraction of the coking vessel prior to steaming to be based on engineering calculations and (2) the mole fraction of methane in coking vessel gas to be based on two samples per year.	Greater accuracy required for cap-and-trade.

§	Change to EPA Rule	Rationale
98.253(k) 98.256(m)	Require the use the same method for process vents (paragraph (j)) and uncontrolled blowdown systems.	Consistent with WCI.200.
98.254	New (m) added to require installation of equipment needed for daily sampling of carbon content and molecular weight of gaseous fuels (other than natural gas and biogas) by no later than first reporting year of harmonized ERs.	Needed to ensure Tier 3 calculations of emissions from refinery gas are sufficiently accurate for cap-and-trade.
98.257(m)	New (b) added to require retention of records of the method used to demonstrate that the thresholds in §98.253(j) are not exceeded.	Needed for third-party verification.
Subpart Z—Phosphoric Acid Production		
No change.		
Subpart AA—Pulp and Paper		
98.273(a)(1), (b)(1), (c)(1)	Require use of applicable Subpart C methodology rather than specifying the use of Tier 1 for combustion at chemical recovery furnaces and pulp mill lime kilns.	Consistent with WCI.212(c). There does not appear to be any reason to treat combustion at these sources differently from combustion elsewhere. Note: Although Subpart C generally allows the use of higher tiers, even when a lower tier is specified for a particular unit or fuel, section 98.273 could be read as *requiring* the use of Tier 1. WCI is seeking clarification of the correct interpretation of section 98.273 in order to assure that the proposed changes are consistent with harmonization principle 1.

§	Change to EPA Rule	Rationale
Subpart CC—Soda Ash Manufacturing		
98.294(d), 98.296(a)(5), (b)(12)	Added requirement to determine CO2 recycled to carbonation tower.	Consistent with WCI.232(f).
Subpart GG—Zinc Production		
No change.		

5 Stakeholder Comments and Response

5.1 General Comments

Several commenters expressed concern or support for implementation of a cap-and-trade program in New Mexico, or addressed other concerns specific to New Mexico's current proposed rulemaking for cap and trade. These issues were not within the scope of the WCI harmonized Essential Requirements, but the comments have been transmitted to the New Mexico Environment Department for their consideration.

One commenter expressed general support for the principles of harmonization, for working with EPA to ensure that additional data elements can be submitted, for third-party verification, and for the emissions reporting threshold.

5.2 General Provisions

5.2.1 Time to Respond to Requests for Information [§98.3(g)]

Several commenters objected that the 10-day time period allowed for response to jurisdictional requests for information is not long enough to allow for retrieval and aggregation of the data. Commenter-recommended time periods ranged from 20 to 60 days. One commenter also recommended that the period start with receipt of the request in writing.

Each of the WCI Jurisdictions have data request procedures currently in-place which have been established to effectively deal with data access issues. The current WCI language in this section is, by necessity, generic to some extent, in order to allow WCI Jurisdictions the flexibility to utilize their existing data request procedures. Thus it is not advisable to be overly specific as to the form in which a formal data request is made. In regard to the time allowed for responding to a data request, we note that this data must be compiled and maintained by the reporter as part of the required GHG Monitoring Plan. We do not believe that 30 days would be needed to respond, but we agree to lengthen the response period to 20 calendar days after receipt of the request, to allow for staff absences and other potential difficulties in assembling the data.

For consistency, we have also modified the response period for requests for information in Subpart C [§98.36(e)(3) and §98.36(e)(4)] to 20 days.

5.2.2 Calibration Deadline [§98.3(i)(6)]

Several commenters objected to the requirement that initial calibrations be performed if there is any unplanned outage of sufficient duration to complete the calibration, noting a number of potential logistical difficulties including an inability to estimate the outage duration at the beginning of an unplanned outage such as a malfunction or emergency repair.

We had added this language to ensure that the initial calibration was conducted at the earliest opportunity. However, we recognize the difficulty in estimating the duration of an unplanned outage. Therefore, we agree to strike this provision. We have added a provision allowing for postponement, subject to jurisdictional approval, in cases where units operate continuously with infrequent outages.

> (6) For units and processes that operate continuously with infrequent outages, it may not be possible to meet the April 1, 2010 deadline for the initial calibration of a flow meter or other measurement device without removing the device from service and shipping it to a remote location, thereby disrupting normal process operation. In such cases, the owner or operator may postpone the initial calibration until the next scheduled maintenance outage, and may similarly postpone the subsequent recalibrations. Such postponements, <u>including the date for the next planned shutdown,</u> shall be documented in the monitoring plan that is required under § 98.3(g)(5) <u>and submitted before December 31, 2011 to the [jurisdiction] for approval</u>.

Reporters understand from the outset of reporting that an initial calibration is required, thus they should be able to plan accordingly to ensure that the required personnel and equipment are available or can be accessed in a timely fashion.

5.2.3 Approval for Method Switching [§98.3(k)]

A commenter objected to the requirement for jurisdictional approval for a reporter to switch between alternative methods allowed under the rule. This provision was seen as introducing an unnecessary bureaucratic delay.

It is an established fact that different calculation methods (e.g., fuel based, mass balance-based, and CEMS) by their very nature each generate unique and slightly different emissions estimates. The requirement that a facility obtain jurisdictional approval prior to switching methods is designed to ensure that changes in emissions estimates are real and the result of facility operational changes rather than simply changes in calculation methodology. Allowing a facility to "*select and change the calculation method at any time*" as the commenter suggests would not promote data consistency, but rather would incentivize method switching to generate the most favorable emissions data. Therefore, we will retain this provision.

5.2.4 Reporting Threshold [§98.2]

Two comments objected to retention of the 10,000-metric-ton-per-year reporting threshold for the WCI reporting program. One commenter argued that "[r]etaining the lower reporting threshold will result in confusion among the regulated community because it is different than the EPA reporting threshold and will result in added cost." This commenter also argued that retention of the WCI threshold was not necessary to fulfill the second harmonization principle because "the lower threshold does not relate to a quantification method that is sufficiently reliable and accurate to be employed in a cap-and-trade program." Another commenter simply stated under the heading "Reporting Threshold" that it "supports uniformity in emissions accounting standards used across reporting programs and across jurisdictions."

The 10,000 ton per year design threshold was a Partner design recommendation and was not subject to reconsideration as part of the harmonization effort. It should be noted, however, that the possibility of "confusion among the regulated community" as a result of the lower threshold is minimal, because facilities in U.S. WCI jurisdictions with emissions at or above 10,000 but below 25,000 metric tons per year will be subject *only* to the WCI reporting program.

5.2.5 Third-Party Verification [§98.3(f)]

One commenter objects to the WCI third-party verification requirement "unless and until there is a uniform federal law requiring such." The commenter also maintains that the verification provisions of the harmonized ERs are ambiguous.

Third-party verification is a Partner design recommendation and was not reconsidered in the development of the harmonized ERs. WCI has attempted to clarify the applicability of the third-party verification requirements by substituting a reference to WCI.8 for the EPA self-certification and audit language in 98.3(f). It should be noted that the harmonized ERs are intended to serve as a guide for U.S. WCI jurisdictions to use in developing incorporation-by-reference rules and not as model rule language. Thus the precise manner by which incorporated EPA requirements are integrated with WCI-only requirements, such as third-party verification, will be up to the individual jurisdictions.

Another commenter was concerned that because it will not be possible to complete third-party verification by the EPA March 31, 2010, reporting deadline, the verification requirement "will place emitters in the problematic position of reporting different data to EPA and WCI."

This concern is misplaced. Under the harmonized ERs, U.S. facilities subject to third-party verification will submit their reports on the same date, March 31, 2010, to both EPA and the WCI state. Under WCI.8, they will then have to submit a verification statement for that report to the WCI state by September 1. (This date may be moved forward in the future.) Any errors discovered as a result of the verification process would have to be corrected with a revised report under both the EPA and WCI programs (see section 98.3(h)). Thus, the data reported to both programs will remain consistent.

5.2.6 Sampling Frequency [§98.3(j)]

One commenter objected in general to the increased sampling frequency and the related weighted average calculation method imposed in section 98.3(j). According to this commenter:

> [T]he increased sampling frequency requirements and the weighted average calculations impose an additional cost burden on those businesses [in] the WCI Partner jurisdictions. This increased cost does not necessarily result in increased accuracy of the estimated greenhouse gas emissions. The WCI has not presented a cost-benefit analysis that justifies the increased sampling frequency or the weighted average calculations.

In the few instances (Subparts P and Y) where the harmonized ERs impose a sampling frequency greater than that imposed in EPA's rule, they do so in order to conform the quantification methodology to the original WCI ERs. Those ERs in turn reflect the WCI's judgment on the minimum sampling frequency needed for reliable emissions determinations. In the case of Subpart P, WCI has added a provision allowing facilities to composite up to 30 weighted samples in order to allow for monthly analysis, which should reduce the cost burden.

Use of weighted average data results in more accurate emissions data since the fuel composition is mass or volume "weighted" by the amount of fuel consumed to more accurately reflect the amount of total carbon entering the combustion process during a specific time period. The calculation of a weighted average is a simple matter.

We note that for some calculation methodologies [e.g., §98.33(a)(2)(ii)(A)], 40 C.F.R. 98 specifies arithmetic averaging of parameters measured at greater than the required frequency. Accordingly, we have modified the requirement for weighted averaging to avoid conflict with the EPA rule, but weighted averaging will still be required in those cases where the EPA rule is silent on this issue.

5.2.7 Data Substitution [§98.3(m)]

Two commenters objected to section 98.3(m), which states that notwithstanding the data substitution procedures "failure to conduct monitoring in accordance with the schedules established in this Article shall constitute a violation."

One commenter notes that "EPA has long recognized that data collection systems have down time associated with various monitoring system problems" and suggests that WCI consider a maximum data substitution rate as an alternative.

Unless the monitoring obligations of the harmonized ERs are directly enforceable regardless of whether there is a data substitution method available, facilities (with the exception of Acid Rain facilities, as noted below) will have no incentive to comply with those requirements. They can decide that it is simply less expensive or even advantageous for purposes of compliance with their cap-and-trade obligations to omit samples or temporarily shut down monitoring equipment. A maximum data substitution rate would not provide a complete solution to this problem.

The inclusion of this language does not mean that every monitoring failure will be subject to enforcement action. As always, state agencies administering the ERs will exercise enforcement discretion and will consider factors such as whether the failure was deliberate or accidental, whether it could have been avoided and whether the facility acted expeditiously to correct the failure in deciding whether an enforcement action is appropriate.

Another commenter noted that the data substitution procedures for Acid Rain facilities *are* punitive and therefore provide a disincentive for failing to monitor. This commenter suggested amending 98.3(m) as follows:

> Notwithstanding the missing data procedures specified in this Article, the failure to conduct monitoring in accordance with the schedules established in this Article shall constitute a violation, <u>except in respect of electricity generating units subject to 40 CFR Part 75</u>.

We note that the data substitution procedures for Acid Rain facilities may or may not be punitive in a cap-and-trade context, depending on whether the data substitution occurs in a period when baselines are being set.

We believe the intent of this provision can be more accurately stated with rewording as follows:

> Notwithstanding the missing data procedures specified in this Article, the failure to conduct monitoring in accordance with this Article shall constitute a violation.

5.2.8 First Jurisdictional Deliverers

One commenter noted that the reporting requirements for electricity importers were not included in the EPA rule markup. This commenter stated that "First Jurisdictional Deliverers will presumably be required to submit a separate report in addition to the WCI/ EPA report."

The WCI.60 Imported Electricity quantification method is part of the WCI program design. WCI members are exploring how to integrate electricity import reporting into the federal (or jurisdictional) reporting systems for both the U.S. and Canada.

5.3 General Stationary Combustion (Subpart C)

5.3.1 Tier 3 or 4 for Facilities Subject to Cap [98.33(b)(1) and 98.33(b)(2)]

Two commenters objected to the WCI's decision not to allow combustion units at facilities subject to third-party verification to use Tier 1 or Tier 2 methodologies. According to one commenter:

> In general, only relatively small facilities (i.e., with maximum rated heat input capacity of 250 mmBtu/hr or less) are eligible to use these tiers. Such facilities are likely to be only modest players in a cap-and-trade system, yet the most significantly impacted by the cost and administrative burdens of employing the more rigorous Tier 3 or 4 methodologies to calculate their GHG emissions. We do not believe WCI has adequately justified that use of Tier 1 or 2 quantification methods by these facilities would adversely impact a cap-and-trade program.

The WCI has determined that all facilities above 25,000 metric tons per year need to be included in the cap-and-trade system for the system to achieve the WCI's emission reduction goals. In order for the cap-and-trade system to function, emission reports from covered facilities must be accurate. For facilities burning fuels with highly variable high heating values and carbon contents, Tier 3 is required.

However, we recognize that if a facility is burning a standard fuel with a predictable HHV and carbon content, an acceptable level of accuracy may be achieved using the Tier 1 or Tier 2 methodology. We have therefore revised §98.33(b) to allow the use of Tier 1 or Tier 2 by any facility for the following fuels as listed in new Table C-1a, if combusted in a unit with maximum rated heat input capacity of 250 mmBtu/hr or less:

- Distillate fuel #1, 2 and 4
- Kerosene (normal and jet)

- LPG (commercial "propane")
- Pure propane (C3H8)
- Pure propylene (C3H6)
- Pure ethane (C2H6)
- Pure ethylene (C2H4)
- Pure isobutene (C4H8)
- Pure butane (C4H10)
- Pure butylene (C4H8)
- Gasoline (including. aviation, natural, motor)

If the facility is subject to verification requirements, then Tier 2 is required for combustion of pipeline quality natural gas, because the gas supplier is normally able to provide HHV information, and billing for natural gas is often based on heat content.

In addition, one commenter objected to the general requirement to use Tier 2 if the facility can obtain HHV values from the fuel supplier. We agree that the "can obtain" provision is too broad in that it does not include any limits on costs for HHV sampling that might be imposed by a fuel supplier. We have therefore restored the EPA rule language, which requires use of Tier 2 if the facility routinely receives HHV data from the supplier.

5.3.2 CO_2 CEMS [98.33(a)(4)(iv)]

One commenter objected to the requirement in 40 CFR 98.33(a)(4)(iv) to install a CO_2, rather than just an oxygen, sensor in all new CEMS.

After further investigation, the Reporting Committee remains unconvinced that the use of an oxygen sensor together with EPA methods for converting oxygen to CO_2 will produce results reliable enough for a cap-and-trade program. The requirement to include a CO_2 sensor in all new CEMS therefore has been retained in the final harmonized U.S. ERs. The Committee, however, is continuing its investigation of this issue and may publish a supplement to the harmonized ERs if a change is determined to be necessary.

The final ERs continue to allow the use of oxygen sensors in existing CEMS. In order to generate data on the relative accuracy of using oxygen sensors to determine CO_2 emissions, however, the ERs have been amended to include optional language allowing individual WCI jurisdictions to impose a requirement to include CO_2 analysis in RATA testing for existing CEMS.

5.4 Petroleum Refineries

5.4.1 Refinery Fuel Gas [98.254(m) and 98.34(b)(3)(ii)(E)]

One commenter objected to the requirement in 40 CFR 98.34(b)(3)(ii)(E) and 98.254(m) to monitor refinery fuel gas composition on a daily basis.

This requirement is consistent with established GHG sampling protocols (e.g. EU ETS). Refineries typically have multiple independent fuel gas systems and this fuel which is derived from many process units within the refinery can exhibit significant short term compositional variation. In most refineries, refinery fuel gas also represents the major fuel combusted at the refinery. Thus the compositional variability and importance of this fuel require an accurate quantification methodology.

5.4.2 Flares

One commenter objected to restriction of the use of Equation Y-3 only for flare emissions during startups, shutdowns and malfunctions during which measurement of the parameters required by Equations Y-1 and Y-2 were impossible.

Equation Y-3 gives a much less accurate estimate of emissions than Equations Y-1 and Y-2. In cases of normal operation of flares reporters are required to determine HHV or composition of the material flared and use Equation Y-1 or Y-2, but use of Equation Y-3 is allowed when use of the more accurate methods is impossible. These requirements are designed to promote data consistency across reporting entities while still providing an alternative methodology in cases of "unforeseen malfunctions and start-up and shut-down" when operators are unable to measure the required parameters – flow and composition.

5.5 Other

5.5.1 Fugitive Transmission And Distribution Emissions And The Cap

One commenter indicated that fugitive emissions from gas transmission and distribution systems should be excluded from the cap/trading system due to inherent difficulties in ensuring accurate measurements at a reasonable cost. The 'Proposed Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule' document does not directly consider gas transmission and distribution systems as these are part of the EPA's proposed Subpart W (Petroleum and Natural Gas Systems' quantification method (to which the Western Climate Initiative has made comment). The 'Proposed Harmonization' document does, however, outline emission sources which are considered to be 'reporting only'. During the future harmonization process for Subpart W, the WCI will consider whether these transmission and distribution fugitive emissions should be considered to the reporting only or included within the cap.

5.5.2 Canadian Operations Should Be Able To Use Equations, Emission Factors, Etc. In Use In Canada

One oil and gas industry commenter indicated that Canadian facilities should not have to use all of the same functions, equations, sampling protocols and measurement criteria as U.S. facilities. Since it is essential that the quantification methods derive the same measured emissions in both Canada and the U.S., in most cases these quantification methods need to be the same, recognizing that standard emission factors do vary between the jurisdictions. For oil and gas operations, however, it is recognized that there can be different standard quantification methods in use in Canada and the States, and the WCI's Oil and Gas Subcommittee is considering cases where existing measurement systems (e.g. those in the B.C. Oil and Gas Commission Measurement for Upstream Oil and Gas Operations manual) can be used to quantify/sample specific emission sources in place of those outlined in the EPA's Subpart W proposal.

6 Other Changes to the Proposal

6.1 Amendments to EPA Rule

On July 12, 2010, EPA published a final rule adding four additional quantification subparts the EPA rule. 75 Fed. Reg. 39736. Due to time constraints, the WCI is not including these subparts in the final harmonized ERs. The July 12, 2010, rule revisions, however, included conforming changes to Subpart A that will go into effect this year. To ensure the harmonized ERs are consistent with the EPA rule, Subpart A of the harmonized ERs has been updated to reflect these changes.

6.2 Verification Deadlines

Deadlines for the submission of verification statements were added to the U.S. version of WCI.8. These deadlines were established by WCI.2, which is not included in U.S. harmonized ERs.

6.3 Accreditation

WCI.8(c)(2)(C) was amended to allow jurisdictions to develop their own accreditation programs for verification bodies that meet specified standards.

6.4 Pipeline Quality Natural Gas

A definition of pipeline quality natural gas was added to Subpart C in order to clarify when the use of Tier 1 or 2 is permitted for natural gas fuels.

6.5 Method Selection for Combustion of MSW and Biomass Fuels

Section 98.33(b)(1)(ii) of the EPA rule, which allows the use of Tier 1 for the combustion of municipal solid waste (MSW) in all non-steam-producing units, was marked for deletion in the proposal. The Reporting Committee proposed this change in order to achieve consistency with the ERs, which would have allowed the use of Tier 1 for these units only if located at facilities that are not subject to verification.

On further analysis, however, the Reporting Committee concluded that Tier 1 is the only viable quantification method for non-steam-producing MSW combustion units without CEMS. The highly variable, heterogeneous content of MSW would make it extremely difficult if not impossible to conduct the sampling required under Tier 2 to determine the high heating value or under Tier 3 to determine carbon content. Eliminating section 98.3(b)(1)(iii) could be construed as requiring the installation of a CEMS for all non-steam-producing MSW combustion units, which was not the Reporting Committee's intention. In addition, the Committee noted that section 98.34(d) requires quarterly radiocarbon analysis to determine the biogenic portion of CO_2 emissions from all MSW combustion units, regardless of the method used to determine total CO_2 emissions. Section 98.33(b)(1)(ii) therefore has been restored in the final harmonized ERs.

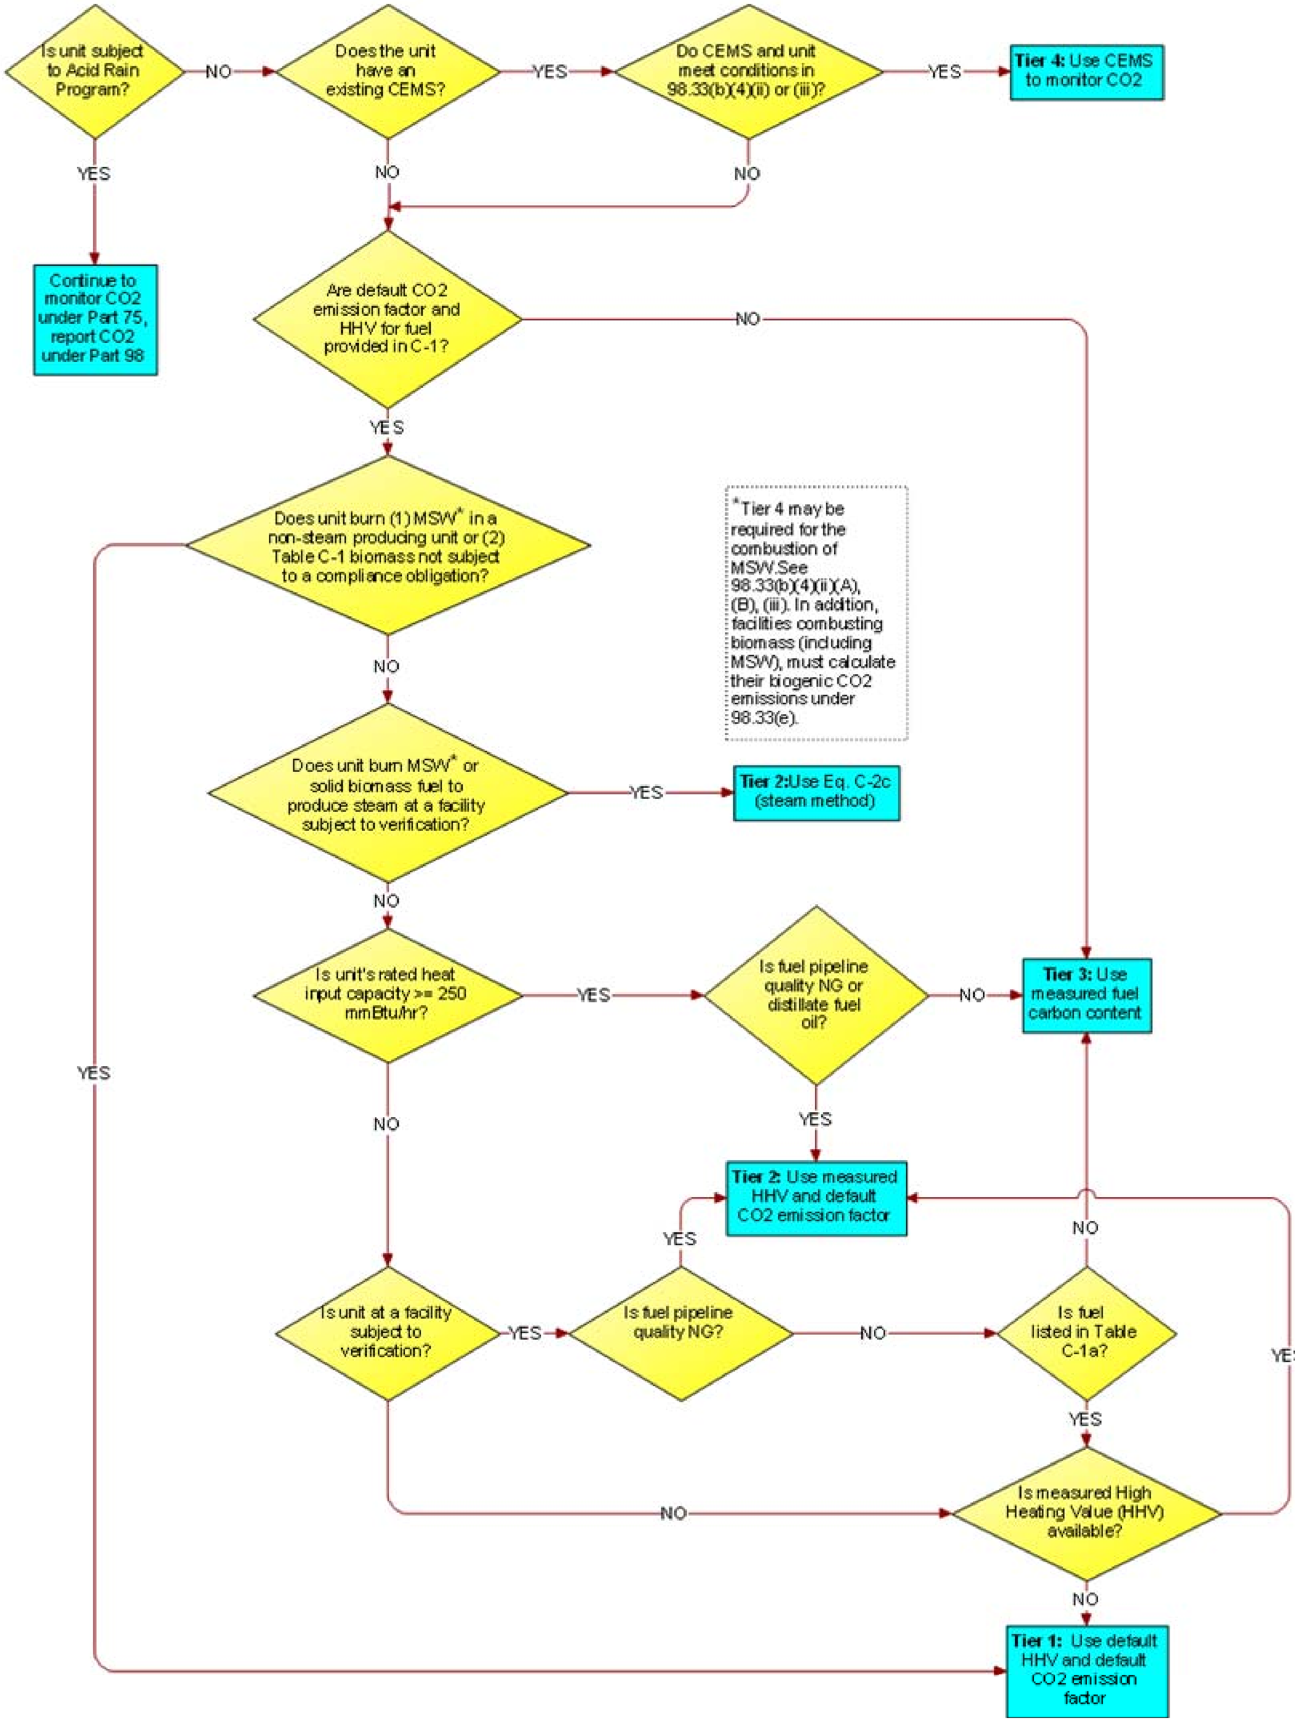
Section 98.33(b)(1)(iii) of the EPA rule, which allows the use of Tier 1 for all biomass fuels listed in Table C-1, was also marked for deletion in the proposal to achieve consistency with the original ERs. The verification rule, however, contemplates that CO_2 emissions from biomass fuels determined by the jurisdiction to be carbon neutral will not be subject to the cap-and-trade program. The Committee concluded that the additional cost of using a higher tier would not be justified for combustion emissions that are not subject to cap-and-trade. Section 98.33(b)(1)(iii) therefore has been restored with the proviso that it applies only to the combustion of biomass fuels that have been determined by the jurisdiction not to be subject to a compliance obligation.

6.6 Clarification of GSC Tier Selection Language

The Reporting Committee concluded that after some of the other changes identified above, the tier selection language for Tiers 2 and 3 required clarification. Specifically, rule language needed to make it clear that (a) Tier 2 is always allowed for the combustion of a Table C-1 fuel at a facility not subject to verification and (b) Tier 3 is required for the combustion of Table C-1 fuels at a facility that is subject to verification, unless Tier 1 or 2 is specifically authorized by another section. The Committee added new section 98.33(b)(2)(iv) and revised section 98.33(b)(3)(ii) to make this clear.

6.7 Flowchart

The Reporting Committee developed the following flowchart to clarify the CO_2 combustion method selection process under the harmonized U.S. ERs. The flowchart may be used in a jurisdiction's rule language or guidance material.



Is unit subject to Acid Rain Program?
NO
Does the unit have an existing CEMS?
YES
Do CEMS and unit meet conditions in 98.33(b)(4)(ii) or (iii)?
YES
Tier 4: Use CEMS to monitor CO2
YES
Continue to monitor CO2 under Part 75, report CO2 under Part 98
NO
NO
Are default CO2 emission factor and HHV for fuel provided in C-1?
NO
YES
Does unit burn (1) MSW* in a non-steam producing unit or (2) Table C-1 biomass not subject to a compliance obligation?
*Tier 4 may be required for the combustion of MSW. See 98.33(b)(4)(ii)(A), (B), (iii). In addition, facilities combusting biomass (including MSW), must calculate their biogenic CO2 emissions under 98.33(e).
NO
Does unit burn MSW* or solid biomass fuel to produce steam at a facility subject to verification?
YES
Tier 2: Use Eq. C-2c (steam method)
NO
Is unit's rated heat input capacity >= 250 mmBtu/hr?
YES
Is fuel pipeline quality NG or distillate fuel oil?
NO
Tier 3: Use measured fuel carbon content
YES
YES
NO
Tier 2: Use measured HHV and default CO2 emission factor
YES
NO
Is unit at a facility subject to verification?
YES
Is fuel pipeline quality NG?
NO
Is fuel listed in Table C-1a?
YES
YES
NO
Is measured High Heating Value (HHV) available?
NO
Tier 1: Use default HHV and default CO2 emission factor

Subpart A—General Provisions

§ 98.1 Purpose and scope.

(a) This part establishes mandatory greenhouse gas (GHG) reporting requirements for owners and operators of certain facilities that directly emit GHG as well as for certain fossil fuel suppliers and industrial GHG suppliers. For suppliers, the GHGs reported are the quantity that would be emitted from combustion or use of the products supplied.[1]

(b) Owners and operators of facilities and suppliers that are subject to this part must follow the requirements of this subpart and all applicable subparts of this part. If a conflict exists between a provision in subpart A and any other applicable subpart, the requirements of the applicable subpart shall take precedence.

(c) Except as otherwise specifically provided:

(1) Wherever the term "Administrator" is used in the rules incorporated by reference in this Article,[2] the term [director/secretary/administrator] of the [jurisdiction] shall be substituted.

(2) Wherever the term "EPA" is used in the rules incorporated by reference in this Article, the term [jurisdiction] shall be substituted.

(d) The following emissions data shall be submitted for information only and may not be subject to cap-and-trade requirements:[3]

(1) Data submitted by a source category designated as "reporting only." This provision does not apply to emissions from general stationary combustion at a source in a "reporting only" category.

(2) Emissions data calculated with a methodology identified as "reporting only."

(3) Data submitted by a facility not subject to verification under WCI.8.

---

[1] WCI jurisdictions will require reporting by fuel suppliers for reporting year 2012 and later and may in part rely on EPA methods

[2] "Article" is a placeholder for a jurisdiction-specific cross reference to whatever subdivision of its administrative code contains the WCI's Essential Requirements for Mandatory Reporting in their entirety. Any WCI methodologies that are not sufficiently accurate for cap-and-trade purposes, such as the coal storage method, should be designated "reporting only" in the jurisdiction's rules.

[3] The identification of data as "reporting only" will be subject to review possible revision before the adoption of a cap-and-trade program. On adoption of a cap-and-trade program, the jurisdiction will want to substitute a citation to the rules implementing the program for the words "cap-and-trade requirements." Any WCI methodologies that are not sufficiently accurate for cap-and-trade purposes, such as the coal storage method, should also be designated "reporting only" in the jurisdiction's rules.

(e) On approval by [jurisdiction], reports that conform to this Article and that are submitted to the EPA GHG reporting system shall be deemed to satisfy, in whole or in part,[4] the requirement to submit a report to [jurisdiction] under this Article.[5]

§ 98.2 Who must report?

(a) The GHG reporting requirements and related monitoring, recordkeeping, and reporting requirements of this part apply to the owners and operators of any facility that is located in the United States and that meets the requirements of either paragraph (a)(1), (a)(2), or (a)(3) of this section; and any supplier that meets the requirements of paragraph (a)(4) of this section:

(1) A facility that contains any source category that is listed in Table A-3 of this subpart in any calendar year starting in ~~2010~~2011. For these facilities, the annual GHG report must cover stationary fuel combustion sources (subpart C), miscellaneous use of carbonates (subpart U), and all applicable source categories listed in Table A-3 and Table A-4 of this subpart.

(2) A facility that contains any source category that is listed in Table A-4 of this subpart that emits 25,000 metric tons CO2e or more per year in combined emissions from stationary fuel combustion units, miscellaneous uses of carbonate, and all applicable source categories that are listed in Table A-3 and Table A-4 of this subpart. For these facilities, the annual GHG report must cover stationary fuel combustion sources (subpart C), miscellaneous use of carbonates (subpart U), and all applicable source categories listed in Table A-3 and Table A-4 of this subpart.

(3) A facility that in any calendar year starting in 2010 meets all three of the conditions listed in this paragraph (a)(3). For these facilities, the annual GHG report must cover emissions from stationary fuel combustion sources only.

(i) The facility does not meet the requirements of either paragraph (a)(1) or (a)(2) of this section.

(ii) The aggregate maximum rated heat input capacity of the stationary fuel combustion units at the facility is ~~30~~ 12 mmBtu/hr or greater.[6]

---

[4] Supplemental reports may be needed for facilities subject to both EPA reporting requirements and WCI-only quantification methodologies, e.g. facilities that include coal storage (subject to WCI.100).
[5] Applies in U.S. jurisdictions only. Procedures for approval will be established by the jurisdiction.
[6] 30 mmBtu/hr * 10,000/25,000.

(iii) The facility emits ~~25,000~~10,000 metric tons CO2e or more per year in combined emissions from all stationary fuel combustion sources.

(4) A supplier that is listed in Table A-5 of this subpart. For these suppliers, the annual GHG report must cover all applicable products for which calculation methodologies are provided in the subparts listed in Table A-5 of this subpart.

(5) Research and development activities are not considered to be part of any source category defined in this part.

(b) To calculate GHG emissions for comparison to the ~~25,000~~10,000 metric ton CO2e per year emission threshold in paragraph (a)(2) of this section, the owner or operator shall calculate annual CO2e emissions, as described in paragraphs (b)(1) through (b)(4) of this section.

(1) Calculate the annual emissions of CO2, CH4, N2O, and each fluorinated GHG in metric tons from all applicable source categories listed in paragraph (a)(2) of this section. The GHG emissions shall be calculated using the calculation methodologies specified in each applicable subpart and available company records. Include emissions from only those gases listed in Table A– 1 of this subpart.

(2) For each general stationary fuel combustion unit, calculate the annual CO2 emissions in metric tons using any of the four calculation methodologies specified in § 98.33(a). Calculate the annual CH4 and N2O emissions from the stationary fuel combustion sources in metric tons using the appropriate equation in § 98.33(c). ~~Exclude carbon dioxide emissions from the combustion of biomass, but include emissions of CH4 and N2O from biomass combustion.~~

(i) For stationary combustion units, carbon dioxide emissions from the combustion of biomass fuels shall be included in determining whether a facility is subject to the reporting requirements of this Article with the following exceptions:

(1) Until such time as [jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, a maximum of 15,000 metric tons of carbon dioxide emissions from the combustion of pure solid biomass fuel may be excluded from calculation of GHG emissions for comparison to the 10,000 metric ton CO2e per year emission threshold in paragraph (a)(2) of this section, provided that total GHG emissions including emissions from solid biomass fuel are less than 25,000 metric tons CO2e.
