California Global Warming Solutions Act of 2006 (AB 32)	…the reduction is in addition to any greenhouse gas emission reduction otherwise required by law or regulation, and any other greenhouse gas emission reduction that otherwise would occur [from 38562(d)(2)]
Clean Development Mechanism (CDM)	A PoA is additional if it can be demonstrated that in the absence of the CDM (i) the proposed voluntary measure would not be implemented, or (ii) the mandatory policy/regulation would be systematically not enforced and that noncompliance with those requirements is widespread in the country/region, or (iii) that the PoA will lead to a greater level of enforcement of the existing mandatory policy /regulation. This shall constitute the demonstration of additionality of the PoA as a whole.
Gold Standard	Additionality – All Gold Standard project activities must be demonstrated to be additional, meaning that they shall reduce anthropogenic emissions of greenhouse gases below those that would have occurred in the absence of the registered Gold Standard project activity.

Offset System	Requirements
ISO 14064-2	From 5.4 - The project proponent shall select or establish, justify and apply criteria and procedures for demonstrating that the project results in GHG emissions reductions or removal enhancements that are additional to what would occur in the baseline scenario.
Offsets Quality Initiative (OQI)	Offsets Should Be Additional. Because offsets are used to compensate for emission reductions that an entity operating under an emissions cap would otherwise have to make itself, the reductions resulting from offset projects must be shown to be "in addition to" reductions that would have occurred without the incentive provided by offsets. The revenue from selling the project's emission reductions should be reasonably expected to have incentivized the project's implementation for an offset project to be considered additional.
Oregon Offset Standard	Offsets must be regulatory surplus and will be evaluated based on the "extent to which the CO_2 reductions would have occurred in the absence of the offset project"
Regional Greenhouse Gas Initiative (RGGI)	Except as provided with respect to specific offset project standards in section XX10.5, the following general requirements shall apply. (1) CO2 offset allowances shall not be awarded to an offset project or CO2 emissions credit retirement that is required pursuant to any local, state or federal law, regulation, or administrative or judicial order. If an offset project receives a consistency determination under section XX10.4 and is later required by local, state or federal law, regulation, or administrative or judicial order, then the offset project shall remain eligible for the award of CO2 offset allowances until the end of its current allocation period but its eligibility shall not be extended for an additional allocation period. (2) CO2 offset allowances shall not be awarded to an offset project that includes an electric generation component, unless the project sponsor transfers legal rights to any and all attribute credits (other than the CO2 offset allowances awarded under section XX10.7) generated from the operation of the offset project.
Voluntary Carbon Standard (VCS 2007)	"Project-based GHG emission reductions and removals must be additional to what would have happened under a business as usual scenario if the project had not been carried out." The VCS has requirements that a project pass one of three additionality tests, a "Project Test", a "Performance Test" or a "Technology Test". All protocols specify at a minimum that the project cannot be required by any law or regulation.
WBCSD/WRI GHG Protocol for Project Accounting	A criterion often applied to GHG projects, stipulating that project-based GHG reductions should only be quantified if the project activity "would not have happened anyway"—i.e., that the project activity (or the same technologies or practices it employs) would not have been implemented in its baseline scenario and/or that project activity emissions are lower than baseline emissions.

Once additionality has been defined, the WCI will need to develop an approach to ensure that offset projects can be evaluated against it. There are various methods of evaluating additionality, but the two most common approaches are project-specific and performance standard additionality tests. Project-specific tests (Option A below) seek to scrutinize the particular circumstances of an individual project to ensure that it would not have occurred in the absence of offsets. This approach is used by the CDM. Alternatively, a performance standard approach (Option B) seeks to determine through initial study of a sector or project type what level of performance is necessary to provide confidence that projects meeting or exceeding the standard are additional. The standard may be the identification of a particular technology (such as a methane digester) that is nearly always additional to common practice or the establishment of a set performance baseline that project reductions are measured against. Performance standards have been employed by the CAR. The WCI could also choose to have the additionality assessment vary by protocol, which would be advantageous if some sectors or activities are better suited to developing performance standards while others are more suited to project-specific analyses.

Summary of approaches to assessing additionality:

- Option A: Project Specific –
  The additionality of each individual project activity is scrutinized through application of specific additionality tests
- Option B: Performance Standard –
  For each sector or project type, a performance standard is established where projects meeting or exceeding the standard are considered to be additional. Performance standards may be uniform among the WCI Partner jurisdictions or differentiated by jurisdiction to reflect regulatory and economic differences.
- Option C: Protocol Specific Approach –
  Approach to additionality assessment may vary by protocol, seeking to adopt the best approach for each sector or class of activities
- Option D: Hybrid Approach –
  A combination of Options A, B, and C; a hybrid approach would set a performance standard, but still include some aspects of a project-specific additionality analysis, and may vary by protocol. A single approach may limit project types and inhibit innovation; a hybrid approach may be better able to cover more possibilities.

Options A and B have advantages and disadvantages. A combination of those two options may also be possible (Option C). Project-specific approaches have the advantage of looking more closely at individual projects and in theory they should be more effective in reducing the risk of non-additional projects being credited. However, the additional scrutiny increases transaction and oversight costs, as well as investor uncertainty, and it is not clear whether a project-specific approach would achieve better results than a performance standard approach. The CDM has developed rigorous project-specific additionality tests that include investment analysis, barrier analysis, common practice analysis and the identification of project alternatives. Performance standards provide greater clarity and investor certainty and require less administrative scrutiny once a standard has been set. They may however, require significant initial study to set an appropriate standard for a class of projects under certain circumstances (for example, if the performance standard for a project type in one state/province differs in another state/province) and would need to be periodically reviewed and revised as necessary. The performance standard approach accepts that some projects meeting the standard may not be additional, but that these would be few in number and be compensated by the benefits of having a clear standard that ensures most projects meeting the standard are additional. If a performance standard approach is adopted, regulatory additionality would likely still be evaluated on a project-by-project basis to ensure that a given project is not required by any laws, regulations, or permitting agreements. New technologies or practices will likely need a case-by-case approach. Once investments and implementation in specific new innovations become more established, a performance standard approach can be more readily applied.

5.2 Supporting principles and technical considerations

This section discusses three supporting principles and technical considerations in the context of defining additional. The concepts of "baseline," "eligbility date," and "crediting period" will likely have a role in which reductions the WCI considers to be additional.

5.2.1 Baseline

A baseline is commonly viewed as the business-as-usual (BAU) scenario that would likely occur in the absence of offset project activity. There are two key issues with respect to baseline determinations. First, offsets credited to a project are often calculated as the difference between baseline scenario emissions and project activity emissions. In this sense, correctly modeling the baseline scenario is crucial to ensuring that the offsets generated are both real and quantifiable. Second, as illustrated in Table 5.1, several programs define additionality in relation to a baseline (e.g., CDM and CAR), where reductions beyond what occurs in the baseline scenario are considered to be additional. This concept represents an alternative or complementary way of evaluating additionality when compared to other additionality tests.

A question the WCI will need to answer is to what extent baseline modeling will be considered together with additionality evaluations and whether this should vary by project type. Defining and determining a baselineis not always straightforward and an appeal to baseline modeling to evaluate additionality may not be any less complicated than employing project-specific additionality tests. One example of this complication is determining how many scenarios should be considered when determining the baseline.

Any project activity that would have occurred without offsets is by definition part of the baseline scenario and thereby would not be eligible as an offset even if it did result in emission reductions. Baseline scenario definitions are included in Table 5.1. The project-specific additionality tests discussed previously attempt to answer these questions and help to identify what would be the most likely outcome by taking into account financial information, common practices, and barriers to the offset project under consideration. Protocols that favor a performance standard approach may provide a standardized approach to modeling a baseline based on common practices in a region and regulatory requirements. This approach avoids much of the subjectivity involved in baseline modeling, but has the tradeoff that an "average" baseline for a project type will not necessarily reflect the actual baseline for a particular project. Some existing protocols also assume that current conditions represent the baseline conditions, which may not always be a valid assumption.

Table 5.1 Definitions of baseline in offset systems

Offset System	Definition
Alberta-base Offset Credit System	Hypothetical reference case that best represents the conditions (GHG emissions) most likely to have occurred in the absence of a GHG reductions/removals project.
British Columbia Emission Offset Regulation	Baseline emissions, in relation to a project, means an estimate of GHG emissions from all selected sources and reservoirs, assuming the project is not carried out.
California Global Warming Solutions Act of 2006 (AB 32)	Not defined
Clean Development Mechanism (CDM)	'Baseline methodology' is an application of an approach as defined in paragraph 48 of the CDM modalities and procedures, to an individual project activity, reflecting aspects such as sector and region. No methodology is excluded a priori so that project participants have the opportunity to propose any methodology. In considering paragraph 48, the Executive Board agreed that, in the two cases below, the following applies: (a) Case of a new methodology: In developing a baseline methodology, the first step is to identify the most appropriate approach for the project activity and then an applicable methodology; (b) Case of an approved methodology: In opting for an approved methodology, project participants have implicitly chosen an approach.
Gold Standard	'Baseline' means the amount of greenhouse gas emissions that would be produced in the absence of the carbon credit project, also known as the 'Business as usual' scenario, which forms the basis for calculating a project's emissions reductions and helps determine additionality.
ISO 14064-2	Baseline Scenario - hypothetical reference case that best represents the conditions most likely to occur in the absence of a proposed greenhouse gas project.
Offsets Quality Initiative (OQI)	Offsets Should Be Based on a Realistic Baseline. A GHG emission baseline must be established in order to quantify an offset project's GHG reductions. A baseline represents forecasted emission levels in the absence of the offset project; this is sometimes referred to as the baseline scenario, or the "without-project" case. The difference between the baseline and the actual emissions after the offset project is implemented represents the reductions achieved by the project, and this amount is credited as an offset. Offsets are only as credible as their baselines.
Oregon Offset Standard	Required but not specified.
Regional Greenhouse Gas Initiative (RGGI)	Each approved offset methodology has a unique "Emission baseline determination" method.

Offset System	Definition
Voluntary Carbon Standard (VCS 2007)	Baseline Scenario - hypothetical reference case that best represents the conditions most likely to occur in the absence of a proposed greenhouse gas project (from ISO 14064-2). Also, "The project proponent shall select the most conservative baseline scenario for the methodology. This shall reflect what most likely would have occurred in the absence of the project. The principle of conservativeness as set out in clause 3.7 of ISO 14064-2:2006 shall apply."
WBCSD/WRI GHG Protocol for Project Accounting	A hypothetical description of what would have most likely occurred in the absence of any considerations about climate change mitigation. Baseline emissions are an estimate of GHG emissions, removals, or storage associated with a baseline scenario or derived using a performance standard (see baseline procedures).

5.2.2 Eligibility Date

In the context of additionality, the beginning date of a project has important implications as to whether it would have occurred without the possibility of offsets. The most conservative approach in setting an eligibility date would be to only allow projects that have been undertaken after the initiation of a WCI offset program and that meet all of the requirements specified in the program design. However, such an approach would exclude projects that were undertaken in advance of the offset program's implementation that may still be additional if project developers either took the risk of implementing early projects with the expectation of being able to generate offsets under the WCI program, or if the projects are additional as a result of revenue from other GHG offsets not related to the WCI. To be eligible for WCI offsets, it may not be necessary that the offset project would have been undertaken without the WCI, just that the project would not have been undertaken without the expectation of carbon finance. Projects that were undertaken without initially seeking to register offsets or that were undertaken before the existence of a relevant carbon market would generally not be considered additional. The attempt to register may be an easy test/demonstration of offset considerations.

The issues regarding eligibility date can be divided into two key questions:

- What is the earliest date that offset projects may been undertaken to be eligible for crediting?
- What is the earliest year in which reductions may be credited as offsets?

The first question seeks to identify a cut-off date, where projects initiated before that date would not be eligible on the basis of additionality or other considerations. The second question to resolve is the earliest year in which reductions may be credited as offsets if the date identified in the first question is before the start of the first compliance period in 2012. For example, if 2007 is chosen to be the earliest year for eligibility purposes and a project that began in 2009 is deemed to be eligible - would reductions that take place between 2009 and 2012 be counted as WCI offsets - or will only reductions occurring after January 1, 2012 be registered as offsets? The consideration behind this question is whether reductions need to occur over the same time period as the emissions that they are offsetting. For projects undertaken before

2012, one approach would be to consider the reductions occurring before 2012 to be early actions, while reductions after 2012 would generate offsets (subject to crediting period limits). Alternatively, all verified reductions occurring after the eligibility date could be credited as offsets. A key distinction between an offset and any other type of early action recognition is that offsets are generated in addition to the total number of emission allowances in the capped sectors. Other types of recognition do not alter the total number of allowances and offsets available for use in the capped sectors. This paper does not seek to address what consideration early actions would receive.

In summary, there are three general options for eligibility dates:
1. Eligibility date and offset generation coincide with initiation of WCI cap-and-trade program in 2012
2. Offset eligibility date precedes 2012, but offsets are only generated for reductions in vintage years beginning in 2012
3. Offset eligibility date precedes 2012, and all reductions occurring as a result of the project activity may generate offsets, including in the period before 2012.

5.2.3 Crediting Period

A crediting period determines how long an offset project is eligible to receive offsets. Crediting periods may vary by project type. They may be fixed or renewable. For example, under the CDM most projects may be registered for a fixed period of ten years or may be registered for a period of seven years with the possibility of renewal for two additional seven-year periods. A renewable crediting period allows regulators to reevaluate a project after a number of years to determine if it is still eligible given current regulatory and market conditions and if there are any other issues regarding the project that would alter its ability to receive offsets (e.g., if an updated quantification methodology were required). A clearly defined crediting period is important for project developers and investors to have greater certainty in evaluating project financials. For example, OQI has endorsed the idea of conservative, multi-year, and potentially renewable crediting periods to provide certainty to market participants and allow for periodic review of a projects ongoing eligibility. Though additionality is one of many considerations that may be used to set crediting periods, crediting periods should in general reflect the amount of time that project activities would be additional.

If a previously additional technology used in an offset project becomes required, then the project would generally not be renewed for an additional crediting period. A provision in the program could allow regulators to void any project's eligibility as soon as a law or regulation would cease to make it additional, without waiting until the end of a crediting period. Alternatively, a declining sunset trajectory could be assigned to ease transition for project developers. An ongoing review of additionality could be a part of annual project verification and monitoring. However, this may have the effect of increasing investor uncertainty and decreasing early actions. If the time between crediting renewals is not too long, then it may be less important to review ongoing additionality each year. This may also be addressed through baseline considerations (i.e, the baseline and project activity become the same).

Different crediting periods for different project types are also possible. Sequestration projects tend to have longer crediting periods because their gradual GHG removals occur over longer timescales and provide an incentive to avoid reversals. In the

CDM, land use change and forestry projects may be credited for a single thirty year period, or up to three twenty year periods. Other programs such as CAR, allow up to a one-hundred year crediting period for these projects. Given changing global and regulatory conditions one may question how realistic these longer crediting periods may be. However this becomes less of an issue if crediting period renewals take place at an adequate frequency.

Crediting periods can affect the financial viability of a project. Shorter crediting periods tend to bias against projects that reduce emissions by a relatively lower quantity per year but that accrue reductions over many years. Projects that may not be financially viable with shorter crediting periods could become viable with longer crediting periods. Renewable periods provide less investor certainly relative to fixed crediting periods and longer crediting periods will tend to provide greater financial returns.

Crediting periods have tended to be conservative and may result in fewer offsets being issued compared to GHG reductions that occur over a project's lifetime. This results when an additional GHG offset project continues to achieve real emission reductions or removals beyond the end of the crediting period. While this may be true for many projects, a crediting period is necessary to prevent the opposite from occurring (allowing projects that are no longer additional to continue to generate offset credits). Therefore, the WCI will need to strike the appropriate balance when setting crediting periods. Improved quantification or improved project performance may yield more emission reductions eligible in subsequent crediting periods.

5.3 Implementation options

The WCI offset system must ensure that emission reductions from registered offset projects are additional to any GHG emission reduction that would otherwise occur as a result of business-as-usual activities or regulatory requirements. Most existing programs have excluded any project activities required by law or regulation from generating offsets in their programs. However, some GHG emission reduction activities not required by law or regulation are still expected to occur under a business-as-usual scenario. Although it is possible that such business-as-usual projects could pass a regulatory additionality test, most existing definitions of additionality include language that excludes these activities, as shown in Table 5.2.

There may be legitimate reasons for incentivizing project activities that do not meet the additionality requirements of the compliance offsets system, such as rewarding voluntary early action or providing incentives for further reductions. However, such reductions are better addressed with other policy instruments, such as early reduction allowance being assessed by the Cap Setting and Allowance Distribution Committee (CSAD).

There are several types of specific additionality tests that could be considered as part of a project-specific or hybrid additionality evaluation. Investment additionality attempts to determine in the absence of carbon finance if a project is financially attractive or the financially preferred alternative. However, this can be difficult to evaluate or verify in practice. Not all financially attractive projects would necessarily occur in the absence of an offset program and an "attractive" rate of return may vary by investor and project type. It may be unclear how much carbon revenue would be needed to make a project additional. A financial additionality test could exclude projects that receive funding from specified sources, such as overseas development assistance for international projects. For example, projects that receive government grant monies for a given technology could be excluded.

With a financial additionality test it may be difficult to precisely know to what degree offset financing was the unique and precise trigger that caused a project 'no' to become a 'yes' decision. In this case, WCI might consider a reverse test such as: "if the incremental offset financing were absent, would the project have not proceeded?"

Barrier removal additionality tests seek to determine if the ability to generate offsets removes realistic and credible barriers to project implementation. Examples of barriers may be investment barriers, such as lack of project capital due to perceived risks, technological barriers and barriers due to a prevailing practice. Under the CDM, a project that is "the first of its kind" also satisfies this criterion. However there has been much debate regarding how unique a project must be in order to be considered the first of its kind. In considering various types of additionality tests, the best approach may depend on program design. For example, a barrier test would be more appropriate for a program that allows unique projects and methodologies to be considered for crediting; while a performance standard approach may be more effective in conjunction with specific protocols.

Table 5.2 Additionality tests in offset programs

Additionality Test	Description
Regulatory	Is the project activity required by any law, regulation, or permitting agreement? (note: does not necessarily exclude project activities that over perform compared to what is required)
*Investment/ Financial	Is the project activity unlikely to be financially attractive or the most financially attractive alternative without revenue from the sale of offsets? Or: does the project go away if the offset financing goes away?
Restricted Financing Sources	Does the project receive financing from specified sources restricted by the offset program (e.g. Overseas Development Assistance, but could theoretically could include others)?
Barrier Analysis	Are there barriers (investment, technological, prevailing practice, etc.) to implementing project activities that are overcome by the ability to register offsets?
Common Practice	Are similar activities observed in the sector/region? Is the project activity common or widespread within the sector/region? Are there essential distinctions between the proposed activity and observed similar activities?

*Note: The terms financial and investment additionality are often used interchangeably. Financial additionality frequently has the same meaning as the description here for investment additionality.

An alternative to an emphasis on additionality tests is to focus on the concept of a baseline when determining additionality. In this case, all emission reductions relative to an established baseline would be considered additional and eligible to generate offsets. The challenge in this case becomes determining what should be used in modeling the baseline scenario. Thus, a focus on baselines does not avoid the problem of determining additionality but rather changes the focus to how to properly model the baseline scenario. A project activity that would have occurred without offsets is by definition the same as the baseline project scenario and therefore would not generate offsets (even if it did result in emission reductions).

The Offsets Quality Initiative (OQI) has argued that national or regional programs should develop "cost-effective, robust, and flexible additionality assessment tools that provide a standardized, transparent, and rigorous framework for the eligibility of offset projects. These tools should account for variations in different project types and other factors, such as project location, market conditions, and existing regulation(s)."[21] It can be difficult in practice to develop appropriate additionality tests across various sectors; financial additionality can be difficult to verify, and appropriate performance standards may be difficult to set in some sectors and could bias against original projects. Additionality in some sectors can be more readily evaluated than in other sectors. For other project types, the distinction is not so clear, such as when there is uncertainty regarding the baseline scenario. The WCI will need to determine the extent to which additionality tests can vary by protocol or if it will have one standard approach to evaluating additionality. Any additionality test or performance standard will need to be rigorous enough to ensure that additionality assessments go beyond regulatory additionality and are consistent with the additionality criteria defined in this task.

6 Permanent

This section describes the criteria that offset reductions be permanent. As an offset element, permanence refers to the duration of an emission reduction. A reduction is said to be permanent if the reduction is maintained through a given period of time (e.g., a 100-year standard). A permanence requirement helps to ensure equivalency of emissions reductions across all sectors and project types. Permanence may be an issue in projects with a risk of GHG reversal, such as sequestration projects (e.g., forestry), controlled sink projects (e.g., carbon capture and storage), or avoided emissions from controlled carbon reservoirs (e.g., deforestation). Concern over the perceived lack of permanence of forest offsetshas so far prevented forest projects from entering into in the European Union Emissions Trading Scheme (EU ETS).

6.1 Policy and operational considerations in defining permanent

The term greenhouse gas reversals implies the release of stored GHGs to the atmosphere. Reversals can includeemissions from natural disturbances such as: fire, insects, disease, and earthquakes. Reversals may also occur as a result of project mismanagement or failure. These risks of reversal challenge project permanence and as a result mechanisms must be invoked to ensure offset permanence. Permanence mechanisms vary among offset programs. Furthermore, risks of reversal are not limited to specific project types but can occur in a number of project settings including: forestry, agriculture, wetlands, rangelands or carbon capture and storage.

It may be useful to consider the legal obligations of permanence, which can be divided into two classes: *ex ante* and *ex post*. Although both are important, it is the latter that carries the bulk of the policy considerations. *Ex ante* obligations establish an up-front commitment by the project proponent to permanently maintain transacted tons[22] and is achieved through a legally recorded and binding instrument

[21] Offsets Quality Initiative. "Ensuring Offset Quality". White Paper, July 2008.

[22] Transacted tons are tons from the legal transaction of an offset, that is tons that have

(conservation easement, contract, etc.) prior to the project. In the case of land-based projects, this document should "run with the land" and hold subsequent land owners liable for the conditions of the legal obligation. An *ex post* permanence mechanism provides assurance in the case of failure of permanence and is achieved through replacement of lost transacted tons. *Ex post* mechanisms can include buffer pools, set asides, third-party insurance contracts, and/or replacement by other offsets.

All legal instruments have differing policy considerations around attributes such as duration, intent, implementation, enforceability and liability in the case of a breach of terms. Policy considerations include establishing, regulating and enforcing liability for permanence along a chain of offset custody. Establishing where ultimate responsibility for permanence rests will impact who makes the greatest effort to ensure permanence. Ultimately, the risk of impermanence may impact emissions if transacted tons are lost and the liable party is not able to make good on their obligation. Therefore, the regulatory authority may establish an institutional offset insurance pool to ensure the reductions.

Several examples of how permanent is defined and/or managed in other offset systems are presented in Table 6.0.

Table 6.0 Definitions of permanent and/or requirements for managing permanence in offset systems

Offset System	Definition/Requirements
Alberta-based Offset Credit System	Assurance factors used to discount the volume of offsets achieved by projects considered to have a reversal risk. Liability for reversal is transferred from the project developer to the Gov. of Alberta. All offsets issued are considerd permanent.
British Columbia Emission Offset Regulation	Though permanence is not explicitly defined, it requires for capture and storage/sequestration projects, controlled sinks projects, or avoided emissions from controlled reservoirs projects, "a risk management and contingency plan for the purpose of ensuring that the atmospheric effect of a GHG reduction achieved by the project will endure for a period (iv) comparable to the period that the atmospheric effect of a GHG reduction achieved by carrying out [a non-sequestration/sink/ reservoir project], or (v) at least 100 years."
California Global Warming Solutions Act of 2006 (AB 32)	Required – not defined
Clean Development Mechanism (CDM)	*Though not explicitly defined in the CDM Glossary, non-permanence is addressed through the issuance of temporary (tCERs) or long-term (lCERs) certified emission reduction credits.
Gold Standard	Not mentioned (No bio-sequestration projects are eligible)
ISO 14064-2	5.7 - The project proponent shall establish and apply criteria, procedures, and/or methodologies to assess the risk of a reversal of a GHG emission reduction or removal enhancement (i.e. permanence of GHG emission reduction or removal enhancement).
Offsets Quality	Offsets Should Address Permanence. There is a risk that emission

---

been sold, retired, or otherwise released from a registry.

Offset System	Definition/Requirements
Initiative (OQI)	reductions generated by certain offset project types can be reversed, and thus are not permanent. Permanence is a type of project risk most often associated with biological and geologic sequestration of emissions. For example, reductions realized through a forest sector project could be reversed through a forest fire. Regulatory regimes should address permanence through policy mechanisms that ensure the minimization of loss in the case of project reversal. Such mechanisms include reserve pools, buffer accounts, and insurance, among others. Permanence is explored in greater detail in section IV, which is titled "GHG Reduction Project Categories and Considerations."
Oregon Offset Standard	Not mentioned
Regional Greenhouse Gas Initiative (RGGI)	Carbon sequestration permanence - The offset project shall meet the following requirements to address permanence of sequestered carbon. (i) The project sponsor shall place the land within the offset project boundary under a legally binding permanent conservation easement, approved by the REGULATORY AGENCY, that requires the land to be maintained in a forested state in perpetuity. (ii) The conservation easement shall include a requirement that the carbon density within the offset project boundary be maintained at long-term levels at or above that achieved as of the end of the CO2 offset crediting period … The conservation easement shall require that the land be managed in accordance with environmentally sustainable forestry practices.
Voluntary Carbon Standard (VCS 2007)	The project proponent shall establish and apply criteria, procedures and/or methodologies to assess the risk of a reversal of a GHG emission reduction or removal enhancement (i.e. permanence of GHG emission reduction or removal enhancement). VCS provides a tool for assessing the risk of non-permanence in agriculture, forestry, and other land use related projects.
WBCSD/WRI GHG Protocol for Project Accounting	Not mentioned

6.2 Implementation Options

Implementing a permanence requirement generally means addressing the risk of reversal. The risk of reversal can be taken on by various entities, including the offset buyer, the project proponent, a registry, or a third party. These options are not exhaustive, but represent some of the leading solutions. The options have differing policy considerations. When the offset buyer assumes the risk of reversal, the buyer's willingness to buy the offsets will be lessened. Where the project proponent assumes the risk, the risk can be managed through risk-mitigating activities such as self monitoring, reporting, inventory verification, or within-project set-asides to replace lost tons. Registries can manage buffer pools made up of non-transactable tons contributed from each of their at-risk projects, used to replace lost tons in the case of a reversal. Risk of reversal may also be taken on by a third party insurance entity. A knowledge and understanding of a range of typical business risk management strategies can inform this element. The transacted tons must be maintained through their permanence period regardless of the duration of the project.

There are several legally binding *ex ante* implementation options. A conservation easement (a legal document binding the land to a project in perpetuity) is an *ex ante* legal instrument used in some land-based projects (RGGI, CAR forest protocols version 2.0). Such a mechanism does not guarantee against reversal of stored carbon due to catastrophic disturbance or other risk factors, but it does commit the land base to the project and can serve to reduce the risk of non-permanence.

Replacing lost carbon through an *ex post facto* obligation is the only real form of permanence and can be achieved through buffer pools, set asides, third party insurance contracts, and/or replacement by other offsets. Offset programs and GHG protocols that require a buffer pool/set-aside or a reversal contingency plan include VCS 2007, CAR, CCX, WCSBD/WRI, and the BC Emission Offset Regulation. Establishing a buffer pool requires removing a percentage of additional CO2 tons (above a baseline) from the project annually and placing them in a reserve, based on the project's risk assessment, or seeking reserve offsets elsewhere. A set-aside is a portion of an individual project which serves as a back-up to transacted project tons.

For offset programs that use buffer pools, the size of a contribution to a buffer pool for a given project is usually established through evaluation of the project's risk of reversal, using a risk assessment procedure. Risk assessment can include these factors:

- Financial risk
- Management risk (illegal removals of forest biomass, conversions, and over-harvesting)
- Social risk (change in climate policy or government stability, social justice issues, employment, environmental perceptions)
- Natural disturbance risk (wildfire, pests, other)

In lieu of risk assessment, a standardized contribution to a buffer pool can be required (e.g., 20% CCX). There are monitoring, verification, and enforcement policy needs that accompany the implementation of a buffer pool.

7 Verifiable

This section discusses verifiable — the final of the four main criteria considered in this paper (i.e. that reductions from offsets be real, additional, permanent, and verifiable). An offset program should seek to minimize uncertainty related to the quantification and assurance of any reductions or removals from offset projects. To establish a high level of trust in the program and address public concerns related to the quality of offset projects, every effort to provide transparency in the offset system should also be pursued. In terms of verification, that means developing clear criteria and definitions for 'verifiable' and its related terms. It also means developing an accreditation process and conflict of interest process that ensure quality in evaluation and prevent potential bias when projects are verified (and possibly validated) by any independent third-parties.

The WCI design document states that an offset must meet the criteria of being verifiable. There are no existing definitions for the term verifiable. For WCI, the idea of verifiable may need to be expressed as a derivative of the definition for verification or of the verification process itself. In the WCI's Final Draft Essential Requirements of Mandatory Reporting document (ER), verification is defined as "the process used to ensure that an operator's emissions data report is free of material misstatement and complies with WCI's reporting procedures and methods for calculating and reporting GHG emissions."

7.1 Policy and operational considerations in defining verifiable

The ER document addresses verification in great detail. For consistency within the entire WCI program it may be prudent to ensure that any definitions relating to verifiable (verification) are consistent with the ER document and with international best practices to the extent possible. If there is some deviation from any existing WCI language it should be reviewed carefully to ensure that changes do not reduce the credibility of the offset program.

Several existing programs have defined verification or established a verification process as noted in the Table 7.0 below.

Table 7.0 Definitions of verifiable from offset systems

Offset System	Definition
British Columbia Emission Offset Regulation	Section 6 (1) A verification body may verify a submitted project report if the verification body is satisfied that (a) the assertions in the project report are materially correct and are a fair and reasonable representation of the project's GHG reductions, and (b) there have been no material changes to how the project was carried out compared to the description of the project in the validated project plan... (2) A verification body may not make a verification under subsection (1) if the verification body considers the project report is subject to material errors, omissions or misrepresentations. [Note: there are several criteria for materiality in subsection (3), including that "the individual or aggregate effect of an error, omission or misrepresentation related to the project report could have resulted in an overestimation of project reductions by more than 5%"]
California Global Warming Solutions Act of 2006 (AB 32)	Operators shall obtain the services of an accredited [third-party] verification body for purposes of verifying emissions data reports submitted under this article. "Verification" means the process used to ensure that an operator's emissions data report is free of material misstatement and complies with ARB's procedures and methods for calculating and reporting GHG emissions. "Verification body" means a firm or AQMD/APCD, accredited by ARB, that is able to render a verification opinion and provide verification services for operators subject to reporting under this article. [From the Mandatory GHG Emission Reporting Regulation] Consistent with ISO 14064-3.
Clean Development Mechanism (CDM)	Verification is the periodic independent review and ex post determination by a designated operational entity of monitored reductions in anthropogenic emissions by sources of greenhouse gases (GHG) that have occurred as a result of a registered CDM project activity during the verification period. There is no prescribed length of the verification period. It shall, however, not be longer than the crediting period.
Gold Standard	Required – not defined.
ISO 14064-3	Verification - systematic, independent and documented process for the evaluation of a greenhouse gas assertion against agreed verification criteria. (ISO 14064-3)

Offset System	Definition
Offsets Quality Initiative (OQI)	Recommended – All GHG reductions should be verified by an independent, qualified, third-party verifier according to approved methodologies and regulations. Verifiers should be entities whose compensation is not in any way dependent on the outcomes of their decisions. Regulatory regimes should have an approved list of offset project verifiers and should have procedures in place to ensure that conflicts of interest are avoided. Ex post monitoring and verification reports should be used as the basis for issuing offsets.
Oregon Offset Standard	Not required
Regional Greenhouse Gas Initiative (RGGI)	Verification - The third-party verification by an independent verifier that certain parts of a CO2 emissions offset project consistency application and/or measurement, monitoring or verification report conforms to the requirements of this Subpart.
Voluntary Carbon Standard (VCS 2007)	Required – following ISO 14064-3:2006 and 14065:2007 process. Verification process: The validator or verifier select samples of data and information to be validated or verified to provide reasonable assurance and to meet the materiality requirements of the specific project
WBCSD/WRI GHG Protocol for Project Accounting	Available data used should be… verifiable. All possible sources for obtaining the necessary information should be documented. Verification – beyond scope of project protocol not addressed

While the WCI will need to clearly define the term verifiable, the practical challenge that exists is to develop meaningful language that can apply broadly to all possible project types but still allows some flexibility to tweak requirements based on individual project characteristics. For some project types a verification schedule with annual site visits may be appropriate. For others a less frequent schedule for site visits may still provide sufficient assurance that reductions are occuring. A distinction may be made between schedules for site visits versus the schedule for verification statements, where having annual reporting and crediting of reductions would not necessarily imply annual site visits for verification. The role of an auditing function, as part of the verification process, may also need to be elaborated and could add to system credibility (as when linked to an enforcement/penalty structure).

Having a verification requirement will require the use of 'verifiers'. The WCI has indicated in the Design Recommendations and Essential Requirements documents that it will pursue third-party verification for annual GHG emission data reports for facilities subject to mandatory reporting. The offset system may incorporate that accreditation process for verifiers of offset projects. This may involve sector or protocol specific training for verifiers accredited under the reporting program. The American National Standards Institute is currently working with representatives from VCS 2007, CCX, British Columbia, and CAR to develop accreditation scopes for their program project protocols. It may be efficient to look at that accreditation scheme when developing scopes for WCI offset verifier accreditation requirements and build on it as needed. This work could be done concurrently with the efforts of the Reporting Committee in developing criteria for its accreditation requirements.

The Offset Committee may want to identify tasks related to administering a verification program that could be delegated to a regional body to ensure consistency in decision making and thus greater efficiency in the overall program. Areas in the offset system that would benefit greatly from consistency in decision making include dispute resolution, conflict of interest determinations and any other areas where decisions become subjective in nature.

7.2 Supporting principles and technical considerations

An established verification process for offsets usually introduces additional terms of art. Some of these verification-related terms may be specific to offsets (e.g., validation). Other verification-related terms may not be specific to offsets (e.g., material misstatement and assurance level). These terms should be consistent with the ER document and international best practices, where possible. Not only would this provide consistency within the WCI program as a whole but would help ensure that the same level of rigor and standards are held for both capped and non-capped sources.

7.2.1 Validation

In basic terms, project validation is the assessment of a project document and its conformity with project protocol as well as assessing the likelihood that implementation of the planned GHG project will result in the GHG emission reductions/removals as stated by the responsible party. For example, CDM and British Columbia have a validation step in their offset systems; but CAR does not require a preliminary validation step, instead requiring verifiers to affirm the project's eligibility during initial verification.

Validation can provide some upfront confidence to potential investors that a proposed project will provide offsets once implemented. It can also provide upfront information to a project developer about any potential issues related to the implementation of a project that could impact the project's ability to provide offsets in a WCI offset system. Validation can help ensure an initial quality standard is met for new projects and help provide information to the public. Potential downsides to validation may be that it imposes additional program costs, has the potential to slow down project development, and may be perceived as an unnecessary step if approved protocols exist and/or projects are subject to rigorous verification their first year.

If required in a WCI offset system, WCI could require the use of third-party validators or implement validation through government agency review. Capacity to conduct validation also becomes a potential issue; if there are insufficient validation bodies or insufficient staff resources to conduct agency reviews, then there is the potential to slow down project development. Validation delays due to high demand may be less likely to occur for third-party validation than for agency review because private sector firms may be able to respond more quickly to market demand in terms of staff and resources.

A hybrid option for validation is currently being employed in another regulatory program. The NSW GGAS utilizes a hybrid approach that includes reviews by both regulators and independent third party validators. In this program, the regulator identifies key areas of potential weakness that must be validated by an accredited third party as opposed to full validation of all documents and conformity requirements.

WCI could also design a system without a validation step. With clearly defined offset protocols such as the performance based protocols in CAR, a validation step could be folded into the initial project verification. In this case, activities that would have been conducted during a project validation, such as review of calculation methodologies and evaluation of conformance with a protocol, would generally still be conducted during the first year of verification. This could also remove an additional cost in the implementation of a reduction protocol and make for a more efficient, less resource intensive program to administer. Investor uncertainty becomes more of an issue for projects developed without validation because they must fully finance and undertake an offset project before it is formally reviewed during verification. As a result, under CAR, project developers may still independently opt for project review by technical assistance providers in the absence of a validation step if they are concerned about ensuring conformance with offset project requirements. Investors are paying for tonnes and need to satisfy themselves that the counts are correct and the quality meets their needs. A validation step would likely be more necessary for an offset program structured like the CDM that allows new methodologies to be proposed by project developers. Allowing carbon financing for new methodologies acts as an incentive for early implementation and commercialization of emerging technologies and practices.

7.2.2 Enforcement

The WCI partners will need to ensure the WCI offsets system is enforceable, which involves regulatory oversight by partner jurisdictions. The WCI stated in its design recommendations that "each WCI Partner jurisdiction will retain and/or enhance its regulatory and enforcement authority and responsibilities to enforce compliance with the cap-and-trade program within its own jurisdiction" and similarly that, "offset projects must also be enforceable by the individual WCI partner jurisdiction that is issuing the credit and the credit must be verifiable by the individual WCI Partner jurisdiction that is accepting it." As a component of the broader cap-and-trade program the offset system provisions must be enforced to ensure that participating parties, project developers and verifiers, follow the rules and do not harm the integrity of the offsets system. Enforcement implies that sufficient enforcement mechanisms are contained in offset provisions and protocols to allow action to be taken against a party who violates the offset rules or protocol requirements. The World Resources Institute also connects the concept of enforceability with the necessity for transparent offset ownership and tracking mechanisms, as well as clarity in identifying who is responsible for project performance, project verification, and potential liability in the case of reversals.[23]

WCI Partners will need to have the staff and capacity in place to enforce various provisions of the offset program. WCI Partner jurisdictions will also need to ensure that enforcement and oversight is consistent among jurisdictions in order to create a "level playing field" where all participants are subject to the same rules regardless of location. One option for this would be to have a regional body address select enforcement issues. However, as enforcement issues are closely related to jurisdictional sovereignty, the WCI Design Document recommended that enforcement not be associated with a regional body. For offset projects that take place outside of a WCI Partner jurisdiction, there will need to be clarity regarding who has oversight and enforcement authority. It may be necessary to have MOUs with other states and

[23] Broekhoff, D. and K. Zyla. 2008. Outside the Cap: Opportunities and Limitations of Greenhouse Gas Offsets. World Resources Institute. Policy Series. December 2008.

provinces to address this.

Enforcement actions may range in scope from revoking accreditation of verification bodies who fail to competently perform their duties, to issuing fines or other penalties to project developers that falsify or misrepresent information. Enforcement may also involve requiring compensation for any offsets that an enforcement audit demonstrates not to have been real. Depending on program design, enforcement may or may not be related to compensation for losses in emission reductions or removals due to reversals. Reversal and permanence issues can also be addressed through mechanisms other than enforcement as discussed in Section 5.

7.2.3 Material

A term of art specific to verification is 'materiality.' This term relates to a threshold where differences above that number in reported emissions/reductions would make a verifier suspect the reliability of an entire project. The WCI ER document has a materiality threshold of +-5%, consistent with EU ETS and The Climate Registry. The WCI offset system could consider a lower materiality threshold to be conservative and could consider applying bound. That would entail not allowing any errors individually or cumulatively that overestimate the emission reductions but accepting errors that underestimate reductions within a prescribed materiality threshold.

The term 'material misstatement' describes any errors that cumulatively exceed the materiality threshold. For the ER document any errors in the emissions data report that could over or underestimate the facility emissions by 5% are considered material misstatements and require correction. In the context of the offset system, the practical criteria of this term would change if the materiality threshold were changed.

The WCI ER document also sets accuracy requirements for metering equipment that provide data for emissions calculations. For the purposes of verification of annual emissions data reports, there is no requirement to assess the propagation of errors through a calculation. As such, any inherent uncertainty within the allowed accuracy level of the metering equipment is an accepted uncertainty. The offset program could consider adopting a similar approach. This approach is already adopted by some existing offset programs.

When a verifier renders their final decision, they provide a level of assurance. There are two levels of assurance provided in the ISO documentation. The WCI reporting ER document only allows for reasonable assurance, which is a more stringent level than limited assurance. The WCI offset system may consider only allowing reasonable assurance to provide the most certainty for any WCI offsets and to remain consistent with other parts of the WCI program.

7.3 Implementation Options

The WCI reporting ER document will require verification to be conducted by accredited, independent third-party verification bodies. A consistent option with the reporting requirements and with existing offset systems is to require third-party verification for the WCI offset system. All accreditation work used to provide qualified professionals for conducting verification activities under the Reporting program may provide a basis for developing accreditation requirements for WCI offset verifiers or verification bodies. The mechanisms that the reporting committee will rely on for the oversight of that verification program (including oversight of verifiers) could be expanded to include offset verifiers.

The WCI offset system could rely on Partner jurisdictions to verify any emissions reductions projects within their boundaries. This would contrast with the approach of third-party verification for facility emissions data reporting. There may be significant cost or capacity issues for all jurisdictions to 'ramp up' to verify offset projects in a manner consistent with existing offset systems or international best practices. In this case, the cost for verification of offsets may be borne by regulatory agencies and the public at large, as opposed to the project developer who can recoup costs for verification from the market program. However, depending on how the program is structured, there may still be mechanisms for jurisdictions to recover costs of running verification programs. In terms of capacity, it may require additional staff within each jurisdiction to oversee verification. WCI will have to weigh the tradeoffs between running verification internally versus harmonizing verification among all jurisdictions to reduce administrative redundancies. This approach would also need to clarify who would be responsible for verification of offset projects that occur in North America outside of a partner jurisdiction.

There is also the option of self-certification by a project developer. In this approach, oversight would likely be coordinated by partner jurisdictions who would conduct periodic reviews or random audits of offset projects. Penalties for audit failure would need to be clarified and provide proper incentives for compliance. This would likely be the least costly approach to administer, but would not be without its potential criticisms and tradeoffs. A self-certification approach would be inconsistent with the requirements of reporters subject to the cap and with international best practice. Because not every project would be subject to a detailed review, the approach may be perceived to lack transparency and consequently may not provide the desired level of confidence needed for the offsets market to function properly.

8 Other considerations

The previous sections of this document have described the key offsets criteria noted in the Design Document. There are other factors worth considering that generally aside from these criteria. This section discusses those other considerations.

8.1 Transparency

An open and transparent offsets system builds confidence in the long-term success of cap-and-trade programs. Ensuring the credibility of an offset system and reducing market uncertainty entails that offset projects be developed and implemented in an open manner. Transparency may include public access to information and public involvement in the project review process. The rules of an offset system may facilitate having project developers gather feedback from stakeholders via public comments and meetings on specific offset projects and document any outreach efforts and responses to feedback from the public. Clear regulations play a key role in building a quality offsets system while also reducing uncertainty for investors and project developers. Transparent offset systems typically provide access to offset project assessments, except in those cases where important confidentiality issues exist.

The implementation of transparency considerations impacts the environmental integrity and administration of an offset system. As a key principle that interacts with offsets criteria, limited implementation of transparency considerations may limit the ability of stakeholders to assess the overall environmental integrity of the offset system and the credibility of the reductions from it.

Other offset programs strive for transparency to create certainty for potential project developers and to build public confidence in the environmental integrity of the offsets. The Canadian Domestic Offset system and ISO guidelines define transparency as disclosing sufficient and appropriate GHG-related information to allow intended users to make decisions with reasonable confidence. U.S. EPA Climate Leaders' guidance primarily addresses public confidence in offsets, stating that "offset procurement best practices include a comprehensive and transparent registry system; partners should transparently and publicly report on their use of offsets when announcing the achievement of their reduction goal."

To achieve transparency, programs have allowed significant stakeholder involvement during the development of project protocols and have pledged to maintain clear offset guidelines to allow users to make decisions with reasonable confidence. The development of the Regional Greenhouse Gas Initiative model rule, which includes an offset program, involved several years of stakeholder involvement and input. Similarly, CAR's project protocol development process is designed to involve a variety of stakeholders and allow public comment on draft protocols. In addition, some programs have made information about individual offset projects accessible to the public. New South Wales allows public access to a searchable registry of offset projects.

8.2 Co-Benefits of Offsets

Besides the direct benefits that an offset project can provide, the project may also lead to a number of other benefits beyond the greenhouse gas reductions or removals from the project. These other benefits ("co-benefits") may include air quality improvements, economic development activity, and other types of benefits. Co-benefits can also help to justify projects and help projects proceed. The WCI recognized the importance of co-benefits in its design principles, which call for maximizing total benefits from the design. When the WCI identified the project types it would initially look at whether projects were chosen primarily for their greenhouse gas reduction potential; and then at their co-benefits.

Although co-benefits have been an important motivating force in the development of offset systems to date, the degree to which a project may or may not offer co-benefits has not been part of the fundamental design criteria of offset systems. Those exceptions are:

- In the Clean Development Mechanism sustainable development benefits are a pre-requisite for project approval, as well as alignment with host country sustainable development objectives.

- All Gold Standard projects must demonstrate clear sustainable development co-benefits, which include environmental, social, and economic benefits. Project developers must use the sustainability matrix provided by the Gold Standard to develop and present their sustainability criteria. Both project developers and stakeholders are consulted to score projects against the sustainability criteria and identify potential positive and negative project impacts.

8.3 *Assessment of Environmental or Social Impacts*

Offset projects are intended to reduce or remove greenhouse gas emissions. However, any project activity has the potential to impact the environment or social environment in which the project is located. Transparency is enhanced with informed stakeholder knowledge about the positive and negative impacts of an offset project on environmental, social, and sustainability factors. Such information can range from qualitative to quantitative description/analysis and is not normally envisaged to cross into environmental assessment territory in scope or scale unless required by law.

The degree to which assessment of these impacts is required varies from one offset system to another. A summary of these requirements follows:

Table 8.0 Impact assessment requirements in offset systems

Offset System	Requirements
British Columbia Emission Offset Regulation	Project plan must contain a description of any analysis undertaken to determine the environmental impact of carrying out the project
California Global Warming Solutions Act of 2006 (AB 32)	No specific requirements related to offset projects.
Clean Development Mechanism (CDM)	Projet participants must submit documentation of the environmental impacts of the project activity, including transboundary impacts. If impacts are considered to be significant an environmental impact assessment is required following procedures set by the host Party.
Gold Standard	In addition to meeting all local environmental regulations, all small and large scale projects must carry out an Environmental Impact Assessment (EIA).
ISO 14064-2	If law requires, a summary environmental impact assessment.
Offsets Quality Initiative (OQI)	Offsets Should Do No Net Harm. Offset projects should not cause or contribute to adverse effects on human health or the environment, but should instead seek to provide health and environmental co-benefits whenever possible.
Oregon Offset Standard	Not required
Regional Greenhouse Gas Initiative (RGGI)	Afforestation projects: must be managed in accordance with widely accepted environmentally sustainable forestry practices and designed to promote the restoration of native forests by using mainly native species and avoiding the introduction of invasive non-native species. If commercial timber harvest activities are to occur, certification must be obtained, prior to any harvest activities at the site, through the Forest Stewardship Council (FSC), Sustainable Forestry Institute (SFI), American Tree Farm System (ATFS), or such other similar organizations as may be approved by the REGULATORY AGENCY.
Voluntary Carbon Standard (VCS 2007)	All applicable environmental regulations must be met.
WBCSD/WRI GHG Protocol for Project Accounting	Not addressed

9 Conclusion

This white paper provides background information for defining a WCI GHG offset and its eligibility criteria: real, permanent, additional, and verifiable. Principles and technical considerations important to establishing offsets criteria are also examined. The WCI Partners invite stakeholders to comment on the options presented in this white paper or alternative options not included here. There are two avenues for stakeholder comments. Written comments will be received via the WCI website until August 21, 2009. Stakeholders may also provide comment during a conference call on July 30, 2009 from 9:30 to 10:30 a.m. Pacific time, during which this white paper will be presented and discussed.

As noted previously in the introduction, the Offsets Committee poses these questions for stakeholders to address in their comments:

- What has been your experience with the offset system examples cited in this paper? What have been the advantages and disadvantages to their approaches?
- Are the appropriate criteria listed?
- Does the paper include the appropriate options for each criteria?
- Are the implications of the options appropriately covered?

As shown in Table 9.0, this white paper offers the first deliverables for Task 1 from the Offsets Committee. Following an opportunity for stakeholder comment and the Offsets Committee's review of those comment, the next deliverable for subtasks 1.1 and 1.2 will be a draft recommendations paper. The Committee plans to release that document in September 2009. While stakeholders comment on this white paper, the Offsets Committee will draft its other Task 1 white paper, laying out options for subtasks 1.3, 1.4, and 1.5.

Table 9.0 Offsets committee task 1 workplan

Task 1 Subtasks	Subtask Description	Deliverables (Dates)
1.1	Define a WCI GHG offset	This white paper – 2009 Q2 Draft recommendations – 2009 Q3
1.2	Develop detailed eligibility criteria for GHG offset projects for compliance purposes under the cap-and-trade system	This white paper – 2009 Q2 Draft recommendations – 2009 Q3
1.3	Develop detailed requirements for the registration, validation, monitoring, quantification, reporting, verification, certification, and issuance of offsets	Next white paper – 2009 Q3 Draft recommendations – 2009 Q4
1.4	Recommend aspects of regulation and enforcement related to offsets that should be included in the cap-and-trade essential elements	Next white paper – 2009 Q3 Draft recommendations – 2009 Q4
1.5	Recommend functions of the regional administrative body and tracking system related to the offset system	Next white paper – 2009 Q3 Draft recommendations – 2009 Q4
1.6	Final recommendation of essential elements for the offsets system	Final recommendations - 2009 Q4

This white paper will support the Offsets Committee draft recommendations on how to define a WCI GHG offset and the detailed eligibility criteria for GHG offset projects for compliance purposes. The development of this white paper and the future development of draft recommendations under Task 1 of the Offsets Committee will continue to be done in coordination with the Task 2 (offsets and allowances from systems other than the WCI) and Task 3 (offset protocols) as presented in the WCI workplan.

[xvi] Alberta is considering development of a "Pasture Management" protocol (http://www.carbonoffsetsolutions.ca/offsetprotocols/protocolsreview.html)
[xvii] As of early July, 2009, the Alberta Offset System afforestation protocol was retracted for revisions. It includes language for converting "urban land to plantations".
[xviii] Version 1 of ACR's *Forest Carbon Project Standard* (March 2009) addresses afforestation/reforestation, forest management, and
[xix] CCX's Exchange Forestry Offsets can be issued for afforestation/reforestation, forest products ("long lived wood products"), forest management, urban forestry ("widely spaced tree plantings") and "Combined Forestation and Forest Conservation Projects", which requires forest conservation activities to be on contiguous sites to forestation.
[xx] Among other CDM methodologies, AR-ACM0001: "Afforestation and reforestation of degraded land (Version 3)" addresses afforestation/deforestation.
[xxi] Afforestation/reforestation, forest management, and forest conservation are included in the Forest project protocol v. 2.1 (September, 2007); Version 3.0 is expected to be adopted in July 2009.
[xxii] Afforestation/reforestation and "land and habitat conservation" project types are being considered for future methodology development.
[xxiii] NSW's *Greenhouse Gas Benchmark Rule (Carbon Sequestration) No. 5 of 2003* addresses afforestation / reforestation.
[xxiv] Climate Leaders Greenhouse Gas Inventory Protocol Offset Project Methodology for Project Type: Reforestation/Afforestation. Version 1.3. August 2008.
[xxv] EPA Climate Leaders fact sheet, http://www.epa.gov/stateply/documents/offsets_factsheet.pdf, and recent presentations by EPA staff.
[xxvi] Forest products are not a unique project type in ACR, CAR, or VCS but they are included as a carbon pool within the forest management project type.
[xxvii] CAR's Urban Forestry protocol version 1.0 was adopted August 12, 2008. A minor revision is planned for summer 2009.
[xxviii] Alberta Environment, 2007. *Quantification Protocol for Landfill Gas Capture And Combustion:* Version 1. September 2007.
[xxix] Among other CDM methodologies, ACM0001: "Consolidated baseline and monitoring methodology for landfill gas project activities" address landfill gas.
[xxx] CAR's U.S. landfill protocol version 2.0 was issued November 17, 2008. A draft version 2.1 is out for public comment until July 10, 2009.
[xxxi] GE-AES's *Methodology for Landfill Gas Methane Capture and Destruction Projects* addresses landfill gas.
[xxxii] Climate Leaders Greenhouse Gas Inventory Protocol Offset Project Methodology For Project Type: Landfill Methane Collection and Combustion. Version 1.3. August 2008
[xxxiii] Alberta Environment, 2009. *Quantification Protocol for Anaerobic Treatment Of Wastewater Projects: Version 1.0.* March 2009. Alberta also has a *Quantification Protocol for Aerobic Composting Projects: Version 1.1.* December 2008.
[xxxiv] Among other CDM methodologies, AMS-III.H: "Methane Recovery in Wastewater Treatment", addresses wastewater. CDM also has methodologies to address organic municipal solid waste, such as AM0025: "Avoided emissions from organic waste through alternative waste treatment processes", address solid waste.
[xxxv] GE-AES's *Methodology for Waste Water Treatment Plant Capture and Destruction Projects* addresses wastewater treatment.

Western Climate Initiative

4 Summary of RED White Options Paper 26
5 Public Stakeholder Feedback on Options 28
6 Recommendations / Decisions 29

1 Purpose and Background

The purpose of the Options White Paper is to present the fundamental design choices for the WCI Regional Emissions Database (RED). The RED will be a system of database components developed by The Climate Registry (The Registry) for collecting, transferring, storing and analyzing greenhouse gas (GHG) emissions data from facilities and entities in WCI states and provinces. This system is described in greater detail in section 1.3 below.

This White Paper will explore numerous options for managing data and designing database functions in order to provide guidance to The Registry. As noted in section 2.3, a key function of the RED will be to meet WCI partner jurisdiction data collection, recovery and analysis needs while at the same time minimizing the burden of satisfying WCI partner jurisdictions' collective and individual GHG reporting requirements as well as the federal GHG reporting requirements.

After engaging in internal review and discussions of, and receiving stakeholder comments on, the White Paper, WCI will provide The Registry with guidance and direction on how it should proceed in defining detailed specifications for the RED. The options that are suggested throughout the White Paper are based on realistic expectations for the cost and schedule of the project.

Chapter 4 provides a high level summary of this document.

This chapter will identify the review process, the work plan that will support the requirements analysis, and provide an overview of the RED Project.

1.1 Regional Emissions Database Review Process

A number of different groups will be involved in the development of the RED:

- RED Workgroup – A subgroup of the Reporting Committee has been formed to focus on this project. It has broad participation from Canadian Provinces and US States so that many perspectives will be represented. The role of the workgroup is to guide the content and requirements that are included, focus on specific issues, review early drafts of documentation, and provide detailed feedback that informs all recommendations and decisions.
- Reporting Committee – Since this project represents Task 2 of the Reporting Committee's objectives as contained in "WCI's Work Plan for 2009-10," all deliverables will be presented to the full committee for interim review and approval before recommendations are presented to Partners. While feedback from the Reporting

Committee is essential, discussions are expected to focus on high level issues. After review by the full committee deliverables will be submitted for Partner review.

- Markets Committee – The RED will have interfaces to the Tracking System developed under Task 4 of the WCI Work Plan for the Markets Committee. Some deliverables will be presented to the Reporting Committee to ensure that the two tasks are aligned and that the Markets Committee has an opportunity to comment on recommendations that may impact the Tracking System. In addition to this, The Registry will participate in Markets Committee calls as an advisor to make the committee aware of potential issues or areas of overlap between the two tasks.
- Partners – Since this initiative will have a broad impact on the implementation of WCI's cap-and-trade program, all deliverables will be made available to Partners to review recommendations and make final decisions.
- Public Stakeholders – Following Partner review, a final version of this Options White Paper will be presented to public stakeholders for comment.

1.2 Regional Emissions Database Work Plan

The RED work plan has been broken into two major phases. Phase 1 will include development and review of the Options White Paper in addition to the preparation of the final requirements specification. Phase 2 will include the system design, implementation and rollout of the completed application.

A high level work plan for Phase 1 is included below to identify major milestones and illustrate how different groups will be involved in the review process. Phase 1 will need to be completed before the work plan for Phase 2 can be developed.

Figure 1 RED Phase 1 Work Plan

WCI Regional Emissions Database - Phase I Review Process	
Project Task	**Group Involved**
Reporting Options White Paper	
Prepare outline of issues for the options White Paper	The Registry
Review options White Paper outline	RED Workgroup
Prepare draft of White Paper	The Registry
Review draft White Paper	RED Workgroup
Revisions to the White Paper	The Registry
WCI Reporting Committee call to review Final Draft	Reporting Committee

Review Options White Paper with the Markets Task 2 Workgroup	Markets Task 2 Workgroup
Review Options White Paper with the Electricity Committee	Electricity Committee

Review by Partners prior to release for public comment	WCI Partners
Revision following Partner review	The Registry, RED Workgroup
Review by Public Stakeholders	Public Stakeholders
Call for Public Stakeholders	Public Stakeholders
Public stakeholders submit written comments to the Reporting Committee	Public Stakeholders
Revise Options White Paper based on public stakeholder comments	The Registry
Requirements Analysis:	
Draft preliminary requirements for the major components of RED	The Registry
Review preliminary requirements	RED Workgroup
Review integration of RED with Tracking System	Markets Committee
Discuss budget options	Reporting Committee Chair, Partners
Incorporate revisions and prepare RED requirements document	The Registry
Review draft requirements specification	RED Workgroup
Incorporate revisions from RED Workgroup	The Registry
Review RED requirements document with the Reporting Committee	Reporting Committee
Revisions, Executive Summary and Recommendations for WCI Partners	The Registry
WCI Partner call to review Executive Summary and Recommendations	WCI Partners
Final revisions to all requirements and recommendations	The Registry
WCI Partner Call to adopt RED requirements recommendations	WCI Partners
Draft Recommended Plan for Phase II	The Registry

1.3 Regional Emissions Database Overview

Based on the requirements outlined under Task 2 of the WCI's 2009 Work Plan for the Reporting Committee, The Registry will develop the RED infrastructure to support the consolidation of GHG emissions from each of the WCI Partner jurisdictions and provide the required data transfer, analysis and user interface tools to support the program.

The Scope of Work for developing this infrastructure can be divided into five major components described below (*See Figure 2, WCI Regional* Emissions *Database Components)*. The term Regional Emissions Database (RED) refers to all five of these components, while the term WCI Central Database refers only to component number 2.

1. **WCI Common Framework Program Module**: Since a number of WCI Partner jurisdictions will use The Registry's Common Framework to collect GHG emissions data from regulated parties in their jurisdiction, The Registry will develop a WCI Program Module that supports the reporting requirements of the WCI Partner jurisdictions. This module will then be used as the basis for WCI states and provinces that adopt the Common Framework to collect and manage emissions data from regulated parties. The module will provide a persistent database for each regulated party's emissions data that exists independently of the WCI Central Database described below. The WCI Common Framework will also provide reporting capabilities for Staff, Regulated parties, and the Public.

2. **WCI Central Database**: The Registry will design and implement the WCI Central Database, which will be used to consolidate all WCI Partners' emissions data. This will serve as a data warehouse that supports the data analysis required for the cap-and-trade program. It will also allow each of the partner jurisdictions to observe measurements over time to track changing trends. The WCI Central Database will also provide source data for reports that are used by key WCI participants, such as the Partners, Staff, Regulated parties, and the Public.

3. **Data Collection from WCI Partner jurisdictions**: Consolidation of WCI emissions data will require the transfer of data from Partner jurisdictions to the WCI Central Database. This data transfer will happen either via The Registry's Common Framework or through data exchanges with programs that collect GHG emissions data using Partner-specific databases. The latter will be based on The Registry's GHG Secure Data Transfer mechanism to the voluntary registry, but will be adapted to meet a WCI Partner jurisdiction's specific needs.

4. **Analysis, Report Preparation and User Interface Tools for WCI Participants**: Each WCI participant will need access to the WCI Central Database for different types of information. Additional requirements planning is necessary to define these tools, but some of the general stakeholder requirements follow:
   a. The WCI Regional Administrative Body will need to manage WCI emissions data and provide information to the cap-and-trade program.
   b. WCI Partner jurisdictions will need to access information at the state or provincial level.
   c. Regulated parties will need to understand their emission footprint across the entire WCI region.
   d. Public stakeholders will need access to data that has not been designated as confidential business information.

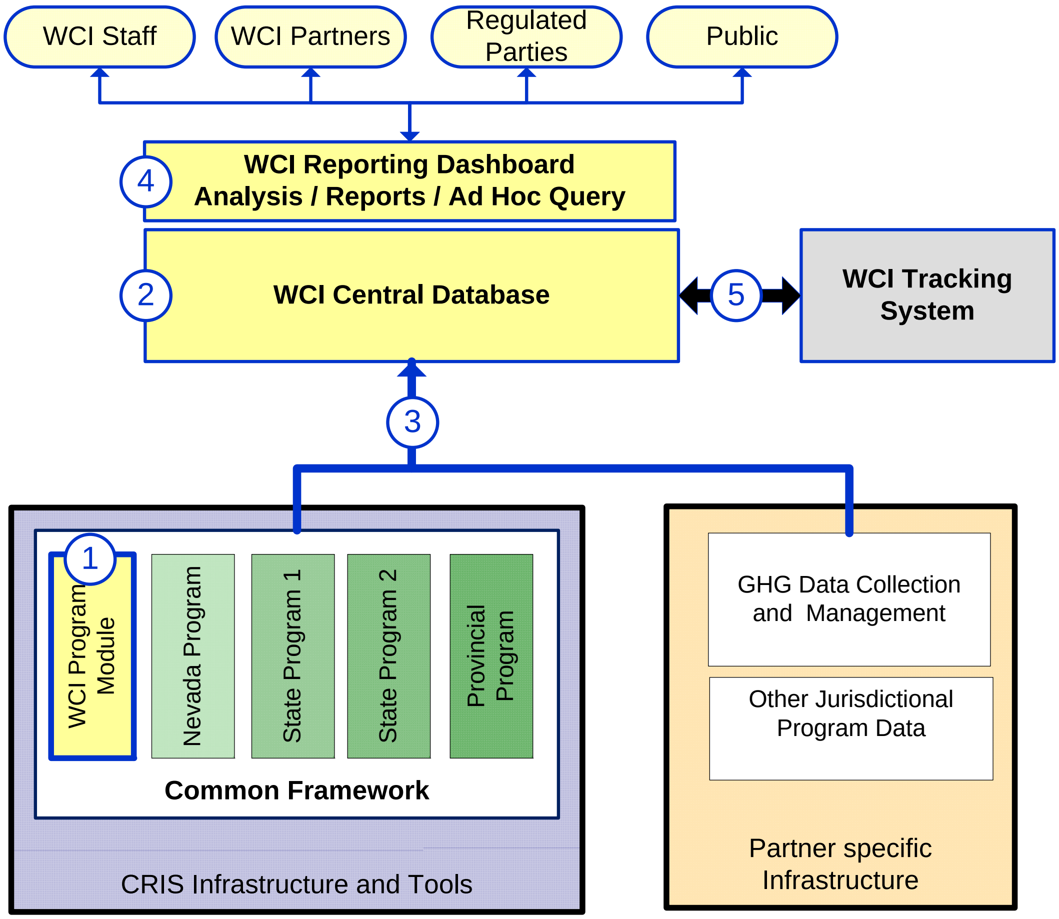
5. **Integration with the Tracking System:** The WCI Central Database will need to be integrated with the WCI Tracking System to share data, identify the relationship of regulated parties with organizations in the tracking system and to ensure compliance. Since the Tracking System will be developed later than the RED, this component will be covered at a high level only.

The diagram below shows an initial view of the components of the complete WCI RED infrastructure. Each of the components in yellow shows additions to The Registry's existing tools that The Registry will create under the Reporting Committee's Task 2 work plan. The numbers in the diagram refer to the infrastructure components outlined above.

The diagram is a conceptual view, and does not make any assumptions about the final technical architecture of the database or the granularity of the data that will be transferred from the program modules or Partner-specific databases to the RED. Stakeholders are invited to comment on the design choices reflected in the diagram.

NOTE: The WCI Tracking System component is shown in the diagram as a conceptual illustration to explain the basic relationship and communications that will be required between it and the WCI RED in order to successfully support WCI's cap-and-trade program. Although the development of this component is outside the scope of work for this Task, The Registry will be asked to work with the Markets Committee to ensure that the development of the tracking system database is compatible with the WCI RED.

Figure 2. WCI Regional Emissions Database Components



2 Assumptions and Principles

As the stakeholders evaluate the options presented in this White Paper, it is important to understand the assumptions that have been made about the RED application that will be developed and the principles that should guide the evaluation. This chapter provides an overview of each, as well as a discussion of the key principle of alignment with federal GHG reporting programs.

2.1 Assumptions

The issues that will be discussed in the Options White Paper are based on the following assumptions that are fundamental to the RED project:

- Development of the WCI RED will be based on The Climate Registry's Common Framework for mandatory reporting.
- WCI Partner jurisdictions will be responsible for collecting WCI GHG emissions data from regulated parties in their individual jurisdictions. Jurisdictions may collect WCI data via their own jurisdictional database or through a Common Framework module.
- All WCI Partner jurisdictions will submit a common set of GHG emissions data and regulated party information to the WCI Central Database. The common set of data will be defined based on the data required for coordinated regional implementation of the program.
- All WCI Partner jurisdictions will transfer the common set of GHG data to the WCI Central Database by a specified date each year.
- All WCI Partner jurisdictions will be able to view and analyze aggregated WCI emissions data in the WCI Central Database. (Individual Partners will have unrestricted access only to data from their regulated parties via their jurisdictional emission databases or Common Framework modules.)
- The WCI Central Database will share emissions data with the WCI Tracking System as needed.
- The WCI Central Database will have an interface to permit all participants to access relevant data, subject to confidentiality restrictions.
- The final (July 2009) WCI Essential Reporting Requirements and individual WCI Partner reporting requirements form the basis of the data collection components of the RED project.
- The WCI Essential Reporting Requirements may require modifications after the proposed U.S. EPA Mandatory Reporting Rule becomes final or when Canadian federal requirements are adopted. If this occurs, new database requirements may need to be developed.

- The WCI Partner jurisdictions are funding the development of a generic module in the Common Framework that may be adopted by WCI Partner jurisdictions to minimize the cost and time required to implement a GHG reporting application that is compatible with WCI. For Partners to maximize this investment, those wishing to develop a Common Framework module to serve as their data collection system will reap the most cost savings if they develop their modules after the WCI Program Module is launched (Q1 2010)
- All partners will follow the same data and communication standards for transferring data to the WCI Central Database.
- Third party verification (where required) and WCI Partner jurisdiction government agency review of emissions data will take place at the jurisdictional level prior to data being transferred to the Central Database.
- The RED will be developed to include multilingual support, initially in English and French.
- WCI Identifiers will be assigned to all facilities and entities that report emissions. These identifiers may be associated in the Program Modules or Central Database with jurisdiction-specific identifiers for the same facilities and entities.
- WCI must provide requirements for minimum QA and compliance checks that all Partner systems for collecting emissions data should adopt to ensure consistency of data quality.
- Stakeholders will have access to reports from the Program Modules and the Central Database.
- The implementation phase of the RED will engage reporters, verification bodies and other participant groups to contribute to the design process and to beta test the application.

2.2 Principles

It is critical to the success of Phase 1, as well as the application that is ultimately developed, to define common principles that will guide how options are evaluated and recommendations are made. The principles are:

- Each of the Partners may have different perspectives on how requirements are defined for the RED. The final requirements should focus on the stated goals of WCI and the shared requirements. At a minimum, the Partners will agree to a set of shared functionality and follow data specifications based on the essential reporting requirements.
- It is important to minimize the reporting burden for regulated parties and promote consistency.

- It is always necessary to balance cost with the depth of functionality in a software application. Cost effective solutions should be identified whenever possible, with approaches to extend functionality when it is needed, or funding is available.
- The RED will need to provide solutions that fulfill requirements of both Canadian and US jurisdictions where differences exist in how specifications (i.e. unit measures, currency, code systems etc.) are documented.
- Technology decisions will favor approaches that maximize flexibility and can be adapted using configurable tools. Technology infrastructure will adopt standards-based approaches when possible.
- The data available to a particular jurisdiction's stakeholders through the Program Modules and the WCI Central Database will be consistent with that jurisdiction's public records laws. Data that is required to be public under the jurisdiction's laws must be readily available through the RED databases. Data that is entitled to protection from public disclosure, such as confidential business information, must be protected.

All application development will adopt intuitive approaches to the user interface, and best practices for security, availability, scalability and performance.

2.3 Alignment with Federal GHG Reporting

The WCI is committed to achieving the maximum possible level of consistency and integration with federal GHG reporting programs, including the final version of EPA's final Mandatory Reporting Rule (MRR). Unlike the WCI essential reporting requirements, the MRR is not being developed at this point to support a cap-and-trade program. Thus, there may be some differences between the two programs. In addition, the WCI and some of the states and provinces in the WCI have other reporting requirements that EPA's proposed rule does not cover, such as the requirement to report emissions from facilities with total CO_2e emissions between 10,000 and 25,000 metric tons per year.

The following list identifies the options for achieving consistency and integration with federal GHG reporting programs that WCI may consider in developing the RED. WCI Partner jurisdictions and The Registry will discuss these options with appropriate representatives from EPA and Environment Canada. Stakeholder comment is also specifically requested on these options.

- Direct reporting to the states and provinces with transmission of data to the federal program, as recommended in WCI's comments on the proposed MRR.
- WCI acceptance of copies of reports submitted under the MRR or Environment Canada regulations in lieu of reports under the essential reporting requirements, to the extent such reports satisfy WCI program needs.

- Dual purpose single window reporting of regulated parties to WCI and federal agencies; EPA's draft rule should be considered in the development of the reporting window.
- Data exchange with EPA or Environment Canada.
- Technical design of the RED to facilitate future harmonization:
  - Collaboration on a harmonized submission template and process so that regulated parties can submit their data once and have the data routed to the appropriate agency.
  - Flexible approach to the configuration of calculation tools.
  - Development of tools based on the WCI Reporting Requirements with flexibility to adapt to EPA and Environment Canada requirements when either or both are final.

3 Options for the Regional Emissions Database

This chapter raises a number of issues and questions that will influence the requirements for different components of the RED. Each section provides background, presents options, and discusses the factors that influence the approach

Options will be presented in six categories:

- WCI Common Framework Program Module
- WCI Central Database
- Data Collection from Partner jurisdictions
- Analysis, Report Preparation and User Interface Tools
- Integration with the Tracking System
- General Considerations

3.1 WCI Common Framework Program Module Options:

Refer to Figure 2 Component #1.

Options for the WCI Program Module are focused on data collection by the Partners but may influence other components in the RED application. Many of the requirements will be determined by the WCI essential reporting requirements. The primary goals of providing a shared data collection module are to minimize cost and develop a consistent approach that simplifies reporting for regulated parties.

3.1.1 Data Submission Interface

Submitting emissions data to the Program Modules should be as simple as possible for regulated parties and leverage existing technology infrastructure when possible to promote consistency and minimize cost. The choices for this option are:

- Online web interface
- Bulk Upload of emissions data
- Allowing a regulated party to select either the online web interface or a bulk upload procedure

An online web interface provides helpful user interface tools that assist reporters in submitting accurate data, calculating data based on the reporting requirements and allowing them to progress through the process at their own rate. An online interface also simplifies the process of changing the data as errors are identified during a QA process. Bulk upload of submissions allows all data to be submitted in one package using an automated process. While it is faster than using an online tool, it requires the reporter to spend time preparing data for transfer. A similar QA process would be provided for bulk upload as in the online system. A reporter should have the option of correcting the data and resubmitting it through bulk upload or of using the online tool to modify the data directly.

Reporter preferences for this option are often determined by the volume of data that needs to be submitted, and even though regulation is at the facility level, many regulated parties will submit emissions data for many facilities. An online web interface is often preferred by reporters with fewer regulated facilities because they gain the advantages of the reporting tools without spending excessive time entering data. Reporters with large numbers of facilities typically prefer to bulk upload data to streamline the process. They are also more likely to use in-house emissions data management systems that simplify the process of preparing the data that will be submitted. While there is a higher cost to support both options, the WCI Program module could leverage the Common Framework to minimize the expense of an online interface.

3.1.2 Data Submissions Formats

Assuming that a bulk upload of submissions to the WCI Program Module is supported, one or more templates will need to be adopted to allow reporters to map their emissions data to a predictable format that can be processed and loaded into the WCI Program Module's database. The options for this format are:

- Consolidated Emissions Reporting Schema (CERS)
- A template that has been standardized across Canadian Provinces

It will simplify the process and reduce the overhead of bulk upload to have a single template for formatting and submitting data that is shared by all Partners using the Program Modules. Data standards for GHG emissions are still evolving and there is no internationally recognized standard yet. In the US, CERS (an XML schema that incorporates GHG data with all other air emissions data) has been adopted for data exchange between agencies at the state and federal level. It is also used by programs that support emissions reporting such as The Climate Registry. It has not been determined if the CERS, at least in its current form will be adopted by the US federal program. While there is no Canadian equivalent for this template, developing a schema that can be shared across North America would be a strong step towards consensus on an international approach.

It is also important to consider the investment that regulated parties may have made in preparing emissions data for submissions to other regulatory programs. Further investigation should be made to ensure that any standard templates that surface during this process are considered.

3.1.3 Accountability for Electronic Certification of Submissions:

Systems for electronic data submission must provide a framework enabling electronic signatures to replace hand-written signatures as a means of ensuring individual and corporate accountability and responsibility. Since emissions reported to WCI will be used to determine compliance with its cap-and trade system, it is critical to provide a high level assurance for all electronic submissions. Defining allowable practices in this type of environment requires specialized expertise in security and identity management technologies based on significant experience with the problems likely to be encountered. It may also be necessary to vary the approach depending on the type of submission (i.e., online system or bulk data upload).

The options presented for electronic submission offer a broad range of accountability and cost:

- Cross-Media Electronic Reporting Regulation (CROMERR) support - US
- One Window to National Environmental Reporting System (OWNERS) - Canada
- Independent Electronic signature support
- Printed copy with signature that is mailed to administrator
- Printed letter with signature that refers to the electronic submission
- Third party solution for certificates and identity management

The US EPA's CROMERR is a set of information technology standards that acts as a legal framework for electronic reporting. Different approaches may be adopted under CROMERR as long as the standards are met and approved by EPA. The Canadian OWNERS solution has similar standards to CROMERR but is implemented through a common portal for all submissions from industry rather that a set of standards. WCI could define its own standards for electronic reporting but this is likely to be time consuming, expensive and require ongoing administrative responsibilities. Adopting a strategy for electronic submission also raises the question of how or if WCI will identify standards for Partners that implement their own systems for reporting emissions rather than adopt the WCI Program Module.

Many emissions reporting programs have relied on hand written signatures on certification statements that accompany reports. While these approaches will cost less to implement it is unlikely that they provide the level of assurance that may be required for this type of program once the cap-and-trade program is operational. The most efficient approach may be to adopt a simple solution for the first year of reporting 2010 data such as a wet ink signature process and to identify a solution that is comparable to both OWNERS and CROMERR for future years. This allows more time to evaluate whether WCI can leverage CROMERR or OWNERS directly, particularly for bulk data submissions.

When an emissions report is certified by the regulated party, a copy of the report will automatically be stored in the database and will be available for review with appropriate access privileges; if data are changed and resubmitted, a new report will also be stored. All versions of the report will remain in the database.

For more information on OWNERS Security see:
http://www.owners.gc.ca/default.asp?lang=En&n=00C654BE-1

For more information on CROMERR see:
http://www.epa.gov/cromerr/about.html

3.1.4 Quality Assurance and Compliance checks:

In this context, quality assurance checks are automated tools that are used to identify conditions suggesting inconsistencies or errors in the emissions data and can be utilized to ensure compliance. Pre-submission check results are automatically presented to a user so that issues can be corrected before final submission. Post-submission check results allow agencies to check for compliance. The Common Framework has a number of standard quality assurance checks that are common to most programs. Individual modules in the Common Framework typically include additional quality assurance checks that are specific to their programs. Options for quality assurance checks are:

- Pre and post-submission quality assurance and compliance checks will be incorporated into the WCI Program Module to minimize third party verification cost and agency review consistently across all programs.
- Quality assurance checks will include options for customization by each WCI Partner jurisdiction in addition to common checks for all jurisdictions.

If WCI Partners expect to implement the reporting requirements without major changes, then the most cost effective approach would be to include quality assurance checks that isolate as many conditions as possible that conflict with the reporting rules. If the WCI reporting requirements will be extended by many of the Partners to accommodate jurisdictional-specific requirements , then they may want to customize quality assurance checks to accommodate individual programs. Since these options depend more on jurisdictional requirements, this is likely to be the deciding factor. It should be noted that Partner customization of QA checks may result in additional cost.

3.1.5 Public, Private and Agency Reports:

Reports are created for all modules in the Common Framework that serve different participants. These reports are available to the different participants at different times based on what stage of the reporting process has been completed. The options listed below reflect the approach the Common Framework uses for most programs. In this case there is not a selection of one option over another, rather the list is presented to develop consensus that all the conditions presented are appropriate for the WCI program Module.

- Regulated parties will have access to all data they have entered into the WCI Program Module at all times. After submission to a jurisdiction the access will be read only, unless corrections are required.
- Agency staff will have access to reports with all facility and unit level data after the data have been submitted to the jurisdiction.
- Stakeholders will have access to all facility and unit reports after the data have been third party verified (if required) and accepted by the Partner Jurisdiction. Confidentiality flags will be included that protect certain types of data from disclosure to public stakeholders.

The reports discussed here should not be confused with reports that will be implemented for the WCI reporting Dashboard for the Central Database, although it may be desirable to minimize overlap between reports generated in the two different components.

The table below outlines the types of reports that might be available to different groups. Stakeholders are invited to suggest additional reports that might be included.

Regulated Party Reports	Agency Reports	Public Reports	Description
Entity Emissions Summary	Entity Emissions Summary	Entity Emissions Summary	A report of Entity or Facility level emissions totals for all facilities for a given entity.
Entity Emissions Detail	Entity Emissions Detail	Entity Emissions Detail	A report of activity level emissions data for all facilities and activities for a given entity.
Facility Emissions Detail	Facility Emissions Detail	Facility Emissions Detail	A report of activity level emissions data for all activities for a given facility.

Other Reported Data	Other Reported Data, including a list of supporting documents	Other Reported Data to the extent required by the laws of the jurisdiction to which the data was reported	Data the ERs require to be submitted in order to allow the agency to evaluate the emissions data.

Reports for stakeholders will respect confidentiality flags in the system. Some Partners require that confidential data be available to the public unless the jurisdiction authorizes the data to be treated as confidential. Other Partners allow regulated parties to declare that data are confidential unless the jurisdiction overrides the decision. The data collection system will need to accommodate the different approaches.

3.2 WCI Central Database

Refer to Figure 2 Component #2.

Many of the decisions that are made about the design of the RED will determine what analysis the Partners will be able to perform on the aggregated data and what information will be available to reporters through the reporting dashboard. With the assistance of the RED Workgroup, The Registry will work with all participants to do further analysis to develop more detailed specifications during the Phase 2 Requirements Analysis for this project.

3.2.1 Technical Implementation

Best practices for all aspects of the technology infrastructure will be followed in the implementation of the Central Database. Expectations for the Service Level Agreements (SLAs) will be determined during the requirements analysis. SLAs establish specific metrics or conditions for performance levels, system availability, security, timeframes for issue resolution and other operational features of the platform.

- Platform Security: An end-to-end security model that incorporates identity management, secure communications, firewalls, and data security in the database and application server tiers will be enforced.
- Availability: High availability of the application will be ensured using appropriate failover technologies and a reliable hosting partner.
- Backups: Both onsite and offsite backup procedures will be in place.
- Technical architecture: The architecture that is adopted for each component will rely on current technologies that are well tested and widely used.
- Data Model: The data model will be designed to provide flexibility, ease of data access and to anticipate future needs.
- Internationalization: The platform will include internationalization that provides support for multiple languages, currencies etc.

- Hosting: A hosting partner that is recognized for excellence of service and comprehensive options for SLAs will be selected.
- The hosting location will be selected to provide optimal service to the WCI Regional Administrative Body, all Partners and the technical support staff.

The Central Database will operate primarily as a data warehouse used for analysis and reporting so the technical architecture and data model should support this requirement. Data will be structured to maximize efficiencies for analysis, query performance and to facilitate inquiry from a broad range of constituencies. The system should support access with ad hoc query and reporting tools using an Open Database Connectivity (ODBC) connection, although this capability may be limited to specific user roles within the system. The system will also support the ability to download data into a spreadsheet for further analysis by WCI Partner jurisdictions.

Hosting is likely to be provided through a third party hosting partner with excellent credentials for reliability and vulnerability protection. It may make sense for the Central Database to be co-located with the tracking system to maximize efficiency of operations for WCI; The Registry will continue to work with the Task 4 Workgroup of the WCI Markets Committee to understand how this would work.

WCI has the option to adopt specific standards for the technical implementation of all systems that support the program. It is also not known yet if there are any legal obligations that will influence the physical location of the servers.

3.2.2 Data Analysis Requirements

The level of data that is transferred to the Central Database will be determined by what analysis the Partners and other participants will need to perform at the regional level. With the assistance of the RED Workgroup, The Registry will identify key members of each stakeholder group to do further analysis to develop more detailed requirements.

The data model should accommodate all data captured at the jurisdictional level, even if not all such data is actually transferred, and also allow new attributes and tags to be added that will make the model extensible.

Types of data that can be stored in the Central Database

1. Regulated party information
    a. Facility name
    b. Facility WCI ID
    c. Facility Alternate Identifiers
    d. Facility address
    e. Facility contact

2. Facility level emissions data
    a. CO2e
    b. Individual GHG's
3. Source level emissions data
    a. CO2e
    b. Individual GHG's
4. Activity data (multiple records per activity)
    a. Fuel type
    b. Fuel consumed
    c. Process data required for emission calculations
    d. Calculation method
    e. Emission factors
    f. Source Category Code
5. Supporting Documentation consistent with the essential reporting requirements:
    a. Entity level documents (e.g. Annual Reports, Organizational Structure)
    b. Facility Level Documents (e.g. Facility Operations)
    c. Emissions Submission Documents (e.g. calculation methodology, verification support)
6. Verification information
    a. Verification Body
    b. Lead Verifier
    c. Verification statement
    d. Date verification completed
7. Agency Review information
    a. Agency staff identifier
    b. Action taken (e.g., review, acceptance, rejection, facility contact, referral for CVE)
    c. Date action taken
    d. Notes

The WCI essential reporting requirements will help define the data that can be stored in the Central Database. For example, precision for reporting emissions data (e.g., fuel quantities, emissions, etc.) will reflect final guidance from the Reporting Committee. In other cases, the Markets Committee or the Cap Setting and Allowance Committee may need to be consulted to ensure interoperability with other WCI functions.

An additional consideration for data analysis is the need to respect that the essential reporting requirements will present a new and demanding challenge to some regulated parties. In the initial years of reporting, the Central Database may need to accommodate data that does not strictly conform to all of the essential reporting requirements. If this is the case, all data points should be stored in the Central Database and made available for research and analysis.

3.3 Data Aggregation from WCI Partner Jurisdictions

Refer to Figure 2 Component #3.

Data will be collected from each of the Partner jurisdictions in the Central Database through transfers of data from Common Framework or Partner-specific databases. Developing standards that are consistent for all transfers is critical to maintain the accuracy of data in the Central Database and to minimize the cost of the process.

3.3.1 Partner Submissions to the Regional Emissions Database

Business rules will guide the date and frequency of Partner submissions of data to the WCI Central Database. Since a complete set of commonly defined data from all Partners is required to manage allowances, clear expectations will be set for when transfers need to be finalized. Options for how Partner jurisdictions are likely to transfer emissions are:

- When the Partner data collection process is complete
- Multiple submissions as regulated parties complete their submissions to the Partner

Once an automated data transfer process between a jurisdiction and the Central Database is in place, repeated submissions from a Partner to the Central Database should be supported, as a number of conditions may cause emissions reports by regulated parties to change (e.g. late submissions, verification changes). As data is updated by any of the Partners, the transfer process should allow all emissions or a subset of the data from the Partner to be submitted. To simplify this process a complete set of data should be included for any facility for which data is transferred.

3.3.2 Data Transfer Schema Usage

As discussed earlier in the paper, data standards for GHG emissions are still evolving. However, it is essential that data are transferred using consistent and stable methodologies. Options for schemas that will support data transfer to the Central Database (from jurisdictional databases) include:

- Consolidated Emissions Reporting Schema (CERS)
- WCI Custom template
- Combination of multiple options

The CERS was developed to support inter-agency transfers of all emissions data and was extended to incorporate GHG emissions. Developing consensus on a shared schema like the CERS is a time consuming process requiring broad participation. Therefore, it may difficult for WCI to develop its own standard given the timeframe allowed. Although it is still necessary to confirm that the CERS will accommodate all of the WCI essential reporting requirements, it does form the basis of a largely complete template. The CERS has also been implemented by The Registry to support the transfer of data from jurisdictions to The Registry, so there is an opportunity to leverage existing work.

3.3.3 Communications Infrastructure

Creating a communications infrastructure that accommodates transfers of high volumes of data in a secured, predictable environment requires extensive investment and WCI will want to leverage existing platforms. Opportunities to do this are:

- Exchange Network only
- Exchange Network plus an additional option for Partners that do not have a node on the Exchange Network

In the US the Exchange Network is managed by EPA to support data exchange to and from federal programs as well as between jurisdictions. All agencies that utilize the Exchange Network for data exchange have nodes on the network that enable secure communications according to standard protocols. The Registry has an Exchange Network node and is completing a pilot project using it this summer.

Exchange Network users who want only to submit data over the Exchange Network do not need a fully functional node but instead would only require a node client. A node is only required if you want to allow other systems to request data from you. This may simplify use of the network by Canadian Partners if there are no other barriers to adoption of this approach. The OWNERS system might also establish a connection to the RED to support data exchange, although existing GHG data collection in Canada is not currently using the OWNERS system.

3.4 Analysis, Report Preparation and User Interface Tools

Refer to Figure2 Component #4.

The ability to provide information to the different participants in the WCI program is fundamental to the success of this project. It is however, difficult to anticipate all of the reports and analysis that will be useful until the system exists. For this reason, it will be advisable to rely heavily on prototyping early deliverables for reports and the user interface to the Central Database during the requirements planning and design phases. The sections that follow attempt to lay the groundwork for options of this component, but they are likely to evolve considerably throughout the rest of the project. As this process evolves, it will also inform the other components of the RED project.

3.4.1 GHG Emissions Data Analysis

Many forms of GHG emissions analysis will be used to manage WCI operations, inform stakeholders, and mine the Central Database for information that will help WCI achieve GHG reduction goals. Some of these are presented here for review; the RED workgroup welcomes additional suggestions as others review this White Paper.

- Geographic Analysis: WCI Program, State, Province, Participant: It is strongly advised that accurate spatial coordinates are incorporated so that a broad array of options for geographic analysis can be supported.
- Sector Analysis: The North American Industry Classification System (NAICS) is one form of sector analysis that is often used and will be incorporated. A more simplified list of industry sectors that is derived from an external standard may also be advisable.
- Analysis by Source Category Code (SCC): SCC codes are used by most WCI Partners to analyze data. Since they classify low level information about fuels and the scale of emissions they are very useful. However, each source activity needs to be classified accurately for the analysis to provide value. Individual Partners will be responsible for ensuring that sources are categorized accurately before the data is aggregated in the Central Database.
- Entity Analysis: Although WCI will apply reporting requirements at the facility level, many entities will report for multiple facilities. This type of analysis will be needed by regulated parties, Partners and public stakeholders.
- Facility Analysis: Facility level analysis will help to determine if the essential reporting requirements are providing the information needed to support the cap-and-trade program. A detailed list of facility-level requirements will be included in the requirements specification phase of this project.
- Individual Gas Analysis: Emissions by each GHG, categories of GHG and total CO_2e will be provided.
- Threshold Analysis: Emissions summarized at the facility level for all facilities with CO_2e emissions of 25,000 metric tons or more, 10,000 metric tons or more, or other increments specified by the user.
- Analysis for Stakeholders: The RED workgroup will seek guidance from stakeholders to determine requirements for this analysis.

3.4.2 Stakeholders

Various stakeholders will be interested in accessing some/all of the GHG data in the WCI RED. In proposing requirements for the system, it is important for WCI to understand the type and form of data that key public stakeholders will be interested in accessing. While WCI's RED may not be able to meet all of the stakeholders' GHG data needs, it aims to make the data it collects as useful and meaningful as possible. In order to prevent duplication of effort, WCI hopes that many stakeholders will be able to use the data contained in the WCI's RED in a way that prevents duplication of effort and promotes centralized consistent GHG data.

As a result, the Partners and Reporting Committee must first work to identify the various needs of stakeholders and then to prioritize their needs to ensure that the scope of WCI's RED is not expanded unnecessarily.

The RED Subcommittee has identified the following stakeholders as potentially interested parties in the RED data.

- Western Regional Air Partnership (WRAP): The WRAP currently manages the Emissions Data Management System (EDMS). The EDMS is an emission inventory data warehouse that provides a consistent and comparable approach to regional emissions tracking to meet the requirements for State Implementation Plan (SIP) and Tribal Implementation Plan (TIP) development and periodic review and updates across the U.S. states in the region. The WRAP has expressed interest in utilizing the data from WCI's RED to supplement its EDMS system.
- Western Governors' Association (WGA): The WGA addresses important policy and governance issues in the West, advances the role of the Western states in the federal system, and strengthens the social and economic fabric of the region. All of the American WCI Partners are members of the WGA. The WGA currently collects emissions data via the WRAP.
- Western Renewable Energy Generation Information System (WREGIS): The WREGIS is an independent, renewable energy tracking system for the region covered by the Western Electricity Coordinating Council (WECC). WREGIS could be interested in utilizing RED data, specifically power related emissions.
- Environmental organizations (Natural Resources Defense Council (NRDC), Environmental Defense Fund (EDF), Union of Concerned Scientists (UCS), Sierra Club, etc.): Environmental organizations have long supported GHG data collection, and will likely be interested in analyzing emission trends, the carbon market, and the overall program effectiveness.
- US Environmental Protection Agency (US EPA): The US EPA is currently finalizing their GHG Mandatory Reporting Rule. Depending on how US EPA chooses to work with states, US EPA may permit GHG data transfer, data sharing or combined data collection.
- Environment Canada: Environment Canada is also currently working on federal regulation of GHG emissions. Like US EPA, depending on the relationship between the Canadian provinces and territories and Environment Canada, Environment Canada may permit GHG data transfer, data sharing, or combined data collection.

- Other GHG Cap-and-Trade Programs (RGGI, EU ETS, etc.): Depending on the programmatic relationship with other cap and trade programs (RGGI, MGGRA, EUETS, etc.), WCI may wish to permit GHG data transfer, data sharing, or combined data collection with other programs.
- Secretaría de Medio Ambiente y Recursos Naturales (Semarnat): Semarnat is the federal agency responsible for environmental protection in Mexico. If the Mexican states (currently WCI Observers) became Partners, Semarnat might permit GHG data transfer, data sharing, or combined data collection with related Mexican programs.
- Carbon Market: A variety of carbon market experts (brokers, traders, offset providers, etc) will be interested in accessing various GHG data information about regulated parties.
- Industries and Trade Associations - These are the facility owners or operators and their representative trade groups that will be either reporting to the RED in compliance with their respective jurisdiction's requirements, or interested in reviewing data submitted by others to support the cap-and-trade program.

Options:
Given the number and diversity of identified stakeholders, WCI has several options to consider when designing the system requirements and resulting data analyses of the WCI RED. WCI could:

- Meet all the stakeholder needs
- Ensure that key stakeholder needs are met within the initial RED, and work to support additional needs in the future
- Focus solely on WCI's needs

Public Stakeholders: The WCI welcomes feedback from all stakeholders on reports and data analysis that would be helpful.

3.4.3 Standard WCI Reports

Reports provided in this section may appear to overlap with reports with the WCI Program Module reports. Since the Central Database will have data for all Partners it will be possible to include more comprehensive views of data and comparative analysis by geography, sector and other categories that provide more value to WCI.

Options for developing Common WCI Emission Reports:
- Canned reports for each of the different groups involved in WCI
- Partner specific reports
- Ad hoc reports (i.e., user defined parameters)
- Public reports

- Consult stakeholder groups to solicit feedback on content to be included in the reports

3.4.4 User Interface

The online user interface for the RED must contribute to a positive experience for the user and ensure efficient access to information. Fortunately, there are a number of open source frameworks that simplify the development of an intuitive user interface. The approach will need to provide flexibility, so that different types of users can view data at the appropriate level of granularity, and in a format that is easy to understand (e.g. graphs, charts, summary data, detailed data). The approach should also ensure consistent views for different users in the same category (i.e. WCI Staff, WCI Partner, Regulated Party, Public Stakeholder).

The interface will enforce access privileges for users with different roles, as well as respect data confidentiality rules. Users with the appropriate privileges should also be able to perform ad hoc queries, or download data using an ODBC connection.

Whenever possible the interface should comply with World Wide Web Consortium (WC3) web accessibility standards.

3.5 Integration with the Tracking System

Refer to Figure 2 Component #5.

The Central Database may need to transfer emissions data to the tracking system, but the details about the schedule, frequency and granularity of information will depend on the findings of other WCI committees. The RED Workgroup will continue to work with the Markets Committee, the Cap Setting and Allowance Distribution Committee and others as need to determine the requirements for integration with the Tracking System.

3.6 System Administration and Support

Once the Central Database has been deployed and is available to use it will require ongoing administration and support services. This includes services such as hosting, technical support, training and call or email response services. It should be noted that the services that support the WCI Program Module are not included in this discussion. Each Partner that adopts the Program Module in The Registry’s Common Framework will make these arrangements individually. Possible options for administration and support are:

- WCI Regional Administrative Body
- The Registry
- Third Party contractor

- Designated Partner staff

Technical support services ensure system continuity, ongoing security upgrades, routine maintenance, performance monitoring, issue resolution and incremental enhancements to the system. Application specific services such as issue resolution and enhancements can be provided more efficiently by staff members who have been involved with the development of the software. System level services such as security upgrades or performance monitoring should be provided by the hosting partner. Since The Registry will have the most familiarity with the application services they are likely to provide the most efficient support during the initial implementation. They can also provide a single point of contact for the hosting partner to minimize overhead for WCI.

Program Services such as call center support, email response and training on how to access data in the Central Database should be provided by staff with significant subject matter expertise and familiarity with the user interface for each type of user. Demand for these types of services vary at different times of the year, so the provider will need to adapt to the WCI the reporting schedule. This is probably easiest for a provider who spreads the staff across multiple programs that have peak activity at different times during the year.

4 Summary of RED White Options Paper

1. **Purpose and Background**

    1.1. Regional Emissions Database (RED) Review Process: A description of the roles that different groups will have in the requirements analysis for the RED.

    1.2. Regional Emissions Database Work Plan: An outline of the milestones in the RED work plan and the participants involved.

    1.3. Regional Emissions Database Overview: Review this section to understand the different components that the project is broken into.

2. **Assumptions and Principles**

    2.1. Assumptions: Note that many assumptions were developed as the RED Workgroup discussed options and recognized that it was necessary to make assumptions about how to proceed.

    2.2. Principles: Common principles that will guide how options are evaluated and recommendations are made.

    2.3. Alignment with Federal GHG Reporting: The WCI will design the RED to achieve the maximum possible level of consistency and integration with federal GHG reporting programs.

3. **Options for the Regional Emissions Database** - Options are presented for the five components of the RED and for system administration and support:

    3.1 WCI Common Framework Program Module: Options for the WCI Program Module are focused on data collection by the Partners but may influence other components in the application. Many of the requirements will be determined by the WCI essential reporting requirements. The primary goals of providing a data collection module that is shared is to minimize cost and develop a consistent approach that simplifies reporting for regulated parties.

    3.2 WCI Regional Emissions Database: The RED will adopt industry standard best practices for technical infrastructure components. The RED must be designed to ensure that the data transferred from program modules and Partner-specific databases supports the WCI's data analysis needs.

3.3 Data Aggregation from WCI Partner Jurisdictions: The Central Database must incorporate business rules for the submission of data from program modules and Partner-specific databases to the Central Database, a schema or schemas for data transfers and a communications infrastructure.

3.4 Analysis, Report Preparation and User Interface Tools: The design of data analysis tools meeting the needs of the WCI, reporters and public stakeholders is likely to evolve considerably over time to adapt to other elements of the RED design.

3.5 Integration with the Tracking System: The Central Database will need to transfer emissions data to the tracking system, but the details for the schedule, frequency and granularity of information will depend on the findings of other WCI committees. The RED Workgroup will continue to work with the Markets Committee, the Cap Setting and Allowances Committee and others as need to determine the requirements for integration with the Tracking System.

3.6 System Administration and Support: Options for implementing system administration and support of the RED include WCI Regional Administrative Body, The Registry, a third-party contractor or designated Partner jurisdiction staff.

5 Public Stakeholder Feedback on Options

This section will be completed following the public stakeholder review of the Options White Paper.

Western Climate Initiative

August 6, 2009

To All Interested Parties:

Today, the Western Climate Initiative (WCI)'s Cap Setting and Allowance Distribution (CSAD) Committee released the *Draft Statement of Principles on Competitiveness* and the *Review of Proposed Options for Addressing Industrial Competitiveness Impacts.*

Under a cap-and-trade program, the cost of switching to cleaner energy and lowering emissions may disproportionately affect competition for sectors that are emissions-intensive and operate in global markets. In contrast, the costs of inaction on climate change in the long term are high and potentially catastrophic. The CSAD Committee, among other things, is responsible for developing the WCI approach to address competitiveness issues. The purpose of CSAD's work in this area is twofold:

- To seek, receive, review and perform analyses from sectors or sources identified (by WCI or through self-identification) as facing a cost within the WCI that their competitors outside the WCI do not. Those sectors or sources may be vulnerable to competitiveness pressures because of the short term regulatory imbalance and could lead to increased emissions outside the WCI, which we seek to minimize.
- To assess options that WCI Partner jurisdictions may use to address competitiveness issues within identified sectors. If a common allowance distribution method is recommended, the CSAD Committee will recommend a distribution method or methods for consideration by the WCI Partner jurisdictions.

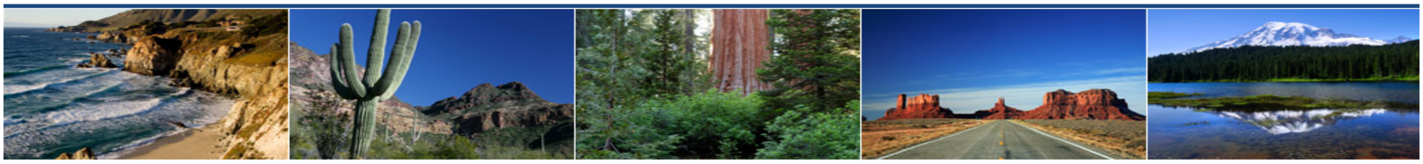
The purpose of the draft statement of principles is to guide the process by which WCI will evaluate competitiveness effects of a regional cap-and-trade program. The principles shall serve as the foundation for a common approach to addressing competitiveness issues agreed upon by the WCI Partner jurisdictions.

In addition, the CSAD Committee reviewed how other programs currently address or propose to address competitiveness issues. These policy options are evaluated in a three page summary and table entitled *Review of Proposed Options for Addressing Industrial Competitiveness Impacts.* Legislative proposals, reports, and programs on competitiveness which the Committee analyzed include:

- Inslee-Doyle Carbon Leakage Prevention Act (H.R. 7146)
- American Clean Energy and Security Act of 2009 (H.R. 2454)
- Australia's Carbon Pollution Reduction Scheme
- Lieberman-Warner Climate Security Act of 2008 (S. 3036)

- California’s AB 32 Global Warming Solutions Act
- The European Union cap-and-trade program – EU ETS Phase III
- RGGI Northeastern cap-and-trade program on the electricity sector
- Two reports published by the Pew Center on Global Climate Change

These programs and proposals provide key background information for Committee’s work on competitiveness. Public comment on the *Draft Statement of Principles on Competitiveness* should be submitted via the WCI website by August 28.



Draft Statement of Principles on Competitiveness

August 6, 2009

The WCI Partner Jurisdictions have developed a Draft Statement of Principles (SOP) to help guide the process by which WCI will evaluate competitiveness effects and leakage due to the regional cap-and-trade program. This draft SOP is primarily informed by the February 2009 work plan as well as an examination of principles used by other regional, national and international carbon management initiatives.

Concerns regarding competitiveness are often expressed as the potential for companies covered by the cap and trade program to lose market share to companies in regions with less stringent carbon constraints. A common measure of competitiveness impacts is a decrease in net exports that results from the carbon constraint of the cap and trade program. For a full list of metrics used in other programs or recommended by the literature as well as options to address competitiveness, please see the summary table: *Review of Proposed Options for Addressing Industrial Competitiveness Impacts*.

Guidance contained in the February 19, 2009 CSAD Work Plan indicates that workgroups on competitiveness will assess how WCI jurisdictions should address competitiveness issues. The CSAD Competitiveness group was also directed to seek, receive, review and perform analyses on competitiveness issues for sectors or sources that have been identified and/or that self-identify as having competitiveness issues related to a regional cap-and-trade program. The WCI Program Design Recommendations specify a process to address competitiveness issues between WCI Partner jurisdictions (Section 8.5):

> *If analysis demonstrates that allocations to a particular sector should be treated uniformly by some WCI Partner jurisdictions in order to address competition among like facilities or entities within that sector, and if from that analysis some WCI Partner jurisdictions determine that it is necessary to address those competitiveness issues between the WCI Partner jurisdictions where the facilities or entities operate, those WCI Partner jurisdictions will standardize the distribution of allowances as necessary to address competitive impacts sufficiently, in advance of the first compliance period.*

Guidance from other regional, national and international carbon management initiatives also provides a starting point for developing principles to address potential competitiveness impacts of the WCI program and risks to emissions-intensive, trade-exposed industries. Notably the proposed Inslee-Doyle Carbon Leakage Prevention Act (H.R. 7146), and key competitiveness elements reflected within the American Clean Energy and Security Act of 2009 (H.R. 2454) provide a solid foundation for the principles.

Specifically, the focus on compensating sectors that demonstrate trade-exposure and emissions-intensity with free allocations and other means are common across GHG cap-and-trade programs, notably the European Union Emissions Trading Scheme or EU-ETS. Also consistent with other carbon management programs is a focus on avoiding carbon leakage and smoothing transitional impacts.

The following Draft Statement of Principles flows from WCI guidance to date, initial stakeholder feedback from the May 28, 2009 CSAD Workshop in Seattle, and a review of other carbon management programs. WCI Partners will:

- Minimize leakage of GHG emissions and the transfer of production and jobs attributable to a regional cap and trade program to the extent feasible, while still rewarding innovation and facility-level GHG intensity improvements.
- Address transitional challenges faced by entities from within covered sectors that may be subject to disproportionate competitiveness risk under a regional cap and trade program.
- Consider a harmonized approach across WCI when identifying and addressing potential competitiveness risks attributable to a regional cap and trade program.

These principles will guide the common approach to competitiveness undertaken by the Partner Jurisdictions.

Summary of Review of Proposed Options for Addressing Industrial Competitiveness Impacts

August 6, 2009

The CSAD Task 3 team reviewed ten major policies, proposals, and analyses on how to address competitiveness risks under greenhouse gas cap-and-trade systems, including two operational cap-and-trade programs (the EU-ETS and RGGI) and five proposed systems including Waxman-Markey and Australia's Carbon Pollution Reduction Scheme. The objective of the review was to inform the development of the Statement of Principles. The results of the review are provided in the table/annex to this summary, and are organized under three major headings:

1) **Policy goals:** what the policy or proposal seeks to achieve regarding competitiveness and leakage impacts;
2) **Assessing competitiveness impacts and defining vulnerability**: which methods and metrics the policy or proposal uses to identify sectors or firms that may be vulnerable to competitiveness impacts and significant emissions leakage; and,
3) **Options for addressing competitiveness impacts**: how the policy proposes to address competitiveness impacts and minimize leakage risks (e.g., through measures including free allocations and border carbon adjustments).

Below is a summary of the review, organized under the three major headings identified above.

1) Policy Goals

Most policies and proposals seek to address competitiveness and leakage concerns, where there is a risk that production and jobs shift or emissions increase outside of the jurisdiction implementing a carbon policy. A second goal is to provide transitory assistance to particular industrial sectors to help them cope temporarily with higher energy and production costs as they transition to more efficient practices or low-carbon technologies, and mitigate competitiveness impacts until outside jurisdictions and trading partners adopt similar carbon constraints. Each of these goals is discussed below.

Leakage to Outside Jurisdictions: Most of the reviewed policies and proposals focus on how to avoid emissions leakage to outside jurisdictions that arise from cost increases due to compliance with carbon mitigation policies. For example:

- **The EU phase III**: The primary EU policy goal is to address competitiveness concerns in energy-intensive and trade-exposed industries, where some might be "exposed to a significant risk of carbon leakage";
- **Waxman-Markey (American Clean Energy and Security Act of 2009)**: ''Carbon leakage'' means any substantial increase in GHG emissions by manufacturing entities located in countries without commensurate GHG regulation, provided that such increase is caused by an incremental cost of production resulting from the carbon mitigation policy; and
- **RGGI**: "A cost increase due to a carbon cap could drive geographic changes in the operation of the electric power system."

Competitiveness Impacts as a Transitory Concern: Many of the policies and proposals reviewed stated that competitiveness impacts resulting from carbon constraints are transitory. They often include provisions, phased out over time, to help industry transition to a lower carbon future while also basing assistance levels or duration on carbon mitigation efforts in other jurisdictions:

- **RGGI**. Leakage is cited as a concern only if no national cap-and-trade system is operating, "a scenario where RGGI sunsets once a national program is implemented, would obviate any potential for emissions leakage."
- **Waxman-Markey**: The proposed program states that assistance to eligible industries would be sufficient to prevent carbon leakage while still rewarding innovation and facility-level energy efficiency improvements. The assistance provided phases out over time, and a number of provisions are contingent on the status of international negotiations on climate mitigation policies and whether carbon constraints have been instituted in other countries.
- **Australia's Carbon Pollution Reduction Scheme**: Australia's proposed system seeks to address transitional challenges faced by emissions-intensive, trade-exposed industries, and would also reduce rates of assistance to these industries on an annual basis.

2) Assessing Competitiveness Impacts and Defining Vulnerability

All policies, proposals, and analyses reviewed provide methods and metrics to measure the likely impacts of the carbon policy on industry, using a mix of quantitative and qualitative information. While a number of different approaches are employed, the review indicates a common set of questions to identify who might be at risk and evaluate the extent of the risk:

- Many policies describe a means for analyzing the extent to which industries may experience production cost increases (often due to their energy- or emissions-intensive nature) and trade exposure (competing in global or inter-jurisdictional markets);
- Many policies then assess the ability of industry to make reductions and/or pass on incremental cost increases resulting from carbon mitigation policies; and
- Many policies then define the extent of exposure as a function of the impact on profits relative to some acceptable threshold level.

Examples from the review include:

- **Waxman-Markey:** Qualifying industrial sectors are determined on the following basis:
    - o The sector has an energy intensity of at least 5 percent, or a greenhouse gas intensity of at least 5 percent; and
    - o The sector must also have a trade intensity of at least 15 percent (sectors with an energy-intensity of 20 percent are eligible regardless of trade exposure).
- **EU ETS Phase III**: In addition to metrics regarding trade-exposure and costs impacts resulting from carbon constraints (defined as a trade exposure of 10 percent, and a cost impact of 5 percent, respectively), the EU has proposed additional metrics to identify those with a significant carbon leakage risk:
    - o The extent to which it is possible for affected industrial sectors to reduce emission levels or electricity consumption;
    - o Market characteristics (current and projected), including when trade exposure or direct and indirect cost increase rates are close to identified thresholds;

- Profit margins as a potential indicator of long-run investment and/or relocation decisions.

With the methods and metrics established to identify who may be at significant risk of carbon leakage and competitiveness impacts, all of the programs and policies then identify what is to be done to address these impacts.

3) Options for Addressing Competitiveness Impacts

With a focus on reducing emissions leakage, policies and proposals provide measures to help ameliorate the competitiveness impact on firms resulting from an imbalance between stronger GHG constraints (and their impacts on costs) within a jurisdiction and weaker GHG constraints outside it. There are two basic approaches common among the policies and proposals reviewed:

- **Granting some amount of free allowances,** as in the case of the EU ETS, Waxman-Markey and the Australian proposal;
- **The option to apply border carbon adjustments** that equalize GHG-related costs for producers within jurisdiction and those without by imposing a cost or other requirement on energy-intensive imports from outside jurisdictions with weaker or no GHG constraints. This option is employed in both the EU ETS and the Waxman-Markey bill.

As mentioned in the goals section above, the policies and proposals reviewed have a provision that recognizes leakage risks may be transitory by providing for an on-going assessment of the leakage risk. For example, the EU-ETS list of sectors or subsectors exposed to a significant risk of carbon leakage shall be determined after taking into account:

> *"… the extent to which third countries, representing a decisive share of world production of products in sectors deemed to be at risk of carbon leakage, firmly commit to reducing GHG emissions ... and the extent to which carbon efficiency of installations located in these countries is comparable to that of the EU."*

Similarly, Waxman-Markey stipulates that unless a binding international agreement requires all major emitters to contribute equitably to reducing GHGs and addresses imbalances in competitiveness, in 2020 importers will be required to hold emission allowances (called international reserve allowances) for the import of products in energy-intensive, trade-exposed sectors. The reserve program would be established automatically in all eligible sectors unless the President determines that it is not in the national interest and Congress concurs. It would not apply if at least 85 percent of imports in a given sector are from countries that: have emission targets as stringent as the United States'; are parties to a sectoral agreement; or have energy or GHG intensities in that sector no higher than in the US. International reserve allowances could not be used by domestic entities for compliance purposes.

Detail on all of the above points is provided in the review tables.

Review of Proposed Options for Addressing Industrial Competitiveness Impacts

Policy, Proposal or Analysis	
"Addressing Competitiveness in U.S. Climate Change Policy." Pew Center Congressional Policy Brief. 2008. Available at http://www.pewclimate.org/DDCF-Briefs/Competitiveness.	
Goals	
Explore the options for minimizing competitiveness impacts to energy-intensive, trade-exposed industries (heavy energy users whose goods are traded globally, such as steel, aluminum, cement, paper, and glass).	
Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	**Options for Addressing Competitiveness Impacts**
Energy-intensive industries defined as those whose energy costs are 4 percent or more of shipped value. The brief notes need to distinguish the "competitiveness" effect of climate policy from its broader economic impact; the competitiveness impact is the portion of the total impact resulting from an imbalance between carbon constraints in one region and the lack of such constraints in other regions. Assessing direct (compliance) costs: the cost of purchasing allowances needed to cover direct emissions regulated under the cap Assessing indirect costs: includes higher electricity and natural gas prices For most energy-intensive industries, the largest potential cost of carbon constraints is higher energy prices.	Options include: 1. Compensating firms for the costs of GHG regulation through allowance allocation or tax rebates. • Need to consider the scope, form, and means of how this compensation would be calculated, and whether (or if) it gets phased out over time. • Could include generous grandfathering of allowance allocations (to help mitigate direct costs), and additional allowances to compensate for indirect costs. Free allocation of allowances does not necessarily help guard against emissions leakage or job losses, as firms could maximize profits by selling their allowances and reducing production. • Compensation could also be "output-based," meaning it is a based on actual production levels and/or energy consumption. Firms could be fully compensated, or an output-based approach might apply a performance standard (i.e. energy or emissions per unit of production) that rewards or encourages lower-GHG intensive production. • Another option would be to provide tax credits or rebates, perhaps using proceeds from the auction of emission allowances. A tax rebate would be a direct payment to compensate a firm for GHG regulatory costs; a tax credit could alternatively offset those costs by reducing other taxes (such as corporate or payroll taxes) or healthcare or retirement costs. • Phasing out compensation over time can provide an additional incentive for firms to improve their GHG emission performance. 2. Transition assistance to help firms adopt lower-GHG technologies, and to help workers and communities adjust to changing labor markets • For firms, this might include tax incentives, such as accelerated depreciation to encourage the retirement of inefficient technologies, or tax credits for the development or adoption of lower-GHG alternatives. Firms could also be incentivized to switch to low carbon

	energy sources by providing subsidies to purchase or generate low-carbon electricity 3. Border measures such as taxes on energy-intensive imports from countries or regions lacking GHG controls (raises interstate commerce clause considerations for WCI or other states) 4. Exempting potentially vulnerable firms from the cap-and-trade system (e.g., excluding coverage of process emissions for energy-intensive industries) • Exclusions could relieve trade-exposed industries of direct regulatory costs (they would still face indirect costs from higher energy prices) • However, exclusions would also undermine the goal of economy-wide GHG reductions and make the overall program less efficient

Policy, Proposal or Analysis
Inslee-Doyle Carbon Leakage Prevention Act (H.R. 7146). Available at http://frwebgate.access.gpo.gov/cgi-bin/getdoc.cgi?dbname=110_cong_bills&docid=f:h7146ih.txt.pdf
Goals
Aims to avoid leakage of GHG emissions to countries outside the United States. Also seeks to compensate the owners and operators of entities in eligible domestic industrial sectors and subsectors for carbon emission control costs.

Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	**Options for Addressing Competitiveness Impacts**
	Approach now incorporated into Waxman-Markey ACESA (with some modification); see below Allocates allowances to compensate for both direct and indirect costs based on a facility's level of output, adjusted by an "efficiency factor" set at 85 percent of emissions/energy use per unit of production within the sector • Eligible energy-intensive industries covered by the cap receive allowances for direct emissions based on a facility's level of production in the previous two years multiplied by 85 percent of average GHG emission per unit of production across the sector • Both covered and non-covered facilities receive allowances for indirect emissions based on their level of production multiplied by 85 percent of the average amount of electricity per unit of production for all facilities in the sector or subsector (adjusted by the average GHG emissions per kilowatt hour of electricity purchased by the facility) • Facilities whose GHG performance is at the sector average would be reimbursed for 85 percent of their costs, while those performing above or below average would be

	compensated for a greater or lesser of their costs, respectively • Provides firms an incentive to switch to lower-GHG processes and energy sources, while providing compensation and lowering risks of emissions leakage and competitiveness impacts. • Total allowances to eligible facilities in any year not to exceed 15% of total allowances available in the first year

Policy, Proposal or Analysis

American Clean Energy and Security Act of 2009 (Waxman-Markey Substitute Amendment) – June 2009. Available at http://energycommerce.house.gov/Press_111/20090701/hr2454_house.pdf.

Goals

Aims to promote a strong global effort to reduce GHG emissions and avoid dangerous climate change.

Aims to avoid leakage of GHG emissions to countries outside the United States as a result of direct, indirect compliance costs.

Would also compensate ("rebate") the owners and operators of entities in eligible domestic industrial sectors and subsectors for GHG emission control costs, but not for costs resulting from other market dynamics. Compensation would be sufficient to prevent carbon leakage while still rewarding innovation and facility-level energy efficiency improvements.

Would eliminate or reduce assistance when it is no longer necessary.

Notes importance of international negotiation in mitigating leakage and threats to industrial competitiveness; pledges that US will work towards an agreement that includes binding agreements, including sectoral agreements, committing all major emitters to equitable contributions to GHG reductions (recognizing that this is the most effective way to meet the purposes outline in the bill).

Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	Options for Addressing Competitiveness Impacts
Owners of qualifying industrial facilities would receive annual emission allowance rebates (free allowances) to help compensate them for compliance costs and prevent carbon leakage. The total number of allowances distributed under these provisions cannot exceed a maximum limit established by the program. Qualifying industrial sectors are determined on the following basis: 1. Must have a 6-digit classification under NAICS 2. The sector or subsector must have an energy intensity of at least 5 percent, calculated by dividing the cost of purchased electricity and fuel costs of the sector or subsector by the value of the shipments or the sector or subsector, or a greenhouse gas intensity of at least 5 percent, calculated by dividing the number 20, multiplied by the CO2e emissions (including direct emissions from fuel combustion, process emissions, and indirect emissions from the generation of electricity used to produce the output of a sector or subsector) by the value of the shipments of the sector or subsector. 3. The sector or subsector must also have a trade intensity	Rebates are provided in the form of free emission allowances. The quantity of emission allowances rebates provided to a covered and eligible industrial entity would be equal to the sum of the covered entity's direct carbon factor and its indirect carbon factor (for non-covered, eligible entities, the rebates would be based on an entity's indirect carbon factor only). However, in years 2012 and 2013, allowance distribution will be based only on entities' indirect carbon factor (described below). • The direct carbon factor is calculated by multiplying the average output of the covered entity for the two years preceding the rebate distribution year by the average direct greenhouse gas emissions (in CO_2e) per unit of output for all covered entities in the sector. • The indirect carbon factor for an entity is the product of its average output (for the two years preceding the rebate distribution year) multiplied by both its electricity emissions intensity factor (the emissions intensity of each facility's electric power supplier) and the electricity efficiency factor (the sector average electricity use per unit of output). o The electricity emissions intensity factor (in tons of CO_2e/kWh) is determined by dividing 1) the annual sum

of at least 15 percent, calculated by dividing the value of the total imports and exports of such sector/subsector by the value of the shipments plus the value of imports or the sector/subsector.

4. Sectors are also eligible if they have an energy intensity of 20 percent (regardless of trade intensity).

Provision is made for administrative determination of additional eligible sectors or subsectors. Any person may petition the program administrator to grant rebates to a given sector/subsector, provided the petitioner can demonstrate that the sector/subsector is subject to carbon leakage comparable to that of sectors or subsectors that already meet the criteria for determination laid out in the bill.

of the hourly product of the electricity purchased by an entity, multiplied by the cost the seller of the electricity passes to the entity per ton of CO_2e per kWh, by 2) the total kWh of electricity purchased by the entity from that seller in that year.

- o The electricity efficiency factor is the average amount of electricity (in kWh) used per unit of output for all entities in the relevant sector/subsector.

Direct and indirect carbon factors for eligible facilities are calculated using average output data for the two years preceding the year of distribution, and the most recent sectoral emissions intensity data (GHG per unit of production). Average direct GHG emissions per unit of output, for all covered entities in each eligible sector, are calculated every four years using the most recent two years of data.

- The average direct GHG emissions per unit of output for a sector will never by greater than it was in a previous calculation
- When recalculated, the electric emissions intensity factor will not be greater than it was in a previous year

There is a maximum limit on the number of allowances available for these purposes. In years 2012 and 2013, up to 2 percent of the total allowances available in those years could be used for industrial assistance. Starting in 2014, 15 percent of total allowances are available for industrial assistance; this percentage declines based on the percent reductions in the emissions cap. Starting in 2026, this decline is accelerated as the number of allowances distributed under this section will be reduced by a further 10 percent/year (phasing out completely in 2035) unless the President alters the phase-out schedule (the President must make a determination as to whether a given sector still requires assistance). For a year in a which the total emission allowance rebates calculated under this section exceed the number allocated for these purposes in a given year, the Administrator shall reduce each entity's distribution on a pro rata basis so that the total distribution equals the number of allowances available for this distribution in a given year.

Unless a binding international requires all major emitters to contribute equitably to reducing GHGs and addresses imbalances in competitiveness, beginning in 2020 the bill requires emission allowances (called international reserve allowances) for the import of products in energy-intensive, trade-exposed sectors. The reserve program would be established automatically in all eligible sectors unless the President determines that it is not in the national interest and Congress concurs. It would not apply if at least 85 percent of imports in a given sector are from countries that: have emission targets as stringent as the United States'; are parties to a sectoral agreement; or have energy or GHG intensities in that sector no higher than in the US. International reserve

	allowances could not be used by domestic entities for compliance purposes.

Policy, Proposal or Analysis

Australia's Carbon Pollution Reduction Scheme: Proposed Cap and Trade System (NOTE: This is subject to change as negotiations continue over the design details of the system). Information on latest proposals available at http://www.climatechange.gov.au/emissionstrading/index.html

Goals

Two goals to address competitiveness concerns:

- Avoid leakage associated with carbon pricing
- Address transitional challenges faced by emissions-intensive, trade-exposed industries

Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	**Options for Addressing Competitiveness Impacts**
Measuring the impacts. Trade exposure assessed through quantitative and qualitative tests: **Step 1:** Define exposed sources based on activity • Activities defined through stakeholder process **Step 2:** Assess emissions intensity • To derive emissions intensity, direct and indirect emissions are evaluated relative to employment, revenue or value added. • Emissions intensity sectoral assessment based on average emissions per million dollars of revenue or emissions per million dollars of value-added (uses 2006-2007, 2007-2008 for emissions data) **Step 3:** Assess competition from lower cost products and ability to pass-through costs (trade exposure) • Responsiveness of customers to price changes (price elasticity) • Parity of import and export prices • Share of trade in the market • Potential for international competition	Output-based allocation of allowances (based on a facility's previous year's level of production). The Australian government expects this will account for about 25 percent of all allowances initially, increasing to around 45 percent of all allowances available in 2020 • Covers both direct and indirect costs • Applies to existing and new facilities (allows for continued industry growth) • If a facility closes, it must relinquish permits for production that did not occur in that year • Initial rates of assistance: 90 percent to sectors with emissions intensity of at least 2000t of CO2e per million dollars of revenue or 6000t of CO2e per million dollars value-added; 60 percent to sectors with emissions intensity between 1000t and 1999t CO2e per million dollars of revenue, OR between 3000t and 5999t CO2e per million dollars value-added (see below for recent amendments) • Initial rates of assistance will be reduced by a carbon productivity contribution of 1.3 percent per year In addition, in May 2009 the Australian government announced changes to its cap and trade system, due in part to the global recession. Changes relevant to industrial competitiveness include: • A more stringent target; Australia's government will commit to reduce emissions by 25 per cent of 2000 levels by 2020 (the original target was 5-15 percent below 2000 levels by 2020) if a global agreement can be reached that will stabilize levels of CO_2 equivalent in the atmosphere at 450 parts per million or less by 2050. • A delay in the start date of the Carbon Pollution Reduction Scheme of one year (from 2010 to 2011).

	• A one year fixed price period, during which allowances will cost \$10 per tonne of carbon in 2011-12, with the transition to full market trading from 1 July 2012. • A new Global Recession Buffer will be provided as part of the assistance package for emissions intensive trade exposed industries. Industries eligible for 60 per cent assistance will receive a 10 percent buffer, while industries eligible for 90 per cent assistance will receive a 5 per cent buffer (see above for assistance thresholds). In practice, the buffer means that where particular industries were before eligible for 60 percent assistance, they will now receive up to 70 percent, and industries that were eligible for 90 percent assistance will receive up to 95 percent. • Eligible businesses will receive funding to undertake energy efficiency measures from 1 July 2009.
Policy, Proposal or Analysis	
Lieberman-Warner Climate Security Act of 2008 (S. 3036). Available at http://frwebgate.access.gpo.gov/cgi-bin/getdoc.cgi?dbname=110_cong_bills&docid=f:s3036pcs.txt.pdf	
Goals	
Avoid carbon leakage to regions/countries outside the U.S., and help firms transition to lower-carbon practices	
Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	**Options for Addressing Competitiveness Impacts**
Energy-intensive industries defined as iron, steel, aluminum, pulp, paper, cement, and chemicals	Process emissions of many energy-intensive industries are exempt from the cap; only process and combustion emissions from use of coal (more than 5000 tons/year per facility) are covered. Energy-intensive industries initially receive 11 percent of total allowances for any covered process emissions and to compensate for higher energy costs, declining to 1 percent of total allowances in 2030. Allowances allocated based on sectors' relative energy intensity and facilities' level of employment.

Review of Proposed Options for Addressing Industrial Competitiveness Impacts

<tr><td colspan="2">AB 32 Global Warming Solutions Act and supporting public consultation material, California Air Resources Board (CARB). Legislative text available at http://www.leginfo.ca.gov/pub/05-06/bill/asm/ab_0001-0050/ab_32_bill_20060927_chaptered.pdf. Updates on implementation and other materials at http://www.arb.ca.gov/cc/cc.htm.</td></tr>
<tr><th colspan="2">Goals</th></tr>
<tr><td colspan="2">Two key indicators of leakage risk:
• Assess potential cost increases due to program compliance costs. Increased costs associated with compliance could result either from the costs of actions taken to reduce emissions at the facility, and/or costs of acquiring emission allowances to cover remaining emissions after all actions to reduce emissions are taken at the facility.
• Assess the ability of industries to pass compliance costs on to their customers. If industries have limited ability to pass on costs because their competitors are not subject to similar emission reduction requirements or compliance costs, then the risk of leakage may be heightened. Existing producers may lose market share, and new investment may shift to regions that do not have similar program requirements.</td></tr>
<tr><th>Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability</th><th>Options for Addressing Competitiveness Impacts</th></tr>
<tr><td>Identify potentially affected industries
• Industries that compete in global markets that are not able to pass on the costs of the GHG emissions reduction program.
• Industries in this category may include non-ferrous metals smelting, iron and steel-making, cement, and other energy and/or emissions intensive activities.
Evaluate possible impacts
• These industries may face significant compliance costs from carbon intensive combustion processes and fuel use.
o Limited ability to reduce costs due to fewer opportunities for emission reductions.
• Inability to pass through costs to consumers.
o Competition from those without similar compliance requirements (trade exposure).

Reviewing EU ETS, Australia CPRS, Waxman-Markey discussion draft and other relevant materials and reporting back with a proposal in summer 2009.
Incorporate appropriate features in the program design (on-going).</td><td>Start stakeholder process in Fall 2009 to discuss different options to address the risk of leakage.</td></tr>

Review of Proposed Options for Addressing Industrial Competitiveness Impacts

Policy, Proposal or Analysis

EU ETS Phase III (final directive and materials available at http://ec.europa.eu/environment/climat/emission/ets_post2012_en.htm)

Goals

A potential concern with competitiveness in energy-intensive industries, with some "exposed to a significant risk of carbon leakage"

Defined as meaning that they could be forced by international competitive pressures to relocate production to countries outside the EU that did not impose comparable constraints on emissions.

Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability

Eligible industries criteria:

"A sector or sub-sector is deemed to be at a significant risk of carbon leakage if the sum of direct and indirect additional costs induced by the implementation of the Directive would lead to an increase in production costs exceeding 5% of Gross Value Added and if the total value of its exports and imports divided by the total value of its turnover and imports exceeds 10%.

- Those experiencing more than a 5 percent cost impact as a result of carbon constraints
- Those with a greater than 10 percent trade exposure (defined as [total imports + exports]/[total production + imports]

By way of derogation, a sector or sub-sector is also deemed to be exposed to a significant risk of carbon leakage if the sum of the direct and indirect additional costs induced by the implementation of the Directive would lead to an increase in production costs exceeding 30% of its Gross Value Added or if the total value of its exports and imports divided by the total value of its turnover and imports exceeds 30%."

Further sectors or subsectors deemed to be exposed to a significant risk of carbon leakage may be added after the completion of a qualitative assessment, "taking into account, when the relevant data are available, the following criteria:

- the extent to which it is possible for individual installations in the sector and/or subsector concerned to reduce emission levels or electricity consumption, including, as appropriate, the increase in costs of production that related investment may entail, for instance on the basis of the most efficient techniques;
- market characteristics (current and projected), including when trade exposure or direct and indirect cost increase rates are close to one of the thresholds mentioned [the threshold that non-EU Trade intensity is above 10%];
- profit margins as potential indicator of long-run investment and/or relocation decisions".

Options for Addressing Competitiveness Impacts

Sector Allocation	EC Proposal, 23 January 2008	Final Directive, April 2009
Electricity Generation, Carbon Capture and Storage	100% auctioning from 2013**	100% from 2013 in electricity generation but with a derogation of at least 30%, rising linearly to 100% in 2020, for certain Member States*** 100% auctioning for CCS
Sectors "at significant risk of carbon leakage"*	Will receive up to 100% of their allowances for free in 2013-2020	100% free allowances "to the extent that they use the most efficient technology" (based on the average of the top 10 percent most efficient facilities in the EU)
Sectors not "at significant risk of carbon leakage"*	20% auctioning 2013, linear increase to 100% in 2020	20% auctioning 2013, linear increase to 70% in 2020 with a view to reaching 100% by 2027

*Defined as meaning that they could be forced by international competitive pressures to relocate production to countries outside the EU that did not impose comparable constraints on emissions. This would simply increase global emissions without any environmental benefit. **Takes account of the sectors ability to pass on the increased cost of emission allowances. ***Member States who, "fulfil conditions relating to their interconnectivity or their share of fossil fuels in electricity production and GDP per capita in relation to the EU-27 average, have the option to temporarily deviate from this rule with respect to existing power plants". The provision refers to new Member States in the east of the European Union. They are required to submit national plans showing how the value of their free allocations will be spent on retrofitting and upgrading infrastructure and clean technologies (submitting an annual

	report detailing investments) and diversifying their energy mix. Free allocation of allowances based on an efficiency benchmark multiplied by historical production multiplied by an exposed or non-exposed factor (trade-exposed industries have a factor of 100 percent); • Benchmark is based on average emissions per unit of production, using data from the top 10 percent most efficient facilities within a given industrial sector in the EU (based on 2007 data). This is what is meant by "best available technology." Benchmark level remains the same through 2020 (this provides planning certainty; sources know exactly how many allowances will be available through 2020). • Total allowances available for free to industry in a given year is based on the average share of industrial emissions from covered industries for baseline years 2005-2007, multiplied by the overall cap in that year (e.g., if industrial emissions accounted for 15 percent of total EU average emissions in for 2005-2007, then in 2013 the total number of allowances available to industry would be 15 percent of the 2013 cap). Added to this are average annual emissions for 2005-2007 for installations that were not part of the EU-ETS in those years (but have since joined) reduced by an annual reduction factor. The list of sectors or subsectors exposed to a significant risk of carbon leakage shall be determined after taking into account, *"the extent to which third countries, representing a decisive share of world production of products in sectors deemed to be at risk of carbon leakage, firmly commit to reducing GHG emissions ... and the extent to which carbon efficiency of installations located in these countries is comparable to that of the EU* Evaluations of exposure are scheduled to be on-going: • no later than December 31, 2009 and every 5 years thereafter; • no later than June 30 2010 (for decisions relating to the outcome of international agreements). Three further conditions relate to the outcome of international agreements: 1. that the Commission will study the possibility of granting additional allowances free of charge to industrial sectors exposed to a significant risk of carbon leakage; 2. "*In its impact assessment of the negotiations of an international climate change agreement, the Commission will take account of the impact of carbon leakage on Member States' energy security, in particular where the electricity connections with the rest of the European Union are insufficient and where there are electricity connections*

	with third countries. The Commission may take appropriate measures in this regard"; 3. The option of applying border measures was added to the possible actions for redress (which were previously the granting of free allowances and including product importers within the ETS). In common with allocation, the net effect of these conditions is to add some uncertainty to the questions of which (sub-)sectors will receive free allocations and how the quantity they receive may change with time. The revised Directive, Article 10a6 also provides for the possibility for Member States to compensate the most electro-intensive sectors for increases in electricity costs resulting from the ETS through national state aid schemes. Therefore, the Commission will correspondingly modify the Environmental State Aid Guidelines by 31 December 2010.
Policy, Proposal or Analysis	
RGGI (Model Rule and other documents available at http://rggi.org/home).	
Goals	
Concern over production leakage, with shifting production to higher emitting sources not covered by RGGI. Implicit in this concept is the notion of causality; specifically that a cost increase due to a carbon cap could drive geographic changes in the operation of the electric power system. This is distinct from a shift in the geographic distribution of electric generation resulting from other market variables and the dynamic nature of the electric power market. Only applicable with no operating national system (i.e. transitional): The implementation of a national CO2 cap-and-trade program for the electric power sector that is equivalent to RGGI, or a scenario where RGGI sunsets once a national program is implemented, would obviate any potential for emissions leakage.[1]	
Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	**Options for Addressing Competitiveness Impacts**
Ongoing measurement of leakage using electricity market information (regional market data). Changes relative to a historical baseline used to identify impacts.	Participating states have agreed to prioritize leakage mitigation measures that have demonstrated effectiveness and that can be implemented quickly, and do not seek to implement a relative to more complex measures that would require greater implementation lead times and pose significant implementation challenges that may limit their effectiveness.[2]

Review of Proposed Options for Addressing Industrial Competitiveness Impacts

Goals	
Transitional support to trade and carbon exposed sectors who can demonstrate hardship impacts with carbon pricing As more jurisdictions increase carbon price, exposure reduces and transitional support is phased-out	
Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	**Options for Addressing Competitiveness Impacts**
Firms must be trade and energy exposed, and have demonstrate hardship relative for baseline firm profits.	Output-based allocations (gratis) transitioning to an increasing share of auction as risks mitigate. Other measures such as border carbon adjustments and income tax relief (tax shifting from allowances) are viable options, but secondary strategies beyond OBA. Safety value in place to address rising concerns over misalignment with trading partners. A new governance structure monitors relative carbon prices and competitiveness risks, and adjusts policy accordingly on five year increments.
Policy, Proposal or Analysis	
Aldy, Joseph E. and William A. Pizer. *The Competitiveness Impacts of Climate Change Mitigation Policies*. Pew Center on Global Climate Change, 2009. Available at http://www.pewclimate.org/international/CompetitivenessImpacts.	
Goals	
Quantify the potential competitiveness effect of domestic greenhouse gas regulation on U.S. manufacturing industries, and outline range of policy options for addressing these impacts	
Metrics/Methods for Assessing Competitiveness Impacts and Defining Vulnerability	**Options for Addressing Competitiveness Impacts**
The competitiveness effect is the economic impact on a firm arising from the fact that it faces a carbon price while its competitor in another state or country faces no or a lesser carbon price. It is important to distinguish the "competitiveness" effect from the broader economic impact on a given industry or firm. Mandatory climate policy will present costs for firms regardless of what action is taken by other countries or regions. In the case of energy-intensive industries, one potential impact of pricing carbon could be a decline in demand for their products as consumers substitute less GHG-intensive products. This is distinct, however, from the international or inter-regional "competitiveness" impact of GHG regulation The Pew report analyzes 20 years of data in order to discern the historical relationship between electricity prices and production and consumption in more than 400 U.S. manufacturing industries. On that basis, the analysis then projects the potential competitiveness impacts of a U.S. carbon price, assuming no comparable action in other countries. The analysis assumes a CO_2 price of $15 per ton. (The U.S.	A number of targeted measures can be pursued within a cap and trade program • Allowances revenue could be used to provide targeted relief through lower taxes on capital for affected energy-intensive firms, or lower payroll taxes on workers. • Free allocation of allowances could be scaled to offset output losses resulting from competitiveness impacts due to climate policy (e.g., if a plant's production drops by 10 percent – 7 percent from a shift in consumption and 3 percent due to competitiveness impacts, then free allowances could be granted equal in value to 3 percent loss in output). • Emissions allowances can also be freely allocated in a manner that subsidizes production (similar to output based allocation of Inslee-Doyle and Waxman-Markey approaches, above).

Energy Information Administration's core case analysis of the Lieberman-Warner cap-and-trade bill estimated a 2012 allowance price of $16.88 per ton CO_2). The analysis finds an average production decline of 1.3 percent across U.S. manufacturing, but a 0.6 percent decline in consumption, suggesting a competitiveness effect of 0.7 percent. For energy-intensive industries (those whose energy costs exceed 10 percent of shipment value), the analysis projects that average U.S. output declines about 4 percent. However, consumption declines 3 percent, so that only a 1 percent decline in production (or one-fourth of the total decline) can be attributed to an increase in imports, or a loss of competitiveness. For specific energy-intensive industries, including chemicals, paper, iron and steel, aluminum, cement, and bulk glass, the analysis projects a competitiveness impact ranging from 0.6 percent to 0.9 percent, although within certain subsectors, the impact could be higher. The analysis demonstrates very clearly that most of the projected decline in production stems from a reduction in domestic demand, not an increase in imports. Most of the projected economic impact on energy-intensive industries reflects a move toward less emissions-intensive products. At the price level studied, the projected competitiveness impacts, as well as the broader economic effects on energy-intensive industries, were fairly modest.

WCI Reporting Committee Releases Regional Emissions Database White Paper

The white paper, prepared by The Climate Registry, is intended to educate the Committee and stakeholders on fundamental design choices for the WCI regional emissions database, including options for managing data and designing functions. A stakeholder conference call to review and discuss the white paper will be held on August 17. (See Upcoming Events for details.) Stakeholder comments should be submitted through the WCI website by September 4.

WCI Cap Setting and Allowance Distribution Committee Releases Draft Statement of Principles on Competitiveness

The purpose of the statement of principles is to guide the process by which the WCI Partner jurisdictions will evaluate the competitiveness effects of a regional cap-and-trade program. The principles serve as the foundation for a common approach to addressing competitiveness issues agreed upon by WCI partner jurisdictions. As part of the principle development process, the Committee analyzed how other program and proposals address competitiveness. A summary of these other programs and proposals in addition to the draft statement of principle are posted on the WCI website. Public comments should be submitted through the website by August 28.

Other documents recently released by the WCI and distributed via the WCI listserv include:

Upcoming Events

August 17: WCI Stakeholder Call to Discuss Regional Emissions Database White Paper

The WCI Reporting Committee will be hosting a call on August 17, from 9:30 - 10:30 a.m. (Pacific) to review and discuss its recently-released Regional Emissions Database White Paper. To join the call, dial 1-800-868-1837 (toll free) or 1-404-920-6440 (direct dial), and enter participant code 659537#.

August 20: WCI Stakeholder Update Call

The WCI Partners will be hosting a stakeholder update call on August 20 at 12:30 p.m. Pacific. To join the call, dial **1-800-868-1837** (toll free) or 1-404-920-6440 (direct dial), and enter participant code **659537#.**

September 16: WCI Partners Meeting

The next WCI Partners meeting will be at the Radisson Hotel Admiral Toronto-Harbourfront, 249 Queen's Quay West, Toronto, Ontario. Stakeholders are invited to attend in-person or via teleconference from 9:00 a.m. to 4:00 p.m. Eastern time. To join by teleconference, dial 1-800-868-1837 (toll free) or 1-404-920-6440 (direct dial), and enter participant code 659537#. Further details will be posted to the WCI website when available.

- Announcement on implementing the first jurisdictional deliverer approach,
- Final Essential Requirements for Mandatory Reporting, and
- Offset Definition and Eligibility Criteria White Paper.

These documents are available on the WCI website. Written comments are being accepted on the offset white paper and should be submitted through the WCI website by August 21. Phase III economic modeling results are not likely to be available until September.

WCI Undertakes Eastern Electricity Emissions Leakage Study

With technical assistance from Navigant Consulting, the WCI has initiated an eastern electricity emissions leakage study for Manitoba, Ontario, and Quebec. The study will address the concern that reductions in fossil-fired electricity generation within these jurisdictions may be offset by increases in fossil-fired generation in non-WCI jurisdictions that is then imported into WCI jurisdictions. The study should be completed in October.

Offsets Committee Seeking Proposals to Review Existing Protocols

The Offsets Committee has identified a number of existing offset protocols potentially suitable for use in the WCI cap-and-trade program and is seeking contractor support to evaluate these proposals against WCI draft offset criteria and identify which are suitable for adoption as-is and which could be suitable for adoption with minor modifications. The Committee's request for proposals is posted on the WCI website. Proposals are due August 21.

WCI Submits Comments on Canadian Proposed Offsets System

Analysis and Studies Underway

WCI Priorities in Light of Federal Activities

Recently Released Materials

Partners are continuing to develop the materials described in the 2009-2010 work plan to meet their objective of putting the WCI program in place by January 1, 2012. Recently released documents include:

- *Offset Limit White Paper* - released on May 19. Final recommendations will be coming in September.
- *Early Reduction Allowances White Paper* - released on May 19. Final recommendations are anticipated in October.
- *Offset Definition and Eligibility Criteria White Paper* - released on July 23. Comments were requested by August 21 and discussed on a stakeholder call held August 27.
- *Draft Statement of Principles on Competitiveness and Review of Options* - released on August 6 and currently open for comment. Comments are requested by August 28.
- *Regional Emissions Database Options White Paper* - released August 6 and currently open for comment. Comments are requested by September 4.

As always, the WCI Partners appreciate stakeholder review of these and future documents

Program Design Milestones

WCI Partners recently achieved two program design milestones:

- The Essential Requirements for Mandatory Reporting were released on July 16.
- A decision on how to implement the First Jurisdictional Deliverer (FJD) approach was announced on July 21.

Comments on Canadian Proposed Offsets System

WCI recently submitted written comments to Environment Canada on the Canadian Offsets System draft documents: Program Rules and Guidance for Project Proponents and Program Rules for Verification and Guidance for Verification Bodies. The letter accounts for WCI's perspectives and concerns on the current draft federal offset system design. The letter focuses on areas of the offset program design that the WCI has completed, although other areas are of interest, such as the length of the liability period, the mechanism to ensure replacement of credits in the event of a reversal, and the application of incrementality.

Analysis and Studies Underway

- WCI Partners recently released two RFPs to support program development. An RFP to develop methods and conduct data analysis to support cap setting was awarded to Pechan, and work is underway on this effort. Partners are currently evaluating proposals that were received for an RFP to review existing offset protocols.
- The WCI Partners have initiated a study of leakage potential for the electricity system in the eastern Canadian provinces, which should be completed in October.
- The Economic Modeling Team is completing the Phase III Economic Modeling Results and Revised Assumptions Book. Results will be released this fall.

WCI Priorities in Light of Federal Activities

WCI Partners are mindful of the developments in both the Canadian and United States national governments. The WCI program design recommendations were developed to stand-alone as a regional program, to be a model for national action, to be integrated into national programs, or be implemented in conjunction with programs that might ultimately emerge from the federal governments of Canada and the United States. Some of the ways WCI Partners are working to influence the federal debate are noted below. See the WCI website for further details.

- ***Comments on Federal Activities*** - WCI Partners have commented and are continuing to comment on federal activities in both Canada and the U.S. In addition to submitting written comments on the Canadian Offsets System draft documents (see article, above), WCI has submitted written comments on the Waxman-Markey legislation (April), oral and written comments on the U.S. EPA proposed mandatory reporting rule (June), and written comments on U.S. EPA's proposed endangerment findings for GHGs (June) Partners are currently working on comments to the U.S. Senate for its deliberations on a pending energy and climate bill.

- ***Regional Collaboration*** - As discussed at the Partner meeting in Portland in July, WCI Partner jurisdictions have initiated discussions with the other two regional programs in North America: the Regional Greenhouse Gas Initiative (RGGI) and the Midwestern Greenhouse Gas Reduction Accord. Collaborating in key areas will expand the footprint of each of the regional program designs, particularly in the area of offsets, and helps influence developments in the national programs.
- ***Development of a Mandatory Reporting Program***- The WCI Partner jurisdictions recognize that an initial point of intersection between federal efforts in the U.S. and the WCI program is the mandatory reporting program. The WCI Partner jurisdictions have advocated that U.S. EPA adopt the WCI Essential Requirements. However WCI expects that the final U.S. EPA reporting rule will deviate in some respects from the WCI Essential Requirements, and consequently expects to harmonize some aspects of the WCI Essential Requirements with U.S. federal requirements once the EPA rules are final. The WCI is committed to doing so as quickly as possible after the EPA rules are final, and is equally committed to preventing double reporting burdens for entities that would potentially be required to report to both a state and U.S. EPA. Similarly in Canada, there is a dialogue underway between the four WCI provinces and the Canadian federal government to inform them about the WCI Essential Requirements.
- ***Focusing Work to Influence the National Program*** - WCI Partners are focusing current work on those areas with a high potential to influence the national programs. These areas include: Offsets, including the quantity and quality of offsets included in the program; Competitiveness Analysis, focusing on approaches for identifying risk of leakage and program design options to address the risks; and Complementary Policies, recognizing that states and provinces have been and will continue to be leaders in areas essential to a comprehensive climate change program. In each of these areas, WCI work is timely and important for the national debate.

<u>**Wednesday, September 16, 2009**</u>

9:00 am	**Convene (Salon B – 3rd Floor)** Welcome and Introductions Agenda Review
9:15 am	**Offset Limit White Paper** Purpose: Discuss Partner comments on the draft recommendations for the offset limit mechanism. Approve release for stakeholder review and comment.
10:15 am	**Mandatory GHG Reporting Protocol for the Oil and Gas Sector** Purpose: Discuss options for WCI Reporting Committee development of a mandatory GHG reporting protocol for the oil and gas sector.
10:45 am	**Break**
11:00 am	**Offset Definition and Eligibility Critera** Purpose: Update from the Committee on the comments received and approach for developing recommendations on the proposed definition and criteria. Provide Partner direction for continued Committee deliberation.
12:00 pm	**Lunch (***attendees are on their own for lunch***)**
1:30 pm	**WCI Interaction with Federal Governments** Purpose: Discuss ongoing activities to interact with federal governments in U.S. and Canada.

2:00 pm **Update on WCI Electricity Team**

Purpose: Apprise stakeholders of modified organization and new leadership.

2:15 pm **Briefing on Market Oversight Issues**

Purpose: Receive Partner feedback on market oversight issues being examined by the Markets Committee.

2:45 pm **Break**

3:00 pm **Briefing on Auction Design Issues**

Purpose: Receive Partner feedback on auction design issues being examined by the Markets Committee.

3:30 pm **Open Comment Period**

4:00 pm **Adjourn**

Markets Committee
Parameters of Auction Design

Markets Committee Overview

September 16, 2009
Toronto, Ontario

Markets Committee Mission

- Coordinate the development of recommendations on issues and elements needed to guide the proper development and operation of a robust allowance and offset credit trading market.

Auction Parameters

- following parameters are essential in defining the structure of the auction:

Auction Format
Reserve Price
Unsold Allowances
Vintages
Lot Size

Timing and Frequency of Auctions
Participant Access
Financial Assurance
Information and Transparency
Preventing Market Manipulation

Parameters Discussion

Auction Format:

- how participants can bid on allowances, for example:

  a) Sealed Bid Single Round

  b) Ascending/Descending Clock multiple rounds

Reserve Price:

- the minimum allowance price that the seller will accept.
- the existing WCI position is that the first 5% of allowances auctioned will have a reserve price.

Parameters Discussion Cont.

Unsold Allowances:

- may occur if the reserve price is higher than the auction market clearing price.
- can be retired, rolled forward, or held as a contingency.

Vintages:

- vintage allowances are sold prior to the compliance period for which they become valid.
- vintages help with price discovery but also increase the complexity of auction.

Parameters Discussion Cont.

Lot Size:

- refers to the number of allowances bundled together for offering as an action unit.
- smaller lot size allows flexibility in the bidding strategy and makes auction participation more affordable for non-compliance entities.
- smaller lot size would increase auction transaction costs due to an increase in the number of lots for sale.

Timing and Frequency of Auctions:

- benefits to frequent auctions include market liquidity, price stabilization and discouraging collusion.
- frequent auctions also increase administrative costs.

Parameters Discussion Cont.

Participant Access:

- restricting access to the auction may benefit compliance entities.
- open access increases market liquidity.

Financial Assurance:

- often required from bidders to ensure they are able to cover the value of their bids (e.g., bonds, letters of credit).
- prequalification of participants is essential to the integrity of the auction.
- prevents defaults.

Parameters Discussion Cont.

Information and Transparency:

- transparency builds trust with stakeholders, covered entities and increases the integrity of the auction program.

Preventing Market Manipulation:

- there are several ways to minimize collusion, manipulation and hoarding. For example:
  - Encouraging many bidders to participate in the auction.
  - auction monitoring, single round bidding, sealed bidding and uniform price method.
  - Preventing participants from purchasing more than a certain amount of allowances at a single auction.
  - Maintaining an open and transparent auction.

Other Jurisdictions

- Regional Greenhouse Gas Initiative (RGGI)
- United Kingdom – European Trading System (UK ETS)
- Australia: Carbon Pollution Reduction Scheme
- US Environmental Protection Agency: SO_2
- US Treasury: Sale of Treasury Bills

Jurisdictional Review:

Regional Greenhouse Gas Initiative

Auction Format	Single round, uniform-price sealed-bid auction
Reserve Price	$1.86
Unsold Allowances	Are to be sold at the next auction
Vintage	Sells future vintages
Lot Size	1,000 tons
Timing and Frequency	Auctions are held quarterly, in each year of the compliance period
Participant Access	Interested entities must register to obtain access to auctions
Financial Assurance	Participants must submit financial assurance before the auction
Information and Transparency	After each auction, results and auction assessment are released. This is produced by a third party
Monitoring	Third party observation

Jurisdictional Review Cont.

UK European Trading System (ETS)

Auction Format	Single round uniform price auction and a non-competitive bid process
Reserve Price	Not announced in advance. Based on a prevalent secondary market price at the time of the auction
Unsold Allowances	Unsold allowances are sold in future phase II auction
Vintage	No yearly vintages
Lot Size	1,000 in the competitive portion. Max bid of 10,000 allowances in the non-competitive portion
Timing and Frequency	Quarterly. May increase frequency
Participant Access	Mandatory use of primary participants (also called intermediaries)
Financial Assurance	Handled through primary participants
Information and Transparency	Limited information released after the auction
Monitoring	Independent third party monitors the auction and reports on the execution

Jurisdictional Review Cont.

Australia: Carbon Pollution Reduction Scheme

Auction Format	Sealed proxy bids
Reserve Price	Based on market price
Unsold Allowances	Currently being finalized
Vintage	One of the monthly auctions will sell allowances for the current year plus the three following compliance periods
Lot Size	Details are currently being finalized
Timing and Frequency	Held monthly, 16 auctions per vintage
Participant Access	No intermediaries, open to all
Financial Assurance	Subject to financial assurance to participate in auction
Information and Transparency	Auction results will be made public
Monitoring	Independent panel to review operation after it launches. Market manipulation will be investigated and prosecuted

Jurisdictional Review Cont.

US Environmental Protection Agency SO_2

Auction Format	Single round discriminatory price. Descending order
Reserve Price	No reserve price
Unsold Allowances	EPA returns proceeds and unsold allowances
Vintage	Both spot allowance auction and an advance auction (that can be used for compliance 7 years after the transaction date
Lot Size	Can purchase as little as 1 allowance. 1 allowance = 1 ton
Timing and Frequency	Occurs once per year
Participant Access	Open to any qualified bidder
Financial Assurance	Each bid must include a wire transfer or certified check or letter of credit for the total bid cost
Information and Transparency	Share as much data as possible. Details are available through online queries
Monitoring	No rule preventing a buyer from purchasing all allowances sold via auction

Jurisdictional Review Cont.

US Treasury: Sale of Treasury Bills

Auction Format	Sealed bid uniform price. Competitive and non-competitive bids. In a single auction, an investor can buy up to $5 million in bills by non-competitive bidding or up to 35% of the initial offering amount by competitive bidding
Reserve Price	N/A (treasury bills typically sold at a discount from the par amount)
Unsold Bills	
Vintage	N/A
Lot Size	$100.00
Timing and Frequency	All bills except 52-week bills and cash management bills are auctioned every week
Participant Access	Competitive and non-competitive bidders (Corporation, Government-related entity, trust or fiduciary estate, individual, foreign and international monetary authority, other)
Financial Assurance	Depends on bidding method. Treasury direct requires debit entry to a deposit account or submission payment with a bid
Information and Transparency	Results of all public auctions are released in a press release after each auction. Available on website
Monitoring	Penalty for non-compliance of the auction rules or failure to pay for issued securities

Questions?

Western Climate Initiative

National Clean Car Standards

WCI Partners Meeting
Toronto, Ontario
September 16, 2009

Introduction

- An agreement was successfully struck between the Obama administration, the auto makers and the California Air Resources Board.
- The agreement was announced by President Obama on May 19, 2009.

Three Part Agreement

- The agreement has three parts:
  - Federal notice of intent for joint rulemaking by the U.S. Environmental Protection Agency (EPA) and National Highway Traffic Safety Administration (NHTSA).
  - A commitment letter from the California Air Resources Board.
  - Commitment letters from each auto manufacturer and their industry groups.

Overview of the Agreement

- The national 50 states GHG standards will be developed by EPA and NHTSA and will start in model-year 2012, and go to 2016.
- In 2016, the national standard will be the same as the California (Pavley 1) standard.
- Expectation California's waiver for model-years 2009 to 2016 will be approved by EPA.

Overview of the Agreement (con't)□

- California does not give up any authority under the Clean Air Act.
- California will amend its rule to allow compliance with the national standard between 2012 and 2016 to be recognized as complying with the California (Pavley 1) standard.
- The auto industry will drop its lawsuits challenging the California (Pavley 1) standards.

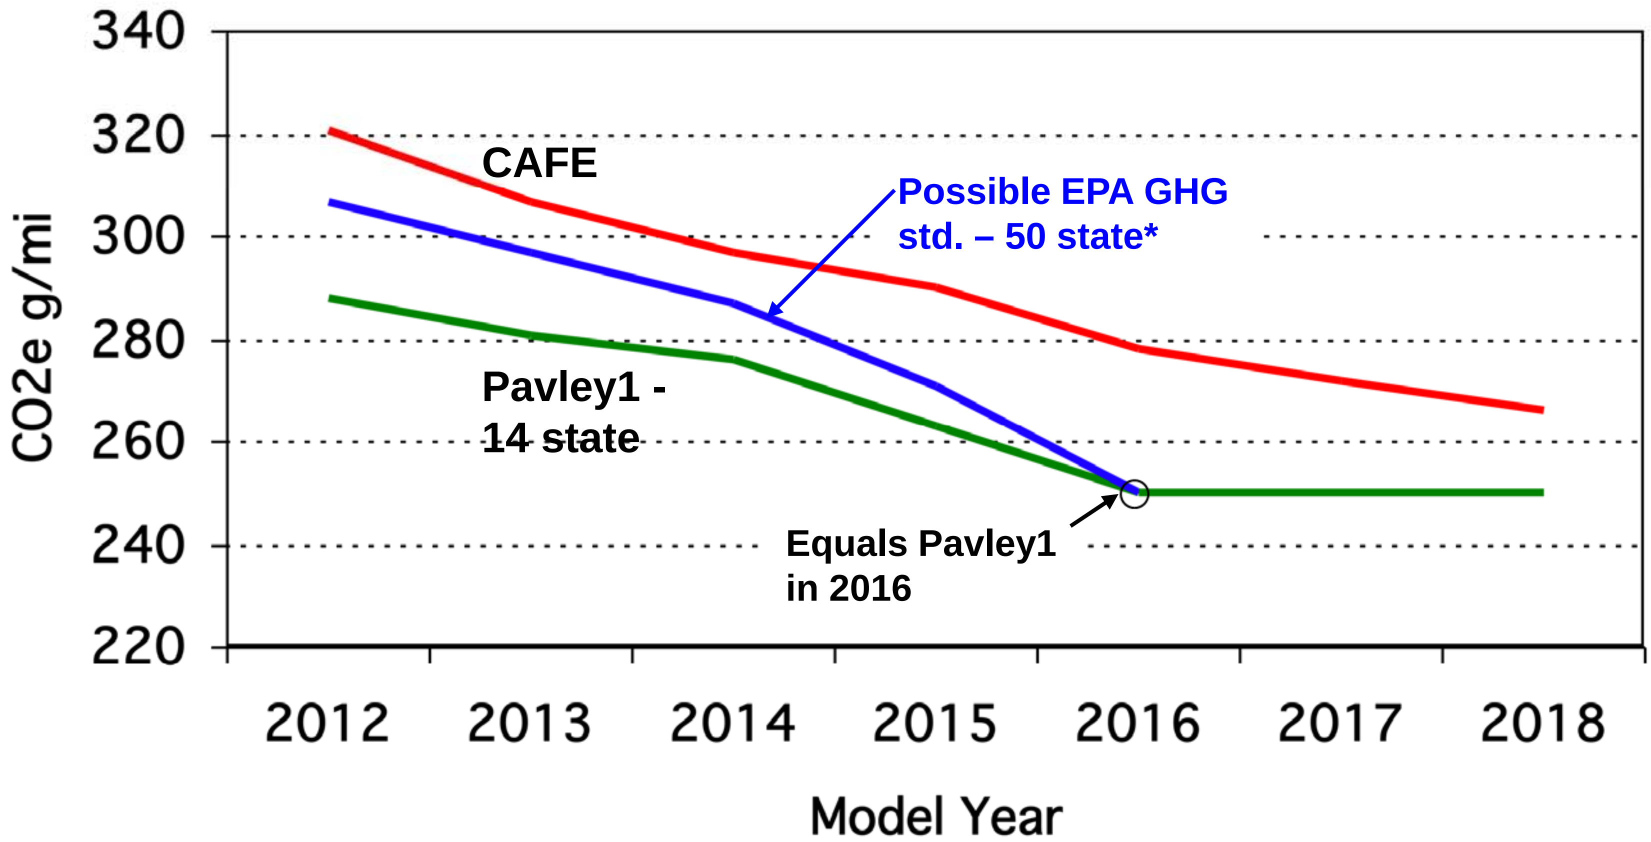
Status of the Agreement

- EPA NPRM for national vehicle GHG standards
  - Released this week (September 15)
- ARB amendments to Pavley 1
  - Board hearing on pooling – September 24
  - Board hearing on accepting National compliance – December 2009
- California Waiver
  - Granted by USEPA on June 30, 2009
  - Dealers/Chamber filed suit last week
- Autos drop lawsuits
  - Done, except NM suit by dealers

GHG Reductions Impact

- California will enforce GHG standards for model-years 2009 to 2011.
- For model-years 2012 to 2016, the national GHG standards developed jointly by EPA and NHTSA will be in effect.
- In 2016 the California (Pavley) standard and the national standard will be the same (250 g/mi).
- ARB/EPA coordinating on post-2016 standards

Pavley 1 – CAFÉ - National GHG Comparison of Stringency



*Pre-NPRM understanding

Pavley 2

- Development of GHG standards for 2017-2025 has begun
  - Likely technologies to further reduce GHG emissions:
    - Wider-spread use of conventional hybrids
    - Lighter weight vehicles
- Schedule
  - Workshops begin this fall
  - Hearing - summer 2010

ZEV 2

- New focus on GHG emission reduction
  - Complements Pavley 2
- Goal: Assure very low carbon vehicles achieve early commercialization
  - Vehicles capable of 80% less GHG emissions
  - BEVs, PHEVs, FCVs
  - Needs to happen by ~2020 to achieve 2050 goal of 80% GHG reduction for 1990 levels
- Schedule
  - Preview of ZEV2 policies: December 2009
  - Board hearing to adopt: October 2010

Western Climate Initiative

Market Architecture and Oversight

Partner Meeting, Toronto, Canada

September 16, 2009

Objectives

- "The recommended design will provide opportunities to obtain low-cost emission reductions through emission trading, allowance banking, and inclusion of an offsets component."

WCI Design Recommendations, September 23, 2008

- "The WCI Partner jurisdictions and stakeholders want appropriate safeguards and oversight of the allowance and offset credit trading markets and want them to function efficiently."

Materials for Markets Workshop, April 9, 2009

Architecture and Oversight

- “Market Architecture:” Market participants and institutions, and the connections between them
- “Market Oversight:” The regulators’ relationship with the market

Markets Committee

- Purpose of Market Architecture and Oversight task is "to provide recommendations that are designed to ensure that the allowance and offset credit trading market is organized properly to operate reliably and prevent or minimize manipulation."
- Public workshop April 9, 2009 in Seattle
  - Principles to guide Committee
  - Questions for stakeholders

Types of Markets: A Convenient Taxonomy

- Primary: Initial distribution of allowances issued by governments (auction, sale, or allocation).
- Secondary: Trading of allowances by participants for immediate delivery
- Derivatives: Value based on another instrument (e.g., a contract based on the price of allowances)

Secondary Markets

- WCI tracking system
  - Major part of architecture of market
  - Rules for system a significant part of oversight choices
  - Important resource for monitoring

Ways to Trade Allowances

- "Over the Counter" (OTC) transactions
  - Between two (or more) parties
- Exchanges
  - Standardized terms
  - Clearing
    - Centralized counterparty
    - Margin requirements
  - Data recording and disclosure requirements
  - Position limits

Derivatives

- Allowance market expected to have some volatility
- Derivatives can be used for risk management
  - E.g., electricity generators may lock in power prices and fuel prices for a period of time, and ensure an operating margin
- OTC and exchange structures similar
- Derivatives markets can be larger and more active than spot markets

Market Participants

- Could be a wide variety: Compliance entities, brokers, investors
- Have heard calls to limit access to markets to compliance entities
  - Could be difficult to implement
  - Counterarguments are that broad participation can add liquidity, reduce opportunities for exercise of market power
  - Requires assumption that compliance entities form an exclusive class that is somehow different from class of all participants

Monitoring

- Develop WCI in-house capacity
- Rely on existing regulators (US Commodity Futures Trading Commission, provincial Securities Commissions)
- Contract with independent monitor
- Role of public information

Questions?

WCI Markets Committee

Co-Chair Jim Whitestone, Ontario

Jim.Whitestone@ontario.ca

Co-Chair Michael Gibbs, California

mgibbs@calepa.ca.gov

April 9, 2009 Stakeholder consultation documents and comments available at http://westernclimateinitiative.org/public-comments/document/2

Offset Committee Task 1

Task 1.1: Definition of a WCI emissions offset and Task 1.2: related eligibility criteria for offset projects

1. Identify options for a definition of a WCI emissions offset and related eligibility criteria for offset projects
   - White paper released July 24, 2009 for stakeholder input
2. Analyze options and stakeholder input
   - Draft Recommendations paper Sept/Oct 2009 for stakeholder input
3. Recommendation with stakeholder input and any further analysis required
   - Final Recommendations paper December 2009

Offsets Committee White Paper

The Offset Committee solicited stakeholder feedback on options to inform recommendations to WCI Partner jurisdictions.

- What has been your experience with the offset system examples cited in this paper?
- What have been the advantages and disadvantages to their approaches?
- Are the appropriate criteria listed?
- Does the paper include the appropriate options for each criteria?
- Are the implications of the options appropriately covered?

Definition of an offset

Many suggestions offered on definitional issues.

Supporting principles and technical considerations:

1. Ownership Issues
   - Need clear expectations for evidence of ownership
2. Use of Approved Protocols
   - Strong support to adopt and adapt existing protocols
3. Geographic Limits
   - Support for WWCI approach
4. Implementation options
   - Majority of support for general description of an offset with detailed requirements in a separate section

Real

Some suggestions of what constitutes Real

Supporting principles and technical considerations

1. Quantification
   - Support for rigorous, scientifically sound approached building on existing knowledge
2. Uncertainty and accuracy
   - Support for assessing uncertainty with guidance and standard approaches in protocols
3. Conservativeness
   - Support for the principle with guidance on evidence
4. Leakage
   - Support to address in protocols to streamline

Additional

Strong support for performance standards with the understanding that they will not apply in all cases and some flexibility should be incorporated

Supporting principles and technical considerations

1. Baseline
   - Main concern is interpretation of additionality in baseline development
2. Eligibility Date
   - General support for pre-2012 start
3. Crediting Period
   - Support for 10 years or less with opportunity to renew, longer for forest projects

Permanent

Support for 100 year definition

Support for a buffer pool, reserve or holdback.

Other options for risk mitigation

Verifiable

Strong support for third party verification

Supporting principles and technical considerations

1. Validation
   - Less support for validation
2. Enforcement
   - Few comments, likely indicates agreement with necessity (white paper contained discussion only, no explicit options)
3. Material
   - Support for 5%, no objections

Other considerations

Supporting principles and technical considerations

1. Transparency
   - Support for transparent process, different interpretations
   - Public involvement/consultation at important decision points highlighted
   - Support for publicly available documents
2. Co-Benefits
   - Near-universal lack of support for requiring
3. Environmental and social impacts
   - Mixed support for assessment

Offset Committee Task 1

Task 1.1: Definition of a WCI emissions offset and Task 1.2: related eligibility criteria for offset projects

1. Identify options for a definition of a WCI emissions offset and related eligibility criteria for offset projects
   - White paper released July 24, 2009 for stakeholder input
2. Analyze options and stakeholder input
   - Draft Recommendations paper Sept/Oct 2009 for stakeholder input
3. Recommendation with stakeholder input and any further analysis required
   - Final Recommendations paper December 2009

Western Climate Initiative

Offset Limit Recommendation Paper

September 16, 2009

CSAD Committee Recommendation to Partners

CSAD Task 5 Committee
Scope of work

- The September 2008 Design Recommendations for the WCI Regional Cap-and-Trade Program specify that a majority of emission reductions required under the program occur at covered entities and facilities :
  - limit use of offset credits and allowances from other systems to no more than 49% of the total emission reductions from 2012-2020.
- The committee limited its work at how this limit could be implemented.

5 Principles

- **Fairness** : to provide fair access to offset markets for offsets offset project developers and covered entities.
- **Economic Efficiency** : to assure efficient market operations and least cost reductions (an offset limit should not unduly inhibit the realization of the least-cost offsets).
- **Cost containment** : help contain compliance costs and maintain fungibility across the WCI.
- **Effectiveness and enforceability** : to ensure that the limit is enforceable and is effective at achieving the WCI goal that offsets are supplemental to emission reductions at covered sources.
- **Administrative simplicity and cost** : to provide a clear path forward and to minimize administrative costs to all parties.

Offset Limit White Paper

- **White Paper issued May 19, 2009**
- **Options for implementing the limit :**
  - general approach (use vs. supply)
  - across jurisdiction (common vs. differentiated)
  - over time (equal absolute number, percent, 49%, ...)
- **Workshop in Seattle (Washington) May 28th, 2009**
- **Consultation period :**
  - about 20 written comments from industry associations, environmental NGOs, electric utilities, power industry representatives, financial institutions, carbon market participants, and individual firms in the cement, aluminum, forest product, and petroleum industries.

Stakeholders' input

- **General approach to limiting offsets :**
  - Strong preference for limiting the use rather than the supply and for reflecting this limit as a percentage of an entity's compliance obligation;
  - Few support for a "surrender certificate" approach.

- **Implementation across jurisdictions :**
  - Split between common and differentiated limits.

- **Implementation over time :**
  - Range of options : equal absolute amount, fixed percentage, higher percentage in early years, no restriction, ...
  - Carry-over of unused offsets from one compliance period to the next.

Committee recommendation (1)

- The Committee recommends a **use limit** be applied at the **entity level**, more precisely as a **percentage of compliance obligations** (i.e. emissions):
  - Compared to a supply limit, a use limit should result in lower overall compliance costs for covered entities;
  - Provides predictability for covered entities;
  - Administratively simple to implement; and
  - Tends to minimize both administrative and compliance costs of the program relative to a supply limit.

Committee recommendation (2)

- The Committee recommends a **common use limit** be implemented **across Partner jurisdictions** :
  - Provides equal access to offsets to entities across the WCI cap-and-trade system, and helps to ensure that the overall limit would not be exceeded.

- Jurisdictions could still adopt a lower limit lower.

- The CSAD Task 3 (competitiveness) group will consider whether the common use limit might pose competitiveness concerns for entities in jurisdictions that have adopted lower emission targets relative to historical levels, and if so, how to address these concerns.

Committee recommendation (3)

- The Committee recommends that the limit be set at an **equal percentage of compliance obligations across compliance periods**:
  - This option would allow for the use of a greater absolute number of offset credits in earlier compliance periods (adjusting for the expansion of program scope in 2015), thus easing the transition into the cap and trade program.

Committee recommendation (4)

- The Committee also recommends the implementation of region-wide "**carry-over**" approach:
  - Under such an approach, if the total amount of offsets used across WCI in a given compliance period are less than the total amount of offsets allowed, then the difference in these two amounts would be added to the subsequent period's offset limit (in absolute terms), with the percentage offset limit adjusted appropriately.

- The committee recommends adopting a "**region-wide**" rather than "entity-specific" carry-over approach:
  - simplicity, lower administrative cost, transparency, and ability to enable fuller overall use of offsets.

"Region-wide Carry-over" : an example

- Offset limit : 5% of compliance obligations (i.e. emissions)
- First compliance period : 1 000 kt
  - allow up to 52 631 offset credits to be used
- Second compliance period : 900 kt
  - allow up to 47 368 offset credits to be used

- If only 40 000 offset credits are used for compliance in the first period then, under a carry-over mechanism :
  - we would allow 59 999 offset credits (47 368 + 12 631) to be used in the second compliance period
  - which would increase the offset limit to 6.25% of compliance obligations (1-(900 000/959 999))

EU ETS
Setting the Cap

Jill Duggan
Visiting Senior Fellow
World Resources Institute
September 2009

Phase I 2005 – 2007

- In line with the Directive – *Prior to 2008, the quantity shall be consistent with a path towards achieving or over-achieving each Member State's target under Decision 2002/358/EC and the Kyoto Protocol*
- And *consistent with the potential, including the technological potential, of activities covered by this scheme to reduce emissions.*

UK experience Phase I

- Sector level data
- Projections of BAU
- Political decision
- Top down bottom up approach – cap top down, share of allocation – bottom up
- using historical emissions data 1999 – 2002 average dropping lowest year (but other MSs used different methods)
- The total quantity of allowances allocated in the first phase of the EU ETS (2005-7) was 736.3 MtCO2.
- This was around 65 MtCO2 (around 8%) below projected emissions of the installations covered by for that period.

Process for approval

- Member States presented plans to Committee of all states for challenge and then to the Commission
- European Commission called for cuts to total allocation equivalent to 220 million per annum
- Process was long and drawn out – Polish and Italian plans approved in 2006!

What happened

- During 2005 and early 2006 prices had jumped whenever a plan was approved or allowances came onto the market
- the average price across 2005 was 17 euros a tonne, but the price had been as high as 31 euros a tonne.
- Reconciliation of first annual data – spring 2006 – and results of allocations and actual emissions in May that year
- No banking in this learning phase
- Excess allocations across most of Europe
- Price of allowances plummeted

60
Surplus / deficit of allowances (M)
Actual surplus/deficit 2006
Actual surplus/deficit 2005

What Happened Next

- European Commission announced that the plans for 2008-2012 would have to be in line with
  - Kyoto targets under the effort sharing agreement
  - The proportion of emissions covered by ETS in any member state and
  - Implementation of mitigation policy in other sectors
  - And would use verified 2005 compliance data as basis for assessment

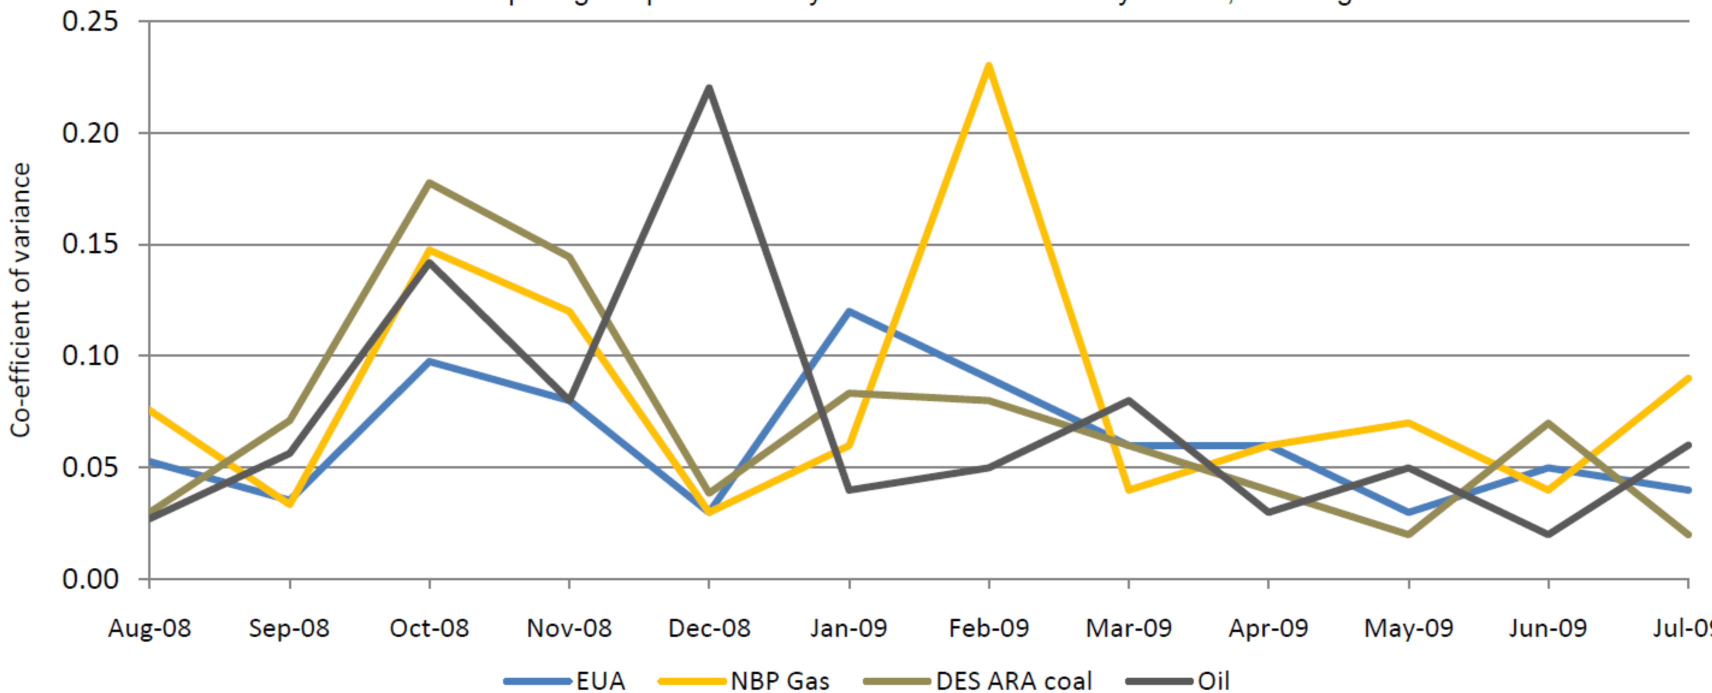
Which meant

- All but two (UK and Sweden) of first Phase II plans rejected or withdrawn – strong political will to make the ETS work (backed by UK and then by Germany)
- Harmonisation of scope brought new emissions into the system (in UK 9 mtonnesCo2, in Germany 11 mtonnes CO_2)
- Restrictions on the use of credits introduced – and a nod to the principle of supplementarity
- **But the political will following the fall helped stabilise prices and provided certainty for industry**

How's this worked to date

- Fairly stable carbon price
- Recession caused drop in price – but stabilised around 14 – 15 euros a tonnne
- 2008 – across EU only 29% of CERs allowance used for compliance – 24% in UK
- But further changes with amended legislation…..

Chart 8. Comparing the price volatility of EUAs to the volatility of coal, oil and gas



Phase III – 2012 and beyond

- 2020 package performed an ‘efficient split’ to divide the overall effort of 14% below 2005 levels (20% below 1990 levels) between the ETS and the non-ETS.
- This led to reduction targets of 21% for the ETS and 10% for the non-ETS (against 2005). Common rules for allocation – and full auctioning for electricity generators (~50% emissions)
- Effort sharing for the non traded sector

Setting the cap Phase III

- Unlike EU ETS Phases I and II, the overall cap not aggregate of the Member State caps, but set centrally, and divided up among the Member States.
- Starting point for the linear reduction factor is the average quantity of allowances issued by MSs under their NAPs – the Phase II annual cap.
- This was then increased to reflect the expanded scope of Phase III compared with Phase II, and decreased to reflect any small emitters that are opted-out of the scheme for Phase III.

ETS cap

- The Commission has published an ETS cap that is consistent with the Phase II scope of the system,
- the full cap for 2013-2020, including new sectors, by 30 June 2010.
- No end-point for linear factor but will be reviewed between 2020 and 2025.
- Therefore linear factor can be revised if new scientific evidence.
- Or the cap and linear factor will be reconsidered if the EU makes reduction commitments deeper than 20% as part of an international agreement on climate change.
- If the linear trajectory of 1.74% were followed long-term, then the EU ETS cap would reach zero in the early 2060s.

Determining Free Allocation and Auction Pot

- The Phase III annual cap will be divided free allocation for competitively traded sectors, with the remainder to be auctioned.
- This split will be done on the basis of the share of emissions in sectors eligible for free allocation over the base period 2005-2007, compared with the share of emissions in those sectors not eligible for free allocation.

Benchmarking Free Pot

- Any free allocation will be distributed according to harmonised methodologies (most likely to be product based benchmarks) and the percentage of that benchmark that the sector will receive, depending on whether the sector is determined to be at significant risk of carbon leakage or not.
- The allocation according to benchmarks could = the free allocation pot,
  - be greater, in which case the allocation will be scaled down by applying an adjustment factor
  - or smaller, in which case the remainder will be added to the auction pot.
- A very few MSs could receive free allocation for electricity production. These allowances will deducted from the auction pot that those MSs would otherwise receive

Auction Rights Allocation

- After applying the benchmarks and the percentages remainder from the free allocation pot will be added to the auction pot.
- 5% of the annual cap will be deducted from this amount and placed into the new entrant reserve to provide any free allocation to which new entrants are entitled.
  - 300m of the allowances will be set aside to fund projects to demonstrate CCS or innovative renewable technologies.
  - Any allowances remaining in the NER at the end of the phase shall be distributed to MSs to auction, taking into account the levels to which installations in those MSs have benefitted from the NER
- Remainder in the auction pot shall be divided up in the following way:
- 88% distributed among MSs according to their share of 2005 or 2005-2007 emissions.
- 10% shall be distributed to MSs according to GDP/capita
- 2% shall be distributed to MSs that in 2005, had emission levels at least 20% below their base year under the Kyoto Protocol.
- Lithuania (and countries that import more than 15% of their electricity from Lithuania), may auction some of the NER to compensate for possible increased emissions with respect to electricity production following the planned closure of a large nuclear power plant in 2009.

Member States’ *de facto* Cap

- Individual Member States will be able to estimate their *de facto* cap by combining the free allocation that would be given to industry in the various sectors in that MS, and the share of the auction pot given to that MS.
- It will be possible to calculate each Member State’s *de facto* cap more accurately towards the end of 2011, once the Community-level cap has been adjusted to take account of the change in scope of the system and the National Allocation Measures have been approved by the Commission.

The agreement on offsets

- The 50% supplementarity principle was applied to the ETS as part of the 20% target, allowing for a limited amount of additional access which can be provided in Phase III. This additional access is likely to amount to approximately 150mtCO2e and will be distributed in the following way:
  - The first method grants additional access to operators that had low levels of access in Phase II, such that all operators have access of at least 11% of their allocation in Phase II.
  - The second method considers levels of free allocation in addition to levels of access to credits.
  - New sectors and new entrants will be allowed access equivalent to at least 4.5% of their verified emissions, while Aviation will be allowed access equivalent to at least 1.5% of their verified emissions.

Qualitative restrictions on offsets

- 2013-2020 Phase of EU ETS applies same qualitative restrictions as Phase II. This means that nuclear and forests are not eligible in the system.
- All credits that were eligible for use in Phase II are eligible for use in Phase III, subject to the following additional restrictions.
  - Installations may use credits issued in respect of emission reductions that took place before 2013 or from project registered before 2013.
  - Can use CDM from projects in Least Developed Countries.
  - If no international deal Member States may use credits which have been acceptable for use in the EU ETS in 2008-12 <u>or</u> are from new projects where the baseline used is below the level of free allocation in the ETS
  - Once an international agreement can only use credits from countries which have ratified agreement.

Flowchart showing steps in division of cap

Key:
S = Sector
MS = Member State

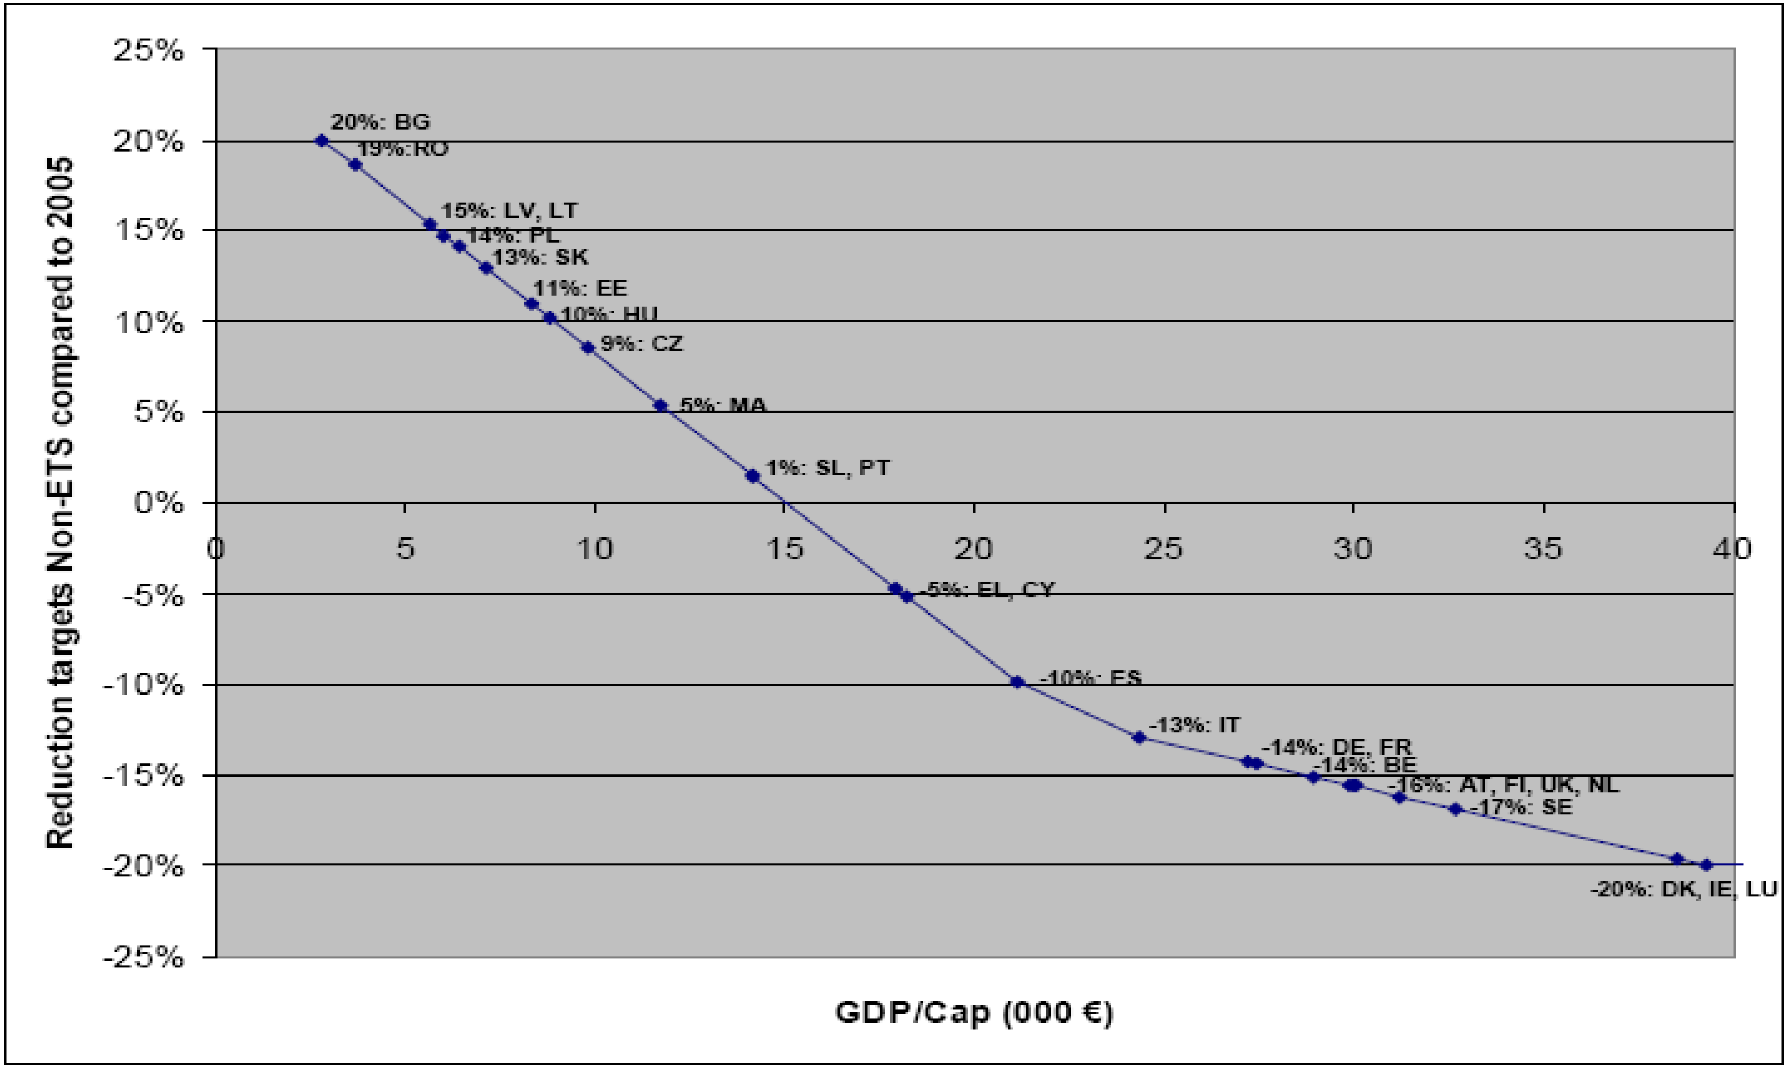
Effort Sharing Decision

- The Effort Sharing Decision covers the emissions from all sectors that are not covered by the ETS.
- This includes transport, domestic heating, agriculture, small emitters etc.
- EU Member States are legally responsible for meeting their quantified targets, and have control over their policies to deliver the reductions.

Effort sharing in the non ETS sectors

- To allocate effort to achieve 10% reduction on 2005 by 2020 in the non ETS sectors.
- For non ETS sectors a Member State’s share is based on BAU weighted by GDP per capita.
- Therefore some Member State’s emissions can increase (tho’ below BAU) whilst others have absolute emissions reductions – to achieve overall absolute emissions reductions in Europe.
- UK must reduce emissions in the non ETS sectors by 16% by 2020

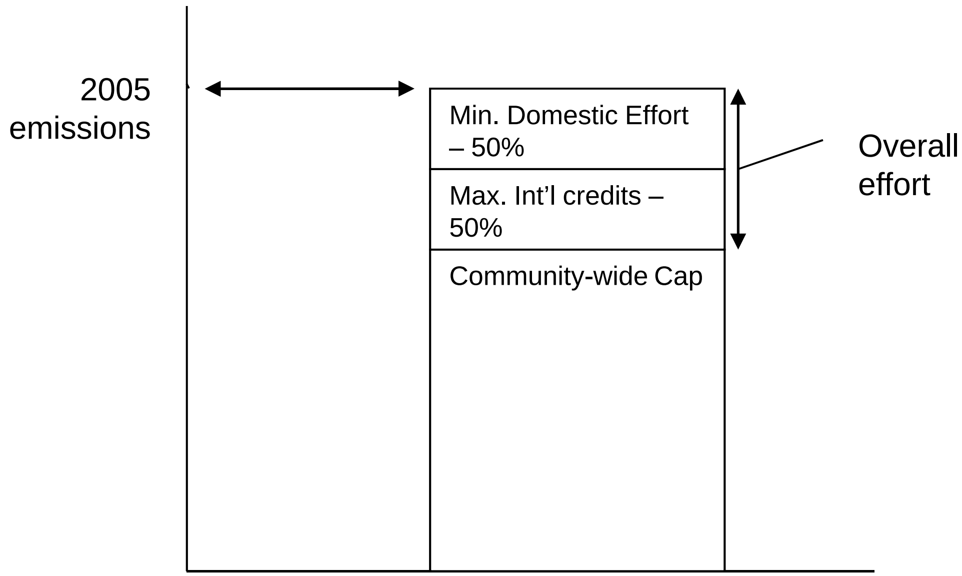
Effort sharing in the non-traded sector



Flexibilities to help meet the non ETS targets

- **Borrowing**: Member States are able to borrow a up to 5% of their emissions allocation from the following year to allow for emissions exceeding the annual allocation. In the first 2 years (2013 & 2014) before countries have had a chance to build up a stock of banked surplus, and in case of extreme meteorological conditions that have led to an increase in GHG emissions, Member States may borrow more than 5%.
- **Banking**: any unused allocation can be banked for use in subsequent years. There are no limits on the amount that can be banked or the length of time they can be banked for, up to 2020.
- **Trading**: a Member State may transfer up to 5% of their annual allocation to another Member State. There are no restrictions on level of allocations that Member State can receive this way.
- Member States may use **international project credits** up to an annual limit of 3% of their 2005 emissions. This is subject to the same qualitative requirements as for the ETS
- However, Member States are also permitted to use credits from **forestry** activities (tCERs & lCERs) provided that they are replaced by credits of equal value when they expire.

Use of offsets



Use of Auction revenues

- Member States can determine how to use auctinoing revenues, but the ETS Directive indicates that they should spend at least 50% of the proceeds from auctions on measures to tackle climate change within the EU and in developing countries.
- Appropriate use of revenues for this purpose includes: contributing to funds under the UNFCCC; development of renewable energy; afforestation, reforestation and avoiding deforestation in developing countries; forestry in the EU; CCS; low-emission transport; development of energy efficiency and low-carbon technologies; and measures to promote energy efficiency in vulnerable groups.

1 Background and Purpose

As part of the design for the WCI Regional Cap-and-Trade Program, the WCI Partner jurisdictions recommended that a rigorous offset system be developed and implemented. The purpose of the offset system is to reduce compliance costs while encouraging emission reductions, innovation, and technology development for sources and sinks not covered by the cap-and-trade program.

Offsets are GHG emission reductions, GHG emissions avoided, or GHG removals from the atmosphere, measured in metric tons of CO2e. Offsets are achieved through activities that are often referred to as “offset projects.” Offset credits (also measured in metric tons of CO2e) are issued for offsets that are achieved by offset projects that meet certain criteria. Offset credits can be traded and can be used for compliance purposes or as part of voluntary actions. When used within a cap-and-trade program, offset credits used for compliance purposes come from emission sources or sinks not covered by the cap.

The Design Recommendations for the WCI Regional Cap-and-Trade Program specify that a majority of emission reductions required under the program occur at covered entities and facilities. Consequently, for compliance purposes, the WCI Partner jurisdictions set a limit on the use of offset credits issued by WCI Partner jurisdictions, as well as the use of offset credits and allowances from other GHG emission trading systems that are recognized by the WCI Partner jurisdictions, to no more than 49 percent of the total emission reductions from 2012 to 2020. [1] This limit and rationale are established in the WCI’s Design Recommendations (September 23, 2008). This paper addresses how this limit could be implemented, rather than discussing the limit itself.

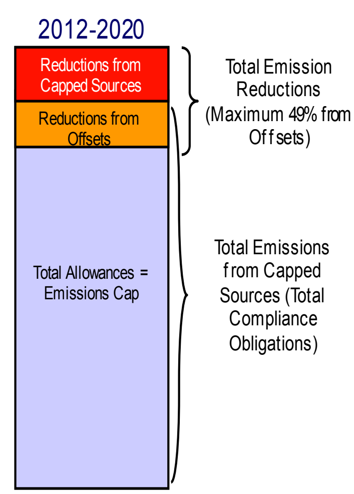

Figure 1. Illustration of the WCI Offset Limit

The offset limit is conceptually illustrated in Figure 1. The bar is comprised of three pieces. The bottom part of the bar is the total number of emission allowances issued from 2012 to 2020, a direct reflection of the emissions cap. The top two pieces combined equal the total emission reductions required of

[1] It is important to note that while we refer to the “offset limit” throughout this paper, it should be understood to encompass not only offsets issued by WCI Partner jurisdictions, but also offsets and allowances issued by other GHG emission trading systems approved for use in the system by the WCI Partner jurisdictions.

the covered entities and facilities for the period 2012 to 2020. The total required emission reductions are divided into two parts: the top part is the total emission reduction achieved at the covered entities and facilities; the second part is the total emission reduction that was achieved through offsets or allowances from other GHG emission trading systems. As specified in the program design recommendations, this second part, the offsets and allowances from other systems, can be no more than 49 percent of total emission reductions.

On May 19, 2009, the WCI Cap Setting and Allowance Distribution (CSAD) Committee issued a white paper describing options to address the following questions related to implementation of the WCI offset limit:

1. What mechanism should be used to impose the limit?
2. How should the offset limit be applied across jurisdictions?
3. How should the limit be applied across compliance periods?

On May 28, 2009, the CSAD Committee held an in-person stakeholder event in Seattle to present the options paper and solicit feedback, and since then, has received numerous written comments. On the basis of this input and further deliberations, the Committee has developed a recommendation on how to implement the offset limit, as presented in Section 6.

The purpose of this recommendation paper is to seek stakeholders' input on the committee's recommendations prior to a final WCI decision. As outlined and explained below, the committee's recommendations include:

- limiting the use of offsets rather than limiting the supply
- implementing a common use limit across WCI Partner jurisdictions
- setting the limit at an equal percentage of compliance obligations across compliance periods; and
- implementing a region-wide "carry-over" approach, which should be construed narrowly, applying only to the specific circumstances of the WCI program design .

2 Offset Limits in Other Trading Schemes

The CSAD Committee reviewed other existing or proposed cap-and-trade programs limit offsets in order to identify options for implementing the offset limit and the implications of these options. In our review, we considered the following programs and federal proposals:

- Regional Greenhouse Gas Initiative
- European Union Emissions Trading Scheme
- The American Clean Energy and Security Act of 2009 – ACESA
- Dingell-Boucher Discussion Draft
- Boxer substitute of Lieberman-Warner (S. 3036)
- Lieberman-Warner Climate Security Act (S.2191)
- US Climate Action Partnership Proposal

Table 1 summarizes how offset limits were designed or proposed in these programs and proposals. As illustrated in Table 1, there is wide variation in how the limits would be applied and how the availability of offsets changes over time. More detailed descriptions of these offset programs and proposals can be found in the Annex to this paper.

Table 1. Summary of Offset Limit Provisions of Cap-and-Trade Systems and Proposals

Cap-and-trade program or proposed legislation	Overall limit description and mechanism of application	Difference in limit across jurisdictions	Change in limit over time
US Regional			
Regional GHG Initiative (RGGI)	3.3% of a covered entity's emissions (in order to contain allowance price, overall offset limit increases as the allowance price exceeds threshold levels)	No difference	No change in % over time (unless price triggers increase limit). Absolute amount of allowable offsets decreases as the number of allowances available decreases.
European Union			
EU Emissions Trading System (EU ETS)	No more than 50% of emission reductions, EU-wide, typically implemented by member states as a percentage of covered entities' emissions (e.g., as a percentage of allowances distributed).	Phase II (2008-2012): Varies across member states from 0% to 20% of allowances distributed	Phase II (2008-2012): Based on National Allocation Plans (NAPs) Phase III (2013-2020): NAPs replaced by EU-wide caps and allocation rules.
US National Legislation and Proposals			
The American Clean Energy and Security Act of 2009 – ACESA	~2 billion metric tons per year. Implemented as a fraction of covered entity's emissions (compliance obligation) that increases from ≈30% in 2012 to ≈60% by 2050 as cap declines.	Not applicable (single jurisdiction)	Allowed offsets increase as a fraction of allowances issued over time.
Dingell-Boucher Discussion Bill	5-35% of a covered entity's emissions		Increasing percentage over time from 5% starting in 2013 to 35% by 2025.
Boxer Substitute of Lieberman-Warner (S. 3036)	Up to 15% of total emission allowances issued per year		No change in % over time. Absolute amount of allowable offsets decreases with cap. Includes a roll-over for unissued allowances for use in subsequent years.
Lieberman-Warner Climate Security Act (S. 2191)	Up to 15% of a covered entity's emissions		No change in % over time. Absolute amount of allowable offsets decreases with cap.
US Climate Action Partnership Proposal (US CAP)[2]	2 billion metric tons per year. A Carbon Market Board would have authority to increase limit to 3 billion metric tons.		No major change in absolute amount of offsets allowed.

[2] USCAP Blueprint for Legislative Action: Consensus Recommendations for U.S. Climate Protection Legislation, January, 2009. USCAP is "an expanding alliance of major businesses and leading climate and environmental groups that have come together to call on the federal government to enact legislation requiring significant reductions of greenhouse gas emissions." http://www.us-cap.org/about/index.asp

3 Principles in Evaluating Offset Limit Options

The CSAD committee applied the following principles in defining the design and operation of an offset limit:

- **Fairness**: An offset limit should be designed to apply fairly to covered entities and not create competitiveness concerns. An offset limit should be implemented in a manner that provides fair access to offset markets for offset project developers and covered entities, as well as other market participants.
- **Economic efficiency**: An offset limit should be implemented so that the market operates efficiently and that greenhouse gas emission reductions can be achieved at the least cost. An offset limit should not unduly inhibit the realization of the least-cost offsets.
- **Cost Containment**: The offset limit should be implemented in a manner that helps to contain compliance costs and maintains offset fungibility across the WCI. Recognizing that offset supply is essential for achieving cost containment, the offset limit should not unduly restrict the ability of offset project proponents to finance and develop prospective projects, the ability of jurisdictions to issue, or market participants to acquire, offsets in a timely manner.
- **Effectiveness and enforceability**: The offset limit should be implemented to ensure that the limit is enforceable and is effective at achieving the WCI goal that offsets are supplemental to emission reductions at covered sources, and thus that no more than 49% of total emissions reductions 2012-2020 are achieved by the use of offsets (and allowances and offsets from other emission trading systems).
- **Administrative simplicity and cost**: Implementation of the limit should provide as clear a path forward as possible for all parties, including administrative bodies, offset project developers, and covered entities. Administrative costs and transaction costs should be minimized for all parties, consistent with the need to ensure effective limit compliance.

4 Options

While the WCI design document specifies a limit on the amount of offsets that may be used for compliance purposes in the WCI regional cap-and-trade program, it does not indicate:

- What offset limit mechanism to implement and how to apply it across WCI Partner jurisdictions, or,
- How to apply the offset limit over time (across the three compliance periods).

These questions are addressed below.

4.1 Options for Implementing the Limit across Jurisdictions

The question of jurisdictional limits is unique to multi-jurisdictional emission trading programs, such as RGGI, the EU ETS and WCI.

There are two approaches Partners could employ to limit the total amount of offsets used. They could either limit the *use* of offsets (e.g., the number of offset credits a covered entity can use for compliance) or they could limit the *supply* of offsets (e.g., the total number of offset credits available to use for compliance). Within these two categories many detailed mechanisms are conceivable.

This paper will consider four detailed mechanisms - three that we categorize as usage limits:

- 'percentage limits' based on total compliance obligations, i.e. on actual emissions;
- 'percentage limits' based on freely distributed allowances;
- 'offset surrender certificates',

and one as a supply limit:

- 'first-come, first-issued'.

For each of these approaches there are also two broad options for addressing offset limits across jurisdictions - a *common* or a *differentiated* approach - and also multiple ways in which the limits could change over time.

Limiting the *use* of offsets

The offset limit could be set as a *percentage use limit* at the individual entity with a compliance obligation. The limit could be applied on a *common* basis across all jurisdictions, whereby the same entity-based percentage limit would apply across jurisdictions to any WCI-covered entity. Under this option, a common entity-based offset use limit specified as a percent of compliance obligations would be applied across the WCI. This is the approach taken by RGGI. The common percentage use limit would be calculated by dividing the total offsets allowed by the sum of the total number of allowances to be issued plus the total offsets allowed within a given time period (see section 4.2).

Alternatively, the WCI could adopt jurisdictionally *differentiated* percentage use limits, whereby the limit in each jurisdiction would differ based on one or more factors, such as the emission reductions below 2012 (or 2005) levels represented by a partner's emission goal. An example of the latter would be to apply the WCI-wide limit—no more than 49% of emission reductions between 2012-2020 from offsets—at the individual partner level. In such a case, jurisdictions with deeper targets relative to a base year level would allow proportionately more offset use per entity.

With a differentiated percentage-use approach, there is a risk that the total regional limit could be exceeded if the limit is specified as a percent of compliance obligations (i.e., total emissions, for which allowances and offsets have been surrendered). This risk occurs because allowances can be traded among jurisdictions, thus actual emissions that will occur in a given jurisdiction—and the corresponding amount of offsets—cannot be known in advance.[3]

---

[3] The following provides an example of how exceedance might occur under a differentiated percentage-use approach. Assume, for instance, a region with only two jurisdictions (K and L) and a total emissions goal of 95 tons for a specific compliance period. Assume also that 49% of region-wide emission reductions equals 5 tons, and thus the total amount of covered emissions in the region could not exceed 100 tons (with 95 tons in allowances plus 5 tons in offsets surrendered). Let's say that jurisdiction K has a emissions cap of 46 tons, and that 49% of emission reductions in jurisdiction K equals 4 tons. Jurisdiction L, in contrast has an emissions cap of 49 tons, and 49% of emission reductions equals only 1 ton. Therefore, jurisdiction K would set an offset percentage use rate of 8% ((4/(46+4)*100), while jurisdiction L would set an offset percentage use rate of 2% ((1/(49+1))*100).

If offsets were fully used in each jurisdiction, and neither jurisdiction was a net buyer of allowances from the other, then the region-wide offset limit would be respected (0.08*50 + 0.02*50 = 5 tons). However, if entities in jurisdiction K were to buy more allowances from jurisdiction L than they sold to it, *and* if all entitles fully used the amount of offsets allowed under its jurisdictional limit, then the overall region-wide offset limit would be exceeded. For example, assume that entities in jurisdiction K were to acquire a net 14 tons of allowances from jurisdiction L:

- Jurisdiction K entities could then surrender 60 tons of allowances (46+14). The offset use ratio is set at 0.08, also equal to x/(60 + x) where x is the amount of offsets that can be claimed along with 60 tons of allowances so that the offset use ratio is still 0.08. Re-arranging so that x appears only on the left hand side of the equation, we get x = 0.08*60/(1-0.08) = 5.2 tons of offsets to cover total emissions of 65.2 tons, and
- Jurisdiction L entities could then surrender 35 tons of allowances (49-14). The offset use ratio is set at 0.02, also equal to y/(35 + y) where x is the amount of offsets that can be claimed along with 35 tons of allowances so that the offset use ratio is still 0.02. Re-arranging so that y appears only on the left hand side of the equation, we get y = 0.02*35/(1-0.02) =and 0.7 tons of offsets)) to cover total emissions of 35.7 tons.

Total offsets used would then total 5.9 tons (5.2+0.7), greater than the region-wide offset limit of 5 tons.

An alternative would be to specify the offset limit as a percent of the number of allowances that are distributed directly to covered entities within a given Partner jurisdiction. This way, the risk of exceedance would be avoided, since the number of free allowances and corresponding number of allowable offsets would be specified in advance.[4] This approach would provide access to offset use only to covered entities that receive allowances directly (and in some proportion to allowances received).

The EU has, thus far, largely taken a differentiated percentage use approach to offset use limits.[5] As noted in the Annex, in Phase II of the EU ETS each member state was allowed to propose an offset limit as part of its National Allocation Plan. These plans are then subject to EU review and approval. As a result, the fraction of compliance obligations that emitters can fulfill using offsets varies from country to country.

The choice between common and differentiated percentage approaches to jurisdictional limits has implications in terms of how offset opportunities and risks are distributed across partners. This comparison is summarized in Table 2.

---

[4] As illustrated in the prior footnote, the reason that the offset limit could be exceeded under a differentiated percentage-use approach is that, while the offset limit percentages are fixed at the outset of a compliance period, the total compliance obligations (i.e. emissions) in each jurisdiction to which they apply will be unknown until the compliance periods ends. If instead the ability to use offsets were applied to the number of allowances that were distributed (a known quantity at the outset) rather than to the number of allowances and offsets surrendered (unknown until the end of the compliance period), the absolute amount of offsets that each entity could use would be known and fixed, and the potential for overage would be avoided.

[5] The EU percentage use limit is specified as the percent of allowance received for free by any given regulated emitter rather than as a percentage of compliance obligations.

Table 2. Comparison of Jurisdictional Percentage Use Offset Limit Options and Implications

Option:	Common % Use	Differentiated % Use
Example	X% of compliance obligations in all jurisdictions	49% of emission reductions in each jurisdiction translated to different percentages of compliance obligations in each jurisdiction
Fairness	Covered entities can use the same percentage of offset across the WCI region. Entities that emit more GHGs could use more offset credits for compliance.	Emitters from jurisdictions that have a deeper reduction goal for 2020 relative to a base year would be allowed a higher percentage of offsets. Within a given jurisdiction, entities that emit more GHGs could use more offset credits for compliance. If the limit is based on allowance distribution (rather than % of compliance obligation), then entities receiving more free allowances would have greater access to offsets.
Efficiency	To the extent that offset use falls short of the overall limit as a result of the mechanism used to implement the offset limit, opportunities for efficiency gains may be unrealized. The relative efficiency impact of each option remains to be evaluated.	
Cost Containment	The relative cost containment impact of each option remains to be evaluated.	
Effectiveness and Enforceability	WCI region-wide limit met. Individual partner limits may not be met.	WCI region-wide limit could be exceeded if individual Partners' limits are specified as a percent of compliance obligations.
Administrative Simplicity	Administratively simple to implement.	Slightly more complex to implement than the common % use approach.

As an alternative to the percentage use limit, the WCI Partner jurisdictions could choose to employ a usage limit which we will refer to as the *offset surrender certificates* mechanism. In this approach, the WCI Partner jurisdictions would issue and distribute (auction, sell or give for free) a number of certificates equal to the offset limit in tons. Covered entities would have to surrender one certificate for each offset credit they desire to use for compliance.

Under this mechanism, individual entities need not be limited by a percentage limit on their use of offsets. This approach could simplify the implementation of limits differentiated at the jurisdictional level and ensure that any regional limit on offsets would be maintained. This mechanism would also increase the likelihood that the full allowed amount of offsets (49% of emission reductions) would be used; under a percentage use limit, all entities not in need of offsets may need to engage in allowance-to-offset arbitrage in order to make the full amount of offsets available.[6]

[6] Assuming that offset credits are available for less than allowance prices, under a percent use approach an arbitrage opportunity could arise. If an individual entity does not need to use the maximum amount of offsets allowed (perhaps due to a generous free allocation of allowances), this entity would have the opportunity to acquire offsets (not needed for its own compliance purposes) up to the percentage limit and free up allowances to trade to others. However, there is no guarantee that this action would be taken by all market participants. If this

In contrast to limits on supply (see below), the offset surrender certificate approach would not inhibit the creation of offset projects or issuance of credits. However, the surrender certificate approach creates an additional market of compliance instruments which would be accompanied by increases in complexity, transaction costs, and associated concerns related to topics such as market manipulation.

Limiting the *supply* of offsets

Another option is to limit the supply of offset credits. Under a common supply limit, the same pool of offset credits would be available to any covered entity in the WCI region. Under a differentiated supply limit, each Partner would have its own pool of offset credits and those offset credits could either be restricted to their covered entities or could be available for any covered entities throughout the WCI Partner jurisdictions.

Conceptually, a supply limit approach would simplify the implementation of jurisdictional differentiated limits. However, limiting the issuance of offset credits especially through a *first-come, first-issued*, mechanism could create significant uncertainty for offset project developers. There is also no guarantee that the lowest cost projects would be the first to enter the market. Furthermore, a supply limit may hamper a regulated entity's ability to ensure that an offset supplier can deliver in a specific year (due to first come, first serve basis).

Similar to the surrender certificate approach described above, individual entities need not have a percentage limit on the number of offsets used for compliance and a supply limit would ensure that no amount of offsets available under the limit would be left on the table due to the lack of allowance-to-offset arbitrage by individual entities. Unlike all of the use approaches described above, a supply limit would allow individual entities to treat offset credits and allowances as perfect substitutes.

opportunity was not acted on by all entities, some offsets could be ”left on the table” from a system-wide viewpoint.

4.2 Options for Applying the Offset Limit over Time

The offset limit could be set at a common level across all three compliance periods or it could be designed to vary over time. Some stakeholders have argued for more offsets in early years in case rapid reductions prove difficult to implement. It has also been suggested that offsets may be more valuable in early years as emerging low-GHG technologies mature and their costs decline. Other stakeholders have argued for greater offsets in later years to provide cost containment as emission caps are tightened and allowance prices might be expected to rise. Another rationale for greater offset availability in later years is that offsets could be more abundant and reliable as offset markets and rules mature over time.

There are several options for addressing variation in time, including, but not limited to, the following:

- **Equal absolute number of offsets in each compliance period:** This is the approach embodied in the US CAP proposal and conceptually in the American Clean Energy and Security Act of 2009 (ACESA) formula described in Table 1.
- **Equal percent of use across compliance periods.** This approach is used by RGGI and was proposed in the Lieberman-Warner Bill (S.2191). While the fraction of emissions that could be covered by offsets would remain constant, the absolute amount of offsets that could be used would decline if and as the number of available allowances declines over time.[7]
- **49% of Emission Reductions in each period.** This option would impose a different absolute or percent offset limit for each compliance period in order to ensure that no more than 49% of emission reductions are in the form of offsets in each period. Since the cap declines over time (for a given scope of covered sources), the amount of emission reductions increases over time as the cap declines, as would the amount of offsets available.[8]
- **No restrictions across compliance periods:** This approach would provide the most flexibility by imposing no restrictions across compliance periods. The total amount of offset credits that can be used under the limit could be available for use in any compliance period. Entities with compliance obligations would decide when they want to use offset credits, so that the distribution of offset credit use over time would be determined by the market as a whole. This option could be implemented using a supply

[7] In the case of the WCI, the introduction of transportation, residential, and commercial fuels leads to an increase in the emissions cap in 2015, and the absolute amount of allowable offsets would increase significantly from the first (2012-2014) to the second (2015-2017) compliance period.

[8] The increase in the 2015-2017 will be even greater due to the introduction of transportation, residential, and commercial fuels in 2015.

limit, a certificate surrender mechanism, or by an offset use limit expressed in tons rather than % use (e.g. if offset use were linked with allowance distribution). However, it would be incompatible with a straight percentage use limit.

- **Other Ramp Up or Ramp Down:** There are other options for specifying increases or decreases in the amount of allowable offsets over time. For example, the Dingell-Boucher draft discussion bill provided a schedule for increasing the percentage of offsets that could be used over time (see Table 1).
- **Carry-over:** Any unused or unissued offsets (under the limit) could carry over to next compliance period and be added to that period's offset limit. This approach, included in the Boxer amendment (S.3036) for adjusting an issuance limit and in EU Phase III directive on a compliance entity-specific basis[9], could be implemented in conjunction with the options above.

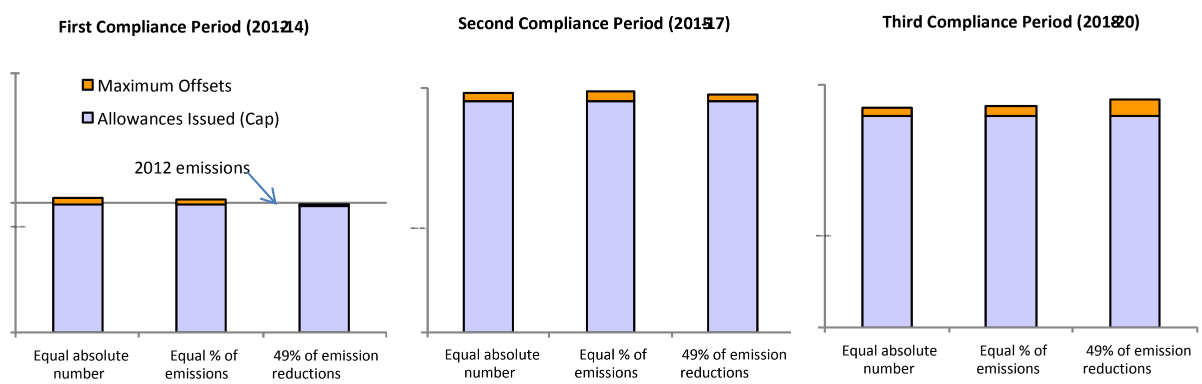
A carry-over provision could increase the ability to fully use the total amount of offsets allowed across all three compliance periods (2012 to 2020), especially in the case that offsets are not available in early compliance periods in sufficient quantity at costs competitive with allowances. The banking of allowances also increases the flexibility in the timing of offset use, by enabling entities to acquire and retire more offsets in early periods than they might otherwise need, and as a result, carry forward banked allowances to the subsequent compliance periods (see footnote 6). Allowance banking increases offset use flexibility in the particular case that offsets are abundant and lower cost compliance options in early compliance periods,

Figure 2 provides a visual comparison of the differences in offsets over time among the first three temporal options listed above, relative to the overall emissions budgets for the three compliance periods. It assumes full offset use (up to the limit in each compliance period) and no carry-over). Offset limit options are grouped by compliance period in order to compare them more easily within each period.

---

[9] To the extent that covered entities do not use their full allowable amount of offsets in Phase II (2008-12), they would be able to use these remaining amounts in Phase III (2012-2020). "In order to provide predictability, operators should be provided with certainty about the possibility to use after 2012 CERs and ERUs up to the remainder of the level which they were allowed to use in the period from 2008 to 2012…" L 140/67, May 6, 2009, http://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=OJ:L:2009:140:0063:0087:EN:PDF

Figure 2. Illustration of offset limit options across compliance periods (grouped by compliance period)



(The higher bars in the 2nd and 3rd compliance periods reflect the expansion of program scope in 2015. All figures shown are illustrative)

Figure 3 has two panels. The upper panel shows the same data as Figure 2, but grouped by offset option in order to illustrate how maximum offset use varies for each option across compliance periods. The lower panel zooms in on the maximum offset amounts. (The charts are illustrative only, since the cap has yet to be established.) As shown, the equal absolute amount and equal percentage limit options allow greater offset availability in early periods. As illustrated in Figure 2, these options would allow emissions to exceed 2012 levels in the first compliance period.

Figure 3. Illustration of offset limit options across compliance periods (grouped by offset option)

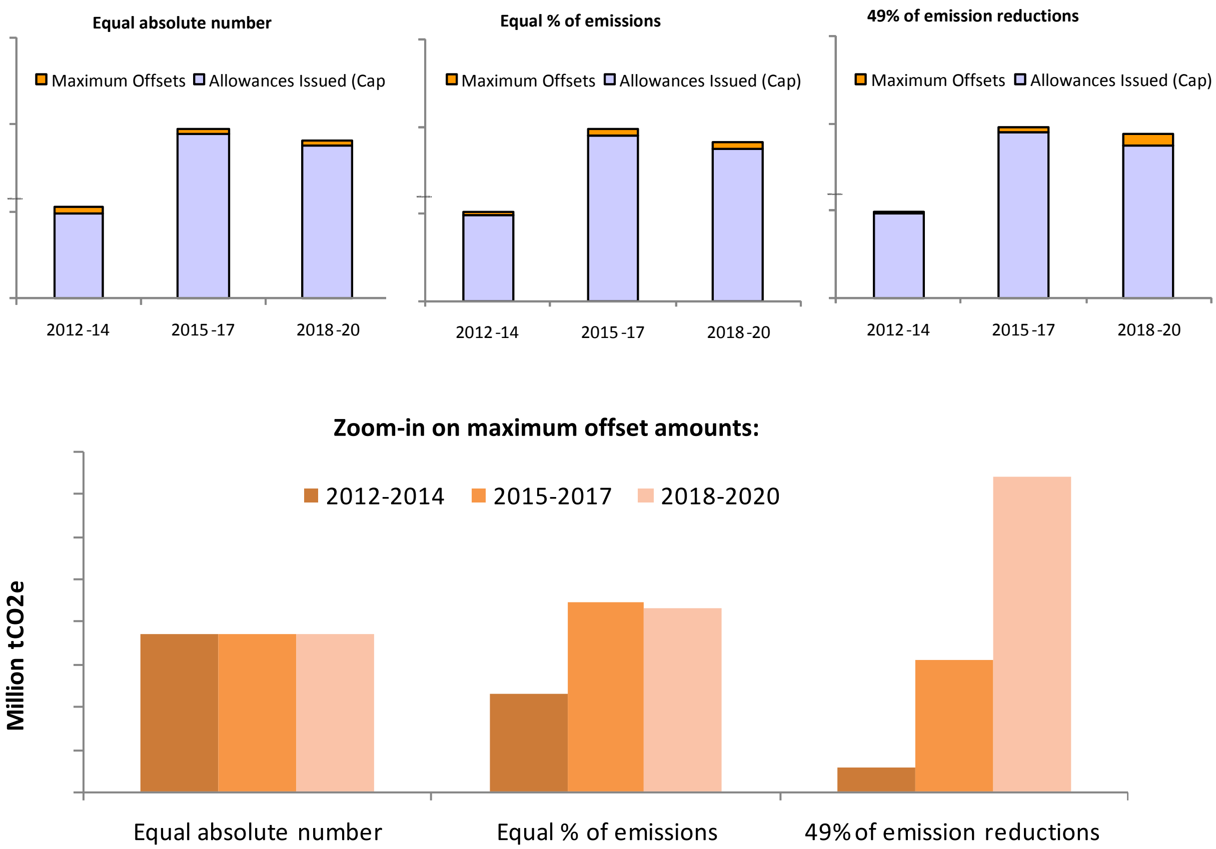


Table 3 compares each of the three options depicted above in terms of the principles listed in Section 3. In terms of fairness, the differences are a matter of perspective: the first two approaches would make more offsets available to covered sources that enter the program in 2012, whereas the third approach shown (49% of emission reductions in each period) would distribute offset availability in accordance with the extent of emission reductions needed (more in last period when deeper reductions are required). With respect to cost containment, as described in the table, the optimal approach will depend on future allowance prices. In terms of effectiveness, each of the first two options (equal absolute number and equal % of emissions) would allow more than 49% of emission reductions to come from offsets during the first two compliance periods, and much less in the third period. While this outcome could be avoided by setting the limit at 49% of emission reductions in each period (the third option), depending on how the limit is implemented (see previous section) this option could enable total emission reductions met by offsets to exceed 49% under the percentage use limit.

While all options shown in the table should be similar in terms of enforceability and administrative simplicity and cost, the carry-over approach noted above might require added administrative effort in the case of the percentage use mechanism, and create could some added uncertainty for the offset market. Data on the total amount of offsets used during a prior compliance period would be needed prior to setting the offset limit for the current period, and this information might not be fully available for several months into the period. Either a supply limit or the surrender certificate mechanism could address concerns about carry-over of excess offset capacity between compliance periods in a more straightforward way.

Table 3. Comparison of options for limiting offsets across compliance periods

Option→ ↓ Principle	**Equal absolute number of offsets in each period**	**Equal % of emissions in each period**	**49% of emission reductions in each period**
Fairness	Would make more offsets available to entities covered in the first compliance period (relative to other options)	Would make more offsets available to entities covered in first compliance period, but less so than the "equal absolute" option	Would make offsets available to covered entities in accordance with the extent of emission reductions required in a given period.
Economic Efficiency	Any proscription of offset use by compliance period has the potential to lead to unrealized efficiency gains.		
Cost Containment	Might provide greater cost containment if internal emission reductions turn out to be more costly in the early period (s).		Might provide greater cost containment if internal emission reductions turn out to be more costly in the final period.
Effectiveness and Enforceability	Would meet WCI 49% limit across all periods, but could exceed it in first and second compliance periods if sufficient offsets are available and are extensively used.		Could exceed overall 49% limit (across 2012-2020) under the percentage use limit, if allowances are banked in early periods and used in later periods when the percentage of allowed offsets is higher. Exceedance could be avoided through a supply limit or surrender certificate approach or linking offset use to allowance distribution (see Section 4).
Administrative Simplicity and Cost	No significant difference among options		

If a supply limit or surrender certificate use limit is chosen instead of a percentage use limit (see Section 4), then the options for spreading offset availability across compliance periods could be set by how certificates are distributed or offsets issued in each period. As noted above, these options could more easily allow for the full targeted amount of offsets to be available across all three periods.

5 Stakeholder Feedback on Options

The CSAD Committee has received considerable feedback on the Offset Limit White Paper. The Committee hosted a stakeholder workshop in Seattle, Washington on May 28th, 2009, and received written comments from approximately twenty stakeholders during the public consultation period. Stakeholders providing input have included industry associations, environmental NGOs, electric utilities, power industry representatives, financial institutions, carbon market participants, and individual firms in the cement, aluminum, forest product, and petroleum industries. This section summarizes this input.

Several stakeholders remarked on the overall stringency or desirability of the offset limit. The limit itself has already been established by WCI, and is not the focus of this paper; no further discussion is provided here.

On the question of the mechanism used to impose the limit, stakeholders generally indicated a preference for limiting the use rather than the supply of offsets, and for reflecting this limit as a percentage of an entity's compliance obligations. Common reasons for this preference included predictability and flexibility for covered entities, concern that the least costly or promising offsets would be those in line to get approval, and concern that a supply limit would result in higher prices than a usage limit. Some of them supported a supply limit, as it would not constrain facilities to a specific usage limit.

Few stakeholders expressed their support for the use of offset surrender certificates, due to the potential to increase offset fungibility across compliance periods and to maximize the number of offsets allowed in the system. However, many of them objected to this approach, citing the potential for reduced cost containment (due to the added costs to compliance entities of acquiring certificates), added complexity, and the potential for market manipulation.

On the question of how the offset limit should be applied across jurisdictions, stakeholders were split in preference between common and differentiated limits. Many favored a differentiation of limits among jurisdictions, on the grounds that it would provide jurisdictions with greater flexibility or provide entities with more access to offsets where tighter emission reduction targets have been adopted. Many also argued for a common percentage use limit, in order to create harmonization among jurisdictions and equal access to offsets by all market participants.

On the question of how the limit should be applied across compliance periods, stakeholders presented a range of opinions, from "fixed and uniform over time" to an equal absolute amount to front-loading with a higher percentage of use in earlier periods. Many stakeholders expressed a desire to have no restrictions across compliance periods. However, as noted above (Section 4), complete flexibility among compliance periods would require that a supply limit, the use of offset certificates, or another form of distributing the "right" to use offsets, such as on the basis of allowance distribution. As noted above, stakeholder support for offset surrender certificates or for a supply limited was relatively limited. On the question of whether access to offsets should be linked with the distribution of allowances, all stakeholders who commented on this approach objected to it, suggesting there is no rationale for such a distribution.

Many stakeholders favored a "carry-over" of unused offsets from one compliance period to the next, as a means to provide flexibility across compliance periods and increase the overall utilization of offsets. One commenter suggested that a carry-over mechanism might be unnecessary, arguing that the market could ensure maximum utilization of offsets through the banking of allowances.

Finally, the Committee asked stakeholders to describe any specific competiveness impacts the Committee should consider in evaluating options to apply the offset limit. Many of the suggestions here were made in reference to comments noted above, and ensuring that the approach to setting the limit does not result in higher prices, and makes offsets available during periods when other compliance options (internal reductions, allowance purchases) are more expensive.

6 Recommendation

The Cap Setting and Allowance Committee offers the following recommendations for implementing the offset limit.

1. The Committee finds that limiting the use of offsets would be preferable to limiting the supply of offsets. Compared to a supply limit, a use limit should result in lower overall compliance costs for covered entities. Furthermore, the Committee recommends a use limit be applied at the entity level, more precisely as a percentage of compliance obligations (i.e. emissions). This option provides predictability for covered entities, is administratively simple to implement, and tends to minimize both administrative and compliance costs of the program relative to a supply limit.

2. The Committee recommends a common use limit be implemented across Partner jurisdictions. A common limit provides equal access to offsets to entities across the WCI cap-and-trade system, and helps to ensure that the overall limit would not be exceeded. (See Section 4 for a discussion of how this might occur with differentiated limits) With a common use limit, a jurisdiction could still adopt a limit lower than this level, an option established in the WCI design recommendations. The CSAD Task 3 (competitiveness) group will consider whether the common use limit might pose competitiveness concerns for entities in jurisdictions that have adopted lower emission targets relative to historical levels, and if so, how to address these concerns.

3. The Committee recommends that the limit be set at an equal percentage of compliance obligations across compliance periods. This option would allow for the use of a greater absolute number of offset credits in earlier compliance periods (adjusting for the expansion of program scope in 2015), thus easing the transition into the cap and trade program.

4. The Committee also recommends the implementation of region-wide "carry-over" approach. Under such an approach, if the total amount of offsets used across WCI in a given compliance period are less than the total amount of offsets allowed, then the difference in these two amounts would be added to the subsequent period's offset limit (in absolute terms), with the percentage offset limit adjusted appropriately.[10] The committee recommends adopting a "region-wide", rather than "entity-specific" carry-over approach due its simplicity, lower administrative cost, transparency, and ability to enable fuller overall use of offsets.[11]

   Fundamental to this recommendation for a carry-over feature is the stringency of the limit on the use of offsets in the WCI program design. Under a program with more generous offset limit provisions, like the one proposed under the American Clean Energy Security Act (ACES), the carry-over feature could be counterproductive in its effect on long-term investment in emission reductions by covered sources. Of particular concern is that unused portions of an offset use limit could accumulate in early years to such an extent that covered sources could rely on offsets in later years to meet most or all required reductions. In the specific case of WCI, this outcome is not of concern, since the implementation of a carry-over will still result in over half of emission reductions occurring at covered sources. Consequently, this recommendation should be construed narrowly, applying only to the specific circumstances of the WCI program design.

[10] A numerical example of a carry-over system is presented in Annex 2.
[11] Under an entity-specific carry-over approach, entities that ceased or significantly reduce operations, and thus emissions, might not be able to use their "carried over" offset amount.

5. While there is some interest in adopting an offset surrender certificates approach, which would permit regulated entities to sell and buy (trade) the right to use offsets, the Committee does not recommend this approach. Compared to a percentage of compliance approach, the surrender certificate approach could be more administratively complex and may increase the overall compliance cost for some regulated entities.

In summary, the Committee recommends that Partners limit the use of offsets and that this limit be expressed as a percentage of compliance obligations at the entity level. The same percentage of compliance obligations should be applied across jurisdictions and compliance periods with a regional “carry-over” system that would permit the unused portion of the limit to be transferred to the following compliance period.

Annex 1: Detailed Description of Offset Limits in Other Trading Schemes

Regional Greenhouse Gas Initiative (RGGI)[12]

Limits: The Regional Greenhouse Gas Initiative (RGGI) allows entities to use carbon offsets to cover a portion of their compliance obligation. Entities can use offsets to cover up to 3.3% of their total compliance obligation. This limit increases to 5% if the carbon price is over $7 per ton, and further increases to 10% if the allowance price exceeds $10 per ton.

Project Eligibility: The RGGI Model Rule identifies five project types that are eligible for offsets:

- Landfill methane capture
- Sulfur hexafluoride (SF6) capture
- Forest sequestration
- Energy efficiency for natural gas, propane and heating oil
- Animal methane management

New project categories will be adopted if they are approved by each of the RGGI states.

In order to receive offset credit, emission reductions from these project types must be:

- Real and quantifiable
- Additional beyond business as usual assumptions
- Verifiable
- Permanent
- Enforceable

Offset Limit Methodology: In order to strike a balance between achieving real emission reductions in covered sectors and providing entities with a flexible compliance option, RGGI states decided that offset use should be limited to 50% of the total emission reduction amount. According to the Staff Working Group (SWG) analysis, the 50% goal was not viewed as a hard target, but rather as a guiding principle in determining a quantitative offset limit. The SWG recommended an entity level offset limit, rather than a state-wide or system-wide limit. The SWG modeled the impact of different offset limit amounts to determine an entity level limit that would approximate the 50% goal. The final SWG analysis recommended limiting offsets to

[12] Sources for this section include: Regional Greenhouse Gas Initiative Model Rule (12/31/08 final with corrections. (www.rggi.org); Analysis Supporting Offsets Limit Recommendation (5.1.06). (www.rggi.org); Offsets Summary: the Regional Greenhouse Gas Initiative. Environment Northeast (http://www.env-ne.org/public/resources/pdf/ENE_RGGI_offset-design.pdf)

3.3% of an entities' total compliance obligation. This recommendation was adopted in the RGGI Model Rule.

The price trigger provision recognizes this modeling uncertainty by making the offset limit a function of the factors that drive price increases. Allowance price increases are partially a factor of the trajectory and the starting cap—allowing the offset limit to increase when the price increases serves as a means of correcting for inaccuracies in setting of these factors. This allows the offset limit to more closely align with the overall RGGI goal of controlling compliance costs.

European Union Emission Trading Scheme

Summary of Limits: The European Union Emissions Trading Scheme (EU ETS) imposes limits on the amount of offset credits that may be used for compliance in both Phase II and III. These limits are percentage use limits applied at the facility level.

The actual limit is different in each phase, for each Member State, and may differ by type of installation. The Phase III limits are likely to be more stringent than the Phase II limits and may be harmonized across the EU; actual limits for Phase III are contingent on the results of international climate change negotiations.

Project Eligibility and Geographic Limitations:
Phase II: The permissible offset credits in Phase II are certified emission reductions (CERs) from the clean development mechanism (CDM) and emission reduction units (ERUs) from joint implementation (JI) projects.[13]

Phase III: Limits on the use of CERs and ERUs in Phase III are contingent on the evolution of these programs as a result of international negotiations. The EU may also begin to explore other types of domestic offsets.[14]

Offset Limit Methodology:
Phase II: In international climate negotiations it was decided that internal (domestic) abatement of emissions should take precedent over external participation in flexible

[13] For a list of approved CDM methodologies see:
http://cdm.unfccc.int/methodologies/PAmethodologies/approved.html

[14] See point 22 of the following document:
http://europa.eu/rapid/pressReleasesAction.do?reference=MEMO/08/796&format=HTML&aged=0&language=EN&guiLanguage=en

mechanisms such as the CDM and JI.[15] In the context of the Kyoto Protocol this concept is referred to as "supplementarity."

The requirement to take significant action domestically was included in the international agreements partially at the behest of European nations. Therefore, the concept of prioritizing domestic action (from capped sources located in the EU) was included in the design of the EU ETS.

Each member state in the EU ETS has a different limit on the use of offsets credits from the international flexible mechanisms (CDM and JI credits) in the second phase of the EU ETS.[16] These limits are usually specified as a percentage of the total amount of allowances freely allocated to an installation.[17]

There is currently no EU-wide agreement on the definition of supplementarity. It is roughly interpreted that at least 50% of reductions (also referred to as the "level of effort") should be met by direct reductions at covered facilities. However, in actual implementation it appears that the levels set for use of offsets in Phase II may allow for more than 50% of reductions to be met through offsets.[18]

Wide discretion was given to the Member States as limits on the use of CDM/JI credits were set in Phase II. The European Commission considered that, as a rule of thumb, installations should be allowed to use JI and CDM credits to supplement their allowance allocation by up to 10%.[19] However, each member state set the actual binding limit in its national allocation plan, which was then subject to approval by the Commission. Some approved limits were 20% and above.[20] In aggregate these limits would allow operators in the EU ETS to import approximately 1.4 billion metric tons of credits from 2008-2012.[21]

---

[15] See the Kyoto Protocol. Available from: http://unfccc.int/resource/docs/convkp/kpeng.pdf
[16] Phase II of the EU ETS runs from 2008-2012.
[17] For example, the United Kingdom limits on project credits in Phase II is 9.3% of allocation for large electricity producers and 8% of allocation for all other installations. See page 16 of the DEFRA's *An Operator's Guide to the EU Emissions Trading System* available from:
http://www.defra.gov.uk/environment/climatechange/trading/eu/pdf/events-guide.pdf
[18] Some environmental groups estimate that between 88-100% of the emission reductions required under the combined cap for the EU ETS could theoretically take place outside of the EU through the use of offset credits. See for example, WWF, *Emission Impossible: access to JI/CDM credits in phase II of the EU Emissions Trading Scheme* June 2007. Available from: http://assets.panda.org/downloads/emission_impossible___final_.pdf

[20] According to the WWF analysis, Irelands limit is 21.9%, Spain and Germany's limit is 20%. See each country's Phase II NAP for more details.
[21] The Carbon Trust (2008) *Cutting Carbon in Europe: The 2020 plans and the future of the EU ETS* Available from: http://www.carbontrust.co.uk/publications/publicationdetail.htm?productid=CTC734

Phase III: The EU has recognized that the level of offsets allowed in Phase II is likely to prevent achievement of the supplementarity goal and has proposed changes to prevent this in Phase III of the EU ETS. Beyond the supplementarity considerations, motivations for this increase in stringency are strategic in nature. The EU is attempting to use the EU ETS's influence on the demand for CERs as a tool in the international negations. The goal is to motivate large-emitting non-annex 1 countries (e.g., China) to increase action on climate change, including considering firm caps on emissions.

The rules for Phase III have recently been established as part of a comprehensive Climate and Energy Package.[22, 23] This package specifies that the level and type of offset credits allowed in Phase III is contingent on a successful implementation of an international agreement on climate change that will cover this period (post-2012). In the absence of an international agreement, the offset limit will be much tighter than in Phase II.

Limits proposed in US National Cap-and-Trade Legislation

Lieberman-Warner Climate Security Act (US Senate Bill 2191, 110th Congress)[24]

Senators Lieberman and Warner introduced the Climate Security Act, which was referred to the Environment and Public Works Committee, on October 18, 2007. Hearings were held to discuss the bill at the subcommittee and committee level in the fall of 2007.

Summary of limits: The Lieberman-Warner Climate Security Act stipulates that the owner or operator of a covered entity may meet up to 15% of their total compliance obligation using offset allowances. This percentage use limit is applied to each year or each compliance period. The limit does not change from year to year and there is no roll-over option for unused allowances to be used in future years or compliance periods.

Offset limit methodology: Covered entities may submit offset allowances that satisfy up to 15% of their total allowance submission requirement each year. These offsets must be generated in accordance with the bill—specifically the eligibility criteria and provisions in

[24] S.2191 bill http://thomas.loc.gov/cgi-bin/query/z?c110:S.2191

Subtitle D (the offsets section). This option may be provided as a means to contain cost while also creating an administratively simple offsets program.

Boxer Substitute of the Lieberman-Warner Climate Security Act (US Senate Bill 3036, 110th Congress)[25]

The Boxer Substitute of Lieberman-Warner's Climate Security Act (S. 3036) was reported to the US Senate on May 20, 2008. The Boxer Substitute made considerable changes to the Climate Security Act in general and specifically the offsets provisions in the original bill. The Boxer Substitute was debated on the US Senate in the summer of 2008 and did not pass on the floor. The Boxer version shifted to an aggregate supply limit on total offsets allowed in the market, rather than a use based limit.

Summary of limits: The Boxer Substitute sets a supply limit on offsets allowed in the proposed cap-and-trade system. The supply limit would allow EPA to control the issuance of offset credits and cap the total supply to the cap-and-trade market. Language in the bill places an aggregate limit on how many offsets are available for purchase from three categories: domestic, international, and forestry offsets. The total supply limit for each of these categories is 30%: 15% domestic, 5% international, and 10% international forest offsets. The bill proposes the following:

- EPA limits the creation of ***domestic offsets*** to 15% of the total quantity of emission allowances issued in each year. The limit applies to the total number of offsets, not to an individual entity's compliance obligation.
    - Any unissued portion of the offsets for one year may be added to the 15% limit for the following year.
    - Offsets will be issued (at an appropriate discount rate determined by EPA) for each offset issued under RGGI.
- EPA limits the use of ***international offsets*** to 5% of the total quantity of emission allowances.
    - Any unused portion of international offsets may be added to the 5% limit for the following year.
    - International offsets from a project at a facility that competes directly with a US facility will not be allowed.
- EPA limits the use of ***international forest offsets*** to 10% of the total quantity of emission allowances for each year.

[25] S.3030 bill http://thomas.loc.gov/cgi-bin/query/z?c110:S.3036; ; Summary of S. 2191: Lieberman-Warner Climate Security Act of 2008 Manager's Substitute Amendment by the World Resources Institute. URL: http://www.wri.org/publication/summary_lieberman_warner_climate_security_act_2008_substitute_managers_amendment

- Forest offsets can be generated from reductions in deforestation and forest degradation as compared to caps or reference scenarios used by foreign countries.
- After enactment of the bill, EPA will periodically review the performance of the forestry offset program.
- Ten years after enactment, the EPA may discount offset credits from countries that have not reduced total emissions from forests.

Project eligibility: Section 2403 lists projects eligible to generate offset allowances, including:

- Afforestation and reforestation
- Altered tillage practices
- Capture of fugitive emissions
- Capture or combustion of methane at non-agricultural facilities
- Conversion of cropland to rangeland or grassland
- Cover cropping
- Forest management
- Manure management
- Reduced carbon emissions from organic soils
- Reduction of fertilizer use
- Rice-paddy flood management

Offset limit methodology: The Boxer Substitute creates flexibility for covered entities to use offset credits from a variety of projects and locations. The issuance limit was designed to increase the supply of offsets and thus, reduce costs for those sources that have a compliance obligation. By allowing more project types, international offsets, and a roll over clause—the bill seeks to create a large supply of offsets and contain costs.

Dingell-Boucher Draft Discussion Bill (House Draft Bill)[26]

The draft Dingell-Boucher bill was released to the public for discussion purposes by the US House Committee on Energy and Commerce in October 2008. The bill has not been officially introduced in the US House of Representatives.

Summary of limits: Regulated entities may use verified domestic or international offsets for a portion of surrendered allowances rising from 5% starting in 2013 up to 35% by 2024. The percentage of allowable domestic and international offsets increases in each compliance period.

[26] energycommerce.house.gov/images/stories/Documents/PDF/selected_legislation/clim08_001_xml.pdf

Project eligibility: The draft bill permits regulated entities to purchase EPA-approved offset credits for domestic and international emission reduction projects. The proposal requires EPA to recognize domestic offset credits for

- Afforestation or reforestation on acreage not forested after January 1, 2008
- Landfill methane
- Manure management
- Methane collection at coal mines

Other project types will be reviewed for future consideration in the offsets program:

- Controlled wastewater treatment
- Conversion of cropland to rangeland or grassland
- Forest management resulting in an additional increase in forest stand volume
- Methane reduction from reclamation of abandoned surface mines
- Practices that increase agricultural soil carbon sequestration
- Recycling and waste minimization
- Reduced deforestation
- Reduction of nitrogen fertilizer or increase in nitrogen use efficiency

Offset limit methodology: Offsets play a greater role in each compliance period. Covered entities will submit offset allowances that represent up to 5%-35% of their total submission requirement during each compliance period:

- Up to 5% (domestic or international) in 2013-2017
- Up to 15% (domestic or international) in 2018-2020
- Up to 30% in 2021-2024 (15% domestic/15% international)
- Up to 35% in 2025-2050 (20% domestic/15% international)

The American Clean Energy and Security Act of 2009 – ACESA (passed by the House – June 26, 2009)

Summary of limits: ACESA establishes an entity-based limit that is calculated on an annual basis. Covered entities collectively may use offset credits to demonstrate compliance for up to a maximum of 2 billion tons of GHG emissions annually. The use limit is split evenly between domestic and international offsets each. The EPA can increase the allowable percentage for international offsets (up to 1.5 billion), if the agency determines use of domestic offsets will not be maximized (at current emission allowance prices) in a particular year. Starting in 2018, international offsets are discounted such that 1.25 international offsets would be equivalent to 1 allowance for compliance purposes.

Project eligibility: Additionality is determined by the following criteria: 1) not required by law or regulation, 2) not commenced prior to January 1, 2009, except for projects that commenced after January 1, 2001 and that were registered with the EPA as of the date of enactment or are readily reversible and 3) based on activity baselines based on a standardized baseline that reflect “a conservative estimate of business as usual” performance or practice.

Other key project eligibility criteria include:

- Accounting for leakage
- Activity baselines
- Addressing reversals, including mechanisms such as an offsets reserve and/or insurance
- Approval via crediting periods
- Auditing
- Verification and verification accreditation

Offset project types, including international offset projects, will be reviewed and approved within two years with consultation from the offset integrity advisory board. This board will prioritize offset project types for consideration.

Offset limit methodology: Offsets could play a greater role over time in the proposed program—increasing from approximately 30% use limit in 2012 to 67% by 2050. The formula to calculate the use limit requires EPA to divide the number 2 billion by 2 billion plus the emission allowances available in the previous year and multiply by 100 (for a percentage limit). The President may make a recommendation to Congress as to whether the number 2 billion should be increased or decreased. In addition, the program will recognize offsets for reduced deforestation that meet specific eligibility criteria.

Annex 2: Illustration of a Region-Wide "Carry-Over" mechanism

The WCI Partners limit offsets to no more than 49 % of the overall reductions, in order to ensure that a majority of emission reductions required under the program occur at covered entities and facilities. Considering the important role of offsets in reducing the overall compliance cost of the system, the Partners recommend the implementation of a region-wide carry-over mechanism that can help to maximize the number of offsets used for compliance under the proposed limit. As noted above, such a mechanism is only appropriate to consider where the overall offset limit is sufficiently stringent.

Under the region-wide carry-over approach, if the total amount of offsets used across WCI in a given compliance period is less than the total amount of offsets allowed, then the difference in these two amounts would be added to the subsequent period's offset limit (in absolute terms), with the percentage offset limit adjusted appropriately. The numerical example below illustrates how the offset limit would be adjusted by the carry-over mechanism.

For simplicity of illustration, assume a cap-and-trade system with three compliance periods. Assume also that 49% of emission reductions across the three periods is estimated to be 142 105 tCO_2e (referred to as "tons" below), which is equivalent to an offset limit set at 5.0% of compliance obligations (i.e. emissions) across all periods, as follows:

1st compliance period cap (allowances distributed): 1 000 000 tons
2nd compliance period cap (allowances distributed): 900 000 tons
3rd compliance period cap (allowances distributed): 800 000 tons

Total allowances distributed (all periods): 2 700 000 tons
Offset use percentage limit = (offset credits allowed) / [(total allowances) + (offset credits allowed) = 142 105/(2 700 000 + 142 105) = 5.00%

Since the limit is expressed in terms of compliance (i.e. emissions), the "carry-over" is calculated based on the number of allowances surrendered for compliance. Example 1 shows how the "carry-over" works when all allowances are surrendered at the end of a compliance period and example 2 when regulated entities retain some allowances for use in a future period.

Example 1: Carry-over assuming no banking of allowances

1st compliance period :

If all allowances are surrendered at the end of the first compliance period, then the maximum amount of offset credits that could be used during the first compliance period would be 52 632 tons. (In other words, 1 000 000 allowances and 52 632 offset credits could be surrendered to cover total emissions of 1 052 632 tons of emissions; 52 632 offset credits represents 5.00% of 1 052 632 tons of total emissions.)

If all allowed offset credits are use during the first compliance period (i.e. 52 632 tons), then there would be no carry-over and the limit would stay at 5.00% during the second compliance period.

If all first period allowances are used (none banked), but not all allowed offsets are used, let say only 40 000 tons instead of 52 632 tons of offsets, then, with a carry-over, the new offset limit would be calculated as follows:

> Total allowances remaining in the system = (total number of allowances to be issued) – (number of allowances used for compliance) = 2 700 000 – 1 000 000 = 1 700 000 allowances
>
> Total allowed offsets remaining = (total number of offset credits allowed for compliance in the system) – (offset credits used for compliance) = 142 105 – 40 000 = 102 105 offset credits
>
> Offset use percentage limit = (remaining offset credits) / [(remaining allowances) + (remaining allowed offset credits)] = 102 105 / (1 700 000 + 102 105) = 5.67%
>
> Therefore, the use of offsets in the second compliance period would be limited to 5.67% of compliance obligations.
>
> A similar calculation would be performed at the end of the second compliance period to adjust the offset limit percentage for the third compliance period. The third compliance period offset limit would be greater than or equal to the percentage set for the second compliance period (5.67% in the case shown).

Example 2: Carry-over assuming banking of allowances

Following example 1, suppose at the end of the first compliance period only 950 000 allowances are surrendered for compliance purposes (i.e. 50 000 allowances are banked for use in the second or third compliance period). Suppose also that only 40 000 offset credits are used for compliance. Under the carry-over the new offset limit for the second and third compliance period would be:

Total allowances remaining in the system = (total number of allowances to be issued) – (number of allowances used for compliance) = 2 700 000 –950 000 = 1 750 000 allowances

Total allowed offsets remaining = (total number of offset credits allowed for compliance in the system) – (offsets credits used for compliance) = 142 105 – 40 000 = 102 105 offset credits

New offset limit = (remaining offset credits) / [(remaining allowances) + (remaining allowed offsets credits)] = 102 105 / (1 750 000 + 102 105) = 5.51%

Therefore, the use of offsets in the second compliance period will be limited to 5.51% of compliance obligations.

Again, a similar calculation would be performed at the end of the second compliance period, and the third compliance period offset limit would be greater than or equal to the percentage set for the second compliance period (5.51% in the case shown here).

From a stakeholder perspective

If we use this example, a covered entity knows a) that the offset limit will be set at 5.00% of compliance obligations for the first compliance period, and b) that over the subsequent compliance periods, the offset limit will either increase or stay the same as the prior period's limit.

For example, suppose covered entity A emits 50 000 tons during the first compliance period. At the end of the period, the facility will have to surrender a combination of allowances and offset credits equal to emissions (or compliance obligation), i.e. 50 000 tons. Entity A can comply without the use offsets, by surrendering 50 000 allowances (which it may have received through a free allocation and/or purchased in the market or at auction). Alternatively, the entity can acquire and surrender up to 2 500 offset credits, which reflects the region-wide offset limit of 5.00% multiplied times its emissions (5.00% of 50 000 tons) along with 47 500 allowances (50 000 tons minus 2 500 offset credits). If entity A uses fewer than 2 500 offset credits -- for example, 1 700 offset credits -- then the remainder (800 offset credits) are used to calculate the *region-wide* carry-over for the remaining compliance periods.

Let's assume in the second compliance period that entity A emits 45 000 tons. Let's also assume as in example 1 above, that several entities did not use the full amount of allowed offset credits and that, as a result, the second compliance period's offset limit increases to 5.67%. In this case, entity A could use up to 2 552 offset credits (5.67% of 45 000 tons) for compliance in the second period. Because of the region-wide carry-over, entity A has an additional 302 offset credits that it can use, as compared with a system without a carry-over, in which case the allowable offset amount would have been 2 250 (5.00% of 45 000 tons), if the limit stayed at 5.00%.

This example also points out the difference between a *region-wide* (recommended) and an *entity-specific* (not recommended) carry-over mechanism. Under an entity-specific carry-over, entity A in the example described here would have had an additional 800 offset credits to use in the second and/or third compliance periods. The amount of additional offsets available to an entity would be solely a function of how many offsets it had been allowed and (not) used in the past. In contrast, a region-wide carry-over mechanism would adjust the offset limit for *all* entities in subsequent periods.

Draft Recommendations for WCI Offset Limits

In May 2009, the WCI Cap Setting & Allowance Distribution Committee released a white paper and hosted a workshop describing options to limit the use of offsets issued by the WCI, as well as offsets and allowances issued by other trading systems, to no more than 49 percent of the total emission reductions from 2012 to 2020 that are called for by the regional cap. The Draft Offset Limit Recommendation Paper builds on the white paper by summarizing stakeholder feedback from the white paper and workshop and offering the Committee's recommendations for implementing the offset limit.

The purpose of the Recommendation Paper is to seek stakeholder input prior to a final WCI decision. Click here to download and provide comments on the document. Comments should be provided by October 30, 2009.

In addition, a teleconference has been scheduled for 9:00 a.m. Pacific on October 21 to garner further stakeholder input. To join the call, dial 1-800-868-1837 (toll free) or 1-404-920-6440 (direct dial) and enter participant code 659537#.

Formation of the WCI Electricity Team

The WCI Partners reviewed options for continued work on issues related to the electricity sector following their July 21, 2009 announcement concerning implementation of the first jurisdictional deliverer (FJD) approach for regulating emissions associated with imported electricity. Addressing the point of regulation for electricity was the original purpose of the Electricity Committee. With that task largely completed, the Partners considered assigning the remaining electricity issues to other

Upcoming Events

October 15: WCI Stakeholder Update Call

The WCI Partners will be hosting their next bimonthly stakeholder update call on October 15 at 12:30 p.m. Pacific. To join the call, dial 1-800-868-1837 (toll free) or 1-404-920-6440 (direct dial) and enter participant code 659537#.

October 21: Stakeholder Call on Offset Limits

The Cap Setting & Allowance Distribution Committee will host a call with stakeholders on October 21 at 9:00 Pacific to review and discuss its recommendations to Partners for limiting the use of offsets in the WCI cap-and-trade program. To join the call, dial 1-800-868-1837 (toll free) or 1-404-920-6440 (direct dial) and enter participant code 659537#.

November 18: WCI Partners Meeting

The next WCI Partner meeting will be on November 18 in Santa Fe, NM at the La Posada Resort. Stakeholders are invited to attend in-person or via teleconference. More information will be distributed soon through the WCI website and list server.

relevant committees.

However, to ensure that critical issues related to the electricity sector receive adequate attention, and in order to continue the involvement of the Electricity Technical Advisory Group, the WCI Partners decided to maintain a technical staff group dedicated to electricity issues. The Electricity Team will be led by Doug MacCallum, Manager, Energy Markets, Ontario Ministry of Energy and Infrastructure. To read more about the proposed structure and work of the Electricity Team, click here.

November 19: Oil and Gas Industry Collaborative
The WCI is sponsoring an oil and gas industry collaborative in Santa Fe, NM at the La Posada Resort. The collaborative will focus primarily on emissions from exploration, production, and refining. Stakeholders are invited to attend in-person or via teleconference. More information will be distributed soon through the WCI website and list server.

WCI Offsets Committee Launches Effort to Evaluate Existing Protocols

The WCI Offsets Committee has initiated an effort to evaluate existing offset protocols for agriculture, forestry, and waste management against the WCI Offset Draft Criteria. Also of interest is whether the existing protocols are aligned with the ISO framework, as defined by ISO 14064-2, 14064-3, and 14065. The result of this work will identify the existing protocols that are aligned with the ISO framework and satisfy the WCI draft criteria for inclusion in the WCI program as is, or with modifications. The Committee will be assisted in this effort by Det Norske Veritas.

Presentations Available from WCI Cap-Setting Webinar

On September 21, the WCI Cap Setting & Allowance Distribution Committee hosted a public webinar to hear from representatives of the Regional Greenhouse Gas Initiative (RGGI) and European Union Emission Trading System (ETS) on the experience and lessons learned in setting emission caps in those programs. Presentations by the representatives can be downloaded from the WCI website.

Benchmarking Workshop Presentations Available

On September 17, 2009, the Provinces of Ontario and Quebec hosted a workshop in Toronto, Ontario to bring together experts, governments, and sector representatives from across North America and internationally to share experiences, information, and best practices as they relate to cap-and-trade allocations and benchmarking. Several WCI committees are considering some aspect of benchmarking, either through the creation of benchmarks or the use of them as a mechanism for addressing competitiveness issues created by a regional cap. Presentations from the workshop are available here. The WCI Partners anticipate future work on this issue.

WCI Electricity Team Releases Prototype Default Emission Factor Calculator for Stakeholder Review and Comment

The WCI Electricity Team has posted two versions of a default emission factor calculator on the WCI website for stakeholder review and comment:

- The "lite" version contains only the calculator worksheet and its data table and is available at http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/Prototype-Default-Emissions-Calculator-(Lite-Version).
- The full version contains all of the underlying data that were used to create the data table for the calculator, and an embedded document from the original Energy Information Administration files that provides additional information on the data and the codes used to identify fuels and generation technologies (note that the full version is nearly 6 MB). The full version is available at http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/Prototype-Default-Emissions-Calculator/ .

To submit comments go to http://www.westernclimateinitiative.org/public-comments/document/12.

The Electricity Team will host a stakeholder call on October 30th at 10:00 a.m. Pacific Daylight Time to receive initial feedback from stakeholders and answer any questions about the spreadsheet or the process for determining the default emission factors. To join the call, dial **1-800-868-1837** (toll free) or 1-404-920-6440 (direct dial) and enter participant code **659537#.** Written comments are due November 13th and should be submitted via the public comments page on the WCI website.

Default emission factors for attributing emissions to unspecified electricity are needed by WCI jurisdictions for three related reasons. First, WCI jurisdictions must quantify the emissions associated with imported electricity during the base years used for establishing their 2020 caps. Second, emissions associated with imported electricity need to be quantified during recent years leading up to 2012, the first year of the cap and trade program, in order to estimate 2012 emissions and set allowance budgets accordingly. Third, default emission factors are needed on an ongoing basis in order to establish the compliance obligations of first jurisdictional deliverers that deliver unspecified power or determine the number of allowances that must be retired by jurisdictions using the administrative option to account for electricity imports.

Various methodologies can be used to calculate default emission factors. The WCI Electricity Team discussed these options with stakeholders on a conference call in December 2008. The Electricity Team would like to receive stakeholder feedback on a simplified spreadsheet approach that approximates the load duration curve modeling methodology discussed with stakeholders.

The spreadsheet is meant to serve as a proof of concept for stakeholder feedback. This illustrative version only covers 2007 data for plants in the WECC region and does not include data on plants in Canada or Mexico. If the Team, in consultation with stakeholders, determines that this approach is sufficiently robust and the Partners approve, the Team will finalize the 2007 WECC spreadsheet and develop other spreadsheets for additional years and the Eastern Interconnect for stakeholder review. The Team will then calculate the default emission factors that will be recommended to the Partners for use by WCI jurisdictions.

The default emission factor spreadsheet draws on two publicly available data sources: the Energy Information Agency's Form 860 and the Form 923. Together, these two forms contain information on electricity generating facilities including generator types, generator capacities, quantities of fuel consumed, whether the facility is a CHP unit, and net generation produced.

Using the EIA information, the spreadsheet calculates default emission factors by assigning facilities to either a marginal or non-marginal category. The default emission factor is calculated as the total emission divided by the total net generation of all marginal sources. The Team relied on certain rules of thumb in order to determine a facility's "marginality." The first rule of thumb is that a plant is considered categorically non-marginal if it is a CHP unit or uses renewable sources of energy (including hydro).[1] The remaining non-CHP plants using fossil fuels as their main source of energy are considered marginal when their capacity factors are below 60%.[2]

Most of the calculations and database functions in the workbook are performed automatically by formulas or pivot tables, but some important manual corrections were necessary. Facilities listed in the Form 923 data as consuming both coal and natural gas are often actually two facilities collocated on one site. The coal-fired facility uses steam turbines while the gas-fired facility generally uses combustion turbines or a combination of combustion turbines and one or more steam turbines operating in a combined cycle. If these collocated facilities are treated as one facility, the resulting capacity factor misrepresents the true operations of the plants. For example, using 2007 data, the combined capacity factor of the Apache plant in Colorado is 53%, which indicates that it is a marginal power plant. Closer examination reveals that the coal units operated at an 83% capacity factor, and the gas units operated at a 5% capacity factor. In cases where such collocated facilities occur, they were manually separated into two distinct units in the data table that underlies the default emission factor pivot table.

The Electricity Team asks stakeholders to address the questions below in their comments, but stakeholders are not limited to responding to these questions.

---

[1] While hydro is on the margin at times in the Pacific Northwest, the vast majority of hydro generation in that region is produced in jurisdictions that are WCI members. It seems reasonable to assume that the relatively small amount of hydro power generated in non-WCI locations would rarely, if ever, serve as the marginal resource for power imported from those locations into WCI jurisdictions.

[2] This is the threshold used to distinguish baseload and non-baseload plants in California's and Washington's emission performance standards.

1. Is this approach sufficiently analytically rigorous? If not, do you think more sophisticated models are likely to produce significantly different results?
2. Is there any reason that this simplified approach is more appropriate for either the Eastern Interconnect or the Western Interconnect?
3. Are the rules of thumb used to classify plants as marginal or non-marginal appropriate? What specific changes do you recommend?
4. Are there any specific plants that have been misclassified with respect to whether they are marginal? If so, which ones and why?
5. Are there any other corrections or improvements that you suggest?

The following pages document the steps undertaken to create the default emission factor calculator from the EIA data sources. Instructions for using the calculator are provided on the "Instructions" worksheet in both versions of the calculator.

Documentation for Preparing the Default Emission Factor Calculator

Preparation of the "GenY07" and "GenY07PvtTable" Worksheets
Download 2007 EIA-860 from http://www.eia.doe.gov/cneaf/electricity/page/eia860.html

In the Form EIA-860 2007 data folder, open workbook GenY07

Delete columns T – AU (Cogenerator – Planned_Retirement_Year)

Add Column "OP_NAMEPLATE" and insert formula:
=IF(N2<>"RE",K2,IF(S2<>2007,0,R2/12*K2))
[This column lists a unit's operational capacity. If a unit was retired during 2007, it is attributed a partial capacity based on the number of months it was still operational.]

Create pivot table on new sheet: Facility ID in rows; sum of OP_NAMEPLATE in data

Copy data from pivot table and paste on same sheet

Creating the Default Emission Factor Workbook

Download 2007 Form EIA-923 from
http://www.eia.doe.gov/cneaf/electricity/page/eia906_920.html

Open workbook

Return to the GenY07 workbook and move the worksheets into EIA-923 workbook using "Move or Copy Sheet" from the Edit menu

Rename "Page 1 Generation and Fuel Data" as "Generation and Fuel Data"

Delete worksheet "Page 2 Stocks Data"

Insert worksheet "Emission Factors" and add table of factors

Insert names [as indicated in formula below] for cells containing conversion factor values

Preparation of the "Generation and Fuel Data" Worksheet

On "Generation and Fuel Data" delete monthly fuel and output data

Add column for emission factor and insert formula:
=IF(O9="bit",BIT,IF(O9="sub",SUB,IF(O9="ng",NG,IF(O9="pc",PC,IF(OR(O9="jf",O9="KER",O9="dfO"),DFO,IF(OR(O9="WC",O9="lig"),LIG,IF(OR(O9="rfo",O9="WO"),RFO,0)))))))

Add column “Tonnes CO2” and insert formula:
= Q9*S9/1000 and copy to entire column

Add Column U “Mixed Coal/Gas Flag” and insert formula:
=IF(AND(A9=A8,OR(AND(K9="NG",K8="SUB"),AND(K9="NG",K8="BIT"))),"F",""
)
[This formula is used to flag plants for possible separation into distinct coal and natural gas facilities.]

Sort by Facility ID ascending and Elec Fuel Consumption MMBtus descending

Preparation of the “Plant Info” Worksheet

Create Pivot Table on new sheet using the data from “Generation and Fuel Data” as the source

Put Facility ID in rows and SUM OF “NET GENERATION” in the data section.
Copy and paste into “Plant Info”

Return to Pivot Table and replace Sum of NET GENERATION with Sum of TONNES CO2

Copy CO2 values and paste next to NET GENERATION values on “Plant Info”

Add column “OP_NAMEPLATE” on “PlantInfo” and insert formula:
=VLOOKUP($A2,GenY07PvtTable!D$4:E$5745,2,FALSE)

Add column “State” and insert formula:
=VLOOKUP($A2,'Generation and Fuel Data'!A$9:F$2009,6,FALSE)

Add column “NERC Region” and insert formula:
=VLOOKUP($A2,'Generation and Fuel Data'!A$9:H$2009,8,FALSE)

Add column “Primary Fuel” and insert formula:
=VLOOKUP($A2,'Generation and Fuel Data'!A$9:K$2009,11,FALSE)

Add column “CHP” and insert formula:
=VLOOKUP($A2,'Generation and Fuel Data'!$A$9:$C$2009,2,FALSE)

Add column “Facility Name” and insert formula:
=VLOOKUP($A2,'Generation and Fuel Data'!$A$9:$C$2009,3,FALSE)

Add column “WCI Member” and insert formula:
=IF(OR(I8="WA",I8="OR",I8="CA",I8="MT",I8="UT",I8="NM",I8="AZ"),"Y","N")

Add column “Resource Type” and insert formula:

=IF(AND(B2="n",OR(F2="bit",F2="sub",F2="dfo",F2="ng",F2="lig",F2="rfo",F2="ker",F2="jf",F2="pc")),2,1)

Add column “Capacity Factor” and insert formula:
=E2/(J2*8760)

Add column “Marginal” and insert formula:
=IF(AND(G2=2,K2<0.6),"Y","N")

Preparation of the “PlantInfoStatic” Worksheet

Copy all cells from “PlantInfo” and Paste Special/Values in “PlantInfoStatic”

Perform the following manual corrections in PlantInfoStatic:

Plants identified by the coal/gas flag
Split plants having different coal and gas combustion technologies listed on Generation and Fuel Data into two different plants on PlantInfoStatic. [These plants are highlighted in yellow.] Split operational capacities into different gas and coal facilities based on the information in GenY07. Using the data from Generation and Fuel Data, attribute all natural gas emissions and generation to the gas facility, and attribute all coal and fuel oil generation and emissions to the coal facility. Based on the adjusted capacity and net generation data, calculate new capacity factors.

Plants on tribal lands
Change the WCI membership status from Y to N for three plants on tribal lands in WCI member states: Bonanza, Four Corners, and Navajo

Preparation of the “EmFacPvtTable” Worksheet

Create new worksheet “EmFacPvtTable” and create a pivot table using the data from “PlantInfoStatic” as the source

Use Primary Fuel as the column heading, State as the row heading, and Sum of Tonnes CO2 and Sum of Net Gen as the data fields

Use WCI Member and Marginal as page fields

From the Pivot Table menu bar, use Formulas/Calculated Field to create the Emission Factor Field as Tonnes CO2 / Net Gen

Instructions for the Default Emission Factor Pivot Table

The next worksheet, "EmFacPvtTable," contains a pivot table that allows the user to calculate emission factors according to various criteria. When the workbook is first opened, the pivot table is set to display the total CO_2 emissions, net generation, and weighted average emission rate of all U.S. facilities in non-WCI jurisdictions of the Western Electricity Coordinating Council (WECC) deemed to be marginal. The table disaggregates the results by primary fuel type as well as showing the total.

You can change the set of plants the pivot table uses to calculate average emission rates by choosing different parameters from the drop-down boxes above and in the data table. For example, choosing "all" from the "WCI Member" drop-down box will recalculate the default emission factor using all marginal U.S. plants in WECC. Similarly, you can choose to recalculate the factor based on all plants, both marginal and non-marginal, or non-marginal plants only.

Factors based on any combination of states can be calculated by using the "State" drop-down box and selecting any set of states desired. A user in one state can calculate an emission factor for unspecified imports from all other states by simply deselecting his or her own state from the list. Note that if the "WCI Member" drop-down is not set to "all," then the states that appear in the "State" drop-down list will be limited to either member or non-member states.

The pivot table is based on the data in the "PlantInfoStatic" worksheet. If you would like to change the "marginal" classification of a particular power plant, you must do so manually in this worksheet. For example, to change the capacity factor rule-of-thumb (set by default at 60%) to 50%, sort the data in "PlantInfoStatic" by resource type and capacity factor (to sort by two criteria at a time, you must use the Data menu at the top of the screen) and change the value in the "Marginal" column to "Y" for all type 2 plants (leaving the type 1 plants categorically excluded) with a capacity factor between 50% and 60%. Any time that data in "PlantInfoStatic" are altered, you must select a cell in the pivot table, right-click, and choose "Refresh Data" for the changes to be reflected in the pivot table.

Carbon Leakage Provisions in US Climate Policy

November, 2009

Washington, DC

W R I

James Bradbury
Senior Associate
Climate and Energy Program
World Resources Institute
jbradbury@wri.org
http://www.wri.org

Overview

Policies for addressing carbon/ jobs leakage from energy-intensive and trade-exposed (EITE) industries

- Background on the issue
  - Political history on Capitol Hill
- Active Legislation
  - Waxman-Markey (HR 2454) and Kerry-Boxer (S1733)
  - Output-based rebates (OBR)
  - Border measures; International Reserve Allowances (IRA)

Carbon and Jobs Leakage: US Political History

- July **1997**, Byrd-Hagel Resolution passed the Senate (95-0)
- Early **2007**, AEP-IBEW proposed border measures; widely incorporated into House and Senate climate policy proposals
- June **2008**, letter from 10 Senate Democrats opposing Lieberman-Warner ("Gang of 10")
- September **2008**, Inslee-Doyle H.R. 7146
- June **2009**, Waxman Markey passed the House (219-212)

How Congress Proposes to Address Emissions and Jobs Leakage?

Two Integrated Provisions:

1) ***Allowance Rebate Program*:** Temporary rebates (guaranteed thru 2025 & phased out by 2035) for energy-intensive, trade-exposed industries on an output basis.
2) ***International Reserve Allowance Program*:** Border adjustment measures (border taxes) starting in 2020 on imports if international negotiations and actions are not sufficient and allowance rebates do not fully compensate affected industries.

OBR Issue #1: Why Allowance Allocation?

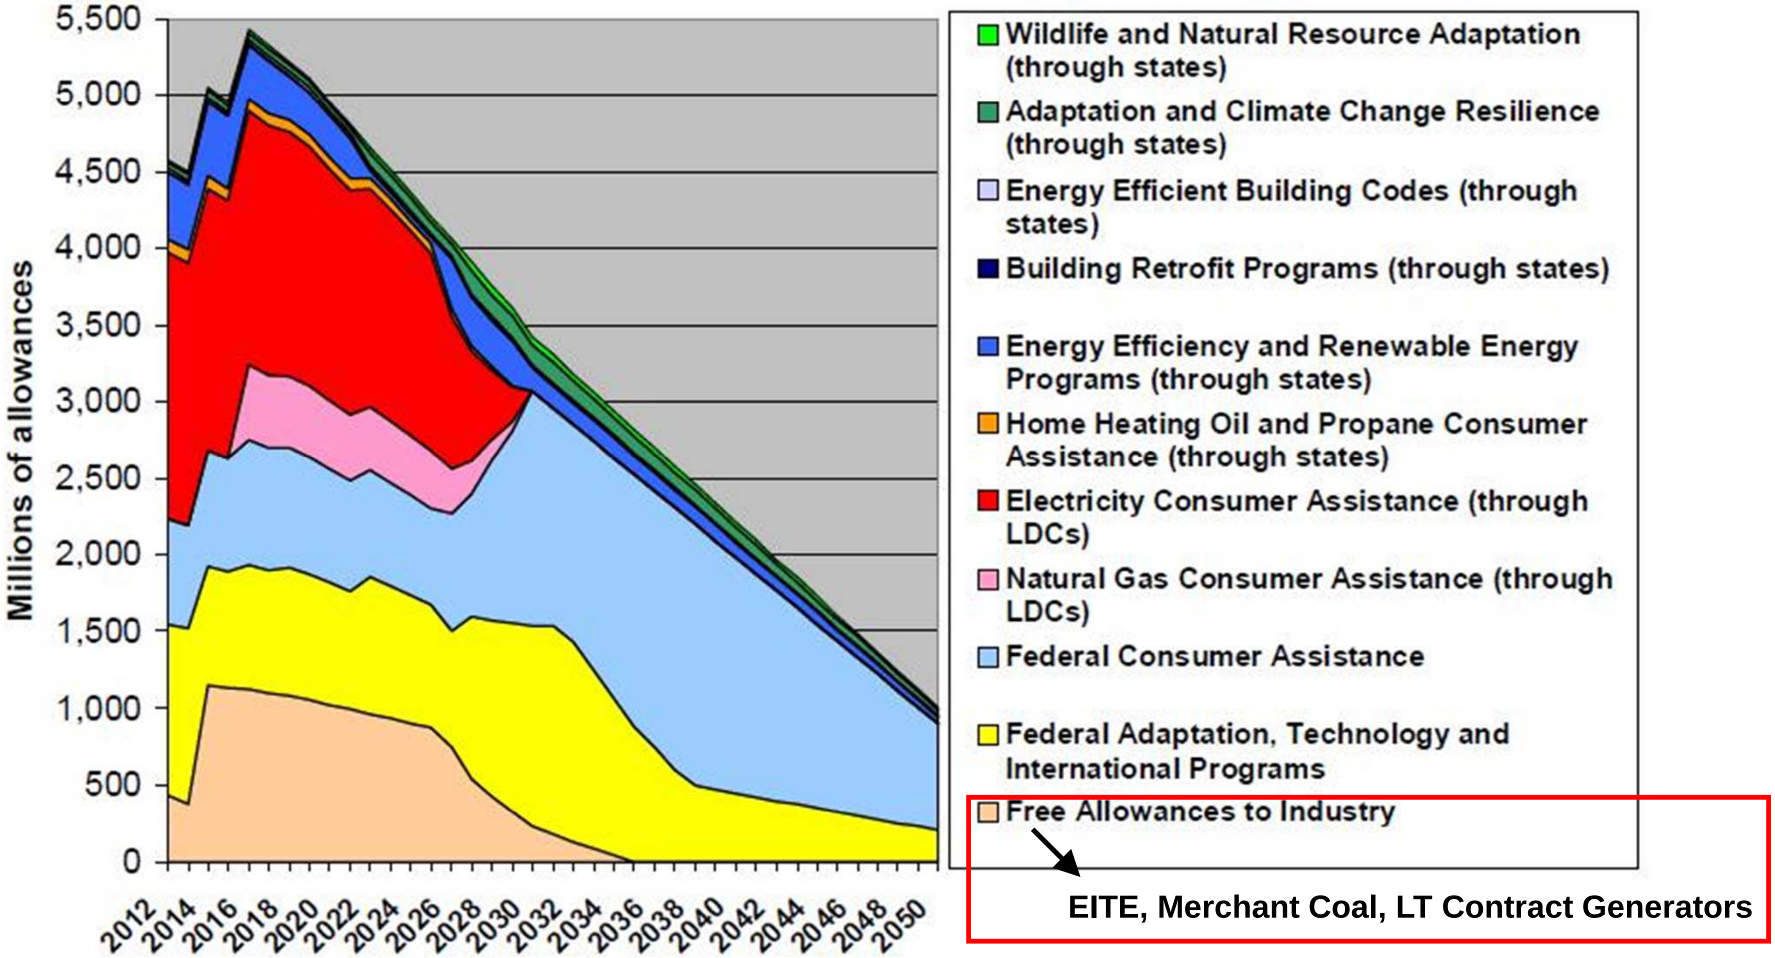
<u>Two distinct reasons - Two different policies</u>

1) Protect shareholders from stock losses
   - Studies find <15% of total allowance value

2) Prevent carbon leakage**
   - For EITE industries
     - Iron and Steel, Aluminum, Cement, etc.
   - Examples:
     - EU ETS phase III; phased out over time
     - Proposed Australia ETS takes similar route
     - Lieberman-Warner; phased out by 2031

Allowances are directed to states and LDCs for clean technology, adaptation, and energy consumer assistance.

ACESA Allowance Distribution, 2012-2050



As assistance through LDCs phases out, additional federal consumer assistance programs phase in.

OBR Issue #2: Eligibility

- Which industrial sectors should be eligible for compensation?
  - Lieberman-Warner (Boxer substitute):
    - *Specified* broad sectors:
      - “Iron, steel, pulp, paper, cement, rubber, chemicals, glass, ceramics, SF_6 and aluminum and other non-ferrous metals.”
  - Inslee-Doyle (HR 1759)
    - Narrowly target recipients based on need, using objective criteria
    - Goals: minimize over allocation; preserve policy integrity

EITE - Eligibility for rebates

EPA Administrator determines eligibility on the basis of whether or not a NAICS code sector (6-digit level) meet certain key criteria:

1) Energy intensity (or Carbon Intensity) > 5 percent

AND

Trade Intensity > 15 percent

OR

3) Energy intensity (or carbon intensity) > 20 percent

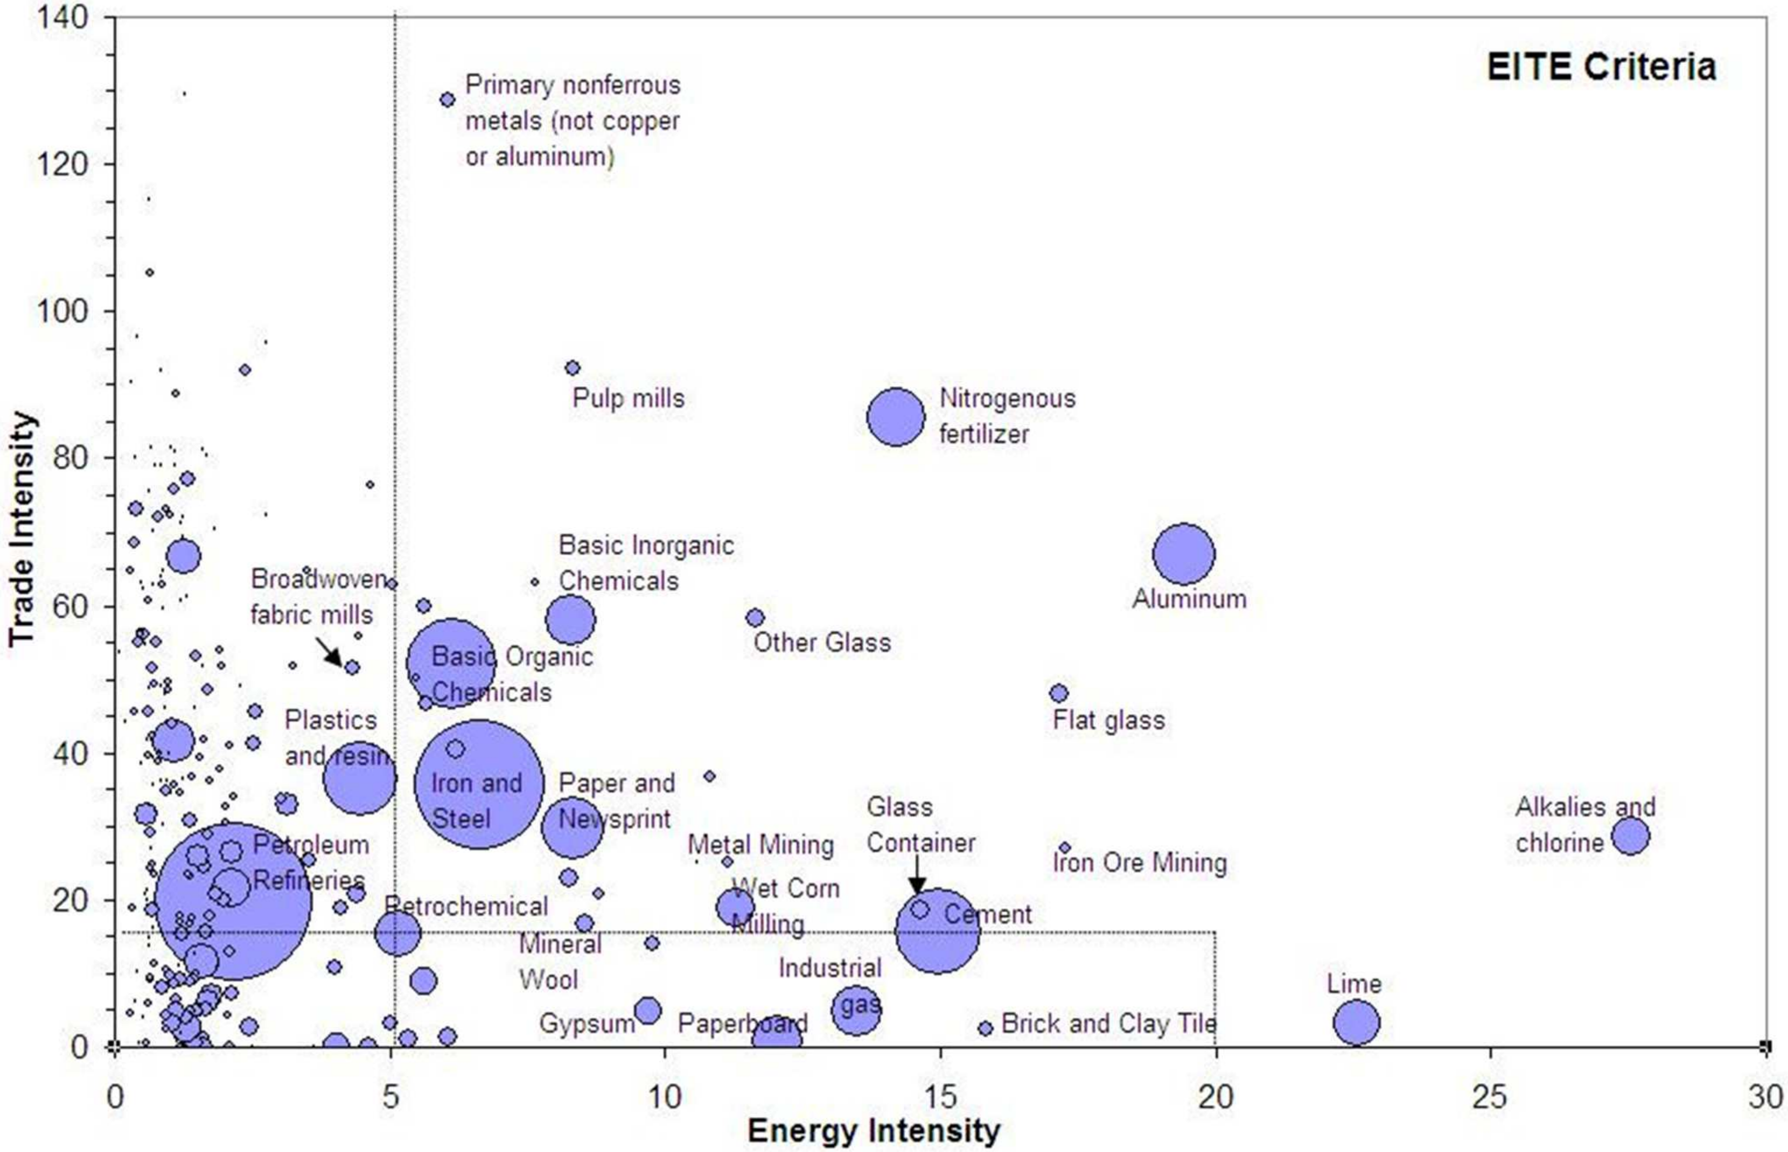
OR

4) Groups of facilities can make an “individual showing” that their subsector is eligible, based on the above criteria

Energy-Intensity = (Energy & Fuel Costs + Generation) / Value of Shipments

Trade-Intensity = (Imports+Exports) / (Value of Shipments+Imports)

OBR Eligibility; Sectors by NAICS Code (6-digit level)



Energy-Intensity = (Energy & Fuel Costs + Generation) / Value of Shipments

Trade-Intensity = (Imports+Exports) / (Value of Shipments+Imports)

OBR Issue #3: Allocation Methodology

- On <u>what basis</u> should allowances be allocated to industry?
  - *Past Emissions*
    - Rewards least efficient plants
    - Creates incentive to collect allowances while relocating production overseas
      - Does not effectively address leakage
  - *Output of Production*
    - Rewards most efficient plants
    - Effectively addresses leakage
    - Implementation is complex and political
    - Reduces downstream price signal
      - Hampers demand reduction (and possibly innovation)

W-M: OBR for Direct Carbon Costs

For onsite combustion or process emissions

$$\text{Facility Output (production)} \times \frac{\text{Sector average emissions}}{\text{Unit of Output}} = \text{Allowance Rebate}$$

Notes:

- Accommodates new market entrants
- Creates incentive to:
  - Invest in efficiency improvements
  - Maintain domestic production

W-M: OBR for Indirect Carbon Costs

For upstream emissions/ electricity use

Facility Output (production) X Sector avg. energy intensity of production X Emissions intensity of local utility = Allowance Rebate

$$\left[\ \text{Facility output (production)} \times \frac{\text{sector avg. kWh electricity use}}{\text{Unit of output}} \times \frac{\text{Utility ton CO2}}{\text{kWh elec. sold}} = \text{Allowance Rebate}\ \right]$$

Note: To account for allowance distribution to utilities, OBR is reduced by value of free allowances passed on by utilities

Issue #4: Phase down

- At what point should allowance allocation be phased down or replaced with an alternative policy mechanism?
  - When the carbon price disparity is reduced or eliminated
  - *Best addressed through international trade and climate agreements*

  - Waxman-Markey (ACESA)
    - Allowance pool reduces with the cap
    - After 2025, allowances phase-down for all sectors, unless exposure to leakage persists

W-M - Conditional Allocations
LDC - Allowances to EITEs

International Reserve Allowance (IRA) Program (with off-ramps)

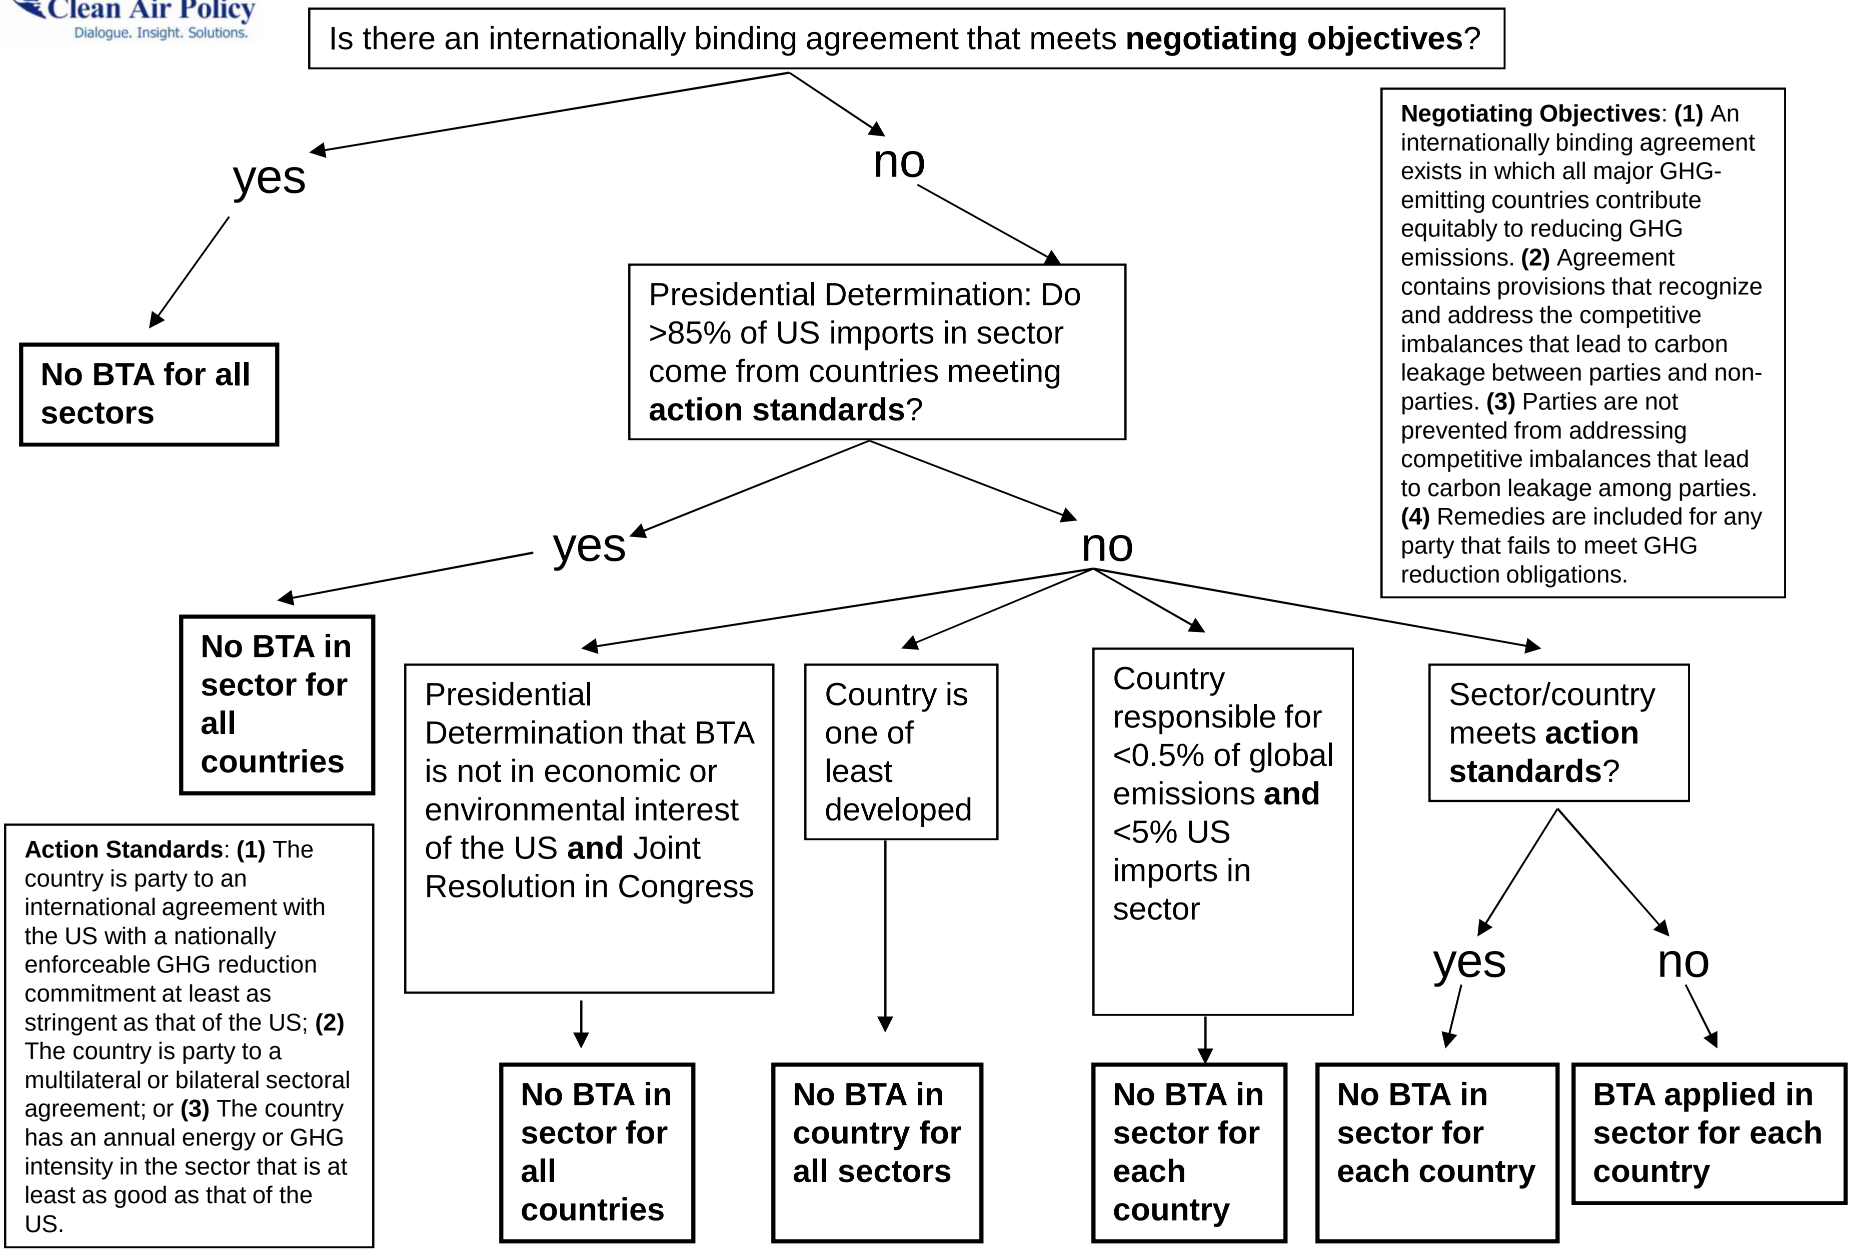
- A required purchase of a IRA credits would apply to **imports of primary products** from EITE industries starting in 2020, unless an international agreement is in place that meets the "*negotiating objectives*".
  - May also apply to imports of "covered goods"
- If negotiating objectives are not met, then imports of products from some sectors and/or countries would be subject to IRA, unless certain conditions are met:
  - Ex: sector is exempt if 85% of US imports within that sector are from countries that have met certain *"Action Standards"*

    OR
  - A country has met the Action Standards, with respect to a sector
  - A country is one of the least developed
  - A country is responsible for <0.5% of global emissions and <5% of US imports for a sector

When are Border Tax Adjustments Applied to Imports of Primary Products?

American Clean Energy and Security Act as passed in US House of Representatives

Center for Clean Air Policy
Dialogue. Insight. Solutions.



For Example:
Border Measures *on Canada?*

- If an internationally binding post-Kyoto agreement is not reached: Like all countries, Canada would have to meet our GHG standards:
  - party to an international agreement with the US with a nationally enforceable GHG reduction commitment at least as stringent as the US *(exempts country)*
  - party to a multilateral or bilateral sectoral agreement with the US* *(exempts sector)*; **or**
  - have an annual energy or GHG intensity, in each sector, that is at least as good as the US *(exempts sector)*

** A NAFTA-like agreement for EITEs?*

Take Away Messages

- Carbon Leakage is a key policy issue of environmental, economic and political significance
- The leakage problem appears to be real, but manageable
- International approach is best option; interim measures needed
  - Best if these are similar (among developed nations)
- *Targeted* allowance allocation provides effective protection for domestic industries
- Border measures may help, but they have substantial limitations

Thank you!

EU ETS and competitiveness: dealing with carbon leakage

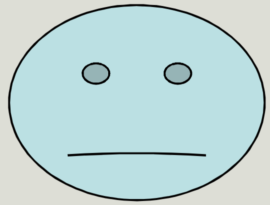
Webinar about Addressing Leakage & Competitiveness in the EU and US

Thursday 12 November 2009

I.Juergens
J. Barreiro-Hurle – J. Bemelmans –
M. Przeor – A. Vasa

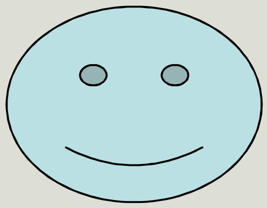
European Commission
Enterprise and Industry

Border Measures



- Considerable administrative cost
- Ensure conformity with WTO and UNFCCC principles
- Avoid retaliation
- Negative effect on Copenhagen negotiations
- Welfare effects?

Co-operative sectoral approaches



- Focus on the development, application and diffusion, including transfer of technologies, best practices and processes that control, reduce or prevent GHG emissions;
- Foster initiatives in R&D, capacity building and technology cooperation (covering) all phases of the technology cycle;
- Include measures to overcome barriers to development, transfer and deployment of technology;

3 Studies

1. “Proof of concept”: assess merits of SA as a tool to engage business to act
2. “Governance” – stakeholders involvement
3. “Efforts and costs to industry in different sectors and world regions”

European Commission’s carbon leakage assessment: Background

- ETS Directive (Dec. 2008): Sectors at risk of carbon leakage will receive ***100% free allocations based on (AMBITIOUS!!!) benchmarks***.

- EC undertook comprehensive assessment of 258 NACE 4-digit sectors covering Mining and Manufacturing activities and specific subsectors where needed.

How have industrial sectors been assessed ?

- **Quantitative evaluation of indicators** (*Article 10a Paragraphs 14-15-16):*
  - Intensity of trade with third countries.
  - Direct and indirect additional costs induced by the implementation of the directive as proportion of gross value added.

- **Qualitative assessment** (*Article 10a Paragraph 17*) **taking into account :**
  - Extent to which it is possible to reduce emission levels
  - Current and projected market characteristics
  - Profit margins

When is a sector deemed at risk ?

- Quantitative assessment
  - Trade Intensity over 30% OR
  - CO_2 cost over 30% of GVA OR
  - Trade Intensity over 10% AND CO_2 cost over 5% of GVA
- Qualitative assessment at NACE 4-digit level
  - No threshold, expert judgement based on economic and technological assessment

What was the reference period ?

- Trade: 2005-2007 / 2004-2006 / 2006-2007

	2004	2005	2006	2007
Turnover	SBS COMEXT	SBS COMEXT	SBS COMEXT	COMEXT
Exports	COMEXT	COMEXT	COMEXT	COMEXT
Imports	COMEXT	COMEXT	COMEXT	COMEXT

- Cost increase: 2005-2006

	2004	2005	2006	2007
GVA	SBS	SBS	SBS	
Direct CO2	MS	CITL MS	CITL MS	CITL MS
Indirect CO2	MS	MS	MS	MS

How has Trade Intensity been measured

- Directive defines trade intensity as:

  "*ratio between the total value of exports and imports to third countries and the total market size for the community (annual turnover plus total imports from third countries)*"

- Data sources: EUROSTAT COMEXT and structural business statistics (SBS) databases

- Key issue:
  - Import and export data needed to be compatible with turnover data
    → annual production sold (not straight forward – different data domains!)
    → Fallback: turnover from SBS

How have CO2 costs been measured?

- Direct emissions:
  - process emissions
  - combustion installation related emissions
- Indirect emissions: cost increase due to CO2 cost pass-through by power sector
- … compared to gross value added at factor cost (GVA)

Direct Emissions in CITL
(Community Independent transaction log)

- CO2 emissions for each current ETS installation
- Matching of installations with NACE sector (AMADEUS, Dan&Bradstreet, Kompass; MS; Industry; …)
- Emissions and GVA of an installation have been allocated to the same NACE sector
- Results of the matching process >95% complete.
  - Emissions not matched do not impact on the position of any given sector relative to thresholds

- Key issues with CITL:
  - No emission data for new (“2013”) ETS sectors and gases
  - Sectors with a substantial number of small installations that are not included in the scope of the EU-ETS
  - Sectors with "opt-outs" or temporary exclusions.

Data Sources other than CITL

- Process emissions data from the European Community' s greenhouse gas inventory.
  - matching of activities with NACE sectors

- Direct CO2 emissions, fuel consumption, (limited) process emissions data by Member States

- Issue with indirect cost: Data on electricity not available

- Response: Electricity consumption reported by MS

Indirect CO_2 Cost

- Primary data source: MS data on net electricity consumption in volume (MWh)

- Calculation of corresponding emissions: Average CO2 content of the EU-27 electricity mix (0.465 CO2 tons per MWh) used to estimate cost increase due to purchasing of allowances by power sector.

- Not all MS reported data but ratios calculated for reporting MS assumed to be representative of EU27 as a whole

- Key issues with indirect emissions:
  - Relevant emission factor
  - NET electricity consumption: auto-generation & double counting
  - Data coverage & representativity

Gross value added (GVA)

- Data sources: EUROSTAT SBS database
- Key issues:
  - Ensure consistency with emissions data
  - Not readily available at company level (for assessment at higher disaggregation)
- Response:
  - Ad-hoc aggregates of GVA estimates < EU-27
  - Business consultants reviewing company data under confidentiality agreements

Quantitative assessment results

- Out of 258 sectors, 146 meet the criteria at NACE 4-digit level
  - Most (117) sectors show a high trade intensity (>30%)
  - Others (27) have both significant CO_2 cost and trade intensity
  - Two sectors qualify through significant CO_2 cost alone (>30%)

Sectors quantitatively assessed at a higher level of disaggregation

- **WHY:** Assessment at NACE 4-digit can be missing specific products or groups of products which would meet the thresholds for the quantitative criteria laid down in the Directive.

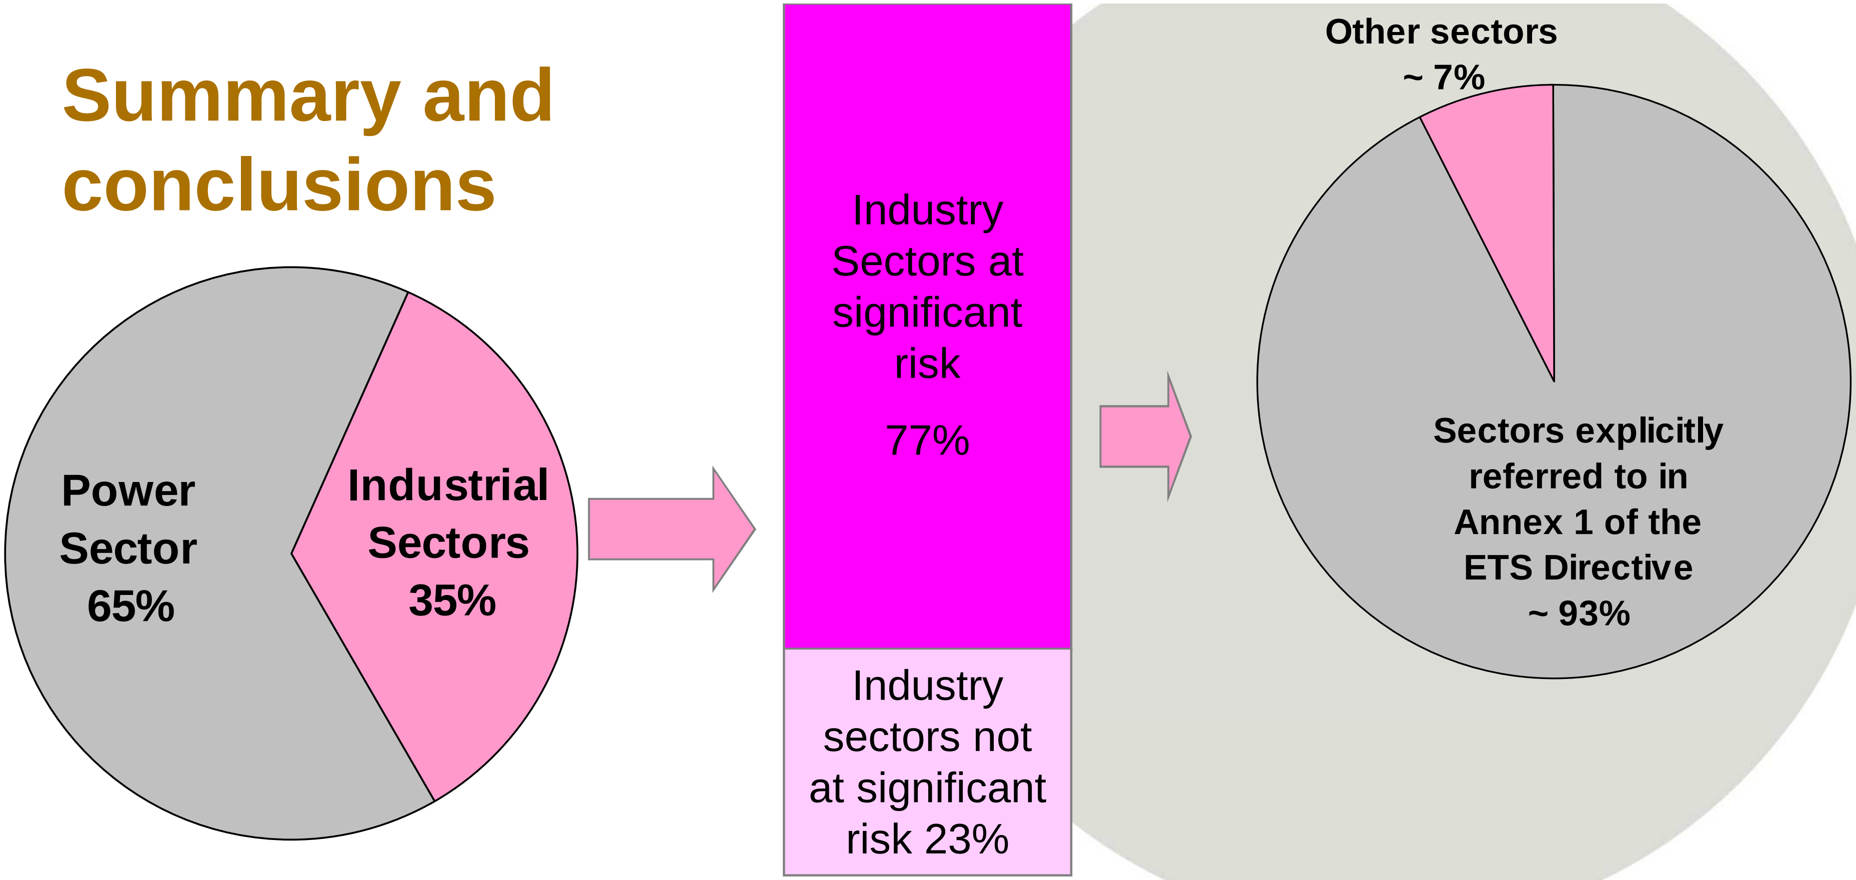
- **HOW:** Same Trade Intensity and CO_2 Cost indicators and thresholds as for NACE 4-digit sectors.

- 9 product groups deemed at risk of carbon leakage, including: Reinforced Glass Fibres; Hydrogen, Nitrogen and Oxygen

Qualitative assessment results

- **What triggered a qualitative assessment**
  - sectors close to the thresholds,
  - absence of data for one of the indicators (ex.: casting sectors → no trade data),
  - doubts about accuracy or coverage of quantitative data (Ex.: discrepancy GVA vs. emissions)
  - integrated production
- **Selective, clear EXCEPTION to the rule:** only 7 out of 94 sectors that did not meet the thresholds were assessed.
- 5 sectors deemed at risk of carbon leakage, including plastics in primary forms and casting of light metals

Summary and conclusions



- A majority of emissions in ETS will be auctioned
- Free allowances focused on sectors explicitly referred to in Annex 1
- The environmental objectives not compromised at all, as cap is not influenced; only distributional effects
- Emission reductions are autonomous and non-conditional, unlike under border measures!

Thank you!

3.3.3 Exchanges and OTC transactions 12

4. Oversight in existing markets 13

4.1 U.S. market oversight 14

4.2 Canadian provincial market oversight 15

4.3 European Union Emissions Trading Scheme market oversight 18

5. U.S. Federal Proposals 19

6. Conclusion 22

1. Introduction

The Western Climate Initiative (WCI) is a cooperative effort of seven U.S. states and four Canadian provinces that are collaborating to identify, evaluate, and implement policies to reduce greenhouse gas (GHG) emissions, including the design and implementation of a regional cap-and-trade program. The WCI began in February 2007 with the governors of Arizona, California, New Mexico, Oregon, and Washington, who have since been joined by the premiers of British Columbia, Manitoba, Ontario, and Quebec, and the governors of Montana and Utah. Participation in the WCI reflects each Partner jurisdiction's strong commitment to identifying, evaluating, and implementing collective and cooperative actions to address climate change.

In September 2008, the Partner jurisdictions released the final "Design Recommendations for the WCI Regional Cap-and-Trade Program."[1] The first compliance period for the cap-and-trade program will begin January 1, 2012, covering GHG emissions from electricity generation (including emissions associated with imported electricity), combustion at large industrial and commercial facilities, and industrial process emissions for which adequate measurement methods exist. Starting in 2015, the program's coverage expands to include transportation fuels in addition to residential, commercial, and small industrial combustion. Thus, by 2015 the cap-and-trade program will cover almost 90% of GHG emissions in the Partner jurisdictions.

In February 2009, the Partner jurisdictions released the WCI 2009 – 2010 Work Plan, describing the approach to implementing the Design Recommendations.[2] The WCI is working through six committees: Offsets, Reporting, Electricity, Complementary Policies, Cap Setting and Allowance Distribution, and Markets. The Work Plan describes the tasks and deliverables for each committee. The purpose of one of the Markets Committee's tasks, "market oversight," is to recommend measures to ensure that the allowance and offset credit trading market is organized properly to operate reliably and prevent or minimize manipulation. This task was included in the work plan based on the consensus among WCI Partner jurisdictions on the need to provide effective oversight to assure an efficient and transparent carbon market.

This white paper reports on the information collected and reviewed by the Markets Committee on market oversight approaches and issues. The information was obtained through several means, including the following.

---

[1] The Design Recommendations and accompanying Background Report can be found at http://westernclimateinitiative.org/the-wci-cap-and-trade-program/design-recommendations.
[2] The 2009 – 2010 Work Plan can be found at http://westernclimateinitiative.org/component/remository/general/workplans/2009-2010-WCI-Work-Plan/.

- The Markets Committee held a stakeholder workshop on market oversight in Seattle, Washington in April 2009. The Committee presented a draft set of principles of market oversight, and a list of questions for discussion with those who attended in person or online.[3] Stakeholders were invited to submit written comments.[4] Stakeholders' responses guided the Committee's consideration of issues and the Committee revised the principles of market oversight as set forth below. The principles guided the Committee's research, analysis, and deliberation, and will continue to do so as the Committee progresses towards draft and final recommendations.

- The Markets Committee held a webinar with the market monitor used by the Regional Greenhouse Gas Initiative (RGGI).

- The Markets Committee consulted with U.S., Canadian, state, and provincial regulatory authorities, and received input from European market regulators, potential market participants, trade associations, market infrastructure providers, and other stakeholders.

- The Markets Committee conducted a literature review with the assistance of our task advisor at the Nicholas Institute at Duke University.

Through this process, the Committee acquired substantial knowledge about the types of regulation in place in existing financial markets, the roles of regulators and exchanges, and the scope of existing carbon-related financial products. This information is presented in this paper as follows:

- Section 2 presents the revised principles being used to guide the development of the market oversight recommendations.

- Section 3 summarizes background information, including an overview of cap-and-trade, market architecture and oversight, and existing market models.

- Section 4 describes oversight of existing markets in the U.S., Canada, and Europe.

- Section 5 identifies recent U.S. federal proposals related to carbon market oversight.

---

[3] The principles and questions can be found at http://westernclimateinitiative.org/component/remository/func-startdown/25/. Market oversight was one of three tasks for which the Committee developed draft principles for comment; the others were auction design and compliance verification and enforcement.
[4] Stakeholder comments were submitted to the WCI website, and can be found at http://westernclimateinitiative.org/documents/public-comments/document/2.

The paper concludes with a brief list of key decisions that are under consideration.

2. Principles

These principles serve as guidelines for developing oversight of the allowance, offset credit, and associated derivatives trading markets to assure maximum environmental and economic benefit to the public.

- **Fairness:** All market participants, especially covered entities, have fair and equal access to the market.

- **Efficiency:** The market is designed to operate efficiently so that greenhouse gas (GHG) emission reductions can be achieved at the least cost. An efficient market means that allowance and offset credit prices reflect supply and demand, and accurately reveal the value of allowances and offset credits.

- **Effective Oversight:** The design and oversight of the market is effective in preventing or minimizing fraud, manipulation, and speculative excess.

- **Transparency and the Reporting and Disclosure of Relevant Information:** Transparency in the design and the operation of the allowance and offset credit market builds and retains public confidence.

    - Reporting of relevant information to regulatory authorities and public disclosure of information has important benefits. It enables regulatory authorities to conduct effective oversight and ensure compliance. It also helps to ensure market efficiency, effective oversight, and compliance and enforcement. The release of information can change the decisions of market participants, which impacts the prices of allowances and offset credits. Timely, accurate, coordinated and consistent release of market-relevant information allows all market participants to have equal access to public information.
    - The reporting and disclosure requirements for compliance verification and enforcement balance these benefits against the need for entities to protect certain sensitive information. The potential to disclose certain information that could be used to manipulate the market is also considered. This balancing is consistent with applicable law relating to the disclosure of information.

- **Administrative Simplicity and Cost:** Proposed rules are designed to be understood and enable entities to have a clear compliance path. Administrative costs and transaction costs are minimized for all parties, consistent with the need to provide effective oversight.

- **Accountability:** All entities involved in the allowance and offset credit market, as either regulators or market participants, are accountable for their actions. The responsibility, authority, and capacity to conduct the necessary oversight and take appropriate action are fully defined for all agencies charged with compliance verification and enforcement.

- **Conflicts of Interest:** Conflicts of interest between market participants, monitors, and regulators are prevented.

The principles were revised as a result of further review after the Markets Committee stakeholder workshop and submitted comments. First, "maximum environmental and economic benefit for the public" was explicitly confirmed as the purpose of the principles. A sentence was added to the principle of "Transparency and the Reporting and Disclosure of Relevant Information" to acknowledge that the release of information can change the decisions of market participants. Timely and accurate release of market-relevant information has been more explicitly noted. These additions are in line with the Markets Committee's intent and highlight concepts that stakeholders were interested in seeing expressed explicitly.

3. Background

In 2008, the value of global carbon market was estimated at €92.4 billion. Though trade volumes were expected to continue growing, anticipated lower prices led to a forecast of €62.6 billion in 2009[5,6]. The volume of transactions is growing each year and further growth is expected as cap-and-trade programs are likely to be launched in North America and elsewhere. Numerous financial products are now available to the firms that face a regulatory obligation under the European Union Emissions Trading Scheme (EU ETS) or the Regional Greenhouse Gas Initiative (RGGI) as well as to investors and intermediaries that participate in the trading of carbon allowance-based financial products. It is likely that the WCI regional cap-and-trade program will generate a substantial volume of transactions and the creation of a number of new financial products based on allowances issued by WCI Partner jurisdictions. The recent financial crisis and market turmoil has further highlighted the potential for disruptions to markets and need to properly address market architecture and oversight to ensure that the carbon market works efficiently and effectively in support of the program's environmental and economic goals.

This background section provides an overview of the financial markets that may develop along with the establishment of a cap-and-trade program. It will help explain the role of the different

---

[5] "Carbon Market Analyst: Outlook for 2009," PointCarbon Research, February 19, 2009.
[6] At October 8, 2009 exchange rates, these values would be $U.S. 136.7 billion and $CAN 144.2 billion in 2008, and $U.S. 92.6 billion and $CAN 97.7 billion in 2009.

participants and institutions in the carbon market and how they might influence the future WCI market. The outline of the section is as follows: Section 3.1 summarizes the foundations of a cap-and-trade program. Section 3.2 defines and describes market architecture and oversight. Section 3.3 outlines oversight of existing financial markets.

3.1 Overview of a cap-and-trade program

In a GHG cap-and-trade program, an emitter must turn in one "allowance" for every metric ton of carbon dioxide equivalent[7] (CO_2e) it emits. An allowance may be a limited authorization to emit GHGs. The regulator(s) implementing the cap-and-trade program issues a limited number of allowances, thus creating a "cap" on emissions. The number of issued allowances can decline over time, resulting in further emissions reductions toward a predetermined goal.

Market participants can buy and sell (i.e., trade) allowances, and the allowances commonly are fungible across the emitters and jurisdictions participating in a cap-and-trade program. The market price for allowances is derived from supply and demand. Supply is determined through establishment of the cap and subsequent issuance of allowances. Allowance demand depends on energy demand and the cost of technologies and strategies that reduce emissions. Emitters will choose whether and how much to invest in allowances, offsets, or reductions of their own emissions based in part on current and projected prices of allowances, offsets, and emission abatement costs. In a well-functioning market, the allowance price will adjust in response to clearly communicated and accurate information aggregated from the broad market. Accurate and timely information about allowance price, trade volume, and current bids and offers helps market participants and observers minimize transaction costs and uncertainty about market activity.

Existing GHG emissions cap-and-trade programs include the EU ETS and the Regional Greenhouse Gas Initiative (RGGI), a collaboration of 10 U.S. states.

3.2 Market architecture and oversight

"Market architecture," for WCI purposes, refers to: 1) the market participants (those who buy, sell, and hold allowances) and institutions that make up a market; and 2) the systems, infrastructure, processes, and tools used by the participants and institutions. "Market oversight" refers to a broad range of activities that ensures allowance and offset credit markets serve the environmental and economic goals of a cap-and-trade program. Oversight includes choices regarding the establishment of a market, the rules governing market participants, and

---

[7] Some GHGs have a greater climate effect than carbon dioxide (CO_2); for example, methane is about 25 times as potent (Intergovernmental Panel on Climate Change Fourth Assessment Report, 2007, Working Group I Report, p. 212). To treat emissions uniformly, GHGs are referenced to their carbon dioxide equivalent, CO_2e.

monitoring of market activity. The WCI Partner jurisdictions intend to consider these choices in accordance with the principles in section 2 of this white paper.

The central purpose of a market mechanism is to aggregate and transmit price information. Market participants require complete, accurate, and unambiguous disclosure of price information on a regular and timely basis to make informed decisions about investments and transactions. In the case of a cap-and-trade program, emitters will use the current and expected price of allowances to assess whether to spend money to reduce emissions or to purchase additional allowances. The carbon market is used to determine the price of allowances, reflecting underlying supply and demand.

A lack of information or inaccurate information in the marketplace can lead to prices that do not accurately reflect the real marginal cost of reducing emissions. Such misinformation would distort emitters' investment decisions, which could raise the overall costs to regulated entities and the public. Market transparency and effective oversight helps ensure an efficient market with prices that more accurately reflect the marginal cost of emissions abatement, as well as preventing distortion of the price through, for example, attempts to manipulate the market.

Given the importance of information in determining prices in markets, market oversight typically includes requirements for disclosure of certain market-relevant information in a systematic and transparent manner. For example, in a carbon market, the accurate and timely disclosure of emissions data can be of particular importance. In addition to the disclosure of information publicly, regulators will want to collect information needed to analyze the market and to ensure that market participants are following the rules and laws that govern a market. This commonly includes collecting data regarding:

- the types of instruments being traded;
- bid, offer, and settlement prices;
- trade volumes and net changes for each contract type;
- the location of trades;
- the number and value of open positions held by market participants;
- price movements;
- changes in price relationships among futures in different delivery months, on different trading facilities (e.g., exchanges), and between futures and the cash markets;
- trade liquidity and severity of price changes; and
- market news and rumors.

Regulators can require that information be provided by market participants to support this analysis. This information can be supplemented with publically or commercially available information. While transparency is important for efficient market operation, some information may reveal competitive positions that would do more to assist manipulation than prevent it. Consequently, care must be exercised in determining which information will be disclosed publicly. Information reporting and disclosure will be at the heart of many decisions to be made on market oversight.

Regulatory authorities may allow one or more exchanges or other commercial marketplaces to offer trading services. In that circumstance, the regulatory authorities may gather and distribute information so that market participants can have good information on which to base their trading decisions. The regulatory authorities also monitor the potential risks of these marketplaces that may affect the securities marketplace operations. Prior to operation and then typically on an ongoing basis, the regulatory authorities assess a marketplace against core operating criteria and evaluate risk to the public and market participants, market integrity, and market efficiency. Examples of core operating criteria include public interest mandates, good corporate governance requirements, conflict management mechanisms, rule-making, -monitoring and -enforcement, clearance and settlement, fair access and fees, and information sharing and cooperation with regulators. Market regulation tools may also include software systems that allow surveillance to determine breaches in market integrity rules, identify suspicious trading patterns, and accurately identify who is trading and when.

3.3 Existing markets as models

There are a variety of market structures that can serve as useful models for the WCI Partner jurisdictions as they create a regional cap-and-trade system. Given the newness of allowance and offset credit markets, the committee examined longstanding markets in securities and commodities for examples of what a fully developed carbon market might look like. For the purposes of this paper only, we use "allowances" to mean both allowances and offset credits, and collectively refer to trading of allowances, offset credits, and their derivatives as a "carbon market."

Securities include stocks and bonds, and represent part ownership of a corporation or debt. Like allowances, they are issued in limited numbers and have serial numbers that allow tracking of ownership of a particular unit.

Commodities are goods that are interchangeable with other goods of the same type.[8] For example, as long as a bushel of grain meets certain standards, the purchaser is indifferent to its source. In contrast to fixed issues of securities, commodity supplies may fluctuate over time depending on economic conditions and production factors—for example, grain supplies depend

[8] "Commodity," Investopedia, retrieved August 3, 2009. http://www.investopedia.com/terms/c/commodity.asp

on the weather in producing regions. Because most are not financial instruments but goods, commodities usually have non-negligible storage costs. “Energy commodities” refers to commodities like oil and natural gas.

There are significant differences between allowances and traditional securities and commodities. First, because allowances may be limited authorizations to emit GHGs, their possession may not imply ownership of property. Second, covered entities must submit allowances for compliance with regulations on GHG emissions.

Participants trading allowances in existing carbon markets have generally treated them as commodities. Many firms that are covered in existing cap-and-trade programs require energy commodities as inputs. As with commodities, allowance prices reflect global economic conditions and demand more than the decisions made at an individual corporation, which affect the value of that corporation’s stock.

Despite differences with commodities and securities markets, there are important lessons from these that can guide the development of the WCI’s carbon market. By examining the regulations that have proven to be effective, as well as the types of market problems that occurred in the past and the proposed solutions, the WCI Partners are identifying best practices in market regulation that can ensure a transparent, efficient carbon market.

3.3.1 Types of markets

If the market for allowances were to resemble those for securities and commodities, it would have several interrelated facets:

- The distribution of allowances by WCI Partner jurisdictions, such as through auctions, would comprise the primary market.
- Trading of allowances after the initial distribution would comprise the secondary market.
- A part of the secondary market important and distinct enough to be treated separately in this paper is the derivatives market. Derivatives are instruments whose value is derived from an underlying instrument—in this case, allowances.

In this white paper, references to the “secondary,” “spot,” or “cash” markets mean the approximately instant trading of allowances themselves, while derivatives markets will be treated separately.

Examples of derivatives include:

- Futures: Standardized contracts (i.e., contracts that are fungible with one another) to deliver something (e.g., allowances) at a certain price on a certain date in the future.

- Forwards: Non-standardized contracts to deliver something at a future date. The price may be fixed when the contract is executed, or may be determined at a time in the future.

- Options: A contract that gives the purchaser the right to buy or sell something at a certain price before a certain date.

- Swaps: A contract to exchange one thing for another.

Derivatives products are generally either "physically settled" or "cash settled," meaning the transaction involves an exchange of goods or solely of money.

Derivatives can be used to manage the risks inherent in fluctuating prices. This is often referred to as "hedging." For example, a natural gas-fired power plant may prefer to hedge against the possibility of an increase in natural gas prices by buying a future. A natural gas producer may similarly want to guarantee a price for some part of its production, and consequently may sell a future. Other firms may be willing to accept some risk of price volatility for the possibility of a higher return, or are confident of their analysis of whether prices will rise or fall. They trade derivatives even though they are not producers or consumers of a good. This motive for trading is commonly called "investing" or "speculating."

Derivative products may serve an important function in a carbon market. The WCI cap-and-trade system, for example, will create a long-term obligation for covered entities. Some of those entities may find it necessary or desirable to lock in future prices to provide certainty to customers, investors, or regulators. Because many of the allowances issued during a compliance period will likely be submitted for compliance, derivative products may provide one of the few options for managing this long-term risk. In addition, derivatives markets may give emitters a sense of the long-term trends in allowance prices, allowing emitters to justify and finance investment in reducing their emissions. Moreover, derivatives may reduce volatility in commodities markets, by accelerating the incorporation of new information into asset prices[9,10].

[9] E.g., "Populists and Theorists: Futures Markets and the Volatility of Prices," David S. Jacks, Explorations in Economic History 44, p. 342 – 362, 2007, http://www.sfu.ca/~djacks/papers/publications/populists.pdf (Accessed October 8, 2009).

3.3.2 Market participants

A WCI carbon market could involve diverse participants who may trade to satisfy a compliance obligation, purchase for resale to emitters, speculate on the price of allowances, or diversify an investment portfolio. Entities that could participate in the carbon market may include compliance entities, investors, brokers and other intermediaries. Each entity would play a different role in the market.

Even if compliance entities receive allowances without charge from a government, the number may not be equal to their obligation, perhaps due to growth or contraction in their emissions or policy decisions on the quantity or formula for distribution. These entities may then choose to purchase additional allowances from the primary or secondary market, or sell allowances they will not require for compliance or for other reasons. In early 2009, industrial facilities in the EU ETS sold allowances, many freely allocated, to raise cash when other finance avenues became more difficult.[11]

Many compliance entities may desire to use allowance derivatives to limit the risks inherent to them in higher or lower prices. Allowance prices will likely rise and fall as new information is incorporated by market participants. Information that may influence prices includes weather data and forecasts, emissions data, economic data and forecasts, and policy choices by governments.

Though they would not be required to hold allowances for compliance, other categories of participants could play market roles. Brokers and other intermediaries may, for a fee, arrange trades of allowances or derivatives between parties, or provide advice or other services. Investors may desire to be market participants to profit from trading.

The WCI Partner jurisdictions have received oral and written comments from stakeholders suggesting that market participation be limited to compliance entities. Many of these comments referred specifically to auctions, which are the subject of a separate WCI white paper, but may also be addressed in the context of secondary and derivatives markets. The concerns expressed can be summarized as:

1) That participation by non-compliance entities will increase the price of allowances.
2) That participation by non-compliance entities increases the chances of market manipulation.

---

[10] "The Impact of Energy Derivatives on the Crude Oil Market," Jeff Fleming and Barbara Ostdiek, http://www.rice.edu/energy/publications/docs/Flemming_ImpactEnergyDerivativesCrudeOilMarket.pdf (Accessed October 8, 2009).

[11] E.g., "Carbon Markets 2009," IFSL Research, July 2009, http://www.ifsl.org.uk/upload/Carbon_Markets_2009.pdf (accessed October 1, 2009).

3) That participation by non-compliance entities will limit access to allowances.

The first concern may be related to questions regarding the role of speculation in markets: particularly speculation in energy markets as the price of oil rose rapidly in late 2007 and 2008 to a peak of $147 per barrel on July 11, 2008. Whether oil prices during this period reflected an understanding of underlying supply and demand, or may have been driven by "excessive" speculation, is a question that will not soon be resolved. Investors *can* play important roles in competitive markets by increasing liquidity and accepting risk. A healthy market is "liquid," meaning there is a sufficient number of buyers and sellers in the marketplace to allow trading to take place. Larger numbers of market participants make it more likely that there will be counterparty (i.e., another party willing to participate in a trade). Derivatives transactions are often described as a transfer of risk from one entity to another. Investors are often willing to act as counterparties and accept the risk. A market with less liquidity may be subject to more price volatility and it may be more difficult for entities needing to buy allowances to locate willing sellers. Consequently, concerns about potential "excess" speculation by investors must be weighed against these benefits of allowing investors access to the carbon market.

The second concern implies either that more market participants increases the ease or risk of manipulation, or that non-compliance entities might attempt market manipulation while compliance entities would not. However, a larger number of market participants would most likely make manipulation more difficult, not less, by increasing liquidity and making control of a significant proportion of allowances by one or a few persons harder. Moreover, there is no assurance that a non-compliance entity is more likely to attempt market manipulation than a non-compliance entity, or that no compliance entity would attempt market manipulation. Limiting market participation to compliance entities would exclude some number of potentially beneficial participants, with no certainty that the risk of market manipulation would decrease.

The third concern is that non-compliance entities may hold allowances for some period of time, making them unavailable to compliance entities who may need them for compliance. There are many possible reasons for holding allowances; the auction design recommendation report commissioned by RGGI identifies five:[12] speculation; allowance market manipulation; electricity market interference; competitive advantage; and external compliance. In none of these cases would market risks be reduced by restricting the market to compliance entities, save potentially external compliance. When restricting a market reduces liquidity, in fact, the risks are increased. "External compliance" is the possibility of another cap-and-trade program accepting WCI allowances in lieu of its own, without any reciprocal acceptance of the program's

[12] "Auction Design for Selling CO2 Emission Allowances Under the Regional Greenhouse Gas Initiative," Charles Holt, William Shobe, Dallas Burtraw, Karen Palmer, Jacob Goeree, October, 2007, section 9, "Hoarding of Allowances," http://www.rggi.org/docs/rggi_auction_final.pdf (Accessed October 6, 2009).

allowances by WCI jurisdictions. Though this risk might be enhanced by allowing non-compliance entities to participate, it is nevertheless very small, as it has not been proposed by the existing GHG cap-and-trade programs, RGGI and the EU ETS.

In addition to considering whether participation limits are desirable, WCI Partner jurisdictions will consider whether they are practical.

One consideration is how to determine who has a compliance obligation, including when that determination is made. The determination could be made the moment a facility emits beyond the cap-and-trade emission threshold of 25,000 metric tons in a calendar year; when it submits its verified emissions report showing emissions in excess of the threshold; at the “compliance event” after the end of a three-year compliance period when it must submit allowances to cover its emissions; or perhaps other choices. Each of these approaches may have different implications for who would be considered to have a compliance obligation for purposes of participation in the market. For example, if a smaller entity will not cross the emissions threshold until November in a given year, would it be forbidden to obtain allowances earlier? This implies that larger entities would be able to start trading earlier than smaller ones. To prevent this, the WCI Partner jurisdictions could allow an entity to participate in the market in anticipation of having a compliance obligation. However, if “anticipation” of an obligation is sufficient, then there would have to be procedures for who determines whether that anticipation is adequately grounded, and when, as well as any the penalties and recourse if the estimates used to anticipate an obligation are incorrect or fraudulent.

Another practical consideration for participation limits is to evaluate whether such limits are enforceable. One example is a person otherwise excluded by participation rules purchasing some fractional interest in a facility that was a compliance entity, with an agreement that the person could trade as a representative of the entity. A second example from derivatives trading is that the Chicago Climate Futures Exchange (CCFE) has been the most active platform for derivative trading of RGGI allowances. The CCFE determines its own membership. WCI states and provinces may not have jurisdiction over either the exchange or traders, so rules about allowable participation may be impossible to enforce.

The Markets Committee continues to evaluate arguments for and against limiting participation by the type of entity, and is investigating markets beyond the financial markets for examples of participation limits and their effects.

3.3.3 Exchanges and OTC transactions

Securities and commodities trading encompass a variety of markets, physical and electronic, where buyers and sellers meet to trade. The U.S. Commodity Futures Trading Commission (CFTC), for example, oversees at least four kinds of markets for trading commodity derivatives.

The markets vary in their restrictions on participation (e.g., some are limited to large investors, assumed to be sophisticated in their evaluation of risks) and contracts offered. The type of market is often defined by a regulator's choices about transparency, participation, and other requirements.

Here two particular kinds of markets are highlighted: exchanges and over-the-counter (OTC) markets, which represent ends of a spectrum in regulation. Exchanges are associated with a higher degree of oversight and transparency. They are centralized marketplaces that offer standardized contracts that are fungible with one another and generally require "clearance." Federal law in the United States and provincial law in Canada generally require exchanges to set rules implementing governance principles on market manipulation, publication of trading information, fair and equitable trading, emergency authority, and more.[13]

In "clearing," a central organization becomes the buyer to the seller and the seller to the buyer—that is, it becomes the counterparty to both sides. The clearing organization, therefore, assumes the obligation to complete the transaction even if one party is unable to perform its part. Most clearing organizations associated with exchanges perform clearing only for members, who set the clearing organization's rules and collectively shoulder the risk of default of any one party. This diffusion of risk facilitates trading by reducing counterparty credit risk to a single entity, the clearing organization; the clearing members have a financial incentive to set their rules to keep the risk of default low. Clearing organizations typically require members to post "margin," liquid collateral (such as cash or government bonds) against the risk of default on a contract.

OTC transactions are executed directly between private parties. There is typically little public disclosure of the contract terms for OTC trades. Some of the contracts are less standardized, and the counterparty credit risks are associated with the specific parties to the transaction. OTC trades are generally subject to less regulatory oversight than exchanges, although both U.S. and Canadian lawmakers are considering proposals to increase regulation of OTC instruments. At the same time, OTC contracts may help to develop new types of standardized contracts, especially in new markets. OTC instruments may provide initial products that evolve into standardized contracts.

4. Oversight in existing markets

Market oversight activities include:

[13] E.g., "Designation of boards of trade as contract markets," 7 U.S.C. §7.

- Establishment of rules for market participants, including standing rules for participants and rules for trades;

- Information collection and analysis to track market activity and verify compliance with market rules and laws (market monitoring);

- Information release to the public; and,

- Enforcement actions in response to suspected violations of rules or laws.

As stated above, there could be many participants in the Western Climate Initiative—compliance entities, exchanges, clearing organizations, investors, brokers, etc.—each of which play different roles in the marketplace. Current practices in market regulation provide useful models for policymakers designing cap-and-trade systems to limit greenhouse gas emissions.

4.1 U.S. market oversight

In the United States, there are four federal agencies whose current experience regulating markets and/or emissions provide useful lessons for the WCI carbon market: the CFTC, the Securities and Exchange Commission (SEC), the Federal Energy Regulatory Commission (FERC), and the Environmental Protection Agency (EPA).

In the federal U.S. climate debate, it appears that allowances and offsets will be treated as a commodity. Futures contracts linked to allowances issued by RGGI states are already trading on CFTC-regulated exchanges. Further, several bills pending in Congress would clarify the definition of a commodity to specifically include allowances and offsets.

The U.S. Commodity Exchange Act (CEA) directs the CFTC and/or self-regulatory organizations (SROs) comprised of industry participants to establish restrictions for regulated transactions[14] that include: (i) trading limits, (ii) position limits, (iii) prohibition of fraud, false reporting and deception, (iv) prohibition of meretricious transactions, (v) registration requirements for market professionals, (vi) reporting and recordkeeping requirements, and (vii) prohibition against falsely holding oneself out as a market professional.

The CFTC has created different regulatory regimes for the following market participants:

- Boards of Trade: The CEA defines at least four categories of boards of trade, each with a different level of CFTC regulation and oversight and a different level of required self-

[14] The CEA exempts certain transactions from regulation. See 7 U.S.C. §§7a, 6 for more detail. These exemptions are a significant part of the definition of OTC markets.

regulation.[15] Designated contract markets (DCMs) are the most closely regulated category. In order to qualify as a DCM, the board of trade must meet designation criteria set out in 7 U.S.C §§ 7, 7a. Examples of designation criteria include the ability to prevent market manipulation by enforcing rules with respect to the "financial integrity of transactions," proper activity by members, public access to contract specifications, and access to information required to carry out its operations. The Food, Conservation and Energy Act of 2008 requires the CFTC to regulate electronic commodities markets in the same manner as DCMs in order to detect and prevent manipulation and to limit speculation in U.S. electronic energy markets.[16]

- Clearing houses: Clearing houses must register with the CFTC and be designated a derivatives clearing organization (DCO) before providing clearing services for regulated commodities.[17] Clearing organizations that only clear exempt contracts are not required to register with the CFTC. Clearing houses are discussed in further detail below.
- Intermediaries: Agents trading on behalf of a principal must register with the CFTC. In addition, they are often subject to "various financial, disclosure, reporting, and recordkeeping requirements."[18] Types of intermediaries include futures commissions merchants, introducing brokers, commodity pool operators, and commodity trading advisors. Any individual or firm wanting to "conduct futures-related business with the public" must register with the National Futures Association, an independent organization authorized to process intermediary registration with the CFTC.[19]

4.2 Canadian provincial market oversight

Regulation of Canadian securities and commodities markets is performed by a combination of provincial regulatory authorities and SROs. SROs exercise authority derived from a range of sources, including provincial legislation, delegation of authority from securities regulators and

[15] We say "at least four categories" because the statute is unclear in a number of areas. For example, 17 U.S.C. § 1a, defines something called an "alternative trading system" that appears to be highly unregulated. It is difficult to determine the scope or breadth of such alternative trading systems from the rest of the statute.
[16] The CFTC also regulates other categories of trading facilities, including derivatives transaction execution facilities, exempt board of trade, exempt commercial markets. Each category is subject to different levels of regulatory oversight.
[17] "Derivatives Clearing Organizations," 7 USC § 7a-1; Commodity Futures Trading Commission, http://www.cftc.gov/industryoversight/clearingorganizations/index.htm (Accessed May 28, 2009).
[18] "Intermediaries," Commodity Futures Trading Commission, http://www.cftc.gov/industryoversight/intermediaries/index.htm (Accessed May 28, 2009).
[19] "Registration of Intermediaries," Commodity Futures Trading Commission, http://www.cftc.gov/industryoversight/intermediaries/registration.html (Accessed May 28, 2009); "Who Has to Register," National Futures Association, http://www.nfa.futures.org/registration/who_has_to_register.asp (Accessed May 28, 2009).

agreement by members to follow rules established by their respective SRO. A more detailed description of Canadian capital markets oversight is presented below:[20]

- Provincial Market Regulatory Authorities: Provinces differ in regulation requirements for exchange and OTC derivatives. In Ontario, OTC derivatives and exchange-traded derivatives are administered by the Ontario Securities Commission (OSC) and are regulated under the Securities Act (Ontario) ("OSA")—if OTC derivatives qualify as securities under the OSA—and the Commodity Futures Act (Ontario) (CFA), respectively. The CFA defines "commodities" to include emissions and emission credits.[21] Like Ontario, Manitoba has commodity futures legislation that specifically regulates exchange-traded futures and options on futures. Other derivative products (generally OTC derivatives) are regulated under the Securities Act (Manitoba). In Quebec, the Quebec Derivatives Act (QDA) applies to both exchange-traded and OTC derivatives. British Columbia, as with several other provinces, regulates exchange-traded derivatives. It regulates OTC derivatives as "securities" under its securities legislation but effectively exempts them from many aspects of its securities regulations.

- Exchanges: There are currently three commodity futures exchanges located in Canada: Bourse de Montréal (the "Bourse") in Quebec, ICE Futures Canada in Manitoba, and the Natural Gas Exchange ("NGX") in Alberta. All of these exchanges are recognized (or authorized) by the provincial securities regulatory authority in their home jurisdiction, and are recognized or exempted from recognition in other provinces where they carry on business. Exemptions are granted on the basis of reliance on the regulation of the exchange by its home jurisdiction regulator (the "lead regulator" model).

- Clearing Houses: Regulation of clearing houses also varies by province. For example, Quebec is the only jurisdiction to require mandatory recognition of clearing houses. The Canadian Derivatives Clearing Corporation (CDCC)—the clearing house for contracts traded on the Bourse—is recognized as a SRO in Quebec and is under the oversight of the Autorité des marchés, financiers (AMF).[22] In Ontario, clearing houses can apply to the Ontario Securities Commission (OSC) for recognition under the CFA. Recognized clearing houses would file their rules and regulations with the OSC and be subject to rules regarding governance, access, fees, risk controls, financial viability, and

---

[20] Provincial governments are currently considering proposals to reform market regulation, including a role for the federal government. It should however be noted the federal initiative is currently the subject of a constitutional challenge.

[21] Under OSC Rule 14-502 – Designation of Additional Commodities

[22] "CDCC (Mx)," Canadian Derivatives Clearing Corporation, http://www.cdcc.ca/accueil_en.php (Accessed October 28, 2009).

information sharing. The OSC has authority to make any decision with respect to those rules. However, no clearing houses are currently recognized under the CFA. British Columbia legislation does not require a clearing agency to be recognized but permits its BC Securities Commission to recognize them. Manitoba has the ability to designate a clearing agency as recognized, and has issued a recognition order for ICE Clear Canada, the clearing house of ICE Futures Canada.

- Intermediaries: Ontario's CFA requires registration of advisers (including commodity trading advisers, commodity trading counsels or commodity trading managers) and dealers (referred to as futures commission merchants or FCMs). Registrants are subject to various requirements imposed by regulation, for example requirements relating to capital, record-keeping, and proficiency. Registrants are also subject to the general record-keeping and compliance review provisions of the CFA. FCMs are required to be members of the Investment Industry Regulatory Organization of Canada (IIROC), a recognized SRO, and to participate in the Canadian Investor Protection Fund, an approved compensation fund. British Columbia requires registration in order to trade in a security or exchange contract. In Manitoba, trading under CFA requires registration as a FCM and the firm must be a member of IIROC. Quebec's QDA, in addition to requiring registration of advisers and dealers, also requires that any person other than a "recognized regulated entity" that seeks to "create or market" a retail off-exchange derivative must be qualified by the AMF and that the derivative must also be approved by the AMF.

The IIROC is a national SRO responsible for overseeing trading activity in the Canadian equity markets. The organization monitors regulated firms and their registered employees to ensure compliance with market integrity rules, including post-trade reviews of trading data to identify any manipulative trading patterns that violate the Universal Market Integrity Rules (UMIR).[23] The IIROC prosecutes violations of UMIRs and refers other violations to the appropriate securities regulatory authority.

The oversight of trading in commodity futures contracts is conducted by the commodity futures exchanges themselves. The Bourse and ICE Futures Canada are recognized as SROs by their respective lead regulators and are required to maintain a separate regulatory division with defined regulatory, compliance, market surveillance and disciplinary responsibilities. They are also required to establish rules to govern and regulate all aspects of their business and internal affairs and to prevent fraudulent and manipulative acts and practices by participants. Regulatory divisions of these exchanges perform real-time monitoring of trading activity to detect trading infractions and market manipulation, conduct investigations and discipline

[23] "Market Integrity Rules – UMIR," Investment Industry Regulatory Organization of Canada, http://www.iiroc.ca/English/ComplianceSurveillance/RuleBook/Pages/UMIR.aspx (Accessed October 8, 2009).

exchange participants. The exchanges also impose and monitor position limits for each of their listed contracts.

All futures contracts traded on the three Canadian futures exchanges are cleared by their respective designated clearing house. Each of these clearinghouses acts as central counterparty to each transaction, manages the financial risk and oversees the final settlement of contracts. Clearing houses impose margin requirements, monitor the financial risk of their members in real time and may issue intra-day margin calls when needed.

4.3 European Union Emissions Trading Scheme market oversight

As part of its efforts to fight against climate change, the European Community ratified the Kyoto Protocol on April 25, 2002, establishing a goal of reduction in greenhouse gas emissions from all 15 Member States of 8% below 1990 levels for the period 2008 – 2012.

The establishment of a cap for a category of GHG emitters was designed to assist Member States and the European Union to meet their commitments to the Kyoto Protocol, while allowing companies to comply at the lowest cost by participating in the purchase and sale of emission allowances. The EU ETS covers around 10,500 installations across the 27 Member States of the European Union plus three other States. The ETS is designed to work in successive and independent phases. The first phase took place from January 2005 to December 2007. The second runs from January 2008 to December 2012 and corresponds to the compliance period of the Kyoto Protocol. The third phase will run from 2013.[24]

The legal framework of the trading scheme does not regulate how and where allowance trading takes place. Companies with commitments may trade allowances directly with each other, or they may buy or sell via a broker, bank or other allowance market intermediary. The Community Independent Transaction Log (CITL) records the issuance, transfer, cancellation, retirement and banking of allowances that take place in the registry.

It is mandatory that each Member State have a national registry. These registries will ensure the accurate accounting of all units under the Kyoto Protocol plus the accurate accounting of allowances under the CITL scheme for greenhouse gas emission allowance trading.[25]

The London-based European Climate Exchange[26] (ECX) provides standardized futures contracts. The underlying unit of trading is EU allowances (EUAs) or certified emission reductions (CERs).

---

[24] "Emission Trading System (EU ETS)," European Commission, http://ec.europa.eu/environment/climat/emission/index_en.htm (Accessed October 28, 2009).
[25] "Emission Trading System (EU ETS): Community Independent Transaction Log," European Commission, http://ec.europa.eu/environment/climat/emission/citl_en.htm (Accessed October 28, 2009).

ECX contracts are cleared through ICE Clear Europe. Margin requirements for ECX products are determined by ICE Clear Europe and rates are reviewed on a quarterly basis based on historic price fluctuations of the contract.

In 2007, the traded volume of EUAs totaled 1,443 million, a daily average traded volume of 5.6 million tons (Mt). Around 70% was traded in the brokered over-the-counter market and the rest was traded on exchanges. The ECX accounted for 87% of exchange traded derivatives by volume in 2007, 92% in 2008, and 99% in the first half of 2009.[27,11]

The Financial Services Authority (FSA) regulates providers of financial securities in United Kingdom, including the ECX. The following is a summary of the FSA's scope of regulation:

- The FSA regulates exchanges and clearing houses, under UK Financial Services and Markets Act.
- The FSA does not have any responsibilities specifically relating to the underlying emission markets. Activities conducted by participants in relation to derivative instruments based on emissions allowances fall within its regulatory perimeter.
- The FSA regulates commodities derivatives that are traded for investment purposes.
- The fact that emissions allowances are a dematerialized allowance certificate, as opposed to a physical commodity does not distinguish this market from other commodities markets. The FSA does not consider that a different approach is required regarding the allowance market.
- The FSA does not regulate spot trading of emission allowances.
- The FSA could investigate behavior on the spot trading market if it appears it has an impact on derivatives listed on a regulated exchange.

5. U.S. Federal Proposals

The U.S. executive and legislative branches have presented various proposals for broad reform of financial markets, reform of energy commodity trading, and regulation of carbon markets that would be created by a federal cap-and-trade program.

---

[26] "What Are Futures?" European Climate Exchange, http://www.ecx.eu/ECX-EUA-Futures-What-are-Futures (Accessed October 28, 2009).
[27] "Carbon 2008," PointCarbon, http://www.pointcarbon.com/polopoly_fs/1.912721!Carbon_2008_dfgrt.pdf (Accessed October 28, 2009).

The U.S. House of Representatives approved comprehensive climate and energy legislation (HR 2454) in June, 2009 that would create a federal GHG cap-and-trade system.[28] The bill would require:

- Creating a separate regulatory frameworks for the trading of allowances and allowance derivative instruments;
- Including verified offset credits in the definition of "allowances" for the purpose of the market oversight provisions;
- Choosing not to restrict who may trade in the carbon market; and
- Allowing multiple registered exchanges to trade allowance-based instruments rather than requiring that all instruments trade on a single platform.

Rather than specifying all of the rules to govern the markets, the HR 2454 articulates a series of general standards for oversight of the allowance market. The regulator of the allowance market must promulgate regulations that:

- Prohibit fraud, manipulation, excessive speculation;
- Facilitate compliance with emissions limits;
- Ensure transparency;
- Set position limits and margin requirements, as necessary;
- Create a national market system;
- Limit or eliminate counterparty risks, market power concentration risks, and other risks associated with OTC trading;
- Create standards for trading facilities (i.e., exchanges) and clearing organizations; and
- Other requirements necessary to preserve market integrity and compliance.[29]

The bill would amend the Commodity Exchange Act to include allowance-based derivative instruments, thereby treating derivatives in a manner similar to agriculture commodities. In addition to the list of market elements that regulations must address, the legislation also includes detailed enforcement provisions.[30]

Senators Diane Feinstein (CA) and Olympia Snowe (ME) introduced a bill (S 1399) in June, 2009 to regulate a federal cap-and-trade system.[31] The bill includes more specific regulatory provisions for both the allowance and derivative markets and would create a new branch at the CFTC specifically to regulate the carbon market. For example, the legislation would require all allowance trading to occur on a registered carbon trading facility and to be cleared through a single Carbon Clearing Organization. Virtually all allowance-based derivative instruments would have to trade on a designated carbon derivative trading facility. The bill technically permits OTC

[31] Carbon Market Oversight Act of 2009, S.1399, 111th Cong.

transactions but it defines "private bilateral contract" very narrowly, effectively requiring most, if not all, derivative transactions to occur on registered derivatives trading facilities.

In October, 2009, Senators John Kerry (MA) and Barbara Boxer (CA) introduced a new cap-and-trade bill (S.1733) in the U.S. Senate.[32] Rather than set forth specific statutory requirements for oversight of the carbon market, the Kerry-Boxer bill includes a nonbinding "sense of the Senate" provision that calls for:

> "a single, integrated carbon market oversight program--
>
> > "(1) to provide for effective and comprehensive market oversight and enforcement;
> > "(2) to lower systemic risk and protect consumers;
> > "(3) to ensure market liquidity and allowance availability;
> > "(4) to enhance the price discovery function of such markets, ensuring that the price for emission allowances and offset credits reflects the marginal cost of abatement;
> > "(5) to prevent excessive speculation that contributes to price volatility, including the establishment of robust aggregate position limits and margin requirements;
> > "(6) to ensure that market mechanisms and associated oversight support the environmental integrity of the program established under title VII of the Clean Air Act ...;
> > "(7) to establish provisions for market transparency that provide authority, resources, and information needed to prevent fraud and manipulation in such markets;
> > "(8) to establish standards for trading as, and operation of, trading facilities;
> > "(9) to ensure a well-functioning, well-regulated market, including a futures market, designed to manage risk and facilitate investment in emission reductions;
> > "(10) to establish clear, professional standards for dealers, traders, and other market participants;
> > "(11) to provide for appropriate criminal and civil penalties; and
> > "(12) to prevent any excessive leverage by market participants that creates risk to the economy."[33]

In addition to legislation specifically aimed at governing a new federal carbon market, the U.S. Congress is also considering broader market reform proposals that may impact carbon markets. Both the House of Representatives' Financial Services Committee and Agriculture Committee

---

[32] Clean Energy Jobs and American Power Act, S 1733, 111th Cong.
[33] S 1733 Title VII, Subtitle D.

have approved legislation to regulate swap markets.[34] Under both bills, standardized swap transactions between dealers and large market participants would be required to be traded on an exchange or electronic platform and cleared through a clearing organization registered by the CFTC or the Securities and Exchange Commission (SEC). The bills would grant new authority to the CFTC and SEC to define the term "standardized," and any swap accepted for clearing by a clearing organization would be presumed to be standardized. The clearing requirement would not apply to transactions intended to hedge a commercial risk (e.g., end users of a commodity). Non-cleared transactions would have to be reported to a trade repository or, if a trade repository is not available for the particular transaction, reported directly to the CFTC or the SEC. The bills include new reporting and recordkeeping requirements for any person who enters into a swap that is not cleared or reported to a repository.

On August 11, 2009, the Obama Administration forwarded a proposal to Congress to bring OTC derivatives markets for all types of commodities under regulatory oversight of a combination of banking regulators, the CFTC and/or the Securities and Exchange Commission (SEC).[35] On October 26, 2009, the U.S. Treasury Department and the House Financial Services Committee released a draft bill to address "systemic risk and 'too big to fail' banks."[36] The draft bill would:

- "Create a mechanism for monitoring and reducing the threats that systemically risky firms pose to the financial system.
- "Establish a process for winding down large, financially-troubled non-bank financial institutions in a way that protects American taxpayers and minimizes the impact on the financial system."[37]

6. Conclusion

There are a variety of market structures that can serve as useful models as the WCI Partners create a regional cap-and-trade system. The Markets Committee is considering a number of key issues, including:

- Whether current U.S. and Canadian regulation of commodity markets is appropriate. Allowance-based derivative instruments in the EU ETS and RGGI markets are regulated like commodities, and the U.S. CFTC has jurisdiction over RGGI-based derivative

[34] Over-the-Counter Derivatives Markets Act of 2009, HR 3795, 111th Cong. Reported by the Committee on Financial Services on Oct. 15, 2009. Over-the-Counter Derivatives Markets Act of 2009, HR 3795, 111th Cong. Reported by the Committee on Agriculture on Oct. 21, 2009.

instruments that trade on exchanges. Based on opinions from outside experts, it may be challenging to structure a derivatives market that does not fall under U.S. CEA. Should the WCI Partners decide to follow existing U.S. and Canadian approaches to commodity market regulation, they may consider establishing relationships with the appropriate market regulators to ensure a properly functioning regional carbon market.

- <u>Whether to place restrictions on OTC instruments.</u> The question of whether to allow OTC trading has received significant attention in the U.S. federal debate regarding the design and regulation of a carbon market. WCI Partners will need to evaluate the potential benefits of and risks posed by OTC instruments, in both secondary and derivatives markets.

- <u>The appropriate transparency and disclosure requirements.</u> There is broad agreement that transparency is a critical element to a well-functioning market. Access to accurate and timely market data helps regulators monitor trading activity, maintains the public's confidence in market fairness and integrity, and allows market participants to make informed investment decisions. Market participants will have access to different types of information and the WCI Partners will need to balance the transparency requirements with the need for confidentiality and the reporting burdens placed on individual market participants. The balance may vary for secondary and derivatives markets.

The WCI's initial market design choices will have a significant influence on overall market activity. By making careful decisions at the outset, the WCI Partners can help ensure a stable, transparent, efficient marketplace that minimize risks of fraud and manipulation

Market Oversight White Paper

Stakeholder Conference Call

11:00 a.m. PST, December 2, 2009

Western Climate Initiative

- A collaboration of seven U.S. states and four Canadian provinces to reduce greenhouse gas emissions
- Signature effort to date has been design of cap-and-trade program; now in implementation phase
- 2009 – 2010 work plan: “Essential elements” by June, 2010
- Markets Committee includes market oversight task

Objectives

- "The recommended design will provide opportunities to obtain low-cost emission reductions through emission trading, allowance banking, and inclusion of an offsets component."

WCI Design Recommendations, September 23, 2008

- "The WCI Partner jurisdictions and stakeholders want appropriate safeguards and oversight of the allowance and offset credit trading markets and want them to function efficiently."

Materials for Markets Workshop, April 9, 2009

Market Oversight Stakeholder Engagement

- Apr. 9, 2009 workshop
  - Principles
  - Questions for stakeholders
- White paper released to public Nov. 18, 2009
- Today's stakeholder call
- Written comment requested by Dec. 18, 2009
- Consideration of stakeholder comments
- Draft recommendations

Market Oversight White Paper

- Purpose is to provide foundation for recommendations
- Background on market oversight, including existing markets, especially environmental trading programs
- Roles of existing market oversight agencies in the U.S. and Canada
- Forum for stakeholder interaction

Principles

These principles serve as guidelines for developing oversight of the allowance, offset credit, and associated derivatives trading markets to assure maximum environmental and economic benefit to the public.

- Fairness
- Efficiency
- Effective oversight
- Transparency and the reporting and disclosure of relevant information
- Administrative simplicity and cost
- Accountability
- Conflicts of interest

Architecture and Oversight

- "Market Architecture:" Market participants and institutions, and the connections between them
- "Market Oversight:" The regulators' relationship with the market

Types of Markets: A Convenient Taxonomy

- Primary: Initial distribution of allowances issued by governments (auction, sale, or allocation).
- Secondary: Trading of allowances by participants for immediate delivery
- Derivatives: Value based on another instrument (e.g., a contract based on the price of allowances)

Secondary Markets

- Immediate delivery
- WCI tracking system
  - Major part of architecture of market
  - Rules for system a significant part of oversight choices
  - Important resource for monitoring
- Unlike traditional commodities markets, supply is fixed and known

Derivatives

- Allowance market expected to have some volatility
- Derivatives can be used for risk management
  - E.g., electricity generators may lock in power prices and fuel prices for a period of time, and ensure an operating margin
- OTC and exchange structures similar
- Derivatives markets can be larger and more active than spot markets

Ways to Trade Allowances

- “Over the Counter” (OTC) transactions
  - Between two (or more) parties
- Exchanges
  - Standardized terms
  - Clearing
    - Centralized counterparty
    - Margin requirements
  - Data recording and disclosure requirements
  - Position limits

Market Participants

- Could be a wide variety: Compliance entities, brokers, investors
- Have heard calls to limit access to markets to compliance entities
  - Could be difficult to implement
  - Counterarguments are that broad participation can add liquidity, reduce opportunities for exercise of market power
  - Requires assumption that compliance entities form an exclusive class that is somehow different from class of all participants

Oversight in Existing Markets

- Existing commodity regulation in U.S. and Canada
- Existing greenhouse gas trading programs:
  - Regional Greenhouse Gas Initiative
  - European Union Emissions Trading Scheme
- Proposals to reform market oversight

Particular Requests for Stakeholder Feedback

- Whether it is appropriate to consider allowances to be commodities for market oversight purposes
- Whether the WCI jurisdictions should favor or require exchange transactions over over-the-counter transactions
- The appropriate requirements for data collection, filing with regulators, and disclosure to the public

Questions?

Wednesday, November 18, 2009

9:00 am	**Convene (Montana Ballroom)** Welcome and Introductions Agenda Review
9:15 am	**Offset Compliance Limit** Purpose: Review and approve final recommended design for implementing the offset limit (as updated based on stakeholder comments).
9:45 am	**Reporting Harmonization** Purpose: Review and approve plan, timeframe and budget for harmonizing reporting requirements. Discuss status of state and provincial reporting rules.
10:30 am	**Break**
10:45 am	**Complementary Policies White Paper** Purpose: Review and approve the complementary policies white paper.
11:30 am	**Competitiveness Analysis** Purpose: Review and approve final statement of principles on competitiveness, the proposed process for addressing competitiveness, and an outline of the industry guidance document for emitters.
12:30 pm	**Lunch** *(attendees are on their own for lunch)*
1:30 pm	**Market Oversight Options** Purpose: Discuss market oversight issues in the context of the regional program. Partner direction to Committee on next steps.
2:45 pm	**Break**
3:00 pm	**Next Steps** Purpose: Discuss plans for upcoming WCI Partner meetings and collaborative
3:30 pm	**Open Comment Period**
4:00 pm	**Adjourn**

Western Climate Initiative

Market Architecture and Oversight

Partner Meeting, Santa Fe, New Mexico

November 18, 2009

Oversight Task

- Purpose of Market Architecture and Oversight task is "to provide recommendations that are designed to ensure that the allowance and offset credit trading market is organized properly to operate reliably and prevent or minimize manipulation."
- White paper
- Stakeholder conference call
- Written comments
- Next step: incorporate comments; write draft recommendations

"Clay Man"

- Aid to focus discussion internally, and list options
- Intended to be malleable
- Will never be final but will be replaced by draft recommendations
- Draft discussed today includes some "proposed" (pre-draft) recommendations and some areas for further exploration

Risks to Markets

- Manipulation
- Fraud
- Excessive speculation
- Systemic problems due to counterparty risk
- Lack of effective price discovery

Tools to Address Market Risks

- Tracking system
- Limits on market participation
- Favoring exchange transactions
- Data & records filing and disclosure
- Position limits
- Cost-containment measures
- Collaboration with other regulators
- Market monitoring

Types of Markets: A Convenient Taxonomy

- Primary: Initial distribution of allowances issued by governments (auction, sale, or allocation).
- Secondary: Trading of allowances by participants for immediate delivery
- Derivatives: Value based on another instrument (e.g., a contract based on the price of allowances)

Tracking System

- WCI tracking system
  - Major part of architecture of market
  - Rules for system a significant part of oversight choices
  - Important resource for monitoring
- Can impose conditions for account holders and allowance transfers

Market Participation

- Limits by type of entity—e.g., has compliance obligation
- Limits by qualifications of person trading—e.g., registration with regulators

Compliance entities

- Benefits to having broad participation
  - Increased liquidity
  - Makes concentration (and therefore manipulation) more difficult
  - More information and analysis may improve price discovery
- Arguments against non-compliance entities
  - Artificial increase in allowance prices
  - Increase chances of manipulation
  - Limit access to allowances

Practical considerations for limiting market participation

- Determining who has compliance obligation
- Ownership or fractional ownership of compliance entity
- First jurisdictional deliverer
- Derivatives challenges—e.g., CCFE is busiest exchange for RGGI

Qualifications for participants

- In general, registration required to trade commodities derivatives on behalf of another person in US and Canada—but not for own trades
- Requirements vary, but may include
  - Passing a proficiency exam
  - Maintaining minimum capital
  - Rules for treatment of customer funds
  - Disclosures to customers
  - Filings to regulators

Ways to Trade Allowances

- "Over the Counter" (OTC) transactions
  - Between two (or more) parties
- Exchanges
  - Standardized terms
  - Clearing
    - Centralized counterparty
    - Margin requirements
  - Data recording and disclosure requirements
  - Position limits

Derivatives

- Allowance market expected to have some volatility
- Derivatives can be used for risk management
  - E.g., electricity generators may lock in power prices and fuel prices for a period of time, and ensure an operating margin
- Derivatives markets can be larger and more active than spot markets

Records and Disclosure

- Transparency key to markets
- Recommend requiring ultimate beneficial ownership of allowances in tracking system
- Recommend immediate recording of transfers with tracking system
- Considering requirements on derivatives records for account holders

Position limits

- Limits on number of allowances or derivative contracts that can be held by an entity
- Need more information on levels
- Potential exceptions or higher limits for compliance entities

Cost-containment measures

- Minimum or maximum prices for allowances (e.g., “safety valve”)
- Strategic reserve
- Price triggers for offsets quantity

Excessive speculation

- “In theory, the price of futures and derivatives should be a reflection of physical market pricing. That is, the price of consumable, commercial goods should be set by the consumers and users of such commodities….A good definition of ‘excessive speculation’ is the market condition where non-commercial interests set the price.”

“Defining Excessive Speculation,” Jeff Korzenik, http://inefficientfrontiers.wordpress.com/2009/07/14/defining-excessive-speculation/ (Accessed Nov. 3, 2009).

Relationships with US and Canadian provincial regulators

- Canadian provinces will coordinate with provincial securities commissions
- US regulators:
  - Commodity Futures Trading Commission
  - Federal Energy Regulatory Commission
  - Securities and Exchange Commission
  - Environmental Protection Agency

Monitoring

- In addition to jurisdictions' own monitoring:
  - Develop WCI in-house capacity
  - Rely on existing regulators (US Commodity Futures Trading Commission, provincial Securities Commissions)
  - Contract with independent monitor
- Role of public information

Offset Credits

- Need to be distinguishable in tracking system to enforce a quantitative limit
- Potential for “reversal”
- Issuance follows different path than for allowances

Next Steps

- Current thinking
- Lines of continued inquiry
- Timing and resource commitment

Questions?

MGibbs@calepa.ca.gov

April 9, 2009 Stakeholder consultation documents and comments available at http://westernclimateinitiative.org/public-comments/document/2

Western Climate Initiative

Reporting Committee
WCI ER/EPA Reporting Rule Harmonization Workplan
November 10, 2009

Task #	Description	Responsibility	Deadline
1	Review EPA General Provisions and identify changes needed for WCI program: • additional elements needed for cap and trade program • change threshold from 25,000 MT/yr to 10,000 MT/yr; • gases covered (e.g. NF3); • addition of verification requirements; • treatment of biomass emissions; • addition of provisions from current WCI general provisions that reflect Canadian regulatory traditions (e.g. operator's representative)	Reporting Committee	12/16/2009
2	Compare EPA quantification methodologies to final and near final Essential Requirements (ERs) and identify significant differences between the two.	Reporting Committee ERG	12/16/2009
3	Analyze differences identified as part of Task 2 for compatibility with a cap-and-trade program and identify necessary modifications to EPA Rule. Consider: • Method accuracy; • Potential for bias. • Choices allowed in the EPA program Sources of information: • EPA Technical Support Documents; • EPA Responses to Comments; • Reports submitted under existing programs for source category.	Reporting Committee ERG	1/13/2010

Task #	Description	Responsibility	Deadline
4	Where EPA has developed a method for a source category that is not covered by a final or near final ER: • Evaluate the EPA method for compatibility with a cap-and-trade program considering the same criteria and sources as in task 3; • If the method is not compatible with a cap-and-trade program, decide whether (1) the method can be modified to make it compatible, (2) the method should be excluded from the WCI ERs or (3) the method should be included in the WCI ERs for informational purposes. Note: The EPA reporting requirements for fuel producers, importers and exporters will not work for a regional, as opposed to a national, program. The Reporting Committee will develop separate fuel supplier reporting requirements in accordance with the current schedule.	Reporting Committee ERG	1/13/2010
5	Draft model incorporation by reference rule for U.S. jurisdictions.	Reporting Committee ERG	3/4/2010
6	Where WCI has developed a draft ER that is not covered by a method included in the final or proposed EPA Rule, proceed to develop a final ER. Note: Where WCI has developed a draft ER that is covered by a proposed EPA method, the Reporting Committee will defer work on the ER until the EPA method is final, unless a Canadian jurisdiction needs to adopt the method by reference for the 2011 reporting year.	Reporting Committee ERG	3/18/2010
7	Align the third party verification rule with the structure and language of the EPA rule (keeping the rigour and principles the same).	Reporting Committee ERG	3/18/2010

Task #	Description	Responsibility	Deadline
8	Modify the EPA rule to serve as new ERs for Canadian jurisdictions by substituting metric units and conforming to Canadian regulatory norms. Alternatively (if regulatory traditions allow and such a decision is made by the Canadian jurisdictions) draft model incorporation by reference rule for Canadian jurisdictions noting changes required for Canadian circumstances and exceptions to the EPA rule. Submit work product for tasks 5 to 8 to Partners for approval.	Reporting Committee ERG	3/18/2010
9	Partner review and approval of proposed model incorporation by reference rule and new ERs. Publication for stakeholder review.	Partners	4/1/2010
10	Stakeholder review and comment on proposed model incorporation by reference rule and new ERs.	Reporting Committee	5/4/2010
11	Publication of final model incorporation by reference rule and new ERs and response to stakeholder comments.	Reporting Committee Partners	6/1/2010

Western Climate Initiative

Oil and Gas Collaborative

November 19, 2009

Montana Ballroom - La Posada de Santa Fe
330 East Palace Avenue, Santa Fe, NM
Call in: 1-800-868-1837 (toll free in the U.S. and Canada), code 659537#

Meeting Objectives:

1) Increase understanding of the oil and gas sector with an emphasis on exploration and production and natural gas processing;
2) Increase understanding of the oil and gas sector's GHG emission pathways and reduction opportunities;
3) Discuss and receive input on critical outstanding issues in the sector including emissions reporting;
4) Determine next steps for continued oil and gas sector engagement in the WCI.

Attendees:

1) Oil and Gas Reporting Protocol Technical Working Group (TWG) Members (http://www.wrapair.org/ClimateChange/GHGProtocol/twg-members.html)
2) The Public will be invited to observe and provide comments during the meeting.

Facilitation: The meeting will be facilitated by Rob Greenwood with Ross and Associates.

		Lead Presenters
8:30 – 8:45	1. Call to Order: Opening Remarks • Introductions • Review Purpose and Agenda	WCI US and Canadian Leads
8:45 – 10:15	2. North American Oil and Gas Industry and Climate Change • Introduction and Overview ○ Defining the Sector (Upstream and Midstream) ○ Major Sources of Emissions ○ Emission Controls ○ Canadian and U.S. similarities and differences • Challenges of addressing upstream Oil and Gas emissions • Industrial achievements in emission reductions and measurements	Tom Moore, Western Governors' Association Krista Phillips Canadian Association of Petroleum Producers Ramon Alvarez, Environmental Defense Fund Reid Smith, BP

10:15 – 10:30	Break	
10:30-11:00	3. Update on key industry issues: • Low Carbon Fuel Standard • U.S. Legislation (How it proposes to regulate oil and gas) • Geologic Sequestration (pore space ownership, surface rights, accounting for CO2 transfers and leakage)	Byard Mosher, CARB Paula Fields, ERG Mark Fesmire, NM Oil Conservation Division
11:00-11:30	4. Status of the WCI Reporting Requirements: • General Reporting Principles • Essential Requirements of Mandatory Reporting • Information on harmonization of WCI and future EPA mandatory reporting (including reflection of Canadian data streams and circumstances) for the Upstream O&G Sector • Developing Mandatory Oil and Gas Protocols	Jim Norton
11:30 – 12:15	5. TWG Discussion on Draft WCI Issues Paper: • Defining the Reporting Entity and Threshold	All
12:15 – 1:15	Lunch	

1:15 – 3:00	6. Cont. TWG Discussion on Draft WCI Issues Paper:
	• Contractor Emissions
	• Quantification Issues
	    • Stationary Combustion and Field Gas
	    • Instrument Gas and Vented Methane Emissions
	    • Storage Tanks
		All

3:00-3:30	7. Public Comment	
3:30-3:45	Break	
3:45-4:15	8. Collaborative Discussion • Comments from group on what was presented. • Summary of what was heard during the day.	All
4:15– 4:45	9. Next Steps	Jim Norton

CAPP CANADIAN ASSOCIATION OF PETROLEUM PRODUCERS

Canada’s Upstream Oil & Gas Industry

Krista Phillips
Policy Analyst, Air Quality & Climate Change

WCI Oil & Gas Collaborative
November 19, 2009

- Large and small producer member companies
- Explore for, develop and produce natural gas, natural gas liquids, crude oil, and oil sands throughout Canada
- Members produce about 90 per cent of Canada's natural gas and crude oil
- Associate members provide a wide range of services that support the upstream crude oil and natural gas industry

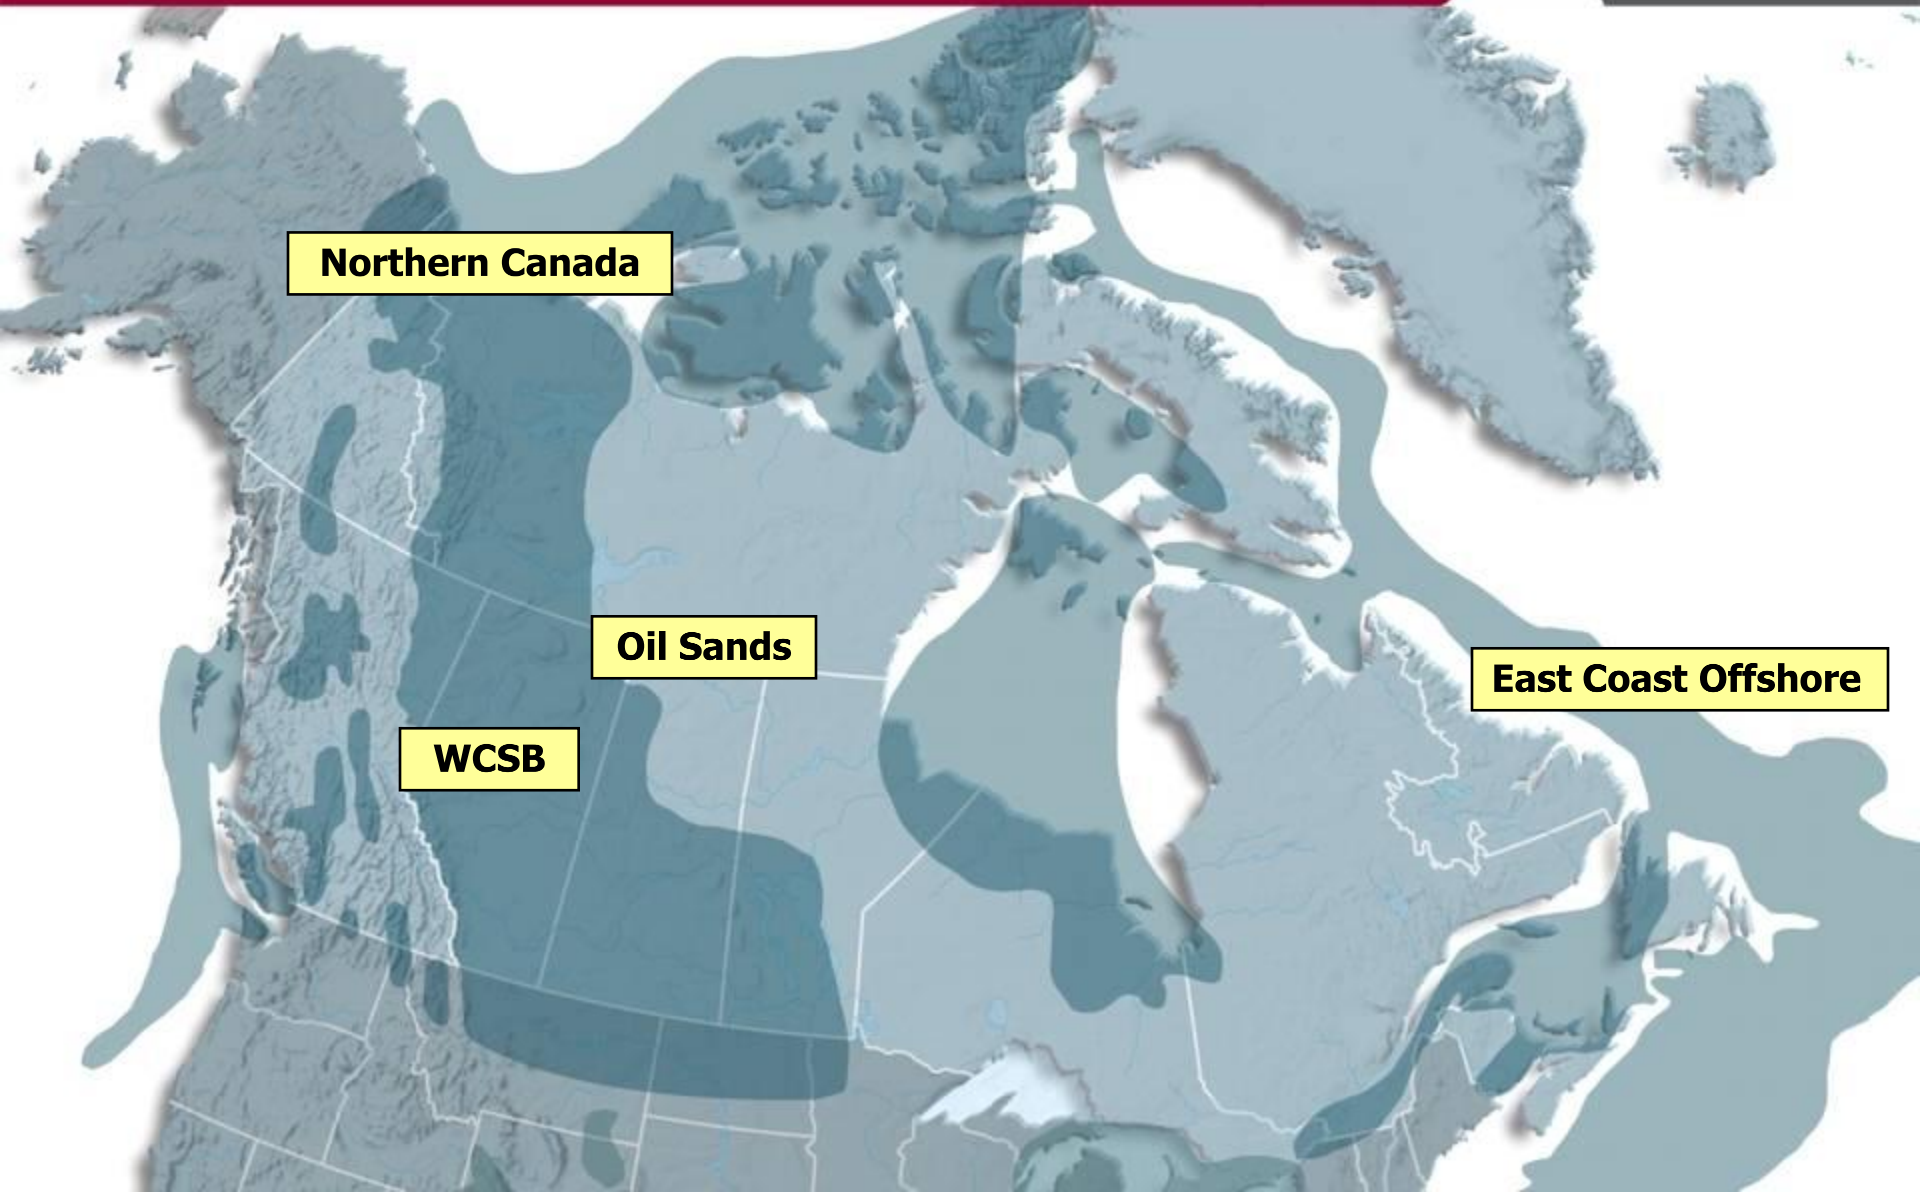
Canada’s Crude Oil and Natural Gas Industry

CAPP

- **World’s 3rd largest natural gas producer**
- **World’s 7th largest crude oil producer**
- **Canada is the 5th largest energy producer in the world**
- **Employment near 500,000 in Canada**
- **Invested $50 billion in 2008**
  - Largest single private sector investor in Canada
- **Canada is the largest supplier of energy to the United States**

2008	Canadian Natural Gas	Canadian Petroleum
Share of U.S. consumption	15%	12%
Share of U.S. imports	90%	19%

Canada's Oil and Gas Basins



Canadian Oil and Gas Production

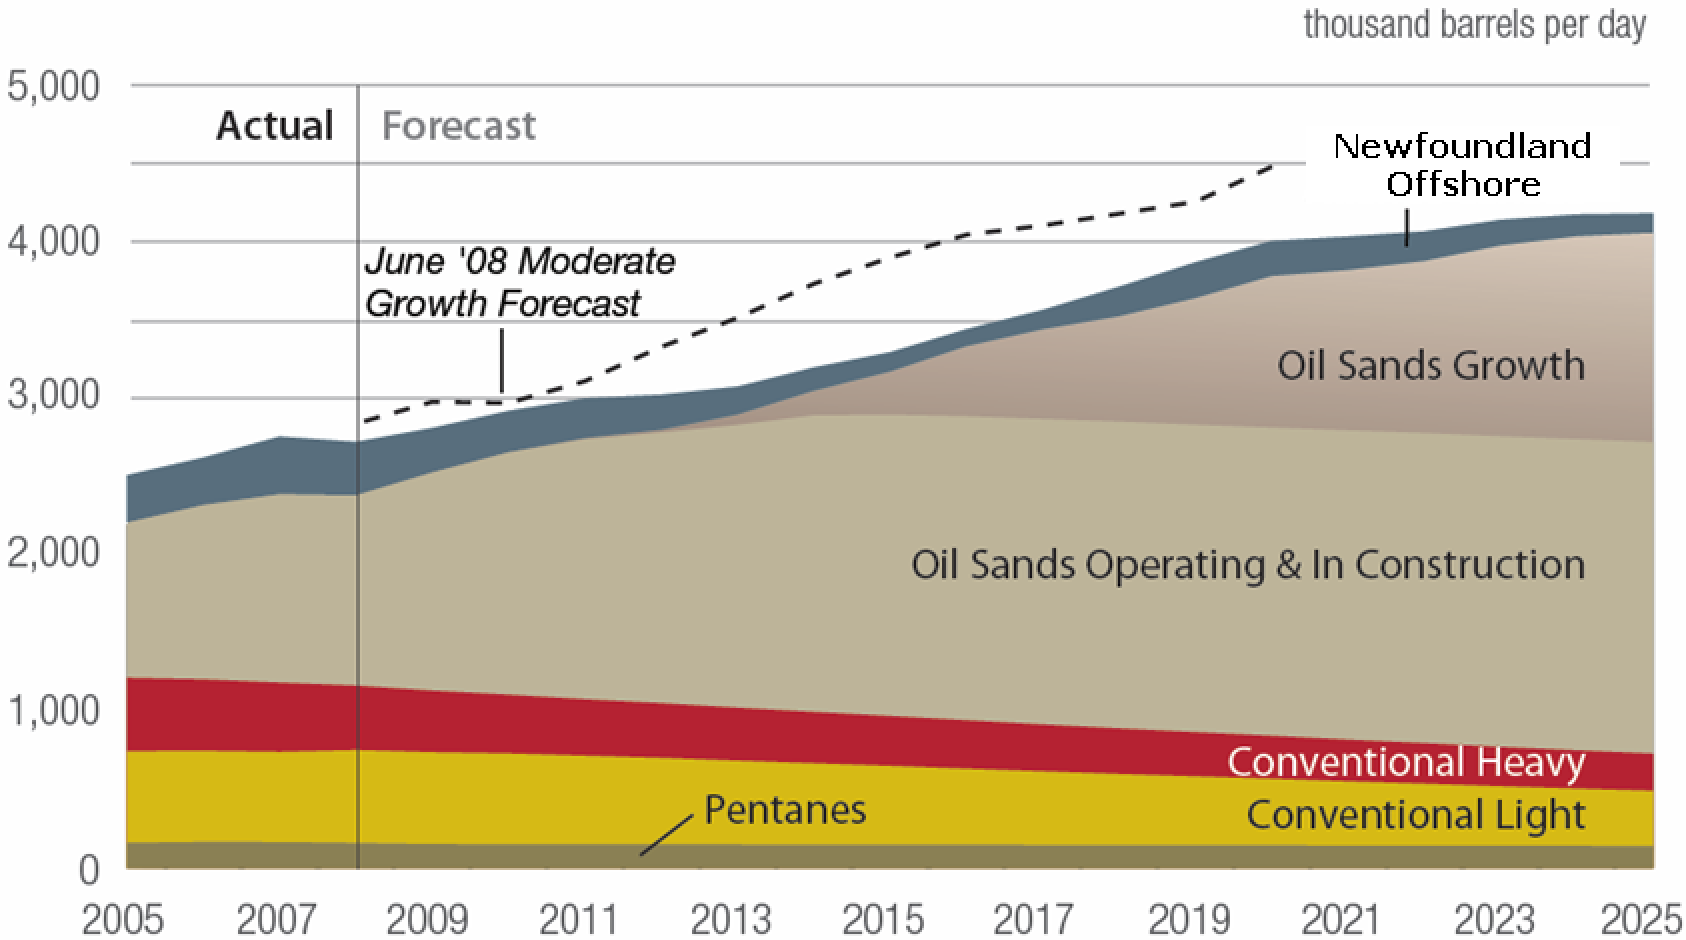
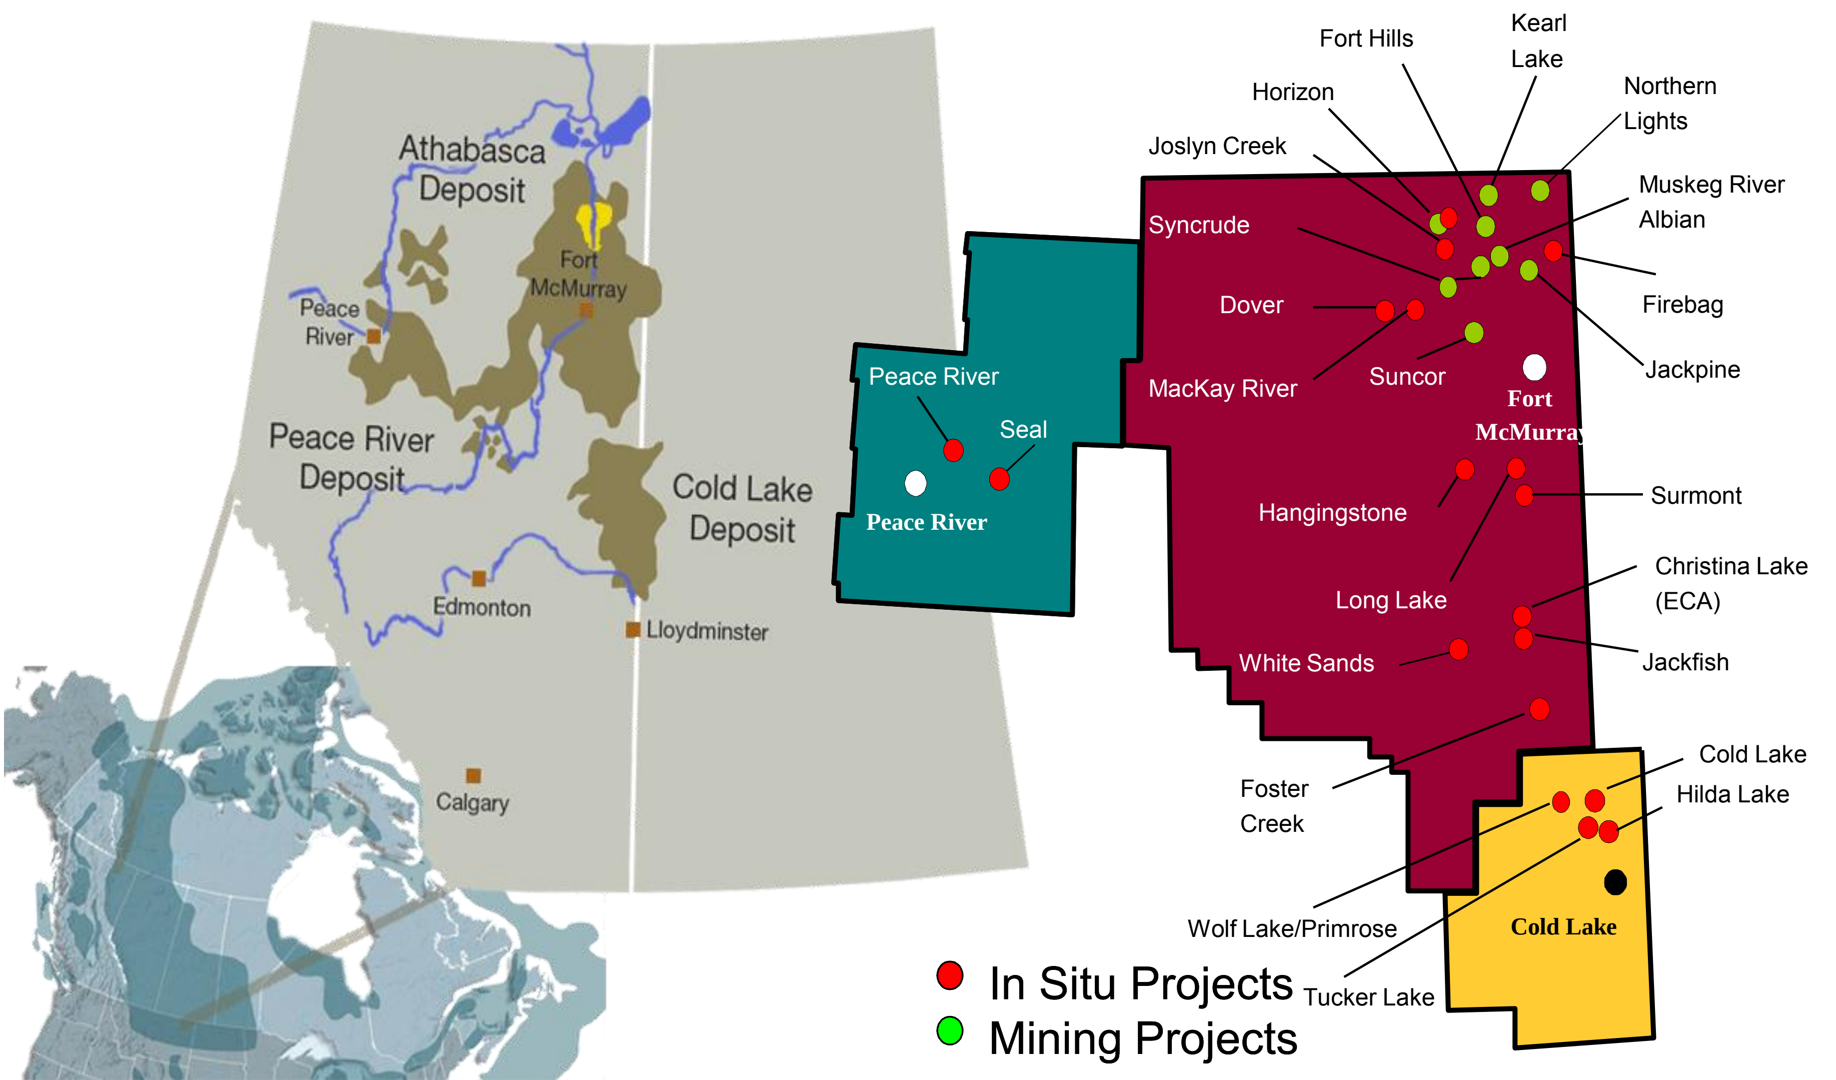
Total Canadian Oil Production



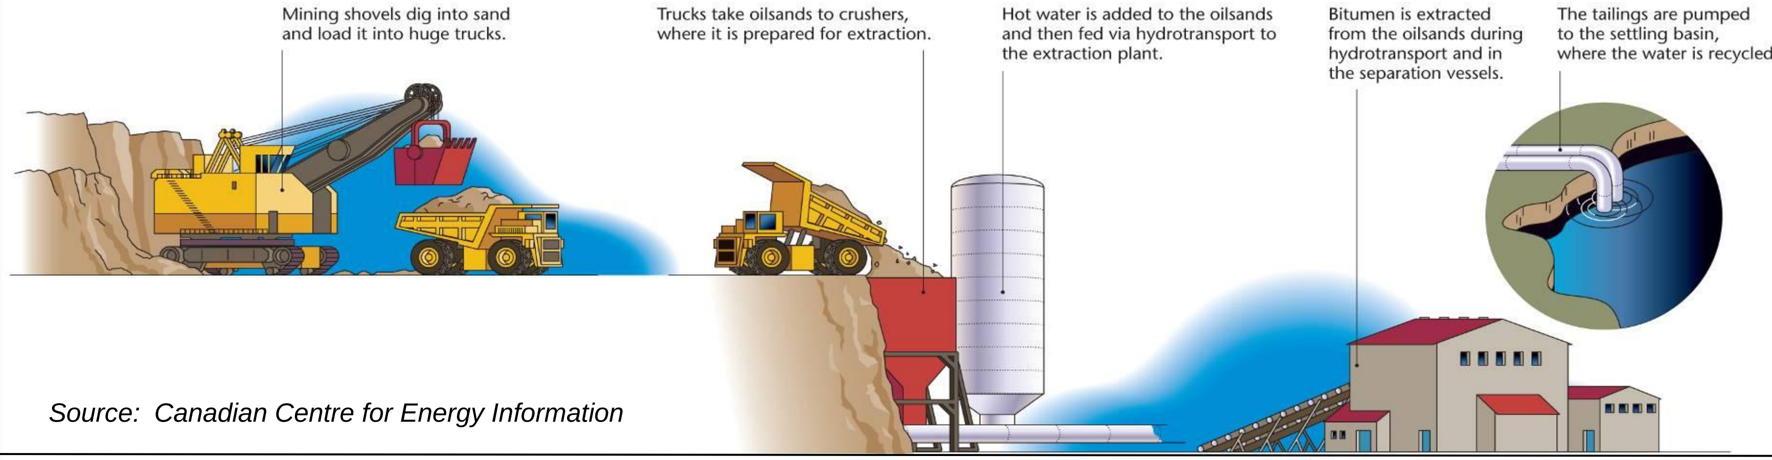
Oil Sands Projects in Three Deposits



Oil Sands Production Technologies

CAPP

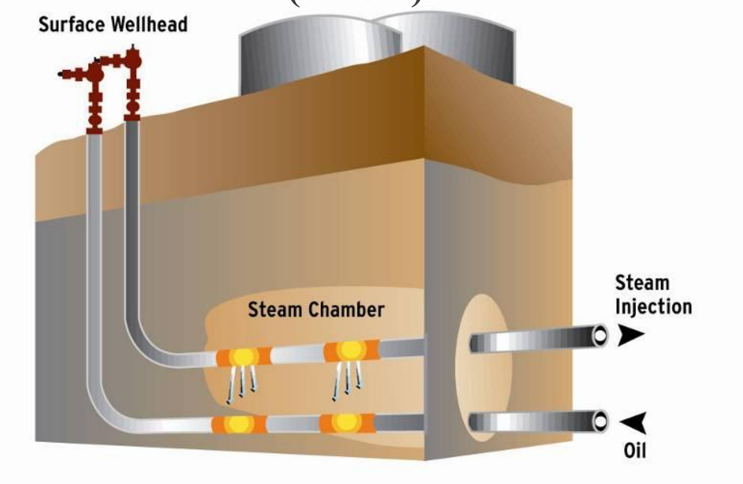
Mining – oil sands less than 200 feet deep



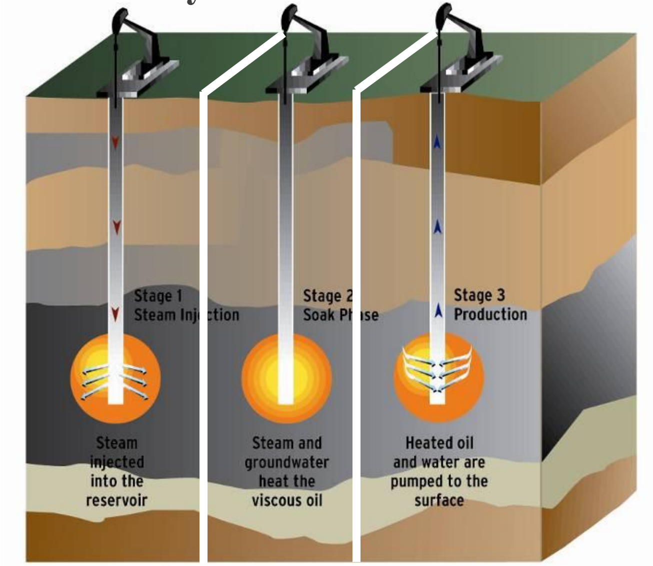
Source: *Canadian Centre for Energy Information*

In situ – oil sands more than 200 feet deep

Steam Assisted Gravity Drainage (SAGD)



Cyclic Steam Process



Oil Sands Mining – Truck and Shovel

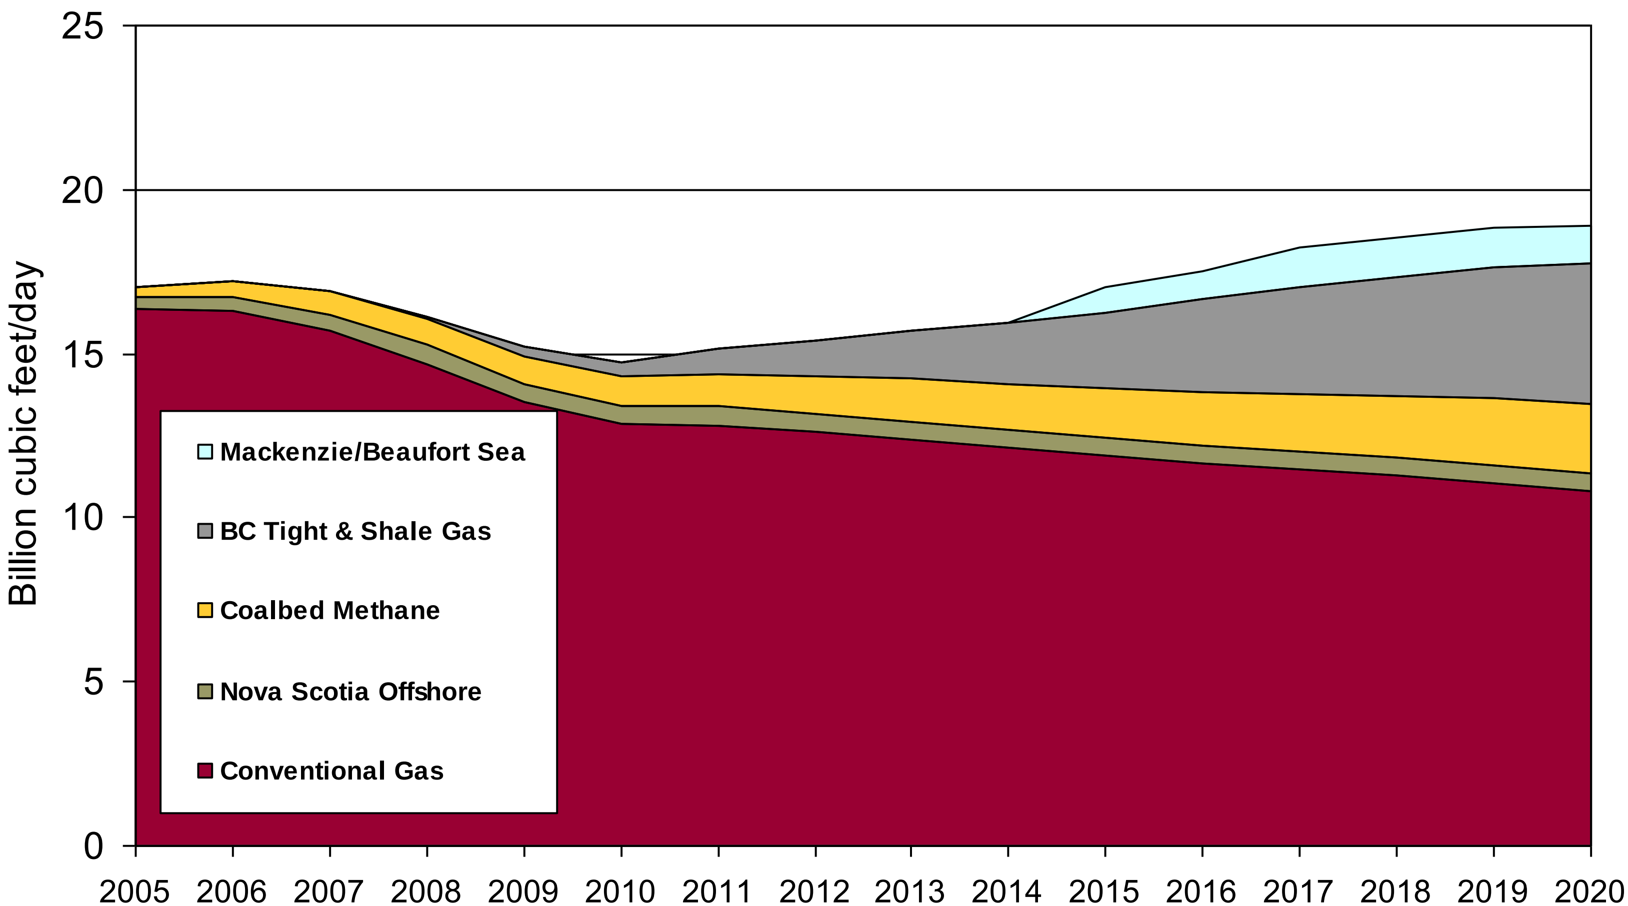
CAPP

- 20% reserves will be produced with mining

In-Situ Oil Sands Production

- **80% of the oil sands will be developed in situ which accounts for 97.5 per cent of the total surface area of the oil sands region in Alberta.**

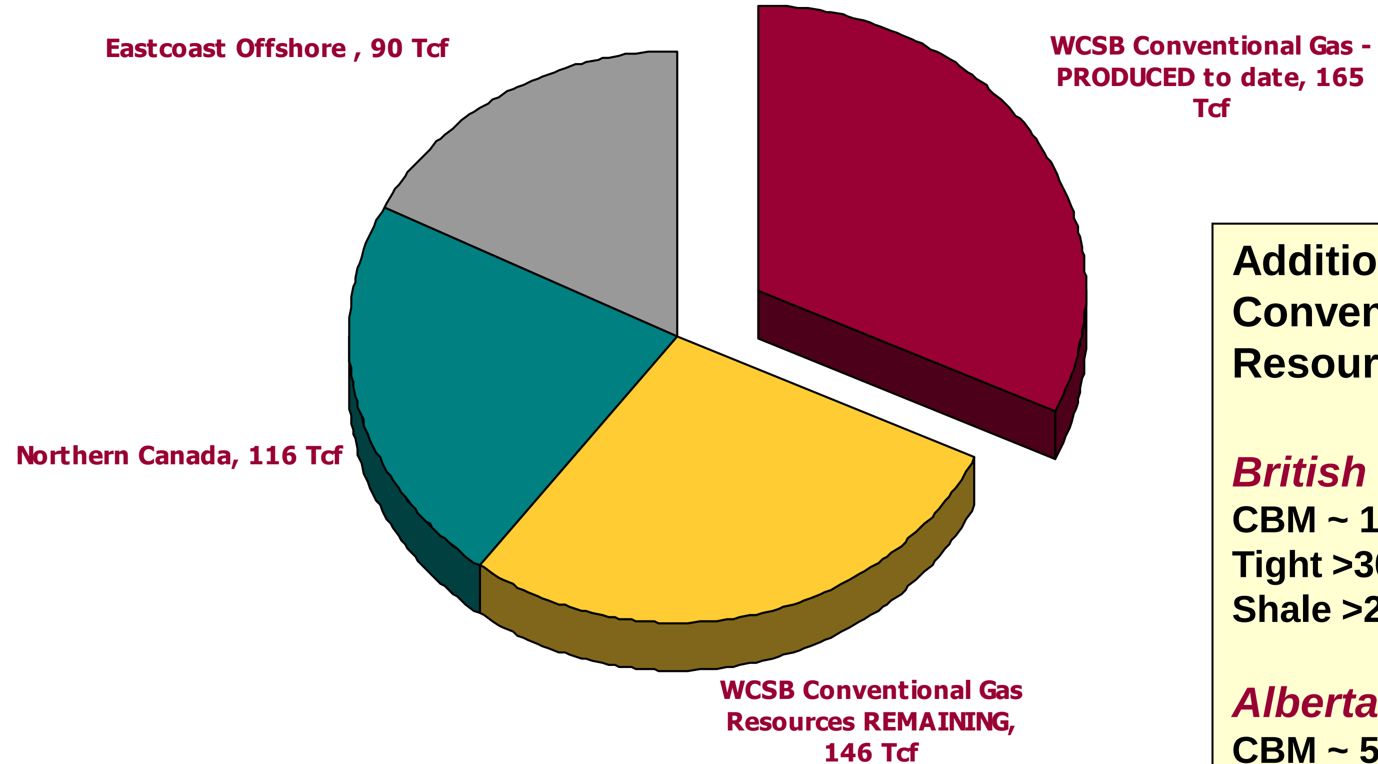
Canadian Natural Gas Production Forecast



Sources: CAPP

Canadian Natural Gas Resources - Conventional and Non-Conventional

RECOVERABLE RESOURCES (Conventional)



Additional Non-Conventional Natural Gas Resources (in place)

British Columbia

CBM ~ 100 tcf
Tight >300 tcf
Shale >250 tcf

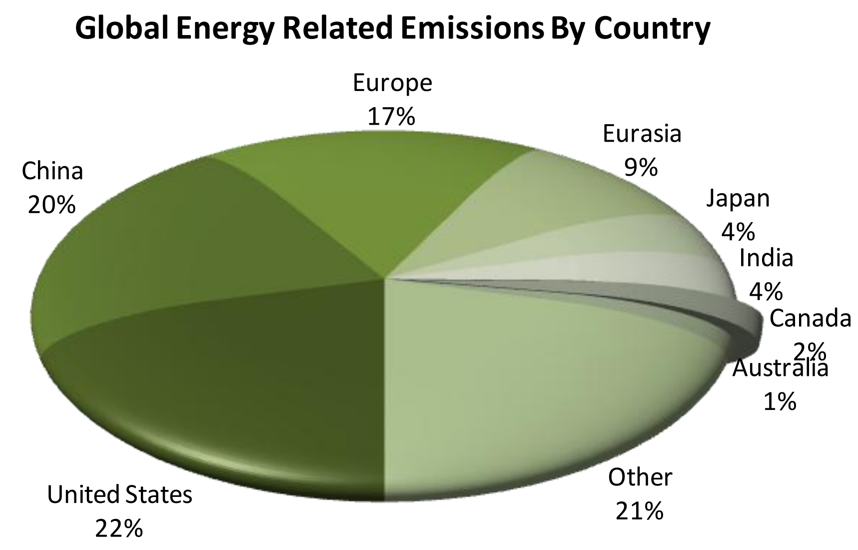
Alberta

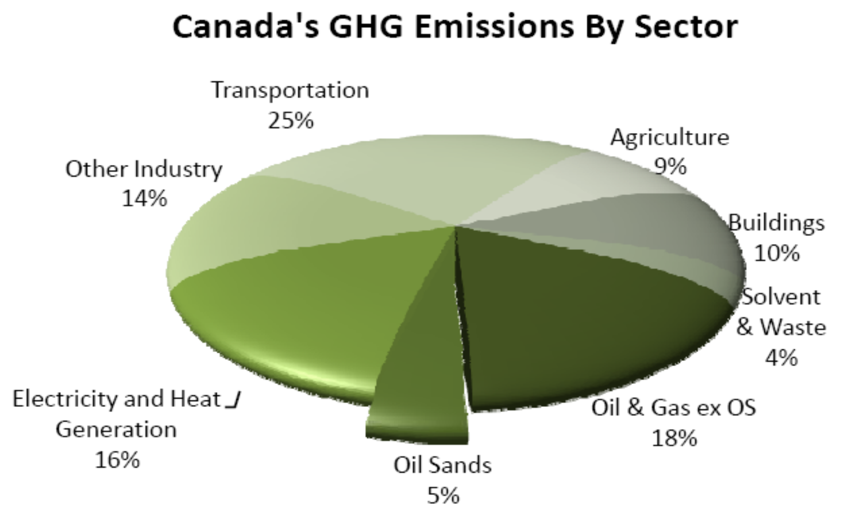
CBM ~ 500 tcf

Source: National Energy Board
British Columbia Ministry of Energy, Mines & Petroleum Resources
Alberta Geological Survey

Greenhouse Gas Emissions

- **All of Canada accounts for 2% of global energy related GHG emissions**
- **Oil Sands is continuing to reduce GHG emissions**
  - Some projects have reduced their GHG intensity by 38% since 1990
  - Increasing energy efficiency
  - Starting CO_2 capture, sequestration and EOR
- **Oil Sands accounts for:**
  - 5% of GHG emissions in Canada
  - 0.1% of global energy related GHG





Canada’s Greenhouse Gas Policies & Programs – British Columbia

- **GHG Emission Reduction Targets**
  - 33% below 2007 by 2020
  - 80% below 2007 by 2050
- **Oil And Gas Flaring Targets**
  - 50% reduction in flaring by 2011
  - Elimination of routine flaring by 2016
- **Carbon Tax**
  - In effect July 1, 2008, starting at $10/t
  - Currently $15/t (rising to $30/t by 2012)
  - Applied to all fuel use (industrial/commercial/domestic)
  - Revenue neutral – reduced taxes for individuals and businesses
- **Reporting Regulation in force January 1, 2010**
  - Verification Required: > 25,000 kt/year
  - Reporting for Oil & Gas: > 10,000 kt/year

Canada's Greenhouse Gas Policies & Programs – Alberta

- **GHG Targets**
  - By 2020: reduce emissions by 50 megatonnes
  - By 2050: reduce emissions by 200 megatonnes, or 14% below 2005 levels
- **Specified Gas Emitters Regulation**
  - Legislation passed, July 2007
  - Requires immediate 12% reduction in emission intensity for large emitters
  - Applies to large emitters >= 100kt
    - ~100 facilities
    - Covers 70% of AB's industrial GHG emissions and 50% total
  - Compliance mechanisms:
    - Direct reductions
    - \$15/tonne CO_2 levy into Technology Fund
    - Alberta-based Offsets
  - Independent verification for baseline report and each annual compliance report
    - Verified to a "Limited Level" of assurance (moderate risk level)
- **Reporting in 2009 > 50kt**

Canada's Greenhouse Gas Policies & Programs – Saskatchewan

- **GHG Reduction Target**
  - Stabilize emissions by 2010
  - 20% reduction from 2006 levels by 2020
- **Regulations expected in 2010**
  - Intensity-based system similar to AB
  - Reduction targets similar to AB
  - Compliance by emissions reductions, offsets or technology fund (100% access)
- **Reduction Plan**
  - Conservation and energy efficiency
  - CCS for oil and gas and power generation
  - Renewable energy
  - Reductions in methane emissions from oil & gas
  - Carbon sinks in soils and forests

Challenges with UOG – GHG Reporting

- **Number of facilities**
  - 200,000 Wells
  - 20,000 Batteries
  - 12,500 Gas Gathering Systems
  - 3,000 Injection Facilities
  - 700 Gas Processing Plants
- **Size ranges (emissions)**
  - Average Well ~20 t/y CO_2e (equipment leaks, venting, pumpjack, dehydrator/line heater)
  - Average Gas Plant ~31,000 t/y CO_2e (separation, sweetening, compression, dew point control, fractionation, sulphur recovery, formation CO_2)

Challenges with UOG – GHG Reporting

- **No CEMS requirements**
- **Measurement challenges**
  - Facilities have total fuel measurement (fuel meter)
    - Fuel is not usually metered at the equipment level
    - Well sites often do not meter fuel use (it is estimated and reported)
  - Production Accounting – reporting measured value or defensible estimate
    - All gas volumes (fuel, flare, vent) > 0.1×10^3 m^3/month must be reported
    - Volumes > 0.5×10^3 m^3/d must be metered
    - Volumes < 0.5×10^3 m^3/d can be estimated
  - Casing gas venting – based on GOR values
    - 24 h GOR tests required annually for venting wells
  - Instrument venting & pneumatic devices
    - Gas volume is required to be reported in the fuel volume
    - Potential to over-report emissions if vented gas is not backed out of fuel
  - Fugitive equipment leaks based on emission factors – OK for large population but may not accurately characterize facility emissions
  - Sampling of fuel streams limited – leads to emission factor uncertainty

Western Climate Initiative

Defining the Reporting Entity and Threshold

Reporting Committee
Dennis Paradine, British Columbia

Defining the Reporting Entity

- Oil and gas industry emission sources are often small and distributed over a large geographic area
- Together these emissions can contribute significantly to total GHG emissions
- To ensure WCI captures 90% of emissions from oil and gas as it does with other sectors, individual oil and gas sources may need to be aggregated into reporting entities

Oil and Gas Reporting Entity Options

A – do not aggregate emissions, apply existing facility definition

B – aggregate emissions to the field level

C – aggregate emissions to the basin level

D – aggregate emissions to the jurisdiction level

- WCI (or EPA) facility definition clause “are under common control of the same owner(s) or operator(s)” would be used in defining the reporting entity, with the adjacency clause discarded

- WCI Oil and Gas ERMR would include not only oil and gas sources in draft EPA Subpart W, but also additional sources that the WCI intends to capture

Defining Oil and Gas Thresholds

- 10,000 tonne reporting and 25,000 tonne verification threshold applies to all other source categories

- There is a direct interaction between how the oil and gas entity is defined and the appropriate threshold level
  - Basin level coverage may allow for higher reporting entity thresholds compared to field level coverage
  - Higher thresholds would lower the number of reporters and lower emissions coverage

- Barrel of oil equivalent thresholds have also been suggested

Feedback – Reporting Entity and Threshold

- Is the basin the appropriate level at which to define a reporting entity for the WCI mandatory reporting program?
- Would a 10,000 tonne reporting (and a 25,000 tonne verification) threshold for an oil and gas reporting entity capture 90% of emissions from the sector?
- Would an analogous barrel of oil equivalent threshold be better to use?

Western Climate Initiative

Contractor Emissions

Reporting Committee

Dennis Paradine, British Columbia

Contractor Emissions

- Oil and gas installation operation varies between producers and contracted service providers
  - With multiple owners, one company can be assigned operational control and perform the work or contract it out.
- Excluding contractor emissions could lead firms to contract out operations to avoid reporting or cap and trade obligations
- The above two points raise issues of equitable coverage
- Concerns have been noted about potential burdens in reporting contractor emissions
  - Are sufficient contracts in place to ensure GHG data is reported?

Contractor Emissions Options

A – Not require reporting of contractor emissions.

- Neither the oil and gas producer nor the contractor report emissions

B – Require contractors to report if aggregated emissions exceed threshold.

- Contractors report all emissions associated with the operations they are contracted for (if > threshold.)

C – Include venting, fugitive and flaring emissions from a contractor in the emissions of the owner/operator.

- The producer reports all emissions (excluding combustion) from contractor operations

D – Include all emissions in C and combustion emissions from contractors, other than portable combustion emissions.

- The producer reports all emissions associated with contractor operations including combustion emissions, other than portable combustion emissions.

E - Include all emissions in D and portable combustion emissions from contractors .

- The producer reports all emissions associated with contractor operations including portable combustion emissions occurring on-site

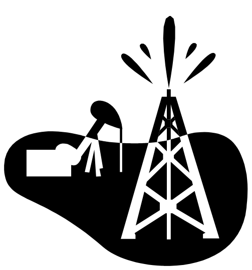
Feedback – Contractor Emissions

- How to minimize inequitable coverage and potential facility splitting?
- What is the appropriate boundary for reporting oil and gas emissions from contractors?
    - WRAP / TCR uses Option C (above). Is it appropriate to extend to include combustion emissions from a contractor for a mandatory reporting program?
- Would phasing in types of reporting of contractor emissions help to reduce burden?

Defining the Upstream Oil and Gas Sector: Exploration, Production, and Natural Gas Gathering and Processing

Western Climate Initiative – Oil & Gas Collaborative
Santa Fe, NM
November 19, 2009

Tom Moore
Air Quality Program Manager, Western Governors' Association



Acknowledgements for those supporting the Upstream O&G Protocol work to date

- Project Sponsors – NM, CARB, TCR

Oil and Gas “Upstream” sources & activities

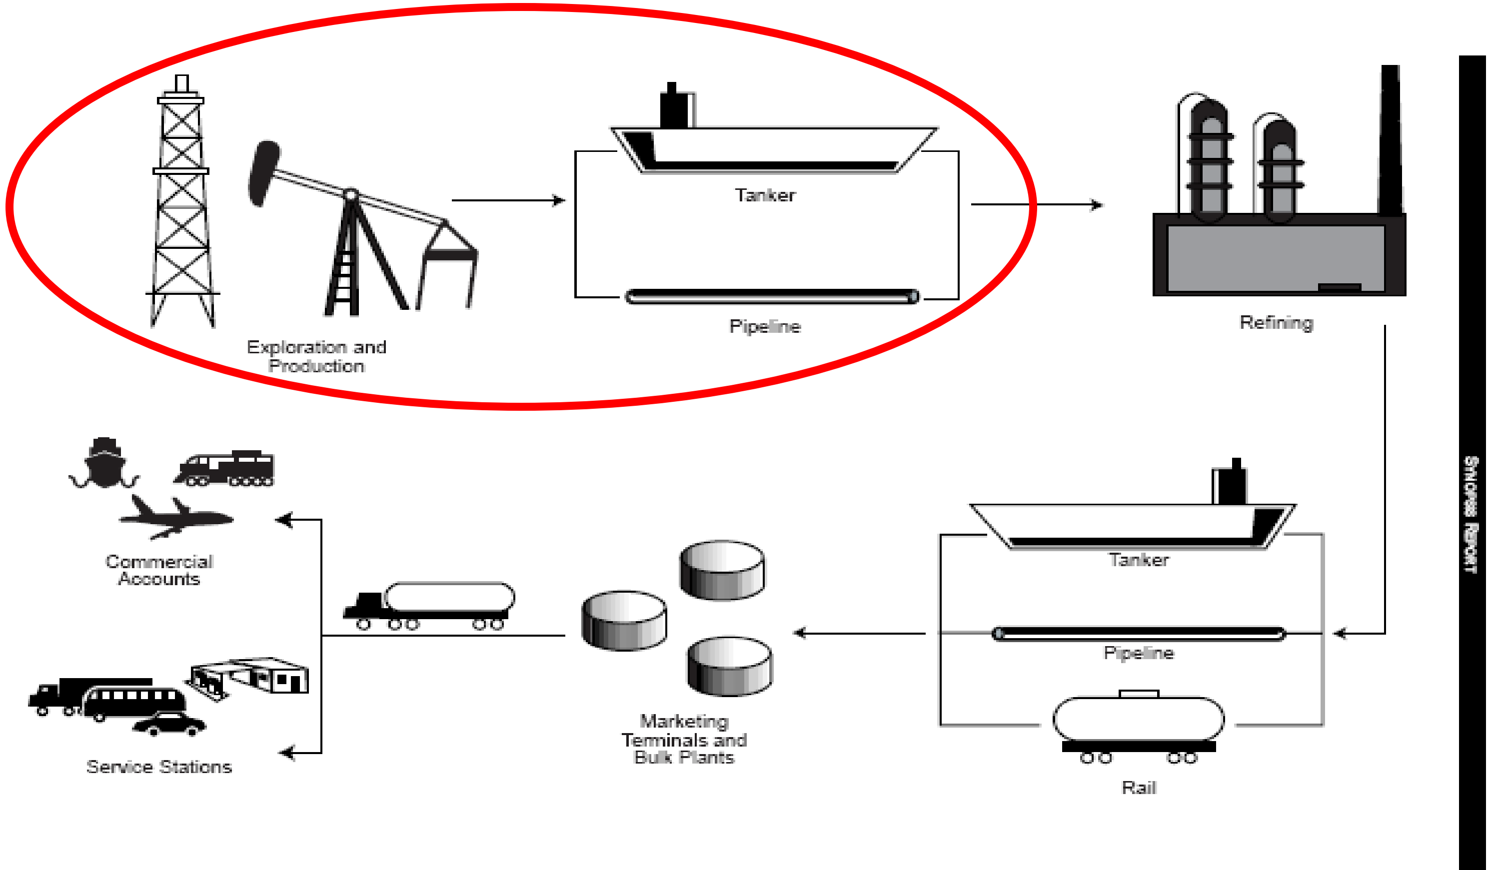

Figure 1—Major Emission Sources for an Integrated Oil Company

Figure 1—Oil and Gas Industry Schematic of GHG Emissions

Source: American Petroleum Institute: Toward a Consistent Methodology for Estimating Greenhouse Gas Emissions from Oil and Natural Gas Industry Operations. Page 4.

Geographic Scope and Source Types addressed in developing work on Upstream Reporting Protocols to date

- North America
- All O&G source activities upstream of:
  - Oil refineries (GHG reporting covered by ARB regulation)
  - Gas sale pipeline transfer points (CCAR/WRI/TCR protocol)
- Types of O&G E&P
  - Conventional Oil & Gas
  - Unconventional Gas
    - Tight Sands Gas
    - Gas Shale
    - Coalbed Methane Gas
    - Oil Sands
  - Oil
    - Offshore
    - Enhanced Oil Recovery
    - Oil Sands

Emissions Inventory Sources addressed in Protocol work to date

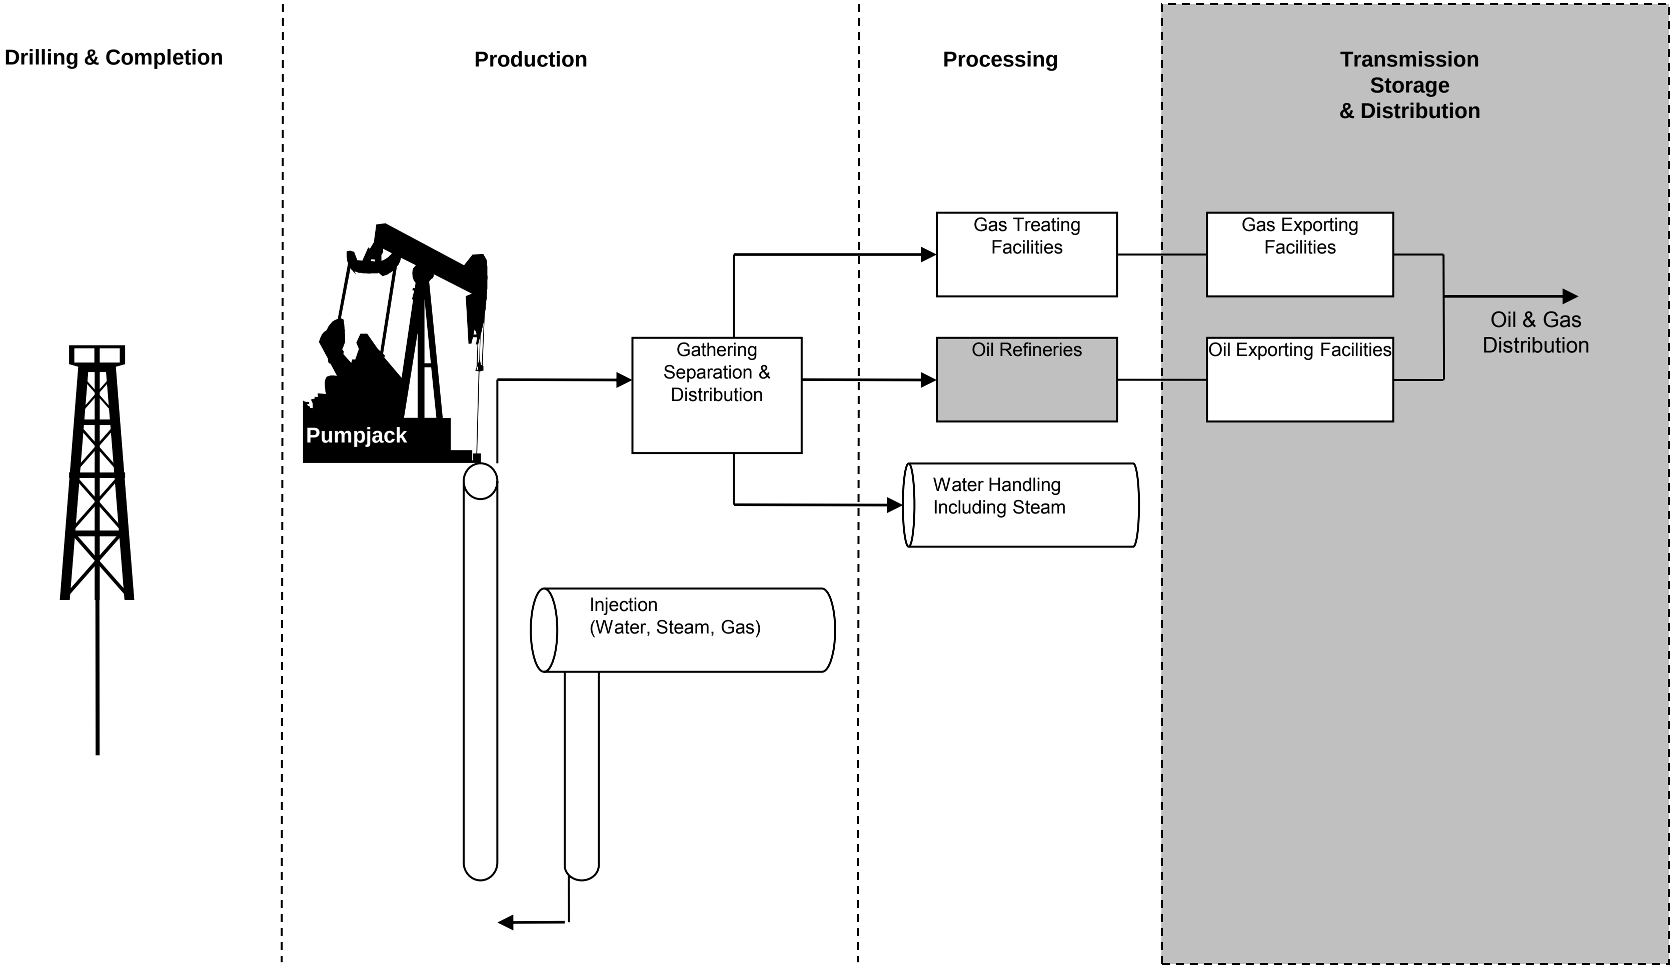
- Gas Processing Plants
- Compressor Stations
- Wellhead Compressor Engines
- CBM Pump Engines
- Miscellaneous/Exempt Engines
- Drilling/Workover Rigs
- Salt-water Disposal Engines
- Artificial Lift Engines (Pumpjacks)
- Vapor Recovery Units (VRUs)
- Oil/Gas Well Heaters
- Hydrocarbon Liquid Storage Tanks

- Well Completions
- Fugitive Emissions
- Completion Venting
- Well Blowdowns
- Dehydration Units
- Amine Units
- Hydrocarbon Liquid Loading
- Landfarms
- Water Treatment/Injection
- Flaring
- Pneumatic Devices
- Produced Water Tanks
- Crude Oil Transportation

Sources included/not included in the Upstream O&G sector

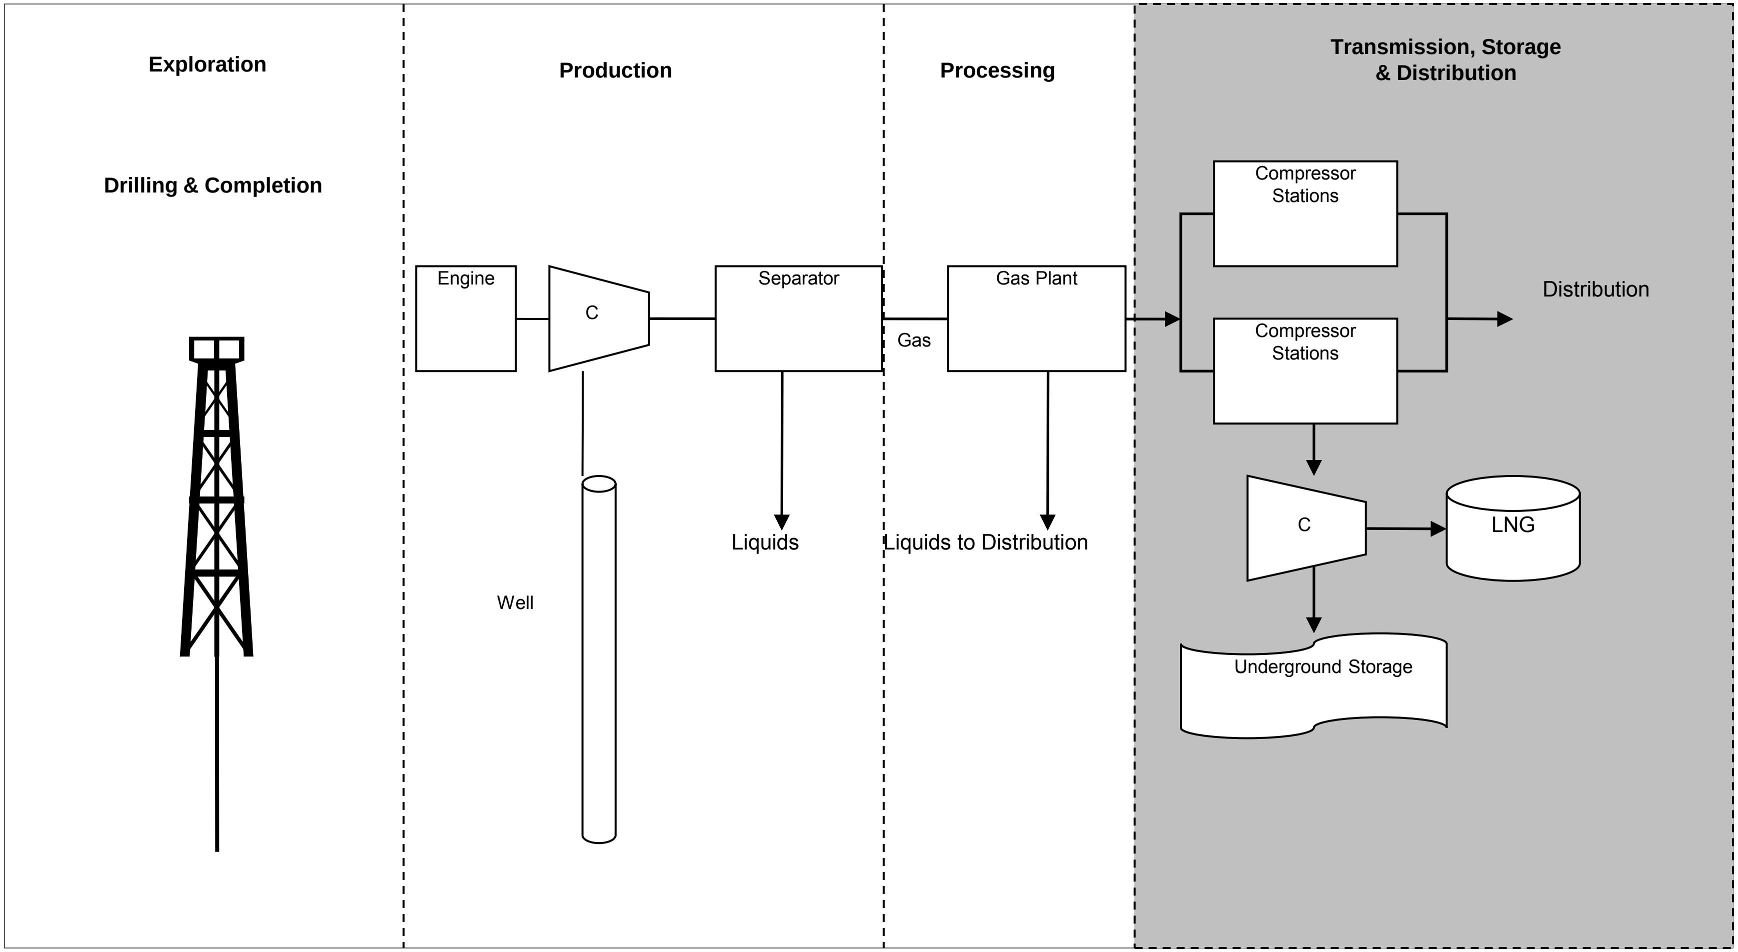
- Includes all emissions sources in the:
  - **Exploration and production** (E&P) sector of **oil** & **natural gas, as well as:**
    - **Gas gathering, collection, and processing** - through to the "tailgate" of Natural Gas Processing Plants
    - **Crude Oil Transportation** (including pipelines, trains, trucks, and marine vessels) to the "entry gate" of Oil Refineries
- ***Does not include***:
  - Oil refining and downstream distribution of petroleum products
  - Transmission, storage and distribution of natural gas downstream of the processing plant
- Includes ***all*** companies involved in any way in E&P, natural gas processing, and/or crude oil transportation, including:
  - Oil and Gas leaseholders
  - Support services contractors (e.g., drilling contractors)

Oil Industry Sector



Upstream O&G Protocols do not address oil operations shown in the shaded area.

Natural Gas Industry Sector



Upstream O&G Protocols do not address natural gas operations shown in the shaded area.

Facility Issue Addressed in Protocol work to date

- Definition of a facility/Aggregation of emissions:
  - **Proposed Solution:** Dispersed emission sources to be aggregated, at a minimum, to "production field" level:
    - *Production field is a well understood, broadly accepted concept within the industry*
    - *Production fields are precisely defined by state, province, or country*
  - Reporters are given the option of aggregating multiple fields together (particularly useful, e.g., for infrastructure common to more than one field)
  - Emissions from sources corresponding to standard definition of a facility (e.g., natural gas processing plants) must be reported by facility

Questions -

Western Climate Initiative

Federal GHG Legislation

Potentially Affecting the Upstream Oil and Gas Industry

Summarized by Paula Fields, ERG

for the Oil and Gas Collaborative

Santa Fe, New Mexico

November 19, 2009

Federal GHG Legislation

- Proposed "Endangerment and Cause or Contribute Findings for Greenhouse Gases under the Clean Air Act" – April 24, 2009
- Promulgation of final Mandatory Reporting Rule (MRR) for Greenhouse Gases – September 22, 2009
- Proposed PSD and Title V Greenhouse Gas Tailoring Rule (September 30, 2009)
- American Clean Energy and Security Act of 2009 (ACES) (Waxman-Markey Climate Change Bill, HR2454)
- Clean Energy Jobs and American Power Act (CEJAPA) (Introduced to Senate on September 30, 2009)

Proposed PSD and Title V Greenhouse Gas Tailoring Rule

- "Tailors" NSR requirements to limit the number of facilities required to obtain NSR permits
- Applicability:
  - Title V major source threshold: 25,000 tons CO_2e
  - PSD permit applicability thresholds:
    - New sources or existing source making major modifications: 25,000 tons CO_2e
    - Significance level for major source modification increase: 10,000 to 25,000 tons CO_2e (single value to be selected)
- Covers ~70% of the national GHG emissions from stationary sources
  - 14,000 large sources will require Title V permits (3,000 new)
  - 400 new/modifications will require PSD review (100 new)

The American Clean Energy and Security Act of 2009 (ACES), H.R. 2454

- Targets
  - Economy-wide reductions from 2005 levels
  - Interim reductions; 17% by 2020
  - 83% by 2050
- Allowance Allocations
  - 85% distributed (incl. 9% to NG distributors; 2% to refineries)
  - 15% for auction in 2012
- Cost Containment
  - Via offsets
  - Sets price, adjusts for inflation
- Offsets
  - 2 billion credit ceiling
  - 1 billion each domestic, international
  - Special provisions for domestic agriculture and forestry sources
- Technology
  - Renewable electricity standard
- Technology (cont.)
  - Electric vehicles and infrastructure development
  - New performance standards for sources individually emitting <10,000 tons CO_2e
- Competitiveness
  - Rebates (allocations) to energy-intensive, trade-sensitive industries, oil refineries, etc.
  - May require border tariffs in 2020
- CAA and Regulatory Authority
  - Establishes GHG registry with 10,000/ 25,000 tons CO_2e thresholds (entities/vehicle fleets)
  - Removes EPA authority to further regulate GHGs from large sources
  - Puts state trading programs on hold from 2012-2017
  - Eliminates NSR applicability to GHGs

Clean Energy Jobs and American Power Act (CEJAPA)

- Targets:
  - Economy-wide reductions from 2005 levels
  - Interim reductions; 20% by 2020
  - 83% by 2050
- Allowance Allocations
  - 78% distributed (incl. 9% to NG distributors; 2.25% to refineries; 30% to LDCs)
  - 22% for auction in 2012
- Cost Containment
  - Via offsets
  - Sets price, adjusts for inflation
- Offsets
  - 2 billion credit ceiling
  - 1 billion each domestic, international
  - (No special provisions for domestic agriculture and forestry sources)
- Technology
  - National strategy, early deployment of CCS program
  - (No renewable standard)
  - Transportation efficiency standards
  - Removes barriers for nuclear
- Competitiveness
  - Rebates (allocations) to energy-intensive, trade-sensitive industries, oil refineries, etc.
  - Will contain border measures
- CAA and Regulatory Authority
  - Maintains EPA authority to further regulate GHGs from large sources
  - Does not put state trading programs on hold
  - Does not eliminate NSR applicability to GHGs

Then there is the collection, compression, treating, and processing

WRAP and TWG Significant Sources

- **Task to categorize significant sources by basin for the 6 member states/provinces in the WCI**
  - **Includes New Mexico, California, Utah, Montana, British Columbia and Manitoba**
  - **Significance = sources contributing to the top 95% of GHG emissions in a basin**
  - **Basins defined using USGS basin boundary definitions**
- **Screening-level inventories vs. reporting**
  - **Screening-level inventories developed at the basin level - attempt to account for regional variations in the significant sources**
  - **This is only for purposes of determining significant sources – not reporting**

Basin Examples

San Juan (South Basin)[1]	Uinta Basin[2]
Permitted Compressor Engines (24.5%)	Heaters/Boilers (21.9%)
Permitted Heaters/Boilers (13.9%)	Unpermitted Compressor Engines (6.3%)
Unpermitted Compressor Engines (13.0%)	Permitted Compressor Engines (5.9%)
Permitted NG Turbines (7.4%)	Artificial Lift Engines (5.6%)
Unpermitted Heaters/Boilers (6.8%)	Drill Rigs (3.8%)
Workover Rigs (1.6%)	
Artificial Lift Engines (1.2%)

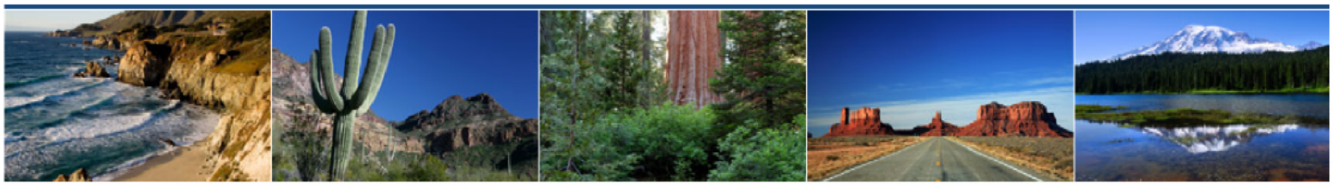
	Well Blowdowns (2.2%)	

Western Climate Initiative



Issue Paper -- Defining the Reporting Entity and Threshold

Issue:

Greenhouse gas emission sources in the oil and gas industry often consist of small sources distributed over a broad geographic area that, when taken together, can contribute significantly to total GHG emissions in their regions. Large numbers of these emissions sources are typically owned and/or operated by the same company, although ownership (and operation) is not necessarily determined exclusively on the basis of geographic proximity. While many of the oil and gas emission sources in the oil and gas sector are small, some individual oil and gas facilities are large enough to be captured under the current reporting and verification thresholds. To ensure that a comparable portion of emissions is captured in the oil and gas sector as in other sectors, individual small oil and gas sources may need to be aggregated into oil and gas reporting entities for the purposes of reporting GHG emissions to WCI jurisdictions.

In discussions of this issue, it should be noted that the oil and gas industry in Canada can be vertically integrated (i.e. the producing company can also own the natural gas plant and/or the transmission company), while in the United States such vertical integration is prohibited by FERC regulations.

WRAP/TCR Approach:

Aggregate and report emissions from small individual oil and gas sources which are owned and/or operated by a company at the field level. Large sources that meet the traditional definition of a standalone facility must be reported separately to maintain transparency. Reporting thresholds would be established at the field level for small sources and at the facility level for sources meeting the traditional definition of a facility. Companies have the option to aggregate multiple fields together up to the state-level for reporting convenience.

EPA Approach:

Not applicable – deferred to final Subpart W.

WCI Options:

The basic option would be to follow the general WRAP/TCR approach (defining the reporting entity as outlined in the first option table below), adding the following detail needed for a mandatory reporting program:

1. Use the WCI.9 (or EPA) facility definition part c clause: 'are under common control of the same owner(s) or operator(s)' for aggregation purposes. Discard part b of the same definition for aggregation purposes.

2. Apply thresholds (as outlined in the second option table below) to the aggregated emissions to create an 'Oil and Gas Installation'
3. Allow jurisdictions flexibility to aggregate emissions to a higher level than the WCI determines.
4. Apply to all oil and gas emissions sources covered under EPA Subpart W and those emissions sources not included in Subpart W but to be included in the WCI Oil and Gas Essential Requirement. Apply similarly to all emission sources involved in carbon transfer.

Defining the Reporting Entity

Option	Pros	Cons
A. Do not aggregate emissions. Apply existing facility definition to oil and gas installations	Simple, follows current WCI facility definition.	Due to disaggregated sources, may not meet WCI principle of covering a significant portion of emissions
B. Aggregate emissions to the field level	WRAP approach Emission factors likely similar at a field level	May not meet WCI principle of covering a significant portion of emissions unless lower thresholds are used. Fields vary in size, potentially creating inequity between leaseholders in different fields
C. Aggregate emissions to the basin level	Extends WRAP field approach to a scale potentially more suitable for a mandatory program. With appropriate thresholds would likely meet WCI design principle of covering a significant portion of emissions with as few facilities and reporting entities as possible.	Appropriate thresholds would need to be determined. Variable emission factors may need to be used in different fields.

D. Aggregate emissions to the jurisdiction level	Extends WRAP approach to a scale potentially more suitable for a mandatory program. With appropriate thresholds would likely meet WCI design principle of covering a significant portion of emissions with as few facilities and reporting entities as possible.	Appropriate thresholds would need to be determined. Variable emission factors may need to be used in different fields.

Reporting Thresholds

Option	**Pros**	**Cons**
A. Existing WCI thresholds: 10,000 tonnes reporting, 25,000 tonnes verification	Follows current WCI standards. Easy to communicate	May not meet WCI principle of covering a significant portion of emissions. May need more detailed reports from a reporting entity to understand the distribution of emission sources.
B. Lower thresholds	Would capture a higher portion of emissions and may meet the WCI principle of covering a significant portion of emissions. May not require more detailed reports from a reporting entity to understand the distribution of emission sources.	May or may not meet WCI principle of covering a significant portion of emissionswith as few facilities and reporting entities as possible. May increase reporting burden for small companies.

C.	**Higher thresholds**	May reduce reporting burden for small companies. Potentially could meet WCI principle of covering a significant portion of emissions with as few facilities and reporting entities as possible.	May not meet WCI principle of covering a significant portion of emissions May need more detailed reports from a reporting entity to understand the distribution of emission sources.
D.	**Base thresholds of a similar amount of barrels of oil equivalent**	May be easier to determine obligations for the oil and gas industry.	Deviates from WCI emissions thresholds approach for reporting and verification

Note: there is a relationship between how the reporting entity is defined and the appropriate thresholds to use. A broader reporting entity may mean a higher threshold could be used. A smaller reporting entity may mean a lower threshold is needed. The optimum combination of reporting entity definition and threshold to meet the design principle may not be known until one or more years of reported data is available at a finer scale than that ultimately required for the long-term.

Possible Quantification Methodology:

'Oil and Gas Installation' emissions could be calculated using the following general approach:

i. Include all oil and gas installations covered by EPA Subpart W, those other installations deemed appropriate and included in the WCI Oil and Gas Essential Requirement and all WCI and/or EPA source categories (e.g. stationary combustion).

ii. Include, exclude, or extend applicability for contractor emissions as determined by the WCI through this process.

iii. Apply emission factors to installations at the well, gathering location or field level (as appropriate in the jurisdiction) for true upstream sources. Apply emission factors as otherwise used in EPA Subpart W or the WCI metric ERMR (for use in Canada).

iv. Sum all oil and gas installations under common control of the same owner(s) or operator(s) to the field, basin or jurisdiction (as determined by the WCI) level

v. To provide sufficient information to understand distribution of emission sources, to determine potential facility splitting and to determine whether equitable coverage is occurring, provide at a minimum disaggregated reporting for each individual installation within the aggregated 'Oil and Gas Reporting Entity'. Determination of reporting and verification thresholds would be from the aggregated 'Oil and Gas Facility' total, including the installations reported individually.

vi. Some emission sources that are required to be reported may be determined not appropriate for market trading in combination with the WCI Cap Setting and Allowance Distribution work.

Attention will need to be paid in the compliance and policies of jurisdictions to change of ownership/leasehold, possible facility splitting and/or outsourcing of emissions to contractors.

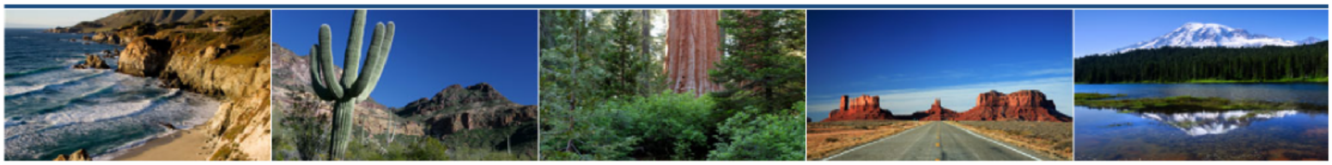
To be completed (Santa Fe Collaborative).

Western Climate Initiative



Issue Paper -- Contractor Emissions

Issue:

Oil and gas installation operation varies – often between adjacent installations that are otherwise similar - between owners/leaseholders and service providers who act as contractors. In some cases there are multiple fractional owners of wells, each owner having a slightly different ownership group. One company will often be assigned operational control and either perform the exploration and extraction operations themselves, or contract them to a service provider.

There is concern from installation owners/leaseholders that reporting contractor emissions could cause significant burden as such emissions are not currently reported in any form and new contractual obligations may be required.

A significant issue could arise in firms contracting out oil and gas installation operation to avoid both greenhouse gas reporting and a future cap and trade system. Equally significant is the WCI's goal of capturing 90% of emissions from each source category. Without capture of contractor emissions it is doubtful that 90% of oil and gas production installation emissions will be captured.

WRAP/TCR Approach:

This issue was discussed in depth in the WRAP/TCR process, and TCR decided that contractor emissions should be considered Scope 3 indirect emissions which are not required to be reported under a voluntary program. The WRAP process did identify that emissions such as venting are in general considered to be the responsibility of the leaseholder to report and are therefore not contractor emissions. That left contractor emissions as primarily the combustion that contractors use to do their work (portable, such as a mobile drilling rig, or stationary). There were various opinions about whether these remaining contractor emissions should or should not be covered by the reporting system.

The importance of including contractor emissions under a mandatory reporting program was not addressed.

EPA Approach:

EPA's definition of facility would not preclude contractor equipment at an installation from being considered a separate facility subject to the MRR and reportable by the owner or operator, or as part of the larger facility. The EPA definition would include in the facility all equipment under "common ownership or *common control*" [emphasis added]; therefore, specifics of the contractual arrangement might determine whether contracted equipment was under the control of the party contracting to purchase services. However, EPA excludes portable equipment from coverage under MRR Subpart C (General Stationary Combustion), and defines portable equipment to exclude equipment which is easily transportable and located at a given site for less than twelve months. Portable contractor equipment is often located at a site for periods less than a year, and therefore much of contractor combustions emissions would thereby be excluded from reporting under Subpart C. EPA deferred on the issues of defining the reporting entity for oil and gas production sources and of reporting vented and fugitive emissions from oil and gas sources.

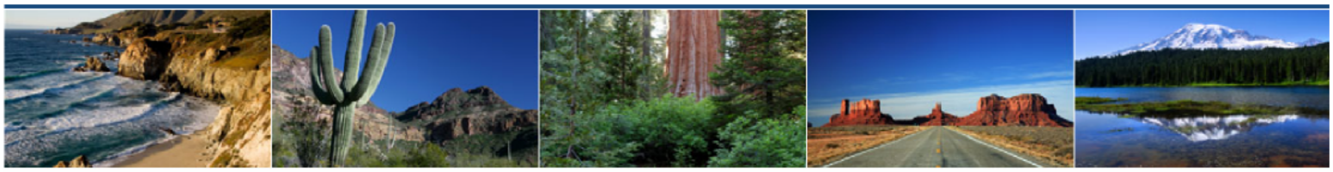
WCI Options:

Option	Pros	Cons
A. Not require reporting of contractor emissions. Neither the oil and gas producer nor the contractor report emissions.	Simple	Facility splitting could be a problem Would capture the lowest amount of emissions Does not match WRAP/TCR approach to leaseholder emissions Inequitable coverage: creates a two-tier system of facilities with and without contractors Could result in under reporting contrary to WCI design principle (See BM Comment 2)
B. Require contractors to report if aggregated emissions exceed threshold. Require contractors to report all emissions associated with the operations they are contracted to perform (if in total they exceed the threshold.	Creates responsibility for contractors to report emissions Would be simplest scenario for combustion and portable emissions	Emission sources could be covered by several operators at a single installation Does not match WRAP/TCR approach to leaseholder emissions Facility splitting could create administrative difficulties Would create a new class of ‘facility’

C. Include venting, fugitive and flaring emissions from a contractor in the emissions of the owner or operator. The oil and gas producer reports all emissions associated with the contractor operations excluding combustion emissions.	Would cover a significant portion of emission sources Reduces facility-splitting potential through intentional use of contractors All emissions are generally considered part of a typical oil and gas installation WRAP/TCR approach identified that these emissions are the responsibility of the leaseholder	Does not include what could be substantial combustion emissions if from a contractor Inequitable coverage: potentially creates a two tier system of facilities with and without contractors (for other emission sources)
D. Include all emissions in Option C (above) and combustion emissions from contractors, other than portable combustion emissions. The oil and gas producer reports all emissions associated with contractor operations including combustion emissions, other than portable combustion emissions.	Creates equitable coverage. Would cover all emission sources that are typically considered as part of an oil and gas installation. Producer consumption is a significant emission source Reduces facility-splitting potential through intentional use of contractors Requirements to track combustion emissions from contractors could be included within contracts	May require phasing in due to contractual issues. (could require owners/leaseholders to estimate combustion emissions in the first years to allow importance to be established) More rigorous than WRAP/TCR approach to leaseholder emissions
E. Include all emissions in D and portable combustion emissions from contractors. The oil and gas producer reports all emissions associated with contractor operations including portable combustion emissions occurring on-site.	Would cover the largest portion of emission sources	Portable combustion emissions (e.g., onsite emissions from a mobile drilling rig) in the oil and gas industry likely would prove hard to track, creating an administratively burdensome system More rigorous than WRAP approach to leaseholder emissions

Stakeholder Input:

To be completed (Santa Fe Collaborative).



Issue Paper -- Stationary Combustion of Field Gas

Issue:

Gas (field or associated gas) of varying composition recovered from oil and gas wells is combusted in the field. Field gas is consumed as a fuel at the well head in devices such as compressors, dehydrators and heaters.

The volume of field gas produced in association with oil production that is not marketed is typically estimated by periodic sampling to determine the gas to oil ratio (GOR) at a particular well. The total volume of gas produced at the well is then calculated by multiplying the oil production by the GOR. Most of the produced gas is marketed; however some of this gas is combusted as a fuel at the site, while other portions may be vented, flared or released to the atmosphere as fugitive emissions. The disposition of the produced gas in terms of use in equipment, flaring and venting is not routinely metered. Existing Oil and Gas regulations, which vary by jurisdiction, typically rely on engineering calculations to estimate the use of field gas in production equipment and estimate volumes flared or vented as the difference between field gas produced and the volume of field gas used by equipment at the production facility.

Field gas CO_2 combustion emissions may represent a significant GHG emissions source. Field gas metering requirements appear to be quite variable across WCI partner jurisdictions.

Accurate estimation of field gas combustion GHG emissions requires an accurate estimate of the volume of fuel gas combusted and gas composition (carbon content or HHV).

Improvements in measurement accuracy for greenhouse gas emission from field gas can be achieved by better measurement of volumes of gas produced and by including metering where expected rates of greenhouse gas emission may differ between different areas of disposition of field gas. For example, it is useful to determine the volumes of field gas consumed in combustion processes versus field gas which is vented to the atmosphere.

WRAP/TCR Approach:

In cases where meter data is not available, TCR recommends the use of an engineering approach where equipment specific data such as device horse power, heat rate, and loaded factor are used to calculate fuel consumption.

EPA Approach:

EPA has not published an emissions calculation methodology specific to field gas. Subpart W – Oil and Natural Gas Systems (which was not included in the final reporting rule) required reporters to use methods in Subpart C- General Stationary Combustion Sources to calculate the CO_2, CH_4, and N_2O emissions for stationary combustion sources.

WCI Options:

.

Option	Pros	Cons
Option A 1. Determine fuel consumption using either installed gas meters (where available) or engineering calculation where metered data is not available. 2. Measure field gas composition periodically 3. Calculate emissions	Simplest approach requiring no installation of meters. Engine run- time meters may be required	Data quality and consistency will vary within a reporting entity and across reporters US data may not be as high quality as Canadian data where there are regulatory requirements to quantify lease gas consumption

Option	Pros	Cons
Option B 1. Meter a significant fraction of field gas consumption 2. Estimate remaining field or lease gas consumption using an engineering method 3. Determine lease gas composition periodically 4. Calculate emissions	More accurate method which would generate more consistent data both for individual reporters and for all reporters. Would provide more consistent data quality between jurisdictions (US and Canada) WCI could require determination of fuel flow for a subset of metered engines using the engineering approach. This would allow evaluation of the engineering approach to fuel consumption determination	Would require the upfront installation of meters on the larger engines. Prior to the beginning of reporting period it may be difficult to determine which engines require metering. Engines changes during the reporting period would also complicate this approach.

Option B is discussed in more detail below. Two engineering methods for the calculation of field gas consumption are discussed.

1. Meter a significant fraction of field gas consumption.

a. Tabulate the annual horse power – hours (hp-hr) for each unit combusting field gas. For example, a 450hp compressor running continuously would annually generate

3.942×10^6 hp-hr (450hp x 8,760 hrs/yr).

b. Sort the resulting list of combustion units by hp-hr generated annually (highest to lowest).

c. Require metering of field fuel consumption for the units which cumulatively (highest to lowest) represent 75% of total annual hp-hr.

2. Estimate remaining field gas consumption (engineering approach).

a. Apply an engineering approach (see below) for the remaining 25% of combustion emissions.

b. For a sub-section of the metered combustion units, use the engineering approach as well. This would allow WCI to compare methodologies (metered field gas consumption versus the engineering calculation).

Engineering Options for Determination of Unmetered Fuel Flow:

API method

See the API Compendium of Greenhouse Gas Emission Methodologies for the Oil and Natural Gas Industry (2009) for specifics (page 4-5, 4.1 Estimating Fuel Consumption Data from Energy Output or Volumetric Flow).

$$FC = ER \times LF \times OT \times ETT \times 1/HHV$$

Where:

FC = annual fuel consumed (volume/yr)

ER = equipment rating (hp, kW, or J)

LF = equipment load factor (fraction)

OT = annual operating time (hr/yr)

ETT = equipment thermal efficiency ($Btu_{input}/hp\text{-}hr_{output}$ etc)

HV = fuel heating value (energy/volume)

This is inherently a less accurate method of determining fuel consumption due to a number of issues (e.g. the estimation of unit load factor).

Fuel Consumption Method Based on Gas Produced and Pressure

A relatively accurate means of estimating the fuel consumption for field gas consumption in well head compressors is to base it on the quantity of gas produced and the pressures the compressor must overcome. The following equation can be offered as an alternative to the equation in the current issue paper on field gas consumption:

$$FC = EE \times V \times 1/HHV$$

Where:

FC = annual fuel consumed (volume/yr)

EE = equipment efficiency (Btu/mscf)*

V = volume of gas produced in the time period (mscf)

HV = fuel heating value (Btu/volume)*

*Note that the EE and HV must be provided on either a HHV or LHV basis, but not a mixed basis.

Manufacturers have tables for their compressor skids which provide the unit's efficiency (EE) based on the model of engine driving the compressor and the inlet and outlet pressures. The inlet pressure is essentially the average well pressure for the year and the outlet pressure is essentially the gathering line operating pressure.

3. **Determine field gas carbon content (quarterly?).**

4. **Calculate CO_2 stationary combustion emissions.**

$$E_{CO2} = \sum_{n=1}^{n} Fuel_n \times CC_n \times MW_n / MVC \times 3.664 \times 0.001$$

Where:

E_{co2} = CO_2 emissions (metric tonnes/yr)

$Fuel_n$ = volume of field gas combusted in quarter n

CC_n = carbon content of field gas in quarter n

MW_n = molecular weight of field gas (from quarterly gas analysis)

MVC = molar volume conversion factor

3.664 = conversion factor (C to CO_2)

0.001 = conversion factor (kg to metric tonnes)

5. **Calculate CH_4 and N_2O stationary combustion emissions**

Use default emission factors.

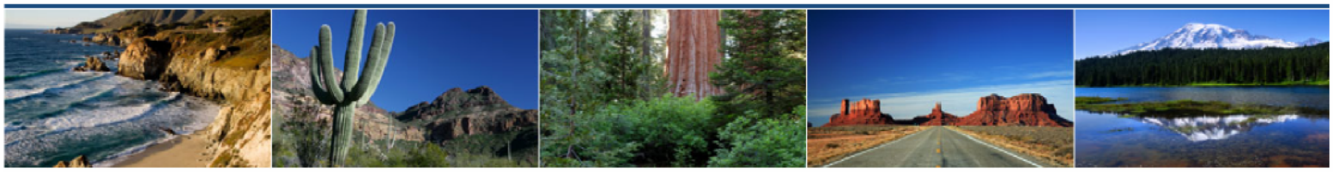
To be determined (Santa Fe Collaborative).

Western Climate Initiative



Issue Paper – Instrument Gas and Vented Methane Emissions

Issue:

Pneumatic control devices employing pressurized natural gas or field gas are commonly used in the natural gas industry. In the production sector these devices perform tasks such as the control and monitoring of gas and liquid flows and levels in dehydrators and separators, temperature in dehydrator regenerators, and pressure in flash tanks. In the processing sector high and low bleed pneumatic devices are used for compressor and glycol dehydration control in gas gathering and booster stations and isolation valves in processing plants. In the transmission sector these devices actuate isolation valves and regulate gas flow and pressure at compressor stations, pipelines, and storage facilities.

Pressurized natural gas or field gas is used as the motive agent and is routinely vented, either continuously or periodically. Many factors influence pneumatic device venting rates and volumes. Important variables are: the gas supply pressure, actuation frequency, and the age, condition and maintenance history of the equipment.

Consequently, these pneumatic devices are a major source of methane emissions from the natural gas industry. In most cases instrument gas is not routinely metered.

WRAP/TCR Approach:

TCR recommends that oil and gas producers who voluntarily report GHG emissions use the method and emissions factors found in the API Compendium .

EPA Approach:

EPA has not published an emissions calculation methodology specific this vented source.

WCI Options:

Option	**Pros**	**Cons**
A. Use Original Equipment Manufactures (OEM) information	Easiest of the methods	Data consistency and reliability questionable
B. API Compendium (2009) – use available emission factors	Simple methodology	Large uncertainty for emission factors

Option	Pros	Cons
C. Measure individual device emissions	Accurate methodology	Labor intensive and expensive Instrument modification and changes in operating conditions may require additional measurements
D. Meter instrument gas	Most accurate method	Requires installation of piping and meters. Does not provide consumption information for individual devices.

Background on available methodologies:
The options are discussed below.

A. Use of OEM data.

In many cases manufacturers' data for equipment bleed rates is available. There are several issues which suggest that significant errors in estimated emissions may result when one uses OEM data. First, there is no industry standard concerning the reporting of instrument bleed rates and thus manufacturers report information in a wide range of units and under varying operating conditions. In addition the data reported by manufacturers has not been independently verified. USEPA has found large discrepancies between OEM bleed rate data and actual field data. As stated above, factors not reflected in available OEM data, such as gas pressure and maintenance history, significantly influence emissions rates. While API (2009) states that the use of manufactures' data is "the most rigorous approach" the Compendium also acknowledges that manufactures emission rates "tend to be lower than emissions observed."

B. API Methods:

API offers several approachs for the calculation of "emissions from a high or continuous bleed device" based on an equation from a Gas Processors Suppliers Association 1987 publication (see API Compendium, Section 5.6 Other Venting Sources, page 5-66). However, this equation is applicable only to high or continuous bleed devices and does not consider factors such as device maintenance history. Emission factors for pneumatic devices have been developed. Many of these EFs were published in the 1997 GRI/EPA Report, Methane Emissions from the Natural Gas Industry. The API Compendium compiles these and other EFs (see Table 5-15, pages 5-68 and 5-69) and estimates uncertainties in some cases. Where specified, reported uncertainties range from ±33% to ±407%. This indicates that use of EFs would result in very unreliable estimates of vented methane emissions. In general, the use of EFs may result in relatively accurate emission estimates on a large scale (e.g. for an annual national inventory) but at the facility level EFs which are not site or equipment specific can introduce significant error.

C. Use of site specific measurements.

Actual site specific measurement of vented emissions from low and high bleed pneumatic control devices is accepted to be the most accurate method to quantify methane (and CO_2 if present in the gas) emissions. There are two approaches one may take when conducting site specific measurements.

One may characterize emissions from each pneumatic device at a facility using a bagging technique (or other method) where emissions from the device are captured and the volume of released gas is measured. Gas analysis then allows one to calculate actual CH_4 and CO_2 emissions. This technique is time consuming, labor intensive and expensive. In addition emissions may subsequently change as the result of factors such as maintenance activities and gas pressure changes.

D. Meter Instrument Gas Consumption:

Actual metering of instrument gas consumption and periodic measurement of gas composition will provide a much more accurate determination of GHG emissions. Changes in instrument gas plumbing and installation of one or more gas meters may be required initially and this will result in upfront material and labor costs. However, reporting in subsequent years will be very simple and easy, especially given the fact that periodic gas analysis will be required for other GHG emission calculations (e.g. stationary combustion emissions). In addition, changes in system operating conditions (e.g. line pressure, maintenance activities, instrument modifications) designed to reduce emissions would be reflected in the volume of instrument gas consumed and thus would be easily quantified. Facility operators receive immediate feedback on their efforts to reduce emissions and can also monitor instrument gas consumption in real time.

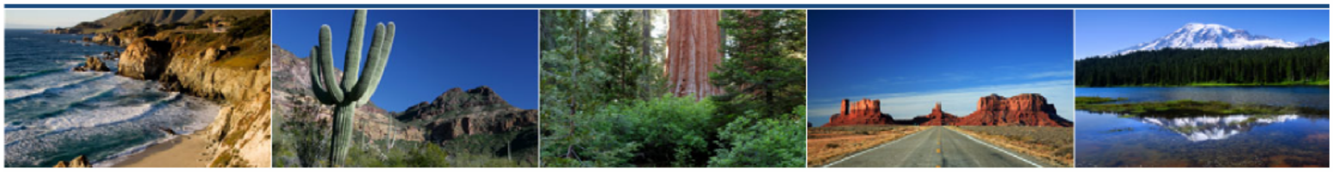
To be determined (Santa Fe Collaborative).

Western Climate Initiative



Issue Paper -- Storage Tanks

Issue:

Storage tanks provide temporary storage of liquids prior to the point when produced liquids are moved off site in a pipeline or mobile tanker for processing. Emissions of methane (and CO_2 if present in significant quantities in produced liquids) occur through several mechanisms.

Flashing losses occur when the produced liquid experiences a change in pressure. For instance as produced oil is pumped from the well it experiences a pressure drop as it exits the pipe and enters the tank. Dissolved gases such as methane and carbon dioxide may flash off as the pressure is reduced.

Working losses occur as a result of the filling and emptying of the storage tank. Tank headspace gases containing methane and carbon dioxide are emitted from the tank as the tank fills. As the tank is emptied the reverse process occurs, outside air is drawn into the tank. The liquid in the tank then re-equilibrates with this introduced air. Finally, breathing losses of headspace air containing methane and carbon dioxide occur as the tank gas volume expands and contracts in response to environmental conditions such as ambient temperature, solar insulation, and atmospheric pressure.

Flashing, breathing and working losses must all be characterized to insure an accurate estimation of storage tank GHG emissions.

Storage tank emissions occur when produced liquids are sent to atmospheric storage at the following locations:

1. wellhead sites
2. tank batteries
3. compressor stations
4. gas plants
5. where liquids in a gas line are "pigged"

WRAP/TCR Approach:

WRAP has not specifically addressed the issue of accurately determining GHG (CH_4 and CO_2) emissions from storage tanks in the up-stream oil and gas sector. A method using the EPA TANKS Model was included in the Essential Requirements for the Refinery sector.

EPA Approach:

EPA has not officially published an emissions calculation methodology specific for this source. A method was published in Subpart W of the Draft Reporting Rule (see §98.233(d)(8) – page 1167). Subpart W was subsequently withdrawn prior to release of the EPA Final Rule.

Briefly, the EPA Subpart W method requires that reporters:

a) Measure the volume of vapor escaping each storage tank over a representative period of operation,

b) Determine the vapor composition by chemical analysis,

c) Calculate fugitive emissions using this data.

The details of this method are shown below:

1. Calculate the total annual hydrocarbon vapor fugitive emissions using Equation W-7

$$E_{a,h} = Q \times ER \qquad \text{(Eq. W-7)}$$

   Where:

   $E_{a,h}$ = hydrocarbon vapor fugitive emissions at actual conditions

   Q = storage tank total annual throughput

   ER = measured hydrocarbon vapor emissions rate per throughput (e.g. cubic feet/barrel) determined from §98.234(j)(2) (page 1181).

   ER is measured using a flow meter described in paragraph (h) for a test period that is representative of the normal operating conditions of the storage tank throughout the year and which includes a complete cycle of accumulation of hydrocarbon liquids and pumping out of hydrocarbon liquids from the storage tank.

2. Estimate hydrocarbon vapor volumetric fugitive emissions at standard conditions using calculations in paragraph (e).

3. Estimate CH_4 and CO_2 volumetric fugitive emissions from volumetric hydrocarbon emissions using Equation W-8 (page 1168).

$$E_{s,i} = E_{s,h} \times M_i \qquad \text{(Eq.W-8)}$$

   Where:

   $E_{s,i}$ = GHG i (CH_4 and CO_2) volumetric fugitive emissions at STP

   $E_{s,h}$ = hydrocarbon vapor volumetric fugitive emissions at standard conditions

   M_i = mole percent of GHG i in the hydrocarbon vapors; the hydrocarbon analysis shall be conducted using ASTM D1945-03

4. Estimate CH_4 and CO_2 mass fugitive emissions from GHG volumetric emissions using the calculations in paragraph (g)

$$Mass_{s,i} = E_{s,i} \times \rho_i \qquad \text{(Eq. W-11)}$$

   Where:

   $Mass_{s,i}$ = GHG i (CH_4 or CO_2) mass fugitive emissions at STP

   $E_{s,i}$ = GHG i volumetric fugitive emissions at STP

P_i = density of GHG i; 1.87 kg/m^3 for CO_2 and 0.68 kg/m^3 for CH_4

Background on Available Methodologies:

A recent study commissioned by the Texas Commission on Environmental Quality (TCEQ) provides an in-depth analysis of available methods for the determination of storage tank emissions. The following modeling methods were compared with actual measurements of storage tank emissions which were conducted in a manner very similar to the EPA Subpart W method detailed above.

1. TANKS 4.09 (EPA model)
2. Vasquez-Beggs + TANKS 4.09
3. GOR + TANKS 4.09
4. Valko-McGagn + TANKS 4.09
5. Hysis VOCs
6. E&P Tank – RVP VOCs
7. E&P Tank – GEO/RVP VOCs
8. AP-42 LPO VOCS
9. GRI-HAPCalc VOCs

The final report concluded that "each model reviewed has limitations and shortcomings. No one model resulted in the extremely strong correlation to measured data." Measurements were made at thirty six production sites. The models also required measurement of input variables such as GOR (gas oil ratio). This is a difficult measurement given that the recovered liquid/gas mixture from a well must be collected and maintained at pressure prior to analysis. The report states that the TCEQ considers direct measurement the most accurate method to quantify storage tank fugitive emissions. A copy of this report, Upstream Oil and Gas Storage Tank Project Flash Emissions Models Evaluation Final Report, July 16, 2009 is available on the WCI RC Sharepoint website.

The API Compendium (2009) also contains a discussion of several of the models available (see Section 5.4 Storage Tank Emissions, page 5-40). API states that direct measurement provides accurate emissions estimates but "*this approach is generally expensive and time consuming for large numbers of tanks."*

WCI Options:

WCI is considering using the method contained in Subpart W – Oil and Natural Gas Systems of the EPA Draft Mandatory Reporting of Greenhouse Gases. It is recognized that direct measurement of the volume and composition of fugitive emissions emitted from storage tanks is the most accurate quantification method. Volumetric emissions at a storage tank can be completed in as little as 24 hours. In addition, the determination of the CH_4 and CO_2 concentration in storage tank fugitive emissions is straightforward and relatively inexpensive.

Other modeling approaches require input data (such as GOR, API, separator pressure, stock tank gas molecular weight and specific gravity, oil gravity, etc.) which may require extensive gas and oil analysis. These models do not provide the level of accuracy that direct measurement does.

Issue Papers

Santa Fe, New Mexico

November 19, 2009

Issue Papers

- Stationary Combustion of Field Gas
  - CO_2, CH_4, N_2O
- Venting – Pneumatic Pumps and Control Devices
  - CH_4, CO_2
- Venting – Storage Tanks
  - CH_4, CO_2

Stationary Combustion –Field Gas

- Combustion of field gas represents a significant GHG source (CO_2, CH_4, and N_2O)
- Field gas consumption quantification requirements vary across the WCI jurisdictions
- Accurate quantification of emissions requires accurate and consistent methodology

Quantification Options

Option A	Pros	Cons
1. Determine fuel consumption w/ meters where available or engineering calculation 2. Measure field gas composition 3. Calculate emissions	Simplest approach requiring no installation of meters.	Data quality and consistency will vary within a reporting entity and across WCI jurisdictions Potential for US and Canadian data inconsistencies Installation of engine runtime meters may be required

Quantification Options – con't

Option B	Pros	Cons
1. Meter a significant fraction of field gas consumption 2. Estimate remaining field gas consumption –engineering approach 3. Determine field gas composition 4. Calculate emissions	More accurate method, w/ consistent data Use of meter and engineering calculation on a subset would allow evaluation of engineering approach	Requires installation of meters on larger engines Potential difficulties determining which engines require metering

Option B - details

- Metered data
  - Tabulate annual horse power-hours for each engine
  - Sort list
  - Meter cumulative percentage of largest units
- Engineering estimation of fuel consumption
  - API method
    - Engine hp, load factor, operating time, thermal eff, HHV
  - Method based on gas produced and operation pressures
    - Engine efficiency, volume produced gas, HHV

Questions for the TWG

- Which engineering approach is more accurate?
- Are US and Canadian lease fuel consumption data consistent?
- Are there difficulties determining which engines require metering?
- Is data available which is useful in determining how many meters are required?
- Do you use another approach for quantification of lease fuel consumption?

Venting – Pneumatic Control Devices

- Pneumatic pumps and control devices are important sources of venting (CH_4 and CO_2) in the NG production, processing and transportation sectors
- Instrument gas is not routinely metered and quality of available EFs varies widely

Quantification Options

Option	Pros	Cons
A. Use OEM info	Easiest of methods	Data consistency and reliability are questionable
B. Use available EFs	Simple methodology	Large uncertainty for EFs
C. Measure individual device emissions	Accurate methodology	Labor intensive, expensive. Device modification requires additional measurements
D. Meter instrument gas consumption	Most accurate method	Requires installation of piping and meters. Does not provide info for individual devices.

Questions for the TWG

- Is OEM data available for all pumps and devices?
- Are there additional methods that should be considered?
- Should we consider requiring metering of instrument gas only about a threshold?
- How would we define a threshold for metering?

Venting - Storage Tanks

- Uncontrolled release of CH_4 (and CO_2) from storage tanks – flashing, working and breathing losses
- Many quantification models are available – none appears to be ideal

Quantification Options

Option	Pros	Cons
A. Direct measurement of storage tank emissions – determine volume and composition of gas emitted	Accurate method if measurements are taken under normal operating conditions	Expensive and time consuming for large number of tanks. Require only for tank batteries above production threshold (bbl/d)?
B. Use one of nine models	Easier approach	Models require measurement of variables (e.g. GOR, pressure, temperature). Each model has limitations.

Questions for the TWG

- What is your experience with available models?
- Should measurement be required for a tank battery only above a production threshold?
- If both measurement and modeling approaches are used, which model is most appropriate?

California

Low Carbon Fuel Standard

(LCFS)

November 18th, 2009
Santa Fe, New Mexico

California Environmental Protection Agency
AIR RESOURCES BOARD

Background

- Transportation sector represents approximately 40% of GHG emissions in California

- A number of legislative and policy directives support the development of a LCFS
  - AB 32 – reduce GHG emissions to 1990 levels by 2020
  - EO S-06-06 – increase production and use of bioenergy
  - EO S-01-7 –develop a LCFS to reduce carbon intensity of transportation fuels

California Transportation Related Initiatives

- Low Carbon Fuel Standard
- Tailpipe CO_2 emissions standards – Pavley standards for new passenger vehicles
- Tire Pressure Strategy
- Reduction in refrigerant loss
- Cool Car Standards

LCFS Goals

- Reduce the carbon intensity of transportation fuels 10% by the year 2020 (same as EU). Equivalent to about 10% of total reduction need to reduce to 1990 levels by 2020
- Establish a durable carbon regulatory template that can be exported to other jurisdictions (no fuel-shifting)
- Complement Federal renewable fuel standards (RFS and RFS2)
- Spur the introduction of lower carbon fuels
- Create a market for clean transportation technology

LCFS – approach and structure

- Two performance standards established
  - Gasoline and alternatives
  - Diesel and alternatives
- Standards based on the premise that each fuel has a "lifecycle" GHG emission value (g CO_{2e}/MJ)
- Fuel suppliers and importers meet standards starting in 2011 to reach 10% goal by 2020
- Standards "back-loaded" – more reductions required in the last 5 years than in first 5 years
- LCFS requirements met with combination of strategies – lower carbon fuels and advanced technology vehicles

Developing Fuel Carbon Intensity Standards

- Fuel based “lifecycle” GHG emission values
  - Updated California-GREET Model Version 1.8b
- Land Use Change Assessment
  - GTAP Model version 6 – Perdue University

LCFS Compliance Schedule

Year	CI – gasoline ($g\ CO_{2e}/MJ$)	CI- diesel ($g\ CO_{2e}/MJ$)	% reduction
2010	Reporting Only		
2011	95.61	94.47	0.25
2012	95.37	94.24	0.5
2013	94.89	93.76	1.0
2014	94.41	93.29	1.5
2015	93.45	92.34	2.5
2016	92.50	91.40	3.5
2017	91.06	89.97	5.0
2018	89.62	88.55	6.5
2019	88.18	87.13	8.0
2020	86.27	85.24	10.0

LCFS – 2009 and Beyond

- 2010 -Reporting only
- 2011 -First compliance year
- 2010- Expert Workgroup will evaluate the Land Use Change component of LCFS
- 2011 –Sustainability of LCFS examined

Program Reviews

Two Programs Reviews are mandated in the LCFS Regulation

In 2011 and 2014 the LCFS Program will be reviewed: new pathways considered, adjustments made to existing pathways, examine economics

North America Gas and GHG Management

- North America Gas
  - Full inventory of GHG's since 1999
  - Reduced our emissions ~41% from a year 2000 baseline (corrected for A&D and Protocol Changes)
    - Focused on reducing methane emissions and flaring
    - Less Emissions = More Production/Sales
      - >48 BCF Reduction; > 17MM Metric Tonnes Gross CO_2e's
  - Active Partners in EPA's Natural Gas Star Program Since Inception
- Major Contributors to Reductions
  - Well Venting Reduction via Advanced Automation Control
  - Pneumatic Controller Replacement
  - Green Completions
  - A Host of Smaller Projects and Efforts

GHG Efficiency = Cost Reduction/ Product Sales

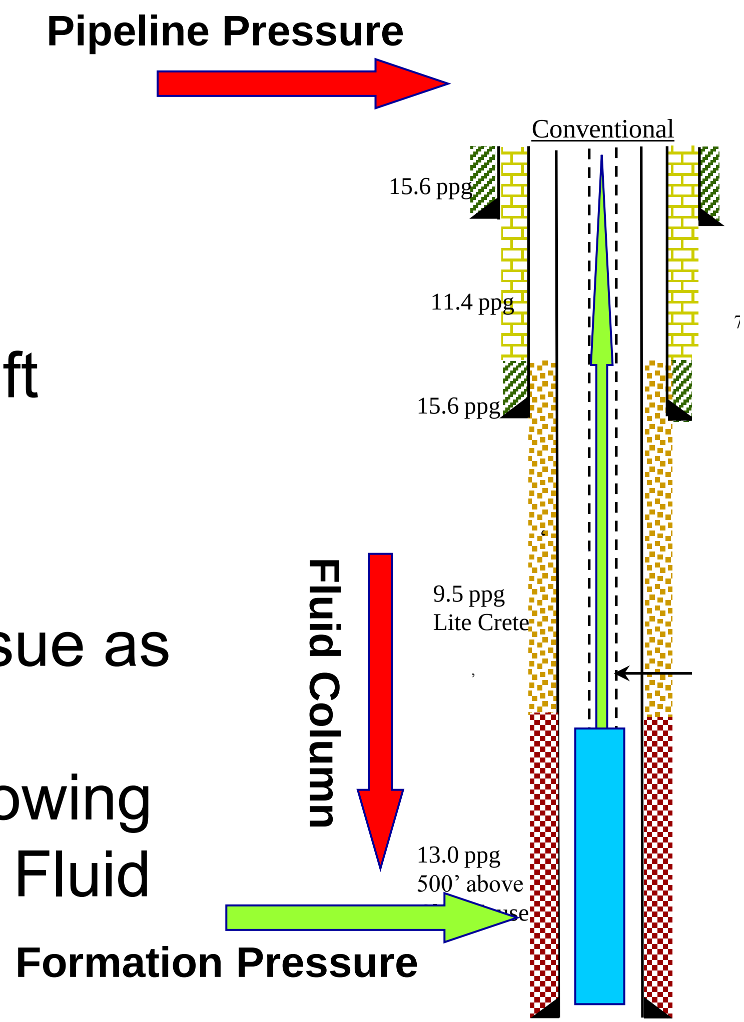
Well Venting – What and Why

Well Flow:

- Depends on Delta P
- Flow Rate is a f of Delta P
- Rate Determines Velocity
- Velocity Determines Fluid Lift

Formations:

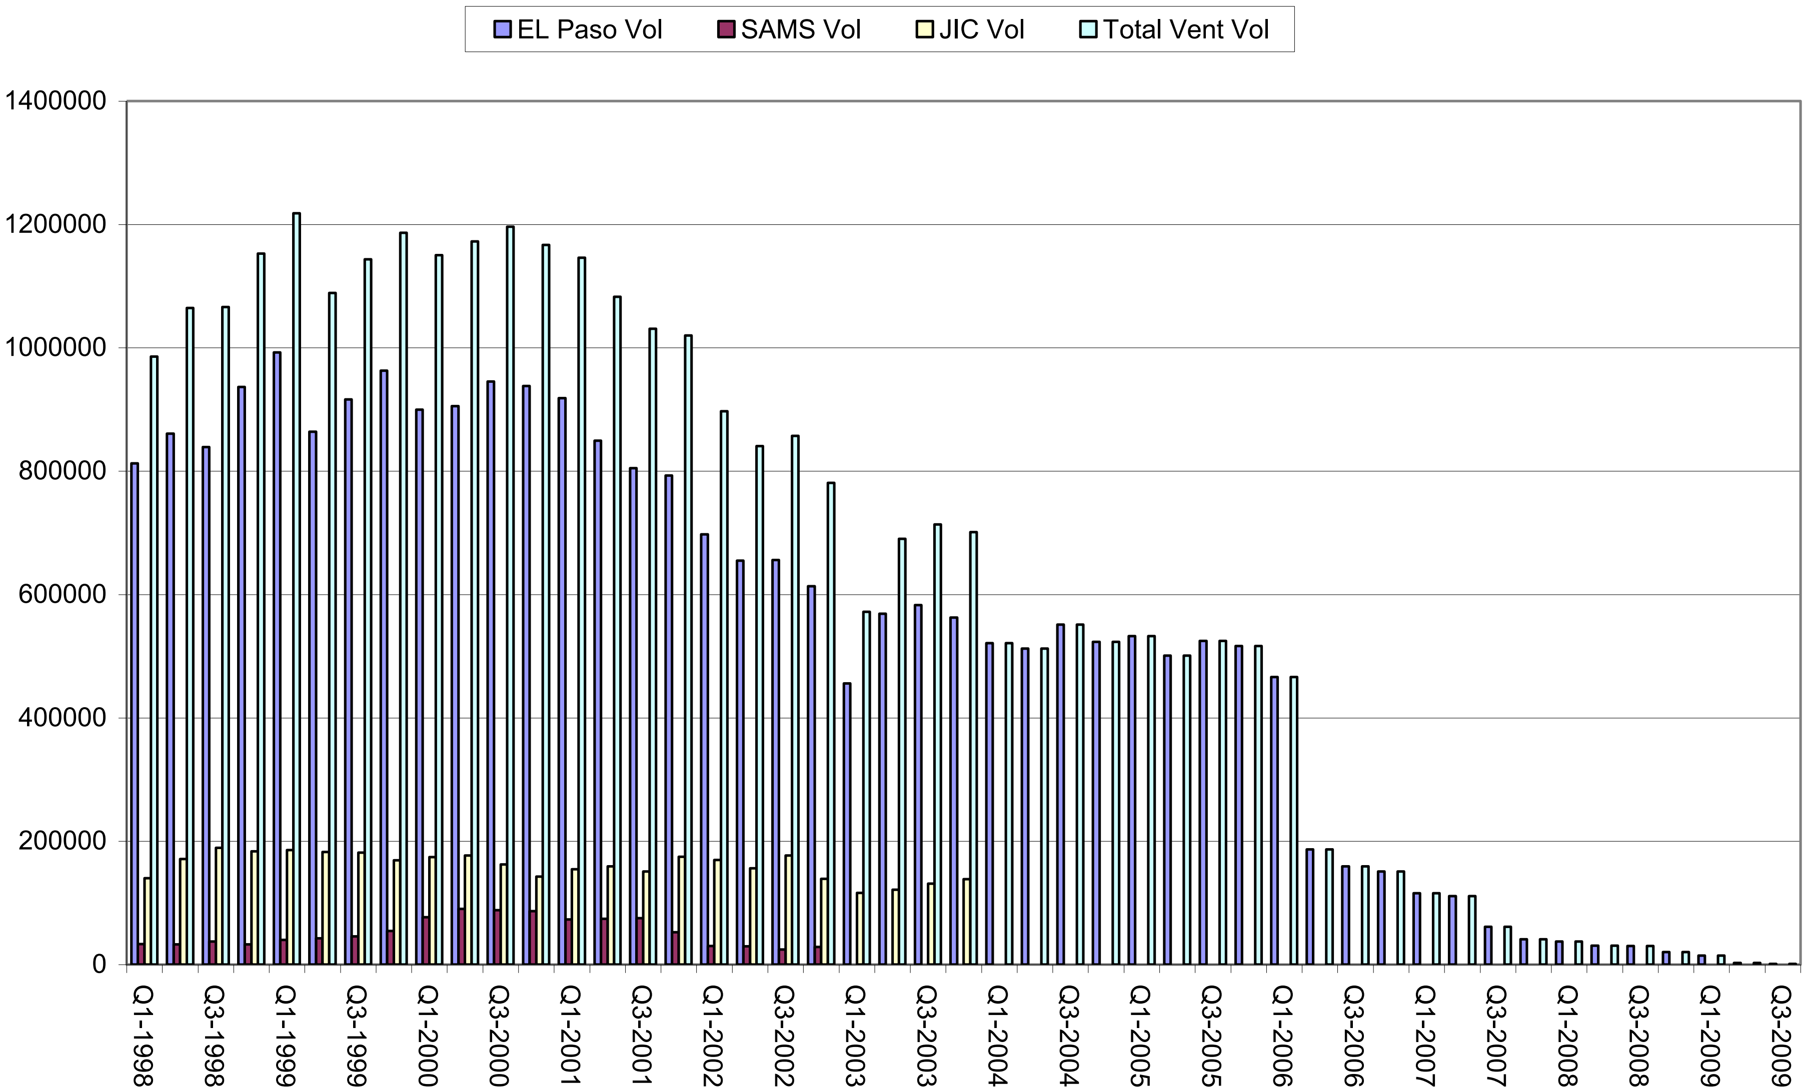
- Deplete over Time
- Liquid Loading Becomes Issue as Depletion Occurs
- Build P While Well is Not Flowing
- Shut-in Time is Important to Fluid Unloading



Low Energy Reservoir Vent Control

- "Smart" Automation"
- Both Plunger Equipped and No Plunger
- On-site PLC Based
- Custom Control Code – Based on "Turner" Lift
- RTU Transmission to Host
- ~2300 Wells Under Control – Beginning in 2001
- Venting Reduced >98% – Positive Production Response

“Smart” Automation Results

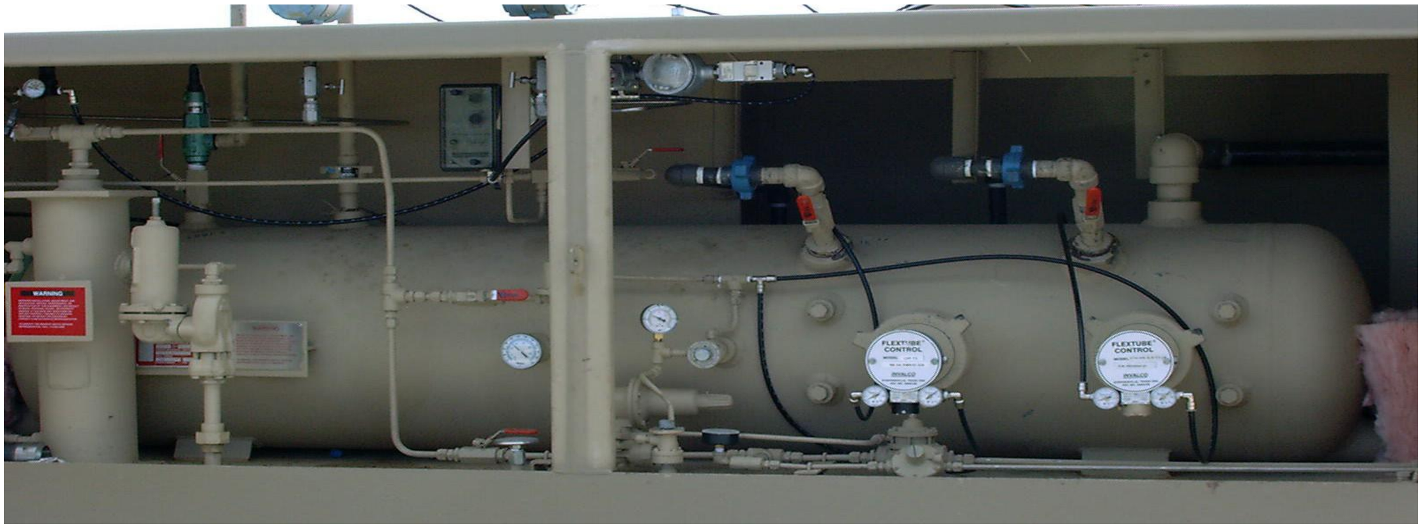


Summary

- Great success >4 bcf/yr to <0.01 bcf/yr
- Technology is only a piece of the solution - most significant recent reductions are due to revised operational beliefs and practices.
- Requires constant focus – Teams deliver on current goals.
- Operational beliefs have shifted from “we must vent to produce” to **“Venting is one of our last options.”**

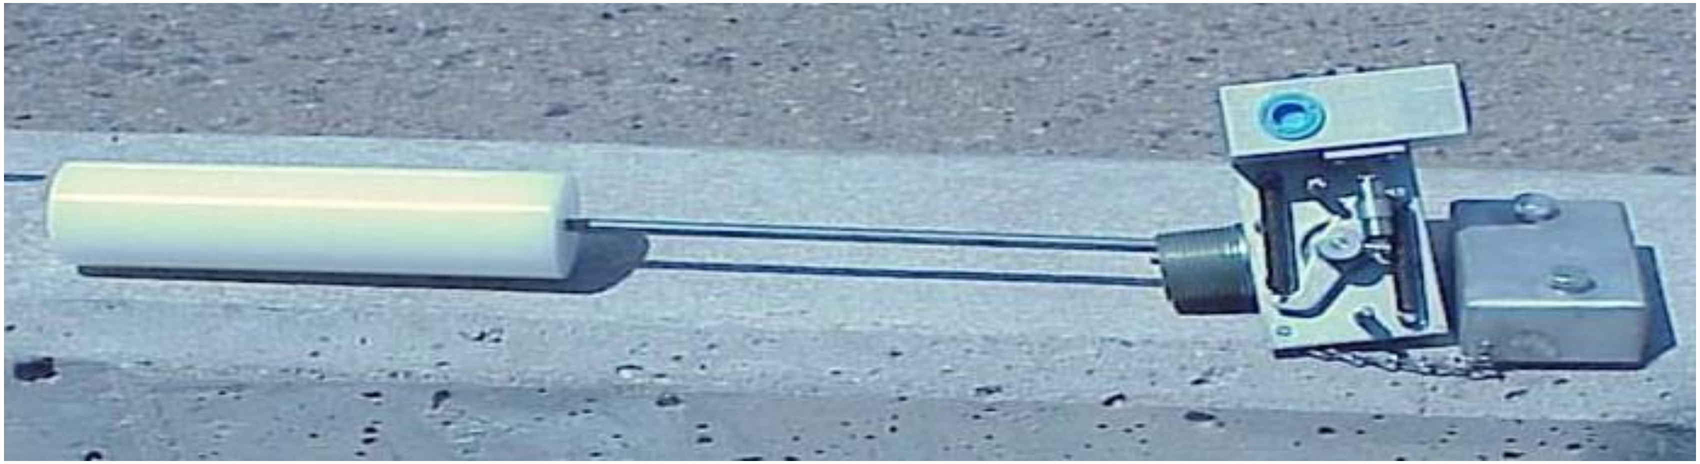
Pneumatic Controller Replacement

- Replacement of “High Bleed” Pneumatic Instruments With “Low or No Bleed” Instruments
- ~11,500 Level Controllers Replaced in 6 States
- Began in 1999 and Complete in 2002



Pneumatic Controller Results

- ~3.4 BCF of Gas/Yr Sold
- Capital Investment ~$4,071,000
- ~ 60,700 Metric Tonnes of Methane Not Emitted Annually
- Reduction of ~ 1,275,000 Metric Tonnes of CO_2 E's Annually
- Does not include effect of low bleed on new wells/facilities (BAU)



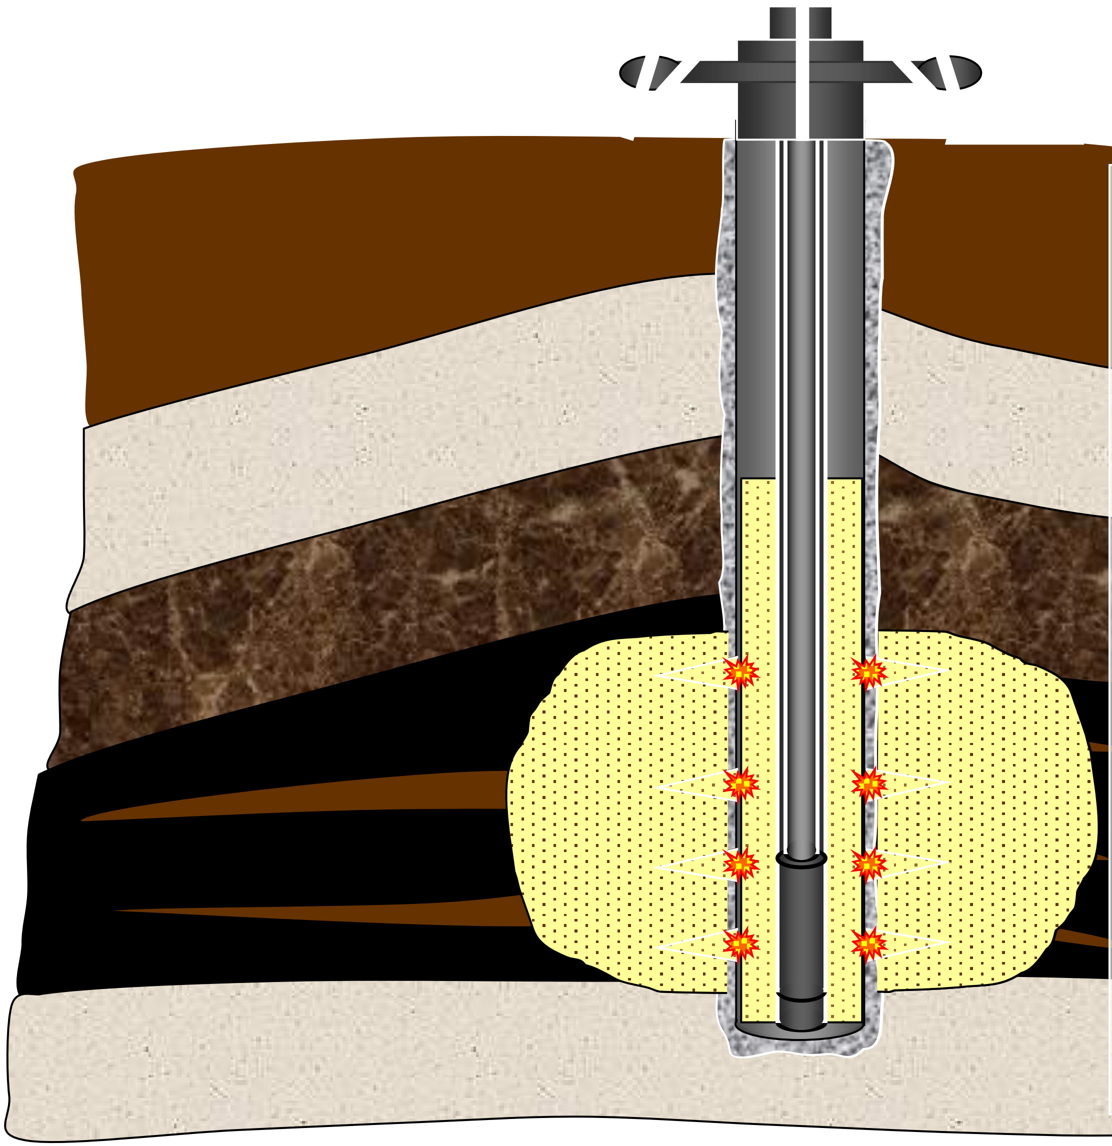
Green Completions

- What are well completions and why do emissions result
- What is different about “Green Completions”
- Enabling Criteria
  - Must have a sales pipeline
  - Must have “salable” gas
  - Must be able to adequately clean-up well and avoid reservoir damage
- Cases
  - “High Energy” Reservoirs – Wyoming Example
  - “Low Energy” Underbalanced
  - “Low Energy” Overbalanced

The Basics of Post-frac Cleanout and "Green" Completions

bp

◆ Drilling and Completing a Typical CBM Well

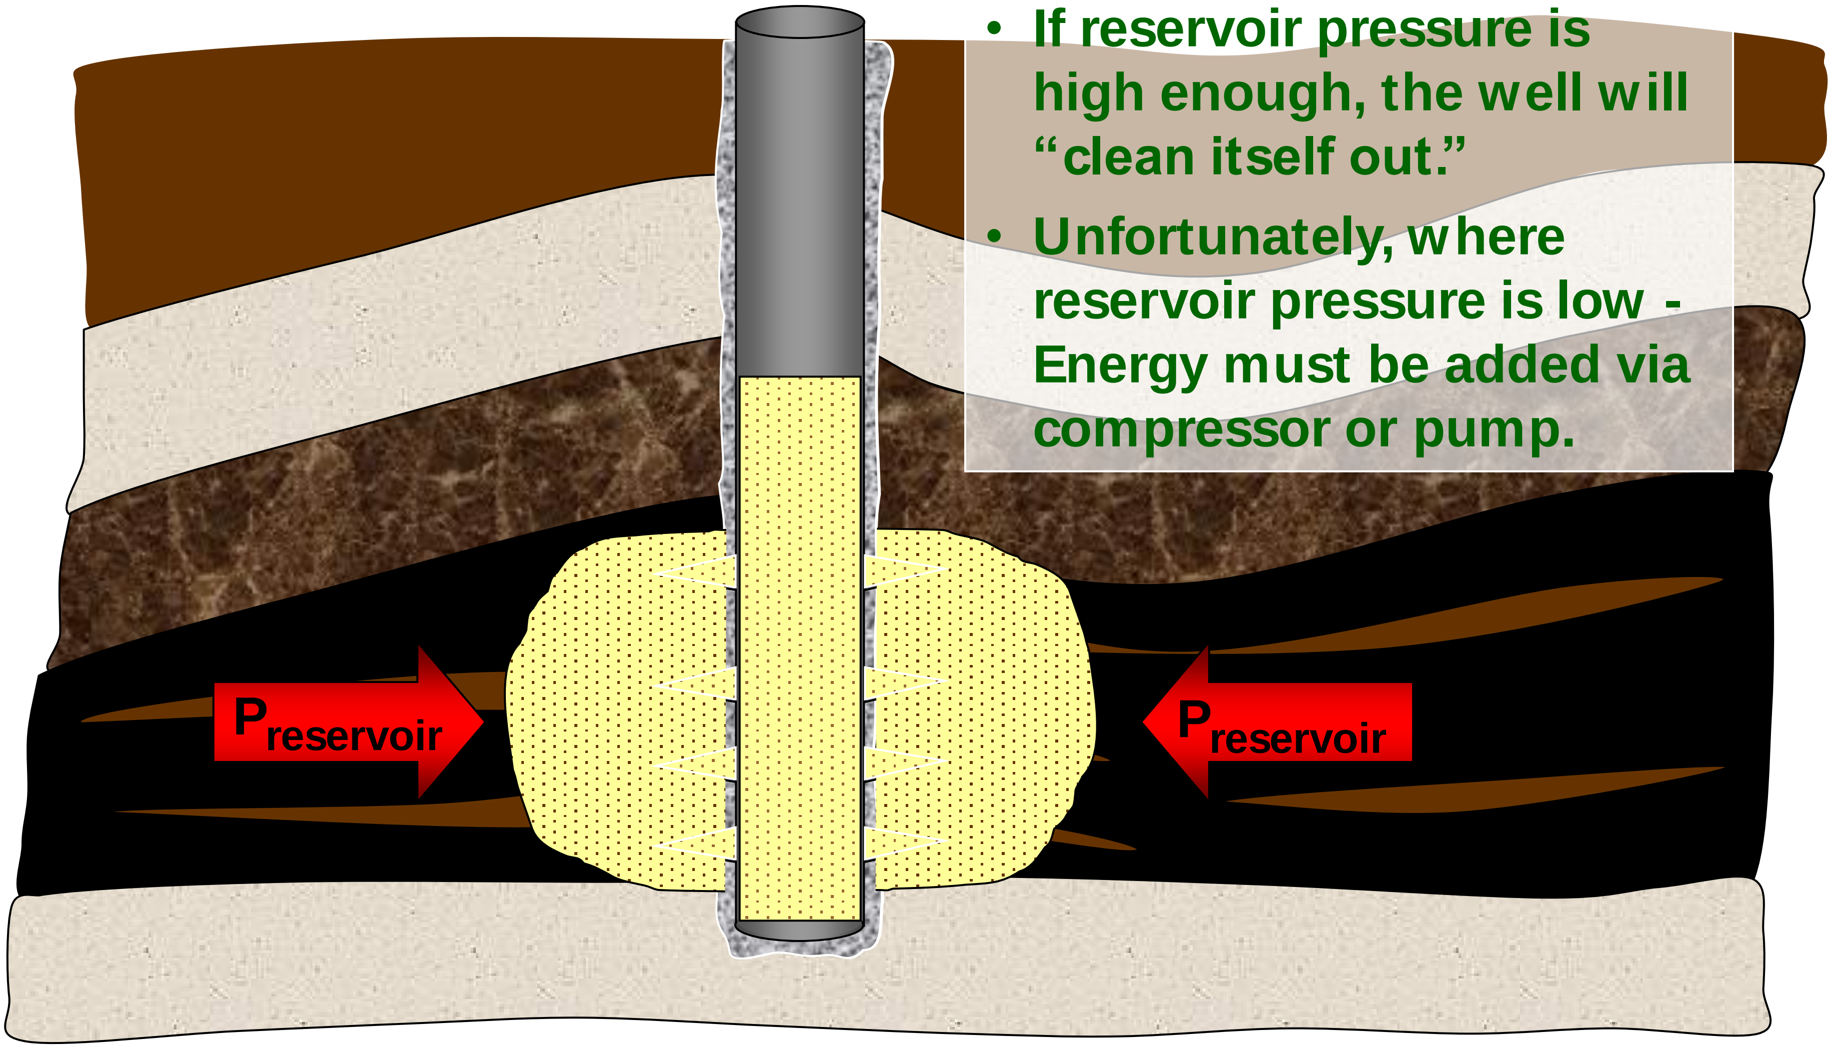


- Move in, rig up drilling rig
- Drill well
- Run casing
- Cement casing
- Perforate casing
- Frac coal
- Cleanout wellbore
- Run pump and tubing
- Rig down, move off drilling rig
- Install wellhead
- Install pump jack

The Basics of Post-frac Cleanouts and "Green" Completions

◆ The Role of Reservoir Pressure in Post-frac Cleanouts

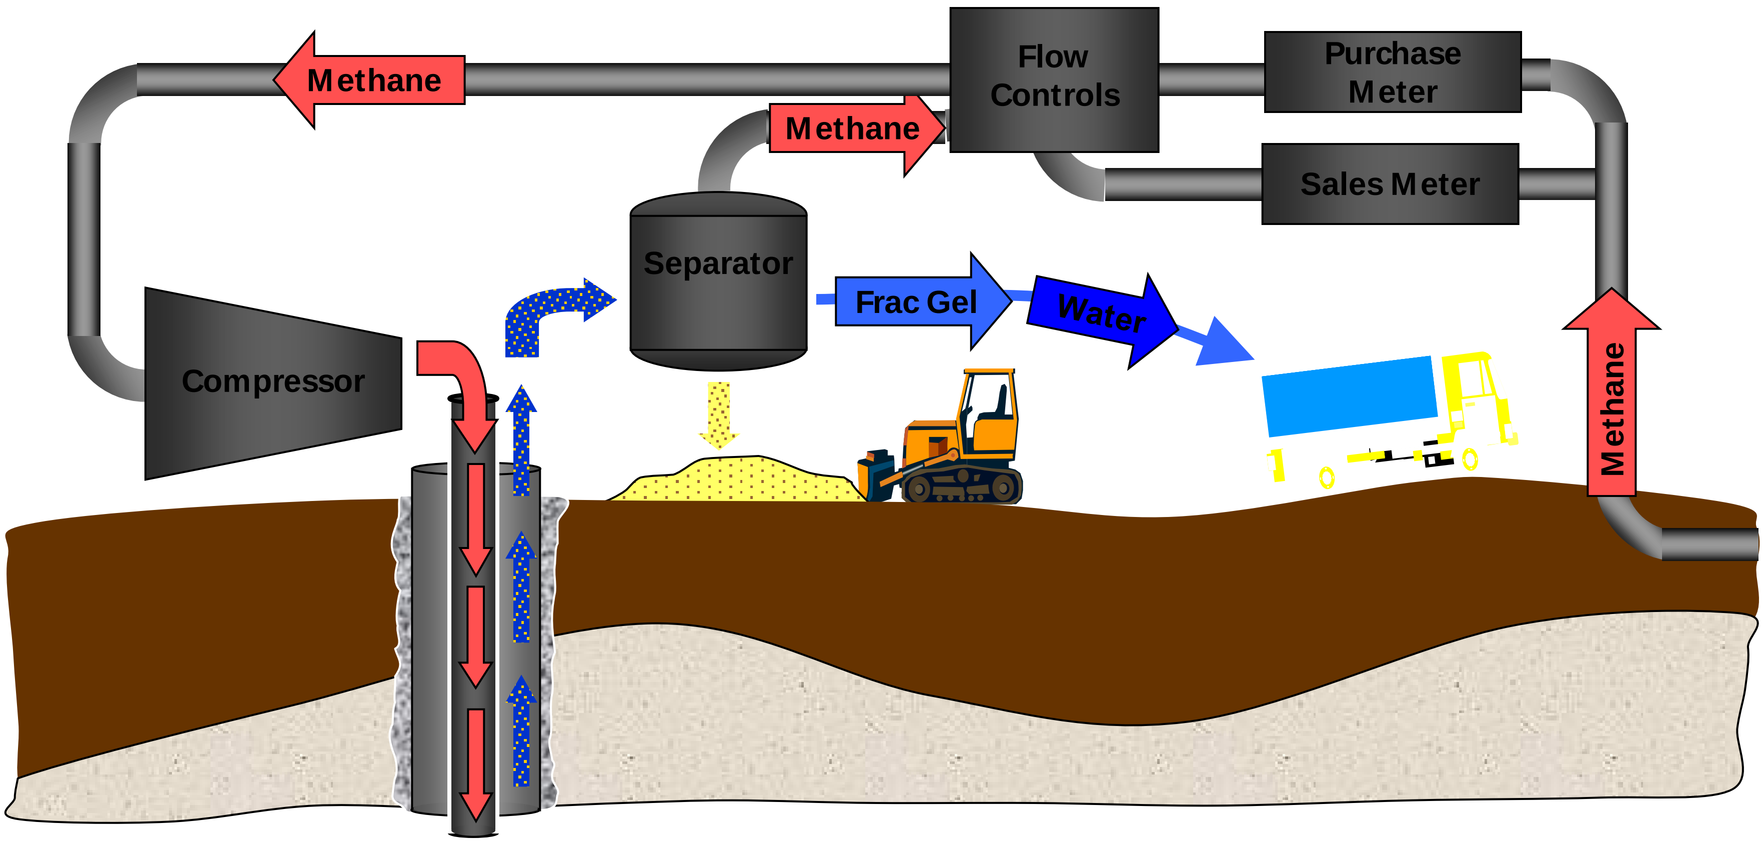
- If reservoir pressure is high enough, the well will "clean itself out."
- Unfortunately, where reservoir pressure is low - Energy must be added via compressor or pump.



◆ "Green" Cleanouts

Q: So, what do you need to make this work?

A: An operational gas pipeline and a great deal of specialized equipment.



Wyoming Green Completions Results

- Piloted in 2000; Operational 2001 Forward
- Higher Energy Reservoirs Without the Need for Supplemental Energy Input
- Cumulative Recovery Since 2001
  – More than 8.7 Billion Cubic Feet of Natural Gas
  – More than 500,000 metric tonnes of CO2 Equivalent Reduction
- Has Spread Widely Through Industry

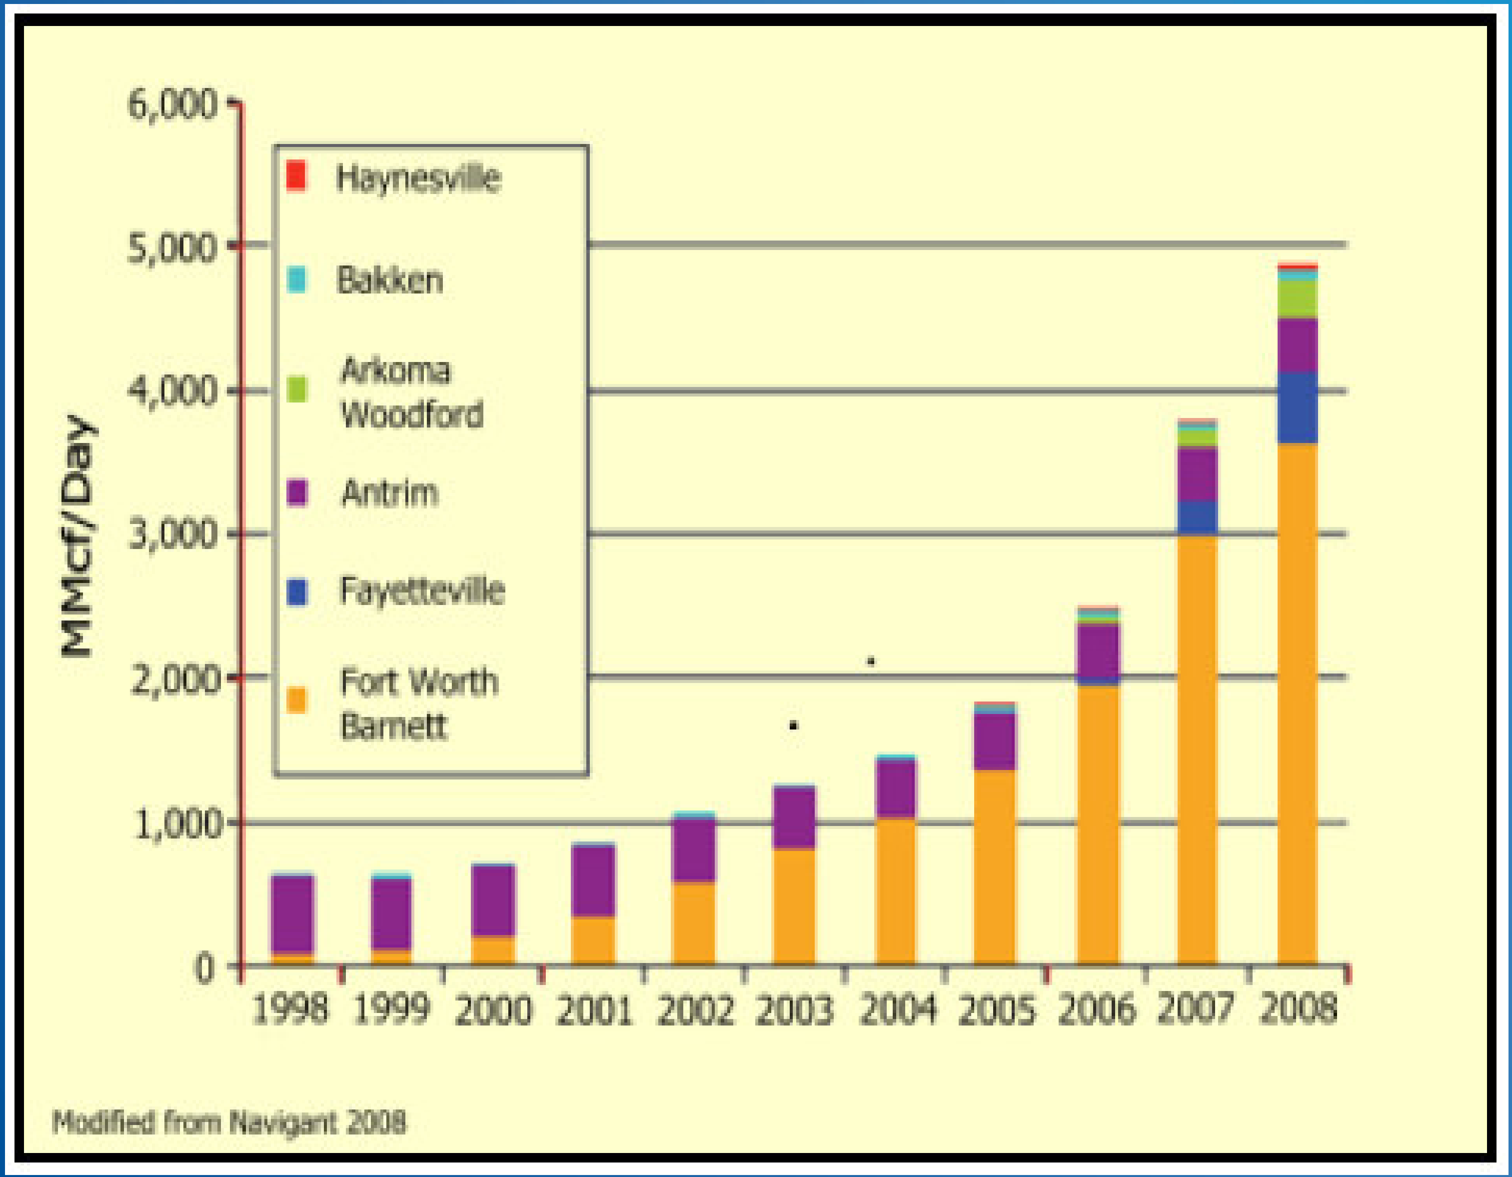
Most Active Shale Plays



Source: DOE, “Shale Gas Primer”

Importance of WRAP and WCI work

- Leveling the playing field
  - Requiring E&P to meet minimum monitoring and reporting standards (should bring all producers up to the same minimum level of emissions estimation competency)

- Capturing potentially undercounted emissions
  - NYT article, Shale Gas example, WRAP Task 1 inventory (showing uncertainty in current emissions estimates)

- Informing the national conversation
  - Assisting the development of a national O&G reporting standard by US EPA

Relevance of Shale Gas Example to WCI O&G Protocol Development

- Supports findings of WRAP Task 1 & 2 reports
  - Although there exists differences between fields and production types, there are significant similarities between the types of equipment used, emissions sources and extraction processes
- Supports the speed of WCI protocol development and need for comprehensive emissions coverage
  - Based on need to capture increasingly emissive and innovative extraction processes

Relevance of Shale Gas Example to WCI O&G Protocol Development

- Significance for protocol development at WCI
  - An expansive protocol that accurately covers as many sources as possible at Oil and Gas E&P sites in the WCI region and uses field level data (metered - rather than default values) will be adaptable to multiple production types and useful outside the WCI region

Relevance of Shale Gas Example to WCI O&G Protocol Development

- Highlights future needs
  - Increased use of fracturing linked to emissions of traditional pollutants and GHGs.
  - Some aspects of E&P may have greater emissions than otherwise expected
  - Comprehensive monitoring and reporting protocol needed at the regional and national level

Barnett Shale Area Wells

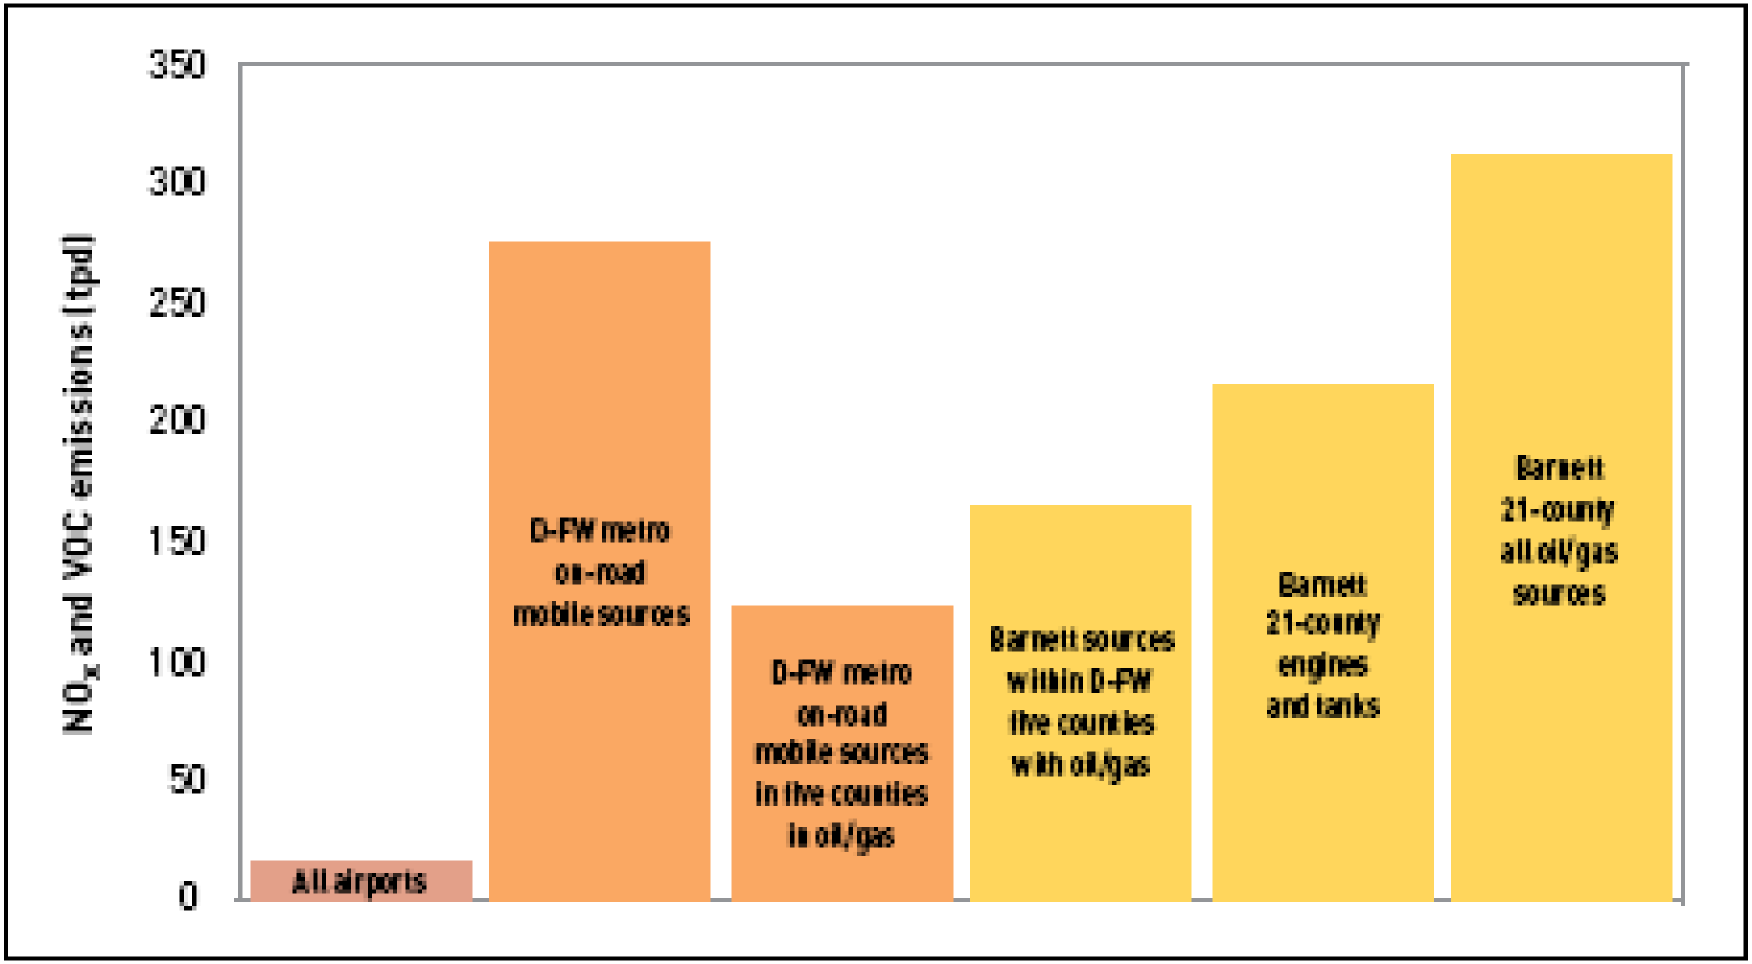
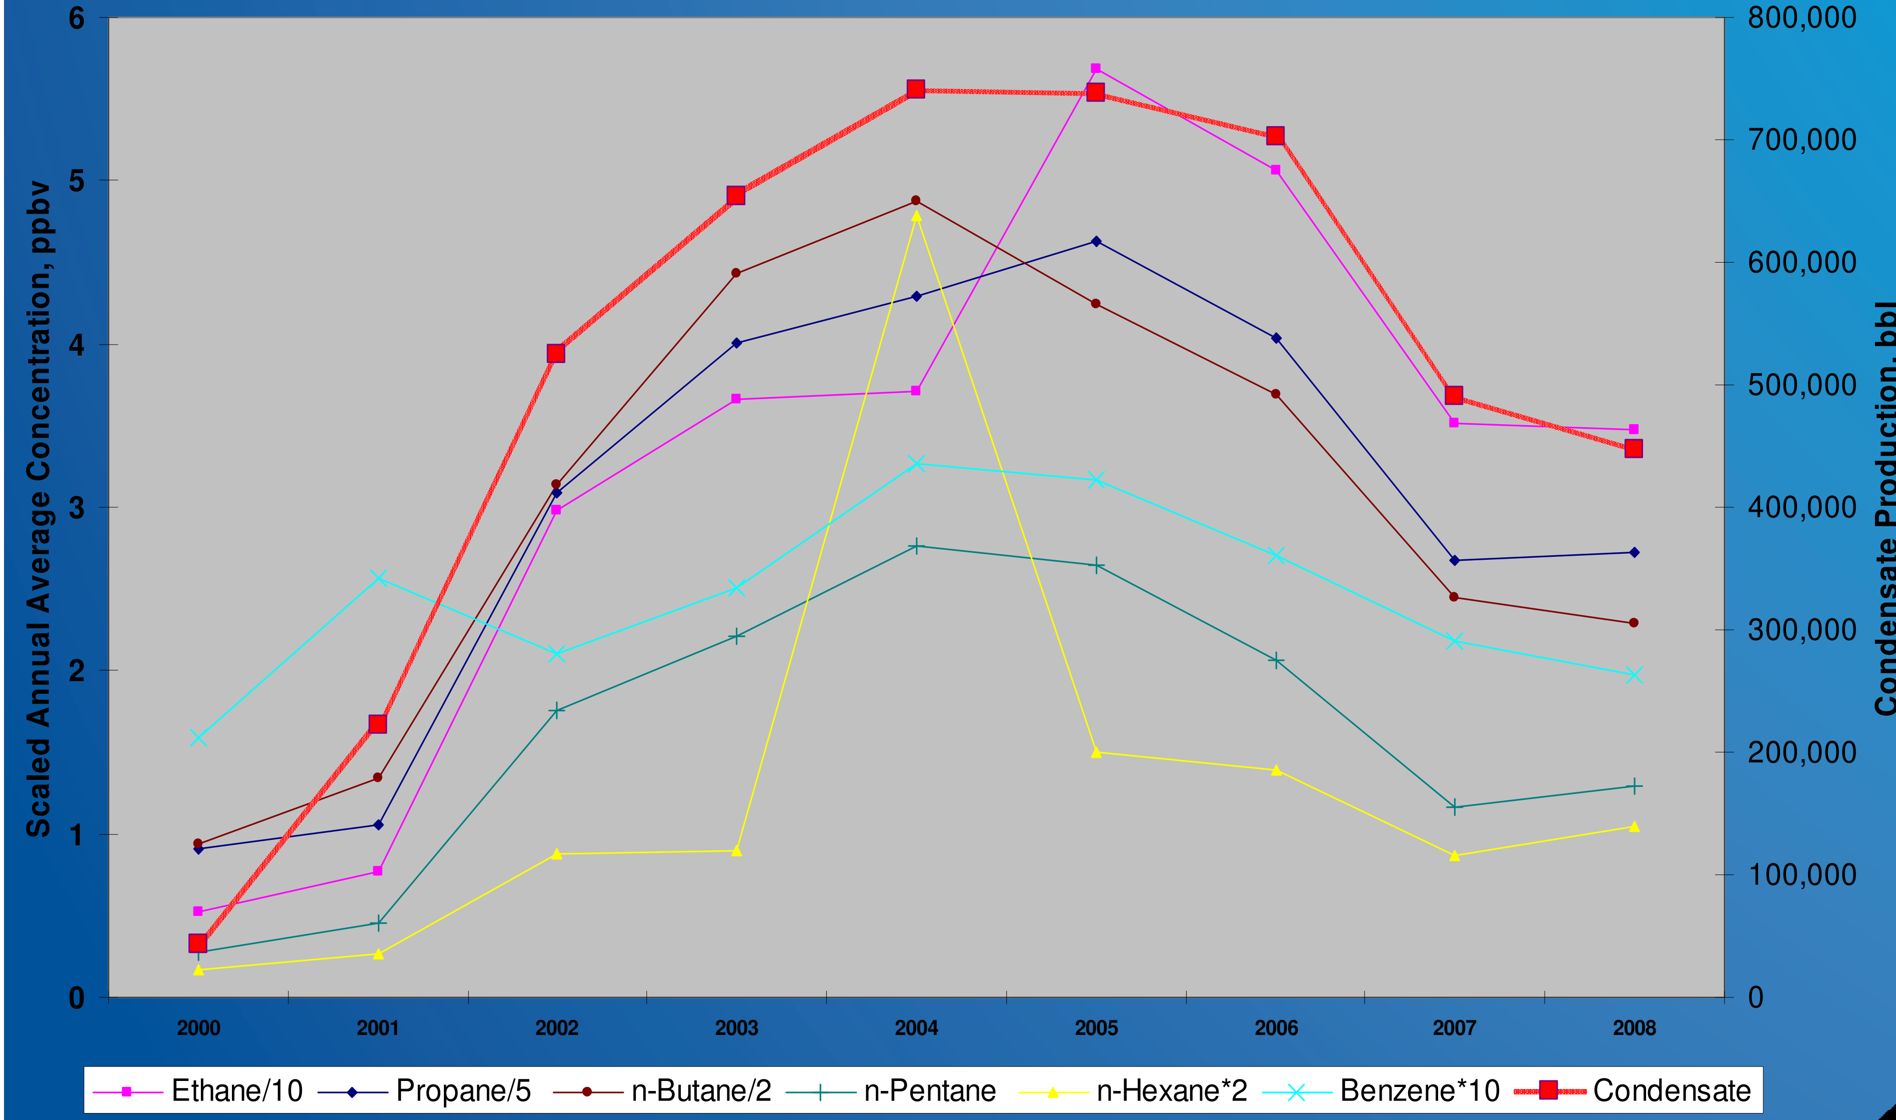
NO_X and VOC 2009 summer emissions



Emissions of NO_X and VOC in the summer of 2009 from all oil and gas sources in the Barnett Shale 20-county area will exceed emissions from on-road mobile sources in the D-FW metropolitan area by more than 30 tpd (307 vs. 273 tpd). Source: Al Armendariz, Ph.D., Emissions from Natural Gas Production in the Barnett Shale Area and Opportunities for Cost-Effective Improvements, 6, (January 26, 2009).

Denton VOC vs. Condensate Production



Haynesville Shale

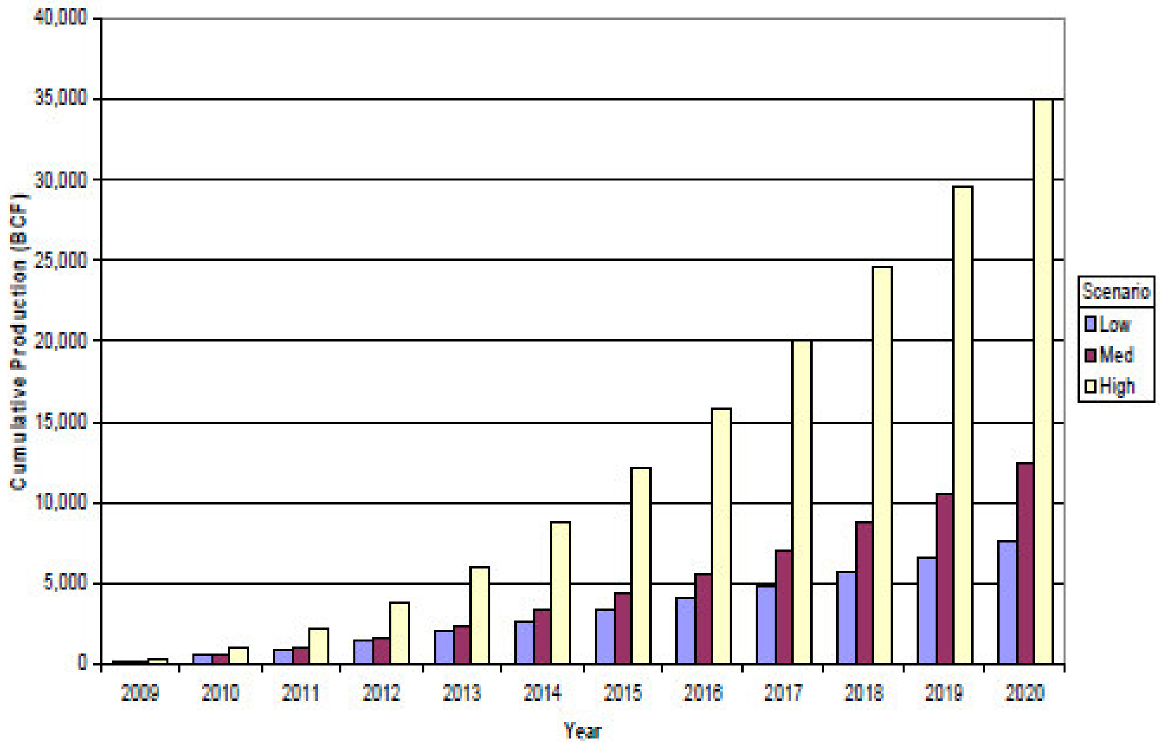
- Environ recently forecasted emissions in this developing play for NETAC
- Three slides borrowed from Environ follow for illustration purposes

Emission Inventory Scope

- Emission inventories developed for 2009-2020
  - Detailed inventory for 2012, the future year for NETAC ozone model
- Red counties define geographic extent of Haynesville for this study
  - Based on TRRC and LDNR well data as of March, 2009

ENVIRON

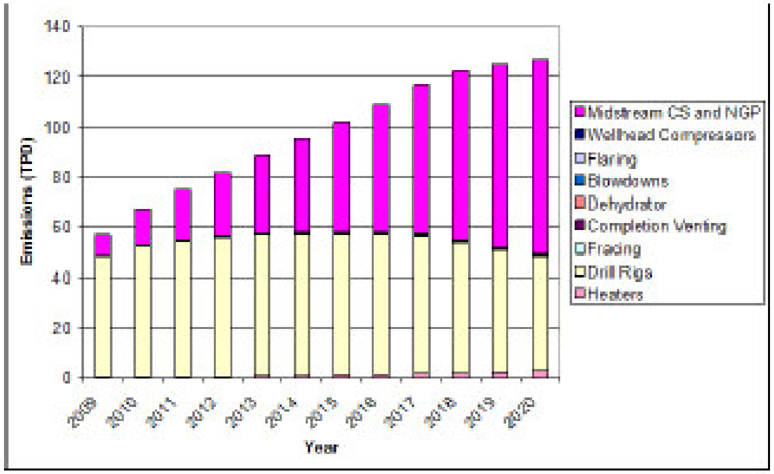
Projected Cumulative Gas Production in the Haynesville Shale: 2009-2020



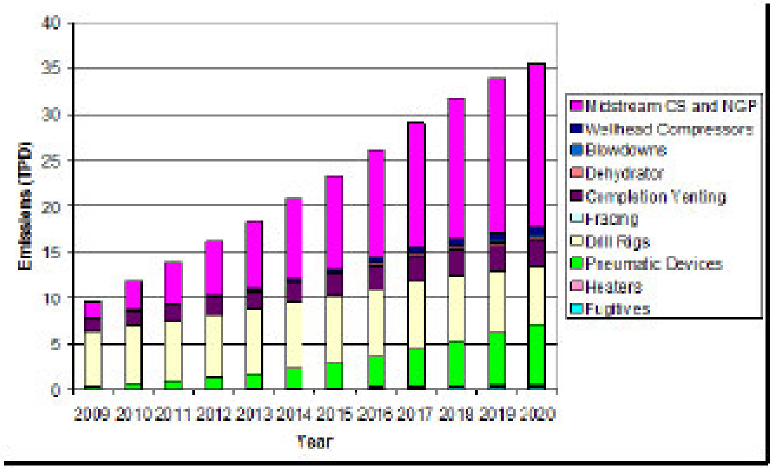
- 2020 production estimates range from 7.6-35 TCF
- Within range of published estimates of recoverable reserves (7-250 TCF)
- Barnett Shale reserves estimated to be 25-50 TCF
- All estimates highly uncertain-will be refined as Haynesville Shale is explored

Haynesville Emissions

NOx: Moderate Scenario



VOC: Moderate Scenario



- Largest NOx and VOC source categories are
  - midstream compression and natural gas processing (NGP)
  - drill rigs
- 2012 NOx emissions:
  - 61 tons/day, low scenario
  - 82 tons/day, moderate scenario
  - 140 tons/day, high scenario
- 2020 NOx emissions:
  - 64 tons/day, low scenario
  - 127 tons/day, moderate scenario
  - 267 tons/day, high scenario

NATURAL GAS FLARING AND VENTING

Opportunities to Improve Data and Reduce Emissions

G A O

Accountability * Integrity * Reliability

GAO-04-809

This is not just an environmental issue

= Lost product

= Lost producer revenues

= Lost royalties and/or taxes

Methane losses in Barnett Shale alone represent about $46 million per year in lost revenues for producers and $3.2 million in lost severance tax payments to TX

~40% of NM general revenues are oil & gas royalty payments

Thank You

DRAFT Summary of Key Emission Source Types in the Oil and Gas Production and Gas Processing Industries (Notes)

- Purpose and Scope:
  - This source list identifies all GHG emission sources that exist within the oil and gas production and gas processing industries operating within the WCI jurisdictions (in the U.S. and Canada).
  - The list will be used for development of essential requirements (ER) for mandatory reporting under the WCI cap-and-trade program.
  - For purposes of ER development, mobile transportation sources are not included, but mobile drilling rigs are included.

Western Climate Initiative

Status of WCI Reporting Requirements

Reporting Committee

Jim Norton, Chair

November 19, 2009

Santa Fe, NM

WCI Cap and Trade Program Design Principles

The program should:

1. ***Be equitable, administratively simple for government and private participants, minimizes administrative costs, and have a clear compliance path;***
2. Maximize total benefits throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts;
3. Require all [offset] reductions to be real, surplus/additional, verifiable, permanent, and enforceable;
4. Stimulate investment, especially in low carbon technologies, and reward innovations that will lead to long-term permanent greenhouse gas reductions;

WCI Cap and Trade Program Design Principles (cont.)

The program should:

5. ***Cover as many sources as is practical, while encouraging pollution reductions beyond the capped sources and sectors;***
6. ***Provide appropriate recognition and incentives for early emissions reductions;***
7. ***Assure a transparent and robust accounting system that will measure and report emissions rigorously and consistently across all sectors and throughout the region;***
8. Minimize the potential for leakage; and
9. ***Facilitate linkage to similarly rigorous regional and international greenhouse gas reduction markets and encourage other states, provinces, and countries to join the market.***

Some Key Design Recommendations
(Sept. 23, 2008)

EMISSIONS COVERED

- ***Combustion at industrial and commercial facilities***
- ***Industrial process (non-combustion) emission sources, including oil and gas process emissions***
- ***Transportation, residential, commercial, and (below-threshold) industrial fuel combustion, at distributor or supplier level***
- ***Adequate quantification methods will be established for emissions sources prior to including them in the program***

Some Key Design Recommendations (Sept. 23, 2008)

THRESHOLDS

- ***For cap-and-trade program: 25,000 metric tons CO2e per year, may adjust for specific industries***
- ***For emissions reporting: 10,000 metric tons CO2e per year; for some source categories, could be based on other parameters such as throughput or capacity***

REPORTING

- ***Third party verification will be required for sources included under the cap***
- ***Prior to start of mandatory reporting program, the WCI Partner jurisdictions will establish essential requirements for reporting***

Essential Requirements of Mandatory Reporting

- ***Developed Spring 2008 – July 2009***
- ***Stepwise development, multiple drafts for stakeholder review and comment***
- ***July 2009 Release - Final ERMR Sections***

  - General Provisions (Applicability, Schedule, General Contents of Reports, etc.)

  - Verification

  - General Stationary Combustion

  - Source Category Specific Sections (Refineries, Pulp and Paper, Lime, etc.)

  - Oil and Gas Production other than General Stationary Combustion not included
- ***September 2009: U.S. EPA finalizes rule for Mandatory Reporting of Greenhouse Gases***
- ***Need for harmonization***

Harmonizing WCI ERMRs with Federal Requirements

- ***Goal is to avoid imposing conflicting reporting obligations on facilities subject to both programs***
- ***Will amend WCI Essential Requirements to achieve harmonization with the U.S. EPA rule***
- ***Will make version of Essential Requirements suitable for use in Canada (regulatory structure, language, emissions factors, standard practices***
- ***Complete tasks in time for jurisdictional rulemaking to cover 2011 emissions***

WCI Principles for Harmonization

- ***A U.S. facility should be able to comply with both the EPA rule and a WCI jurisdiction's reporting requirements by following a single set of monitoring, recordkeeping and reporting requirements.***
- ***The quantification methods included in the amended ERs must be sufficiently reliable and accurate to be employed in a (GHG) cap-and-trade program. Because EPA has acknowledged that it did not develop the MRR with this goal in mind, the Reporting Committee must review each method included in the MRR to assure it meets this criterion. (e.g., WCI may allow only subset of quantification methods in EPA rule)***
- ***The amended ERs must remain suitable for use in Canadian WCI jurisdictions. For example, they must allow reporting in metric as well as English units and must where necessary include Canada-specific emission factors.***

Developing Mandatory Oil and Gas Reporting Requirements

- ***U.S. EPA proposed Subpart W (Oil and Natural Gas Systems) for non-combustion emissions, but deferred in September final rule***
- ***U.S. EPA will address oil and gas requirements in 2010 rulemaking***
- ***Development of WCI requirements will build on WRAP/TCR Protocol development process***
- ***Continue WRAP/TCR Technical Working Group, with some new members***
- ***Include U.S. EPA representation as they develop new proposal for oil and gas***
- ***New roles and responsibilities***

  - WCI Oil and Gas Subcommittee (of Reporting Committee) will assume Steering Committee role; ERG as technical contractor
- ***Completion first quarter 2010***
- ***Amend as needed for harmonization with final EPA rule anticipated in mid-2010***

Western Climate Initiative

Final Draft Complementary Policies White Paper

November 7, 2009

Table of Contents

Final Draft Complementary Policies White Paper **1**

November 7, 2009 .... **1**

1 Background and Purpose **3**

4.2.1 Emissions Performance Standards for Major Industrial Sources ... 28

5 Important Policies Addressed in Other Venues ... 29

Appendix 1: Complementary Policies: Capped vs. Uncapped Sources and Sectors ... 31

1 Background and Purpose

The Western Climate Initiative (WCI) Partners have recommended a comprehensive regional effort to reduce emissions of global warming pollution, combining a broad cap-and-trade program with complementary policies to achieve the WCI 2020 regional emissions goal.[1] Complementary policies can address market barriers that would otherwise limit the use of low-cost GHG emission reduction options, and can reduce emissions from sources excluded from the cap-and-trade program. Thus, complementary policies can lower the overall cost of reducing GHG emissions. This view is supported by the 2008 economic analysis of WCI's cap-and-trade design that incorporated complementary policies related to energy efficiency and tailpipe emission standards, which found that the WCI 2020 reduction goals can be achieved with small overall net savings due to reduced energy expenditures exceeding the direct costs of greenhouse gas emission reductions.[2]

As part of the WCI 2009-2010 Workplan, the WCI Partner jurisdictions formed the Complementary Policies Committee. The charge of the Committee is to recommend to the WCI Partner jurisdictions those policies which, if harmonized across multiple states and provinces both within and outside the WCI Partner jurisdictions, would help achieve the regional emissions reduction goals and assist with the transition to a low-carbon economy. As a first step, the Committee has prepared this white paper to solicit input from stakeholders on:

- the policies it recommends for further evaluation as outlined in its workplan;
- the Committee's recommended evaluation criteria;
- key issues or barriers to harmonization; and
- benefits that could accrue to the Partner jurisdictions and businesses that operate in more than one jurisdiction if implementation is harmonized.

This paper also discusses why and when policies complementary to a cap-and-trade program are useful, how complementary policies help achieve the WCI GHG reduction goals, and which policies would affect emissions under the cap and which would affect emissions from sectors and sources outside the cap.

It is important to note that many important complementary policy initiatives are not proposed to be evaluated by the Committee because they are being fully examined and developed in other venues. These other important policies are described briefly at the end of this paper.

---

[1] The WCI GHG reduction goals, established in 2007, call for an aggregate reduction in the region of 15 percent below 2005 levels by 2020 and, over the long term, a reduction that significantly lowers the risk of dangerous threats to the climate. *See* http://www.westernclimateinitiative.org/component/remository/general/Emission-Reduction-Goal-Aug-2007/.

[2] *See* WCI, Appendix B: Economic Modeling Results, Sept. 23, 2008, at: http://www.westernclimateinitiative.org/component/remository/Economic-Modeling-Team-Documents/.

Forthcoming reports from the Committee will address two additional policy areas: 1) workforce transition, job creation, job retention, and mitigation of community impacts associated with climate-related policies; and 2) climate change adaptation.

1.1 The Role of Complementary Policies

The WCI Partner jurisdictions have designed an economy-wide cap-and-trade program to reduce emissions in accordance with the WCI GHG reduction goals while maximizing market efficiency in achieving those reductions. Putting a price on GHG emissions will result in investments in technologies and other actions that will reduce emissions. However,some activities that reduce emissions cost effectively do not respond to this price signal: so-called market barriers prevent or impede the diffusion of cost-effective technologies and practices that could mitigate GHG emissions. The distribution of the costs and benefits of improving a building's energy performance is an instructive example of a market barrier. In commercial buildings, the cost of building improvements is typically borne by the building owner but the benefits are enjoyed by the tenants through lower energy bills. Because the building owner does not realize directly the financial benefit from the efficiency investment, s/he is less likely to make that investment. A well designed energy efficiency program can provide the needed incentive to make that investment.

Complementary policies achieve a variety of objectives in addition to reducing GHG emissions and removing market barriers. They can:[3]

- Achieve reductions outside (or below) the cap
- Encourage investments in low-carbon technologies
- Lower the cost per metric ton of reductions in GHG emissions covered by the cap-and-trade program
- Lower the cost of transitioning to a low carbon economy
- Prevent emissions and economic leakage
- Create and retain clean energy jobs

Given the role complementary policies play in the transition to a low-carbon economy, a comprehensive program that combines a cap-and-trade program with targeted complementary policies will deliver emissions reductions at a lower cost to consumers, measured as cost per ton of avoided GHG emissions.[4] The WCI Partners would also like to consider the potential benefits of harmonizing complementary programs among not only WCI jurisdictions but among states and provinces that are not part of the WCI. This will require other states and provinces that are not currently part of WCI to participate with the organization as it moves forward in its evaluation of selected complementary policies.

---

[3] Western Climate Initiative 2009-10 Workplan, updated June 23, 2009, at 36.

[4] *See* Testimony of Richard Cowart, Regulatory Assistance Project, Before the Committee on Energy and Commerce Subcommittee on Energy and Environment, U.S. House of Representatives, April 23, 2009, "The Consumer Allocation for Efficiency: How Allowance Allocations Can Protect Consumers, Mobilize Efficiency, and Contain the Costs of GHG Reduction," at http://energycommerce.house.gov/Press_111/20090423/testimony_cowart.pdf.

1.2 Evaluation Criteria

The next step for the Committee will be to more fully evaluate the selected policies based on the following criteria as they may be amended based on stakeholder review:[5]

- The policy will reduce GHG emissions.
- The policy is expected to reduce costs associated with achieving the WCI goals for covered facilities.
- Administrative costs are expected to be manageable.
- Impacts on low-income communities or small businesses can be mitigated.
- Meaningful benefits to harmonizing have been identified.
- Identified barriers to harmonizing implementation can be overcome.
- An opportunity to achieve collateral benefits (e.g., conserving water) has been identified.
- No collateral detriments (e.g., increased use of electricity,[6] increased fine particulates or air toxics pollution) have been identified.
- The policy does not encourage leakage outside the cap.
- The policy has the potential to create or retain clean energy jobs or otherwise transition to a low-carbon economy.

These criteria are intended to help the Committee determine whether and how each policy should be harmonized and how each policy will help achieve WCI's emissions reduction goal. Stakeholders are asked to specifically comment on the criteria and suggest qualitative indicators for determining if a given criterion has been met. Not all of the policies will meet all of the criteria, and some policies under initial consideration will not be recommended for harmonization.

1.3 Policies Recommended for Evaluation

Each of the WCI Partner jurisdictions has a climate action plan that delineates various policy instruments needed to achieve the jurisdiction's own emissions reduction goals or targets. The Committee used these plans to identify policies for consideration in this white paper. Listed below are the policies the Committee is recommending for further evaluation. The policies are grouped into three tiers to assist with scheduling the Committee's work. Policies in the highest tier (Tier 1) will be evaluated first. Stakeholders are asked to specifically provide feedback to the Committee on how it has proposed to tier the policies, the key issues that should be addressed and potential benefits of harmonizing them.

Energy Production

- Small-scale renewable energy resources (Tier 1)
- Emissions performance standards for electric generating units (Tier 1)
- Carbon capture and sequestration (Tier 2)

[5] Refinement of criteria in Western Climate Initiative 2009-2010 Workplan, at p. 38.
[6] Where electricity substitutes for higher GHG-emitting transportation fuels its increased use would be a benefit.

Energy Efficiency

- Energy efficiency targets (Tier 1)
- Energy efficiency programs and incentives (Tier 1)

Transportation

- Low-carbon fuel standard (Tier 1)
- Freight transportation infrastructure (Tier 1)
- Development of algae and ligno-cellulosic biofuels (Tier 1)
- Heavy-duty vehicle equipment (Tier 2)
- Electric and alternative fuel vehicle infrastructure (Tier 2)
- Vehicle emissions labeling (Tier 3)
- Medium and heavy-duty vehicle hybridization (Tier 3)
- Transport refrigeration units (Tier 3)

Industrial Sector

- Emissions performance standards for major industrial sources (Tier 3)

High-Global Warming Potential Gases

- Regulatory measures for high-global warming potential gases (Tier 1)

Agriculture

- Agricultural anaerobic digesters (Tier 2)

Waste Management

- Measures for landfill methane reduction (Tier 2)

Appendix A shows which of these complementary policies, if implemented, would reduce emissions from capped sources and sectors, and which policies would reduce emissions from uncapped sources and sectors.

1.4 Next Steps

This paper will be finalized after stakeholder review and comment. At that time, the Committee will begin to evaluate the policies that are included in the final paper. The key issues and benefits will be more fully identified. The Committee will attempt to identify other related issues such as needed jobs or skill sets to effectuate the policies. The outcome of the evaluation process will be design recommendations to facilitate regional harmonization of the specific policies. Stakeholders are asked to specifically comment on how the Committee can best engage with them as the evaluation process evolves—for example, opportunities for written comments on draft documents, Webinars, phone conferences, WCI's on-line newsletter, or a blog or other electronic discussion board.

2 Tier 1 Policies

2.1 Energy Production

- Small-scale renewable energy resources.
- Emissions performance standards for electric generating units.

2.1.1 Small-Scale Renewable Energy Resources

Small-scale renewable resources include solar photovoltaic systems, solar water heating systems, community-scale wind turbines, geothermal systems, biomass digesters, micro-hydro systems, and generating systems that run on wood waste, agricultural waste, or waste gas from landfills or water treatment plants. These systems can help meet power and thermal energy needs and reduce GHG emissions. They can be installed at homes and businesses to supply on-site energy needs. In addition, utilities and third parties can build small-scale generating facilities as system resources for all customers.

Potential Policies. State/provincial policy options to address the barriers to small-scale renewable energy sources – many of which have been adopted in one or more WCI Partner jurisdictions – include the following:

Workforce Training – Support for local and regional training programs may help ensure sufficient numbers of trained installers. Equipment and installer certification programs and random inspection of installations promote quality workmanship.

Public outreach and education – Public information can help consumers understand the benefits of small-scale renewable energy resources, how to undertake a project, and available assistance and funding options.

Uniform interconnection processes - Uniform technical standards, procedures and agreements can remove barriers and simplify the interconnection of small generators with utility systems, where appropriate. For projects with complex interconnection needs, reasonable timelines, fees and other requirements can be put in place for additional technical review and equipment that may be needed.

Power arrangements with the utility – Among the options:

- "Net metering" is a billing arrangement where the utility bills the customer only for the difference between the energy consumed at the premises and the energy produced by a qualifying system at the site. Any excess energy produced flows onto the utility grid for use by other customers, eliminating the need for the customer to have on-site storage or to to arrange for power sales to a third parties. While net metering programs are widespread, many do not require all utilities in the state to participate or include all customer classes. Programs also may be constrained by low limits for individual project size and aggregate capacity, payment provisions for excess energy, insurance and equipment requirements, standby rates, and restrictions on third-party ownership of systems.[7]

- The Public Utility Regulatory Policies Act (PURPA)[8] requires utilities in the U.S. to interconnect with and purchase all capacity and energy from "Qualifying Facilities" up to 80 megawatts (MW) that use eligible renewable resources[9] at rates equal to the cost of the utility's avoided resource (for example, market purchases or a natural gas-fired power plant). States have broad discretion in implementing PURPA. Among the provisions for successful state programs are long-term contracts with fixed rates, standard avoided cost rates, Commission-approved standard contract forms for small-scale projects, and methods for determining avoided costs that fully account for the value of the renewable energy to the utility system.
- Feed-in tariffs (FITs), also known as Advanced Renewable Tariffs, can provide rates that make it attractive for electricity to be produced by third parties (non-utilities) using renewable resources. Rates may vary by technology, geographic location and project size. FITs can encourage development of a variety of renewable energy projects. Like PURPA, FITs guarantee the right to interconnect and a buyer for the electricity, and payment is based on actual production. However, FIT rates are based on the cost of renewable energy generation, not the utility's avoided resource. Typically included in FIT rates is a return on investment sufficient to make the project worthwhile for investors.
- Targeted procurement of small-scale renewable energy resources that recognizes their unique benefits can incorporate many of the same features as a FIT, such as a must-take obligation and standard contract terms, but allow for market-based pricing through a reverse auction or similar mechanism.

Standby rates –Practices include cost-based rates, providing customer-generators choices for firm and non-firm service, including daily rates, allowing them to self-supply reserves and assure instantaneous load reductions to avoid standby charges, and providing supplemental power and maintenance service – with appropriate advance notice – at the customer's otherwise applicable tariff rate.

Utility resource planning and procurement – Utility resource planning and procurement often does not evaluate and include small-scale renewable resources for meeting generation and transmission needs. Similarly, the value of distributed generation typically is not considered in distribution system planning. Including distributed generation in utility planning and acquisition processes helps states and provinces examine whether and how to use these resources to meet energy, capacity, distribution and transmission system needs.

[7] A third party pays the upfront cost of the system; builds, installs and owns it for a specified term; takes advantage of tax, depreciation and other financial incentives; and sells the energy to the consumer hosting the system. The consumer reduces its bills through a net metering agreement with the utility. This financing model is especially important to local governments, schools, churches and others that can't raise the capital for the project or take advantage of some government incentives.
[8] U.S. Public Utility Regulatory Policies Act, 16 U.S.C. § 824a-3.
[9] And qualifying cogeneration facilities of any size.

Decouple utility sales from utility profits - "Decoupling" removes the link between utility sales and revenue so that the utility is indifferent to, rather than financially harmed by, customer-side distributed generation and efficiency measures.[10] Under decoupling, retail customer rates established to recover fixed utility costs are adjusted periodically to keep utility revenue at the level allowed by regulators.

Key issues to consider in developing small-scale renewable energy resources include:

- **Interconnection** – In the U.S., states generally have jurisdiction over interconnection (and sales) between customer-sited generation and retail electric utilities.[11] Utility interconnection processes may result in undue delays in gaining approval of applications as well as undue costs associated with insurance and equipment which, upon closer examination, regulators may find unnecessary.

- **Power sales** – Utility procurement generally does not adequately consider small-scale distributed systems, despite their potential advantages such as more rapid deployment and lower development risk compared to large projects. Small systems may not meet the minimum bid size for utility competitive bidding processes and wholesale markets, and the market for aggregation of small systems is immature. In addition, the prices utilities pay for renewable energy may be too low to drive significant development of small-scale systems.

- **Standby rates** – Unless prohibited by regulation, utilities may charge customer-generators special rates for back-up power when their on-site generator isn't running and for supplemental power to meet the customer's energy needs beyond the generator's capacity. Unless properly designed, standby rates can render a project uneconomic.

- **Utility planning** – Utility resource planning typically does not adequately evaluate and include small-scale renewable resources for meeting generation and transmission needs. Nor is the value of distributed generation typically considered in distribution system planning, where it could have especially high value in deferring costly upgrades to meet capacity needs in specific locations. Further, those locations are not revealed to consumers or the marketplace.

- **Utility disincentives** – Utilities recover a large amount of their fixed costs through volumetric rates. When customers develop on-site generation, utility revenue declines. Because so many of the costs of providing utility service do not change in the short run,

---

[10] *See* National Action Plan for Energy Efficiency, *Aligning Utility Incentives With Investment in Energy Efficiency*, November 2007, at http://www.epa.gov/cleanenergy/energyprograms/napee/resources/guides.html; Regulatory Assistance Project, *Revenue Decoupling Standards and Criteria: A Report to the Minnesota Public Utilities Commission*, June 2008, at http://www.raponline.org/Pubs/MN-RAP_Decoupling_Rpt_6-2008.pdf.

[11] The Federal Energy Regulatory Commission has jurisdiction over interconnection of generating facilities for wholesale sales.

a small reduction in sales due to customer-side resources can result in a disproportionately large reduction in utility earnings. Also, utilities typically do not earn a return on non-utility resources, nor can they make profits on them through operational efficiencies.

- **Cost** – Homeowners, businesses, local governments and others may have difficulty securing financing at favorable terms. And without subsidies, it may take too long for the investment to pay back.

- **Trained workforce** – Successful programs require a trained workforce to properly size, select and install equipment. If installers are in short supply, the consumer's interest in developing a project may pass.

- **Consumer awareness** – Most consumers are not aware of the benefits of small-scale renewable energy resources, how to undertake a project, and available assistance and funding options.

Benefits to harmonizing. Harmonizing these policies could build a larger market for small-scale renewable energy resources. It also would allow manufacturers to build equipment to meet a uniform set of standards accepted across a large region, make it easier for installers operating in multiple jurisdictions to understand interconnection and program requirements, and facilitate regional marketing of renewable energy systems.

2.1.2 Emissions Performance Standards for Electric Generating Units

An emissions performance standard (EPS) sets a maximum level of GHG emissions per unit of output. An EPS for electric generating units is designed to "raise the bar" for the emissions performance of each power plant, analogous to efficiency standards for appliances. Through the use of an EPS requirement, the construction of high-emitting generating resources with long expected useful lifetimes may be avoided. Similarly, new long-term contracts with existing high-emitting generating resources may be prevented. As a consequence, an EPS may reduce ratepayers' financial and reliability risks associated with plant retirements, retrofits, and emission allowance and offset costs under future emission control regulations. An EPS can also promote technological innovation to advance new power generation systems and to modify existing facilities in order to meet the standard.

An EPS should be considered in conjunction with a cap-and-trade program if:

1. Market prices for electricity would need to increase to an unacceptable level to change the generation dispatch order or to induce new investments and technological advancements in clean generation at a sufficient rate or magnitude to meet GHG emissions reduction goals
2. The level of carbon "leakage" outside the cap-and-trade region is unacceptable.

Key issues to consider in designing an EPS for electric generating units include:

- Establishing the appropriate EPS performance level (emissions rate)
- Determining the point of regulation (Who must comply – for example, generators or distribution companies that serve load?)
- How broadly the EPS should be applied. (Only electricity produced within the jurisdiction or imported power as well?)
- What type of facility or commitment should be subject to the EPS
- New construction only? Also new investments in existing facilities that expand rated capacity, effective useful life, or both?
- Facilities underlying long-term contracts only? Short-term contracts, too?
- Determining the facility threshold (MW size or capacity factor)
- The state of technology and the degree to which it can be pushed
- Start date and implications of building current-technology power plants that will not qualify under the EPS
- Calculation of net emissions for combined heat and power and biomass facilities
- Potential for carbon capture and storage

Benefits to harmonizing. Harmonized EPS policies and standards design would promote consistent signals to the market across a broad geographic region concerning GHG emissions performance for generating units. This would drive technological advancement in low-carbon solutions within a specific timetable linked directly to the carbon reduction goals for the electricity sector.

This policy has already seen a great deal of harmonization in the Western jurisdictions of the WCI. The states of California, Oregon and Washington have enacted similar EPS laws.[12] In addition, Montana has adopted a law imposing restraints on emissions from coal plants.[13] British Columbia requires carbon capture and storage for any new coal-based generating facility.[14]

2.2 Energy Efficiency and Conservation

- Energy efficiency targets
- Energy efficiency programs and incentives

2.2.1 Energy Efficiency Targets

Energy efficiency targets are used by policy makers to set performance goals – binding or voluntary – for energy efficiency investments and savings. The targets may apply to states or provinces, utility companies or third-party administrators of programs.

---

[12] California SB 1368: http://www.energy.ca.gov/emission_standards/documents/sb_1368_bill_20060929_chaptered.pdf; Oregon SB 101: http://www.leg.state.or.us/09reg/measpdf/sb0100.dir/sb0101.en.pdf; and Washington SB 6001: http://apps.leg.wa.gov/billinfo/summary.aspx?year=2007&bill=6001.
[13] HB 25 (2007): http://data.opi.mt.gov/bills/2007/billpdf/HB0025.pdf.
[14] Bill 31: http://www.leg.bc.ca/38th4th/3rd_read/gov31-3.htm.

Energy efficiency targets take various forms. Energy Efficiency Resource Standards (EERS) establish long-term efficiency targets that are typically expressed as a percentage reduction compared to retail energy sales over a baseline period. Both annual and cumulative energy savings targets may be included. Standards may apply to both electricity and natural gas, and they may target reductions in peak electricity demand as well as energy usage overall. EERS are already in place in many states and federal standards have been proposed.[15]

Energy savings generally are achieved through end-use efficiency programs. In some states, savings from building codes, appliance efficiency standards, combined heat and power facilities, and distribution system efficiency improvements also may count toward meeting the standard.

Instead of expressing savings targets as percentages or absolute (e.g., megawatt-hour) savings figures, some states and provinces have made a commitment to acquire all cost-effective energy efficiency or achieve zero load growth through energy efficiency programs. Such efficiency targets can be articulated as part of a utility's integrated resource planning process and incorporated into applicable regulations. The suitability of subsequent utility acquisitions would be measured against that goal.

Energy efficiency targets also can be articulated in contracts or informal proceedings between the jurisdiction and a third-party efficiency provider. In some cases, the third-party provider is remunerated, in part, for achieving savings above the specified targets.

Key issues to consider in setting and achieving energy efficiency targets include:

- Savings potential (as assessed by a resource potential study)[16]
- Performance levels (e.g., percentage rate of savings)
- Baseline measurement (i.e., the starting point)
- Cost-effectiveness tests in screening individual efficiency programs or a portfolio of programs
- Utility disincentives to achieving stated goals[17]

---

[15] In the U.S., for example, the American Council for an Energy-Efficient Economy (ACEEE) reports that 19 states have adopted an EERS requiring achievement of specified energy savings targets. In addition to strict EERS requirements, ACEEE includes states with Commission-ordered efficiency targets, states that allow efficiency to count toward renewable energy standards, and states with a rate cap triggering a relaxation of EERS requirements. *See* Laura A. Furrey, Steven Nadel, and John A. "Skip" Laitner, ACEEE, *Laying the Foundation for Implementing a Federal Energy Efficiency Resource Standard*, March 2009, at http://aceee.org/pubs/e091.htm. Bills pending in the 111th U.S. Congress would establish a national EERS. The United Kingdom and several Australian states are among jurisdictions outside the U.S. that have mechanisms similar to an EERS.

[16] A resource potential study assesses the technical and market potential for energy efficiency efforts and lays the foundation for developing appropriate savings targets. Results generally show achievable potential far in excess of current program scope.

[17] *See* decoupling discussion on page 7 and Regulatory Assistance Project, "The Role of Decoupling Where Energy Efficiency Is Required by Law," September 2009, at http://www.raponline.org/Pubs/RAP_Schwartz_IssuesletterSept09_2009_08_25.pdf.

Benefits to harmonizing energy efficiency targets include helping promote consistent signals to a broader market. Standardized requirements could be expected to reduce implementation barriers and costs for companies operating in multiple states.

2.2.2 Energy Efficiency Programs and Incentives

Energy efficiency programs are business plans or market mechanisms that address barriers to cost-effective investments. Programs can be run by the utility, the state or province, or a third-party administrator. Program costs can be integrated into the utility's cost of service, like other resources, or be paid for through a separate charge on customer bills. The goal of a well-designed program is to motivate action by the targeted decision-makers – consumers, suppliers, stores or contractors – while minimizing program costs. Market mechanisms include tradable Energy Efficiency Credits ("white certificates" or "white tags") that certify specified reductions in energy consumption. In most cases, certificate schemes are combined with an obligation to achieve energy savings targets.

Energy efficiency investments can reduce total utility system costs[18] and avoid the use of fossil fuels and associated GHG emissions. Studies continue to find a vast potential of cost-effective efficiency remaining to be tapped.[19] Securing this potential could dramatically reduce electricity demand and significantly reduce the cost of meeting emissions reduction goals.

Policies include providing programs that offer the following types of assistance:[20]

- **Information, education, marketing and technical assistance** – Information on-line and at point of sale, branding (e.g., Energy Star), phone hotlines, workshops, multi-media advertising, on-site audits, field visits, training, certification and inspections are among the ways programs can increase awareness, knowledge and confidence among consumers, vendors and contractors.
- **Grants and rebates** – Financial incentives can reduce the cost to the consumer of investing in energy efficiency products and services. The incentive amounts are justified by a benefit-cost analysis and can be linked to the desired effect – for example, the number of targeted products installed by a certain date.

---

[18] Preliminary research by ACEEE indicates average program costs of about 3 cents per kilowatt-hour saved and 29 cents per therm saved. (*See* Steven Nadel, ACEEE, Replies to Questions at the April 22, 2009, Hearing on Energy Efficiency Resource Standards, May 12, 2009, at http://aceee.org/tstimony/NadelQuestions04.22.09.pdf.) That's far less than the cost of new generating facilities. Efficiency investments also can avoid expensive upgrades to transmission and distribution systems.

[19] For example, the recent McKinsey study found the U.S. has the potential to cost-effectively reduce non-transportation energy consumption roughly 23 percent by 2020. *See* www.mckinsey.com/USenergyefficiency. The Northwest Power and Conservation Council recently estimated achievable, cost-effective conservation in the four-state region (Idaho, Montana, Oregon and Washington) at 21percent of 20-year forecasted (medium-case) electric load – an amount that would meet about 85 percent of load growth in the region while significantly reducing both system cost and risk. *See* http://www.nwcouncil.org/energy/crac/Default.htm.

[20] Building codes, appliance standards, and new energy efficiency technologies are addressed briefly at the end of this paper.

- **Financing** – Long-term financing of energy efficiency investments can provide consumers with positive cash flow. Financing strategies may focus on "lost opportunities," such as new buildings and new equipment, or they may provide consumers with the means to retrofit buildings or replace inefficient equipment. For example, some programs allow homeowners to add the cost of certain efficiency improvements to their mortgage, extending the repayment period.

Energy efficiency programs can include some form of "market transformation" – changing the way people make energy-related decisions or making efficient products and services widely available. Some programs are devoted exclusively to these purposes. Other programs focus on hard-to-reach sectors, such as multi-family housing and low-income households.

Programs to reduce energy consumption may be more compatible with a utility business structure that decouples utility sales from utility profits and includes performance incentives. Decoupling removes a utility's inherent *disincentive* to sell less of its product. Decoupling does not provide an *incentive* for the utility to acquire energy efficiency in lieu of supply-side alternatives that earn a return on investment. Where aggressive energy efficiency goals are in place, regulators may consider providing financial incentives to utilities for exceptional performance. Many utility commissions have adopted decoupling, incentive mechanisms, or both for electric and natural gas utilities.[21]

Key issues to consider in developing these policies include:
- High upfront cost, long payback on investment, and limited financing options
- Short windows of investment decision-making opportunity are easy to miss
- Trained workforce may be in short supply
- Limited public awareness, information and knowledge
- "Split incentives" between builders/building owners and tenants who pay the utility bills
- Resource planning and acquisition processes that don't evaluate energy efficiency on a par with supply-side alternatives
- Utility disincentives to encouraging energy efficiency

Benefits of harmonizing energy efficiency programs among the WCI jurisdictions and other states and provinces include reducing costs, helping to transform markets for energy efficiency products, technologies and practices, and achieving greater energy savings and GHG reductions. Regional programs can achieve economies of scale that are not possible with isolated programs. Working together, utilities and other program administrators can leverage personnel and funds for resource potential studies, regional marketing and training, developing a broad supply chain of products and services, robust evaluation of programs, and verification

[21] For maps showing status of decoupling in the U.S., *see* http://www.raponline.org/docs/NRDC_Decoupling%20Maps%20US_2009_08.pdf . For examples of incentive mechanisms and modeled results, *see* Chuck Goldman, Peter Cappers, Michele Chait, George Edgar, Jeff Schlegel and Wayne Shirley, "Financial Analysis of Incentive Mechanisms to Promote Energy Efficiency: Case Study of a Prototypical Southwest Utility," report to the Ernest Orlando Lawrence Berkeley National Laboratory, March 2009, at http://eetd.lbl.gov/EA/EMP/ee-pubs.html.

of estimated energy savings. Consistent program features and requirements also make it easier for vendors and contractors to participate.

Many programs rely on a common set of product and service specifications developed by the ENERGY STAR program. Some states already coordinate on energy efficiency assessments, strategy, model standards, programs, and common protocols for evaluating, measuring and verifying program results through such organizations as the Northwest Power and Conservation Council[22] and Northwest Energy Efficiency Alliance[23]. These efforts could be expanded to include a broader set of jurisdictions. Multi-state utilities offer similar programs throughout their service areas.

2.3 Transportation

- Low-carbon fuel standard
- Freight transportation infrastructure
- Development of algae and ligno-cellulosic biofuels

2.3.1 Low-Carbon Fuel Standard

A Low Carbon Fuel Standard (LCFS) is a GHG emissions standard for transportation fuels. An LCFS provides a method for calculating the carbon intensity of fuels and requires fuel providers to reduce over time the carbon intensity of the fuels they sell. The carbon intensity calculation is typically based on *life-cycle carbon emissions* for each fuel type. An LCFS is designed to be technology-neutral across alternative transportation fuels including electricity, biofuels and hydrogen. Fuel providers have the flexibility to provide the lowest priced mix of low-carbon fuels that achieves the intensity standard. This approach differs from a renewable fuel standard, which mandates certain volumes of biofuels.

The state of California has adopted an LCFS program. Oregon recently passed legislation directing the Department of Environmental Quality to develop an LCFS. British Columbia's Greenhouse Gas Reductions (Renewable and Low Carbon Fuel Requirements) Act will be implemented through two regulations: 1) the Renewable Fuel Requirement Regulation, which requires fuel suppliers to meet an annual, provincial average of 5 percent renewable content for gasoline and diesel fuels and 2) the proposed Low Carbon Fuel Requirement Regulation (LCFRR), which would require that the carbon intensity of transportation fuel sold in the province be reduced 10 percent by 2020. The LCFRR would require suppliers to provide transportation fuels with average carbon intensity less than or equal to annual target values beginning in 2010. The state of Washington is evaluating whether a LCFS should be adopted there.

Key issues to consider in designing an LCFS include:

- Carbon intensity reduction goals and schedule

[22] http://www.nwcouncil.org/Default.htm
[23] http://www.nwalliance.org/

- Interaction of an LCFS with the regional cap-and-trade system, including issues such as consistency of signals to industry under the two systems, potential for double counting of emissions reductions, and within-region vs. outside-region emissions reductions;
- Point of regulation (for example, should fuel companies be held responsible for increasing use of electric vehicles?)
- Cost to the public and businesses
- Current and expected regional capacity to produce sufficient low-carbon alternative fuels and opportunities for increasing capacity[24]
- Assessment of current and future technological feasibility
- Requirements for capital investment in low carbon fuels production
- Potential for commercialization of vehicles that can use low- or no-carbon fuels
- Development of a regional low-carbon fuel credit program
- Consistency in estimating carbon intensities, considering fuel mixes, land use issues and other factors
- Options for minimizing the cost of compliance
- Potential use of compliance deferrals to address issues such as fuel shortages, fuel quality problems and significant spikes in fuel costs
- Potential for exemptions
- Refueling infrastructure to support an LCFS
- Environmental and health impacts beyond GHG reductions
- Local needs and conditions

Benefits of harmonized LCFS policies and program design include consistent requirements among states and provinces that participate in the same fuel markets. Looking at the future needs for regional low-carbon fuel capacity may promote coordinated investment and economic opportunities. Regional harmonization could also provide a useful model for any national LCFS program.

2.3.2 Freight Transportation Infrastructure

West Coast ports are North America's links to the rapidly growing Asian economies. The amount of goods imported and exported through these ports will continue to grow. Similarly, as the populations of the WCI states and provinces grow, trade within the region and with the rest of North America also will increase. This continued growth in marine, air, rail and road transport activity poses a challenge to policy makers seeking to reduce GHG emissions. In addition, overlapping jurisdictions among many levels of government results in regulatory challenges for operators.

Many transport sectors have agreed that the solution lies in coordinating, rather than competing, on environmental issues. This is particularly relevant for areas such as the West Coast, where shippers have a choice among numerous air and marine ports of entry and land-based carriers. Through coordinated improvements and standards, states, provinces, port

[24] Regional capacity may be important from an economic impact perspective.

authorities and private carriers can justify investment in environmental improvements, without the fear that business will be lost to a higher-emitting, but lower cost competitor.

Examples of potential regional coordination on freight transportation include the following:

- Jurisdictions could adopt requirements such as the U.S. Environmental Protection Agency (EPA) model rule to reduce heavy-duty truck idling during rest stops to facilitate a uniform approach. Outreach and financial assistance programs could promote energy-efficient and cost-effective alternatives such as auxiliary power units and truck stop electrification. A viable electrification network requires action by multiple jurisdictions to be effective.
- Ocean- and river-going vessels at dock usually run onboard diesel generators for “hotel” power. Using power from the electric utility grid is less expensive, but it may be necessary for multiple ports to provide connection facilities on-shore to make it cost-effective for vessels to install capability to connect to those facilities. WCI members California, Washington and British Columbia have installed on-shore power facilities using the best available and most compatible technology. A regional approach also could help eliminate competitiveness concerns among ports providing on-shore power.
- Smaller engines to provide hotel power, new engine technologies, and electronic start/stop controls are available to reduce pollution from locomotives, which often idle for extended periods of time. A regional approach could coordinate incentives and address jurisdictional issues for cleaning up switchyards and long haul locomotives.
- Regional approaches to increasing the fuel efficiency of heavy duty trucks could be explored, such as lower speed limits and improvements in aerodynamics.

Key issues to consider for freight transportation infrastructure include:

- Competitiveness among ports for docking of ocean and river-going vessels
- Lack of consistent regulations, penalties and funding programs among states and provinces with respect to anti-idling to encourage investment while avoiding impacts on trade competitiveness
- Standards for port electrification under development by the International Maritime Organization and their broader use with increasing certainty regarding the final standards
- High upfront cost, long payback on investment, and limited financial resources and incentives to fund research, development and implementation of new technologies
- Need for public-private partnerships and investments to develop a network of truck stop electrification locations
- Programs developed by the American Trucking Association to reduce GHG emissions from freight movement, which can be implemented and enhanced through coordinated action by states and provinces

Benefits to harmonizing policies include improving uniformity of regulatory and incentive programs, reducing competitiveness issues among states and provinces, leveraging incentives, and addressing jurisdictional issues with interstate freight movement. Because many trucking companies, trains and marine vessels operate between WCI Partner jurisdictions, regional coordination could also help identify or prevent instances where one jurisdiction's compliance mechanism may cause emissions increases in other jurisdictions. A regional approach to on-shore power would allow for pricing strategies to encourage its use, without affecting the competitive balance. Regional strategies to reduce GHG emissions from the freight transportation sector would produce multi-pollutant benefits, reducing toxins, sulfur dioxide, nitrogen oxides and fine particulates.

2.3.3 Development of Algae and Ligno-Cellulosic Biofuels

Research is rapidly advancing into the selective breeding of algae for production of biomass that turns into oil at an extremely rapid rate. Algae grow much faster than other plants used for fuel, including corn and soybeans, and can produce many more gallons of oil per acre of land. There also are significant greenhouse gas emission reduction benefits to this technology. Through a process known as hydrogasification, whereby coal is made into synthetic natural gas (SNG), a portion of the process carbon emissions is used to nourish the growing algae. Algae can then be used as an additional fuel source or as a feedstock for biodiesel fuel production. The result is a cleaner, more efficient use of coal for energy production, and a beneficial use of carbon emissions that adds to fuel production while displacing need for fossil fuels.

Research on algae biofuels is underway in WCI Partner jurisdictions (including Arizona, California, Montana and New Mexico), in some cases with corporate support. Research also is progressing on the production of fuel-grade ethanol and other biochemical co-products from cellulosic biomass feedstocks, and WCI Partner jurisdictions (including British Columbia, Ontario and California) have commercialization efforts underway. By working together, WCI and other jurisdictions may be able to help move the fuel from research to the marketplace.

The Committee is not aware of any policies that act as a barrier to using algae or ligno-cellulosic biomass for transportation fuel. It recommends each WCI Partner jurisdiction conduct an evaluation to determine if such policies exist, and if so, to determine the rationale for that policy. The Committee might then evaluate policies to eliminate barriers and develop recommendations for further consideration.

2.4 High-Global Warming Potential (GWP) Gases

2.4.1 Regulatory Measures for High-GWP Gases

High-GWP gases are of growing concern due to their increasing rate of emissions and persistence in the atmosphere. These gases, from anthropogenic sources, are released as byproducts of industrial operations, primary from electric power transmission and distribution, aluminum smelters, semiconductor manufacturing, production of insulating foam, and magnesium smelters and die-casters. High-GWP chemicals also are used in many applications such as refrigeration, air conditioning and fire suppression. Typically, emissions of high-GWP gases from processes and products are individually too small to be covered by the WCI cap-and-trade program. Nevertheless, just a few pounds of these materials can have the equivalent effect on global warming as several *tons* of CO_2.

Voluntary partnerships between EPA and industry are substantially reducing emissions of high-GWP gases. For example, 81 utilities are participating in a voluntary program to reduce emissions from SF_6 used for insulation of electric transmission and distribution equipment. EPA publishes lists of acceptable substitutes for high-GWP gases.

Key issues to consider for reducing emissions of high-GWP gases include:

- Long timeframe for transitioning to safe and acceptable substitutes that offer lower overall risks to the environment and human health
- Removal and disposal of high-GWP gases
- Voluntary nature of existing programs
- Sizable expansion that is occurring in many industries that emit high-GWP gases

Benefits to harmonizing measures to reduce high-GWP gases include reducing burdens on consumers and manufacturers while encouraging a broader market for lower-emitting substitutes. Regional programs can achieve economies of scale that are not possible with isolated programs. Regional harmonization may promote coordinated investments for research and development of alternatives. Harmonized policies could include design and funding of programs for capturing and disposing of high-GWP gases, incentives for upgrading to newer products in order to more rapidly remove products with high-GWP gases from circulation, and establishing specifications for the use of high-GWP gases in newly manufactured products.

3 Tier 2 Policies

3.1 Energy Production

3.1.1 Carbon Capture and Sequestration

Carbon capture and sequestration (CCS) is a key technology for sustained emissions reductions in the electricity sector. It involves four steps: 1) separating CO_2 before or after combustion of fossil fuels; 2) compressing the CO_2 stream; 3) transporting it to an injection site; and 4) pumping it into underground geologic formations in a manner that prevents its release into the atmosphere.

Given the technical, institutional, and legal risks, solely putting a price on CO_2 emissions may be insufficient to advance CCS deployment. Additional policies for the capture, transport, injection, monitoring and liability of the sequestered CO_2 are needed. Utility resource policies that mandate or promote CCS may be appropriate – such as emissions performance standards[25] – as well as innovative policies for siting and permitting, financing and rate-making.[26] State and provincial policy options to advance CCS include the following:[27]

Managing transport and sequestration – Current rules for transport and injection of CO_2 are for enhanced oil recovery and CCS pilot projects, not large-scale CCS deployment. Existing pipeline laws must be adapted for CO_2 transport. A standard template such as the one produced by the Interstate Oil and Gas Compact Commission[28] may be useful for the development of rules for geologic sequestration of CO_2. Further options can accelerate CCS deployment, such as pre-screening and pre-qualifying the best CO_2 pipeline and injection sites and simultaneous review of permit applications for the power plant, CO_2 pipeline and injection infrastructure.

Limiting liability for CO_2 releases – Large-scale CCS may not be deployed unless companies are able to manage liability associated with the escape or migration of CO_2 from pipelines and storage sites following permanent capping of the site and decommissioning of the injection facilities.[29] Policies designed to address liability must balance the goals of shielding companies from excessive liability while maintaining a strong incentive for companies to minimize the chances of CO_2 release after decommissioning. In the absence of national legislation, states and provinces are beginning to address this issue on their own.

---

[25] See pages 9-10.
[26] Jurisdictions also should consider whether any waivers may be warranted for power plant need determinations and competitive bidding requirements.
[27] For a complete discussion, see Richard Cowart and Shanna Vale, Regulatory Assistance Project, and Joshua Bushinsky and Pat Hogan, Pew Center on Global Climate Change, "Coal Initiative Reports: State Options for Low-Carbon Coal Policy," February 2008, at: http://www.pewclimate.org/docUploads/StateOptions-02-20-08.pdf.
[28] *See* http://iogcc.publishpath.com/Websites/iogcc/pdfs/Road-to-a-Greener-Energy-Future.pdf.
[29] Where those actions were taken in conformance with an approved plan for the cessation of operations.

Liability for releases during transport and injection (prior to decommissioning) also is an important issue. Insurance may adequately address liability during the operational period of a sequestration project, but clarifying legislation also could be beneficial. Other measures might be needed to compel the surrender of allowances for any CO_2 release.

Subsidies for CCS projects at fossil-fuel[30] plants – Among the options for funding are:

- A fee levied on generators or utilities on a per-megawatt-hour basis, or just on the portion attributable to fossil fuels
- A "feebate" system that charges fossil-fuel plants without CCS technology a per-megawatt-hour fee and distributes the funds collected for CCS equipment
- Direct expenditures or tax credits for CCS investments

Other financial incentives – Utilities could potentially receive higher rates of return or accelerated depreciation for CCS investments. Regulatory commissions or legislatures could grant bonding authority for CCS projects. Besides simply providing access to funds, such bonds could provide a lower interest rate.

Cost recovery support – Most regulatory commissions do not pre-approve power plants. Instead, they determine what costs may be included in a utility's retail rates only after the plant has reached commercial operation. Regulators can provide some type of cost recovery assurance for CCS projects even before construction begins, employing such strategies as:[31]

- Preapproval of CCS projects;
- Guaranteed buyer or must-take requirements for CCS-generated power;
- Cost recovery for power supply during unplanned outages of the CCS plant;
- Cost recovery even if the CCS plant is cancelled;
- Cost recovery for early retirement of existing coal plants if replaced with a CCS substitute.

Key issues to consider for CCS policies include the following:[32]

- *Acceleration:* Will it produce investment in CCS that would not otherwise occur?
- *Deterrence:* Will it deter investment in high-emitting technology options?
- *Prudence and accountability:* Will it promote prudent project management? Will those with responsibility be held accountable for performance?
- *Power supply costs:* Does it help to lower the cost premium for CCS power?
- *Administrative costs:* Does it help to lower administrative and regulatory costs for developers, government and other parties?
- *Risk and cost balance:* How well does it balance the interests of ratepayers and investors?

---

[30] Coal, natural gas, biomass, petroleum coke and other fossil fuel plants are candidates for CCS.
[31] State "used and useful" requirements (mandating that a plant be functioning and necessary to be included in the utility's revenue requirement) may need to be modified by statute to implement the last three options in this list.
[32] *See* Cowart, *et al.*

- *Innovation:* Will it promote further CCS research and technical innovation?
- *Standardization:* Will it promote CCS projects that could be replicated elsewhere?
- *Performance:* Does it secure significant carbon reductions? Are any incentives scaled to real-world performance, measured in tons of CO_2 permanently sequestered?

Benefits to harmonizing. Harmonizing CCS policies across jurisdictions might make sense for a number of reasons. First, successful CCS efforts require significant research, development, and demonstration funding that is best spent in a coordinated manner. For example, coordinated mapping of potential sequestration sites and pipeline locations may reduce the need for redundant studies. Second, CCS projects may be developed by multi-state utilities, or developed jointly by utilities in multiple states and provinces, in order to achieve economies of scale and spread the costs and risks. Third, long-distance transmission lines for coal plants with CCS, as well as pipeline transport of CO_2 for sequestration at a remote location, may require cooperation among states and provinces.

In addition, consistent CCS policies could promote replicable CCS projects and reduce administrative costs for utilities and other project developers as well as stakeholders participating in regulatory processes. Further, absent a national policy, consistent policies across the region to address liability risks associated with potential CO_2 leakage could facilitate CCS projects where participating utilities, CO_2 pipeline transport, and sequestration sites involve multiple jurisdictions.

3.2 Transportation

3.2.1 Heavy-Duty Vehicle Equipment

Transborder freight transportation is a significant component of the economies of the WCI jurisdictions. U.S.-Canada surface transportation trade totalled $29.2 billion in May 2009. GHG emissions from heavy-duty trucks are increasing, along with emissions of carbon monoxide, nitrogen oxides and hydrofluorocarbons. Adopting regulations across jurisdictions will facilitate GHG reductions while transborder trading increases. Most trucks built during the last decade are equipped with a speed limiter – an integrated circuit that allows for regulating maximum vehicle speed. Policies could include the mandatory use of speed-limiting devices, equipment for aerodynamic efficiency, supporting the introduction of new energy-efficient and GHG-reducing technologies, and instituting an inspection and maintenance program for heavy-duty trucks in jurisdictions throughout the WCI jurisdictions and in other states and provinces.

Key issues to consider include the following:

- The burden posed by differing requirements on the majority of heavy-duty vehicles, which travel between states and provinces
- Trucks that do not operate in multiple jurisdictions
- Cost impacts of potential policies on individuals and small companies that own heavy-duty vehicles

Benefits to harmonizing. Harmonized policies would mitigate the challenges posed when emissions reduction measures for heavy-duty vehicles differ among states and provinces.

3.2.2 Electric and Alternative Fuel Vehicle Infrastructure

Development of electric and alternative fuel vehicle infrastructure can take a variety of forms including:

- Consumer outreach and education
- Direct purchases of charging stations and alternative-fuel refueling stations by businesses and local, state/provincial or regional governments
- Addressing utility system impacts
- Development and implementation of policies that streamline the permitting and installation of alternative fuel vehicle infrastructure
- Creation of grant, loan or loan guarantee programs to help finance infrastructure
- Enactment of tax incentives to reduce the cost to developers of installing infrastructure

Key issues to consider in developing programs to accelerate the deployment of alternative fuel vehicle infrastructure include:

- How to pay for infrastructure, including revenue-positive public and commercial cost models
- Electric system impacts
- Removing service provider disincentives to supplying additional electric load and alternative fuels through such means as providing additional emissions allowances
- Policies to ensure interoperability of refueling across utility service territories and jurisdictions
- Coordination of these programs with a regional low-carbon fuel standard, if implemented
- Whether public agencies should provide free electric vehicle charging
- Public and private partnerships
- Deployment simultaneously with (or in advance of) alternative-fuel vehicle sales
- Distance between stations for charging/fueling

Benefits to harmonizing. By coordinating the development of electric and alternative fuel vehicle infrastructure, the WCI jurisdictions could foster sufficient market penetration of electric and alternative fuel vehicles to attain significant reductions in GHG emissions, create jobs, foster economic growth, reduce reliance on foreign fuels and reduce air pollution.

3.3 Agriculture

3.3.1 Agricultural Anaerobic Digesters

Anaerobic digesters capture the gases created as agricultural waste materials break down into methane and CO_2. Anaerobic digesters:

- Capture methane, a potent GHG that would otherwise be released into the atmosphere
- Displace CO_2 emissions by producing carbon-neutral electricity, pipeline-quality natural gas, transportation and boiler fuels, feedstocks for commercial chemicals (such as ammonia and methanol), and digested fiber that can be used as a substitute for mined peat moss
- Provide a valuable economic resource to farmers through renewable energy production and cogeneration

Key issues to consider in harmonizing policies to facilitate on-farm anaerobic digesters are:

- The level of necessary capital investment and ongoing transaction costs as well as payback periods, which depend in part on:
    - The amount of financial assistance available
    - The rates available from electric and natural gas utilities for sale of digester-produced power and gas
- The ease with which small independent power producers are able to meet the interconnection requirements of electric and natural gas utilities
- The proportion of agricultural and non-agricultural wastes allowed on-farm by government agencies for the purpose of anaerobic digestion
- Environmental regulation by state and local governments
- Local government requirements on the movement of agricultural and non-agricultural waste
- The degree to which energy production is accepted as a normal farming practice by the public and relevant government agencies, including:
    - Whether there are special rules about what activities can take place on farmland
    - Whether energy production will remain ancillary to other types of agricultural production

Benefits to harmonizing. Anaerobic digestion offers significant potential for permanent, real, additional and verifiable GHG emissions reductions. Harmonizing anaerobic digestion policies by removing regulatory barriers and providing clarity and consistency in implementation of anaerobic digestion regulations would help states and provinces realize these reduction opportunities.

3.4 Waste

3.4.1 Landfill Methane Reduction

Methane gas from landfills is a significant source of GHG emissions due to its high global warming potential and the sheer number of landfills. According to Environment Canada, landfill emissions account for more than a quarter of the anthropogenic methane in the atmosphere.[33] Landfills generate methane as the anaerobic bacteria break down organic waste, a process that usually begins within the first year of landfill operation and can continue for 50 years after landfill closure.

The U.S. EPA defines "large" municipal solid waste landfills and requires that they collect landfill gas and combust it.[34] The regulations do not mandate secondary energy recovery processes. The B.C. Government passed a Landfill Gas Regulation under the Greenhouse Gas Reduction Statutes Amendment Act, which requires that by Jan. 1, 2016, all landfills that are above a certain size and methane threshold must install (and properly operate) landfill gas management facilities.[35]

Collected landfill gas can be used for electricity, heat production and other applications. Beneficial use of collected landfill gas offers potentially significant benefits including further reductions of GHG emissions by offsetting fossil fuels and producing energy from a renewable source. The EPA estimates that more than 450 municipal solid waste landfills in the U.S. operate landfill gas-to-energy programs, and approximately 520 more landfills could effectively do so, providing enough electricity to power 700,000 homes.[36] Environment Canada estimates that 600,000 homes could be powered by electricity generated from Canadian landfill gas sources.

The EPA operates a voluntary Landfill Methane Outreach Program (LMOP) to facilitate and provide assistance for landfill methane capture and conversion to energy. Canada and the U.S. participate in the Methane to Markets partnership with 28 other countries that have interest or expertise in developing methane projects.

Key issues to consider in developing programs to capture landfill methane include:

- Identifying the entire inventory of potential methane-generating landfills
- Closed landfills may be difficult to identify, but still have emissions
- The type of outreach and targeting needed to successfully maximize program participation and how to coordinate that effort regionally

[33] *See* "Harnessing the Power of Landfill Gas" at http://www.ec.gc.ca/Science/sandemay99/article1_e.html.
[34] *See* 2006 Standards of Performance for New Stationary Sources and Guidelines for Control of Existing Sources, and 2003 National Emission Standards for Hazardous Air Pollutants.
[35] *See* http://www.bclaws.ca/Recon/document/freeside/--%20e%20--/environmental%20management%20act%20%20sbc%202003%20%20c.%2053/05_regulations/28_391_2008.xml.
[36] *See Landfill Methane Outreach Program: Benefits of LFG Energy* at http://www.epa.gov/lmop/benefits.htm.

    - Targeting larger landfills that may qualify to participate in the LMOP but aren't yet taking action
    - Targeting a different population of landfills than federal programs
    - Quantifying the amount of methane produced to select target landfills using consistent procedures
- Funding of methane recovery projects, particularly for closed landfills or small municipal landfills
- Availability of electrical infrastructure and proximity of landfills to transmission lines
- Establishing effective and timely monitoring of landfill gas to identify problems or potential problems, including in the area between waste disposal sites and neighboring properties
- Difficulty of determining the percentage of landfill gas captured through a collection of wells and headers, with many uncertainties and variables
- Additional considerations that may explicitly address:
    - Organic waste diversion programs
    - Emission credits
    - Non-methane organic compounds (odors and air quality)

Benefits to harmonization. Reaching out to landfills not subject to U.S. or Canadian regulations could further reduce landfill methane emissions and encourage energy recovery. Guidance for outreach at the regional level – possibly modeled after EPA's Landfill Methane Outreach Program – would reduce the level of jurisdictional effort necessary and provide a consistent message for the goals, benefits and procedures for a program that reduces landfill methane emissions reduction and promotes electricity production from landfill gas.

4 Tier 3 Policies

4.1 Transportation

4.1.1 Vehicle Emissions Labeling

Emissions labels provide consumers with information on GHG emissions from vehicles. This approach has the potential to influence vehicle market decisions by providing information for consumers who might have a preference for purchasing vehicles with lower GHG emissions. Harmonizing the content of emissions labels would provide standardized information for consumers while reducing burdens for manufacturers and regulators.

4.1.2 Medium- and Heavy-Duty Vehicle Hybridization

Medium- and heavy-duty vehicles account for a significant portion of GHG emissions from the transportation sector. Hybridization reduces GHG and other emissions from these vehicles through greater fuel efficiency. Hybrid trucks and buses would likely achieve the greatest benefits in urban, stop-and-go applications, such as parcel delivery, transit and other short-range travel. A harmonized program of standards and incentives could help encourage a broader market for medium- and heavy-duty vehicle technology.

4.1.3 Transport Refrigeration Units

Transport Refrigeration Units (TRUs) are gasoline- or diesel-powered cooling units that are installed on containers used to transport produce, meat, dairy and other perishable goods. TRUs are capable of both cooling and heating and are found on refrigerated vans, trucks, trailers, railcars and shipping containers. Although TRU engines are relatively small, ranging from 9 horsepower to 36 horsepower, significant numbers of these engines congregate at distribution centers, truck stops and other facilities. Some companies use TRUs for extended cold storage and store overflow goods in TRU-equipped trucks and trailers for several weeks before holiday periods, or for more than a 24-hour period throughout the year. Harmonized policies and standards design would encourage more energy-efficient operations that reduce GHG emissions from systems using internal combustion engines. Harmonization also would encourage advancements in electrically-driven refrigeration systems and cryogenic systems.

4.2 Industrial Sector

4.2.1 Emissions Performance Standards for Major Industrial Sources

Emissions performance standards for industrial facilities would set a maximum level of GHG emissions per unit of product produced.[37] These standards would be established by sector, by product, or in some cases by industrial process within a sector.

[37] For example, tons of CO_2 equivalent emitted per unit of product produced at the facility. For energy-related emissions, both direct use of fossil fuels on-site as well as off-site production of electricity consumed at the plant would be included.

5 Important Policies Addressed in Other Venues

A comprehensive program to achieve significant GHG emissions reductions and transition to a low-carbon economy will require a broad range of actions and investments by business, consumers and all levels of government. In addition to the three tiers of policies discussed above, other important initiatives are being examined and developed in other venues. These policies are expected to make critical contributions to achieving the WCI Partner jurisdictions greenhouse gas reduction goals. These other polcies, not being evaluated by the Complementary Policies Committee, include the following:

- **Renewable portfolio standards in the electricity sector.** Already adopted by each of the WCI Partner jurisdictions, renewable portfolio standards direct retail electricity providers to generate or purchase a portion of their power from renewable sources. These requirements promote multiple objectives, including diversifying electricity supply and encouraging deployment of low-carbon technology in the electricity sector.

- **Energy efficiency standards for new buildings and appliances.** State and provincial building and appliance standards ensure that manufacturers and builders bring energy-saving products to market. These standards have proven to be highly effective for reducing energy consumption and GHG emissions. Moreover, their implementation in a similar manner across jurisdictions is key to building larger markets for energy-saving products and green building techniques. States and provinces regularly update building standards. Most of the WCI Partner jurisdictions have adopted residential and commercial building codes consistent with the 2006 model International Energy Conservation Code, which itself provides a degree of harmonization. Most appliance standards in the U.S. are set by the federal government, including recent updates under the Energy Independence and Security Act of 2007.

- **Smart grid infrastructure.** Smart grid infrastructure is under development in several of the WCI Partner jurisdictions in order to facilitate the dynamic transfer of information and electricity between the electric grid and retail customers. The smart grid will enable greater integration of intermittent renewable generation, demand-side resources and energy efficiency into the grid while improving reliability. This work is proceeding in the U.S. with assistance from the federal Department of Energy and funding from the American Recovery and Reinvestment Act of 2009. The National Institute for Standards and Technology is developing smart grid communication standards. The Western Electricity Coordinating Council is likely to have a role in developing harmonized standards for the western states and provinces.

- **Light-duty vehicle emissions standards.** In June 2009, EPA granted a waiver to California to proceed with implementation of its GHG emission reduction standards for new passenger cars, pickup trucks and sport utility vehicles beginning with the 2009 model year. This opened the way for the other 13 states and the District of Columbia that have adopted those standards to also proceed. Shortly thereafter, the Obama Administration announced its intent to adopt these emission standards at the national level.

- **Vehicle miles traveled reductions.** Several WCI Partner jurisdictions have undertaken initiatives to encourage reductions in vehicle miles traveled (VMT) by fostering transit-oriented development or integrating climate change into transportation and land use planning. VMT reductions can be an effective strategy to enhance mobility efficiency while reducing GHG emissions from the transportation sector.

- **Government leading by example.** Each WCI Partner jurisdiction has adopted goals or policies to save energy and reduce GHG emissions in its own operations. These policies build markets for low-GHG materials and equipment and set an important example for the private sector. By demonstrating exceptional emissions reductions in various areas, WCI Partner jurisdictions provide a laboratory for the development of innovative approaches.

- **Assistance for low-income households.** Results from the WCI economic analysis released in September 2008 indicate that the WCI emissions targets can be met through a broad-based cap-and-trade program and complementary policies with a net savings to the economy. However, the WCI Partner jurisdictions are committed to understanding and addressing potential impacts on low-income households that, for example, spend a relatively high portion of their income on energy. Each WCI Partner jurisdiction is examining how best to address this issue, relying on the programs and approaches most suitable to each Partner's circumstances.

Appendix 1: Complementary Policies: Capped vs. Uncapped Sources and Sectors

Table 1. Complementary Policies: Capped vs. Uncapped Sources and Sectors[38]

Policies to Reduce Emissions From Sources and Sectors Capped in 2012 *Energy Production* • Small-scale renewable energy resources (Tier 1) • Emissions performance standards for electric generating units (Tier 1) • Carbon capture and sequestration (Tier 2)
Energy Efficiency • Energy efficiency targets (Tier 1) • Energy efficiency programs and incentives (Tier 1)
Industrial Sector • Emissions performance standards for major industrial sources (Tier 3)
Policies to Reduce Emissions From Sources and Sectors Capped in 2015 *Transportation* • Low-carbon fuel standard (Tier 1) • Freight transportation infrastructure (Tier 1) • Development of algae and cellulosic biofuels (Tier 1) • Heavy-duty vehicle equipment (Tier 2) • Electric and alternative fuel vehicle infrastructure (Tier 2) • Vehicle emissions labeling (Tier 3) • Medium and heavy-duty vehicle hybridization (Tier 3) • Transport refrigeration units (Tier 3)
Policies to Reduce Emissions From *Uncapped* Sources and Sectors *High-Global Warming Potential Gases* • Regulatory measures for high-global warming potential gases (Tier 1)
Agriculture • Agricultural anaerobic digesters (Tier 2)
Waste Management • Measures for landfill methane reduction (Tier 2)
Policies adopted by jurisdictions outside the WCI region

[38]This table only includes policies the Committee will evaluate for further consideration; it does not include policy initiatives underway in other venues.

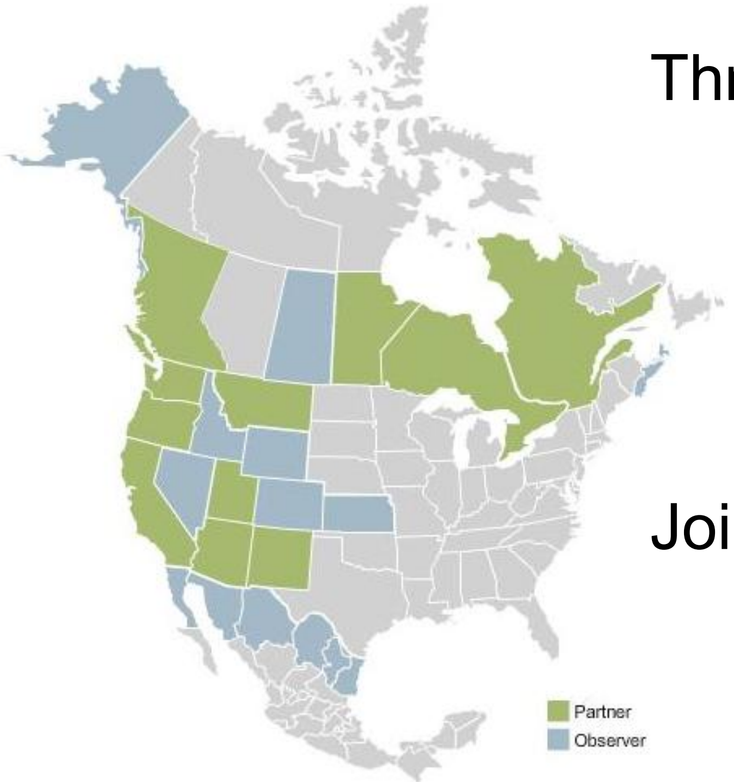
Complementary Policies Committee Draft White Paper

Stakeholder Presentation

December 7, 2009

Western Climate Initiative



Three specific directives:

- Set a regional emissions reduction goal
- Join a multi-state registry to track, manage and credit reductions
- Design a regional multi-sector market-based mechanism

Joint work to:

- Promote clean and renewable energy in the region
- Increase energy efficiency
- Advocate for regional and national climate policies that are in the interest of western states
- Identify measures to adapt to climate change impact

WCI Complementary Policies Committee

-Overview

Charged to recommend policies that:

- Would help achieve the regional emissions reduction goals and assist with the transition to a low-carbon economy if harmonized across multiple jurisdictions.
- Address market barriers to encourage low-cost GHG emission reduction options
- Reduce emissions from sources excluded from the cap-and-trade program.

WCI Complementary Policies Committee
-Overview

Complementary policies are designed to:

- Achieve reductions outside (or below) the cap
- Encourage investments in low-carbon technologies
- Lower the cost per metric ton of reductions in GHG emissions covered by the cap-and-trade program
- Lower the cost of transitioning to a low carbon economy
- Prevent emissions and economic leakage
- Create and retain clean energy jobs

WCI Complementary Policies Committee

Final Draft Complementary Policies White Paper | November 7, 2009 Page 1

How Complementary Policies Were Identified

- WCI Partner jurisdictions climate action plans
- The policies are grouped into three tiers to assist with scheduling the Committee's work.

WCI Complementary Policies Committee

-Draft White Paper

Policies were selected based on their ability to:

- Reduce GHG emissions
- Reduce costs associated with achieving the WCI goals for covered facilities
- Provide manageable administrative costs
- Mitigate impacts on low-income communities or small businesses
- Provide meaningful benefits from harmonization where there are not insurmountable barriers
- Achieve collateral benefits (e.g., conserving water)
- Avoid collateral detriments (e.g., increased use of electricity, increased fine particulates or air toxics pollution).
- Not encourage leakage outside the cap.
- Create or retain clean energy jobs or otherwise transition to a low-carbon economy.
- Provide electricity substitutes for higher GHG-emitting transportation fuels.

Tier 1 Policies

- Energy Production
  - Small-Scale Renewable Energy Resources
  - Emissions Performance Standards for Electric Generating Units
- Energy Efficiency and Conservation
  - Energy Efficiency Targets
  - Energy Efficiency Programs and Incentives

Tier 1 Policies

- Transportation
  - Low-Carbon Fuel Standard
  - Freight Transportation Infrastructure
  - Development of Algae and Ligno-Cellulosic Biofuels
- High-Global Warming Potential (GWP) Gases
  - Regulatory Measures for High-GWP Gases

Tier 2 Policies

- Energy Production
  - Carbon Capture and Sequestration
- Transportation
  - Heavy-Duty Vehicle Equipment
  - Electric and Alternative Fuel Vehicle Infrastructure
- Agriculture
  - Agricultural Anaerobic Digesters
- Waste
  - Landfill Methane Reduction

Tier 3 Policies

- Transportation
  - Vehicle Emissions Labeling
  - Medium- and Heavy-Duty Vehicle Hybridization
  - Transport Refrigeration Units
- Industrial Sector
  - Emissions Performance Standards for Major Industrial Sources

Important Policies Addressed in Other Venues

- Renewable portfolio standards in the electricity sector.
- Energy efficiency standards for new buildings and appliances.
- Smart grid infrastructure
- Light-duty vehicle emissions standards.
- Vehicle miles traveled reductions.
- Government leading by example.
- Assistance for low-income households.

WCI Complementary Policies Committee
-Draft White Paper

Feedback is sought on:

- The recommended evaluation criteria for complementary policies;
- The policies recommended for further evaluation;
- Key issues or barriers to harmonization; and
- The benefits that may accrue to jurisdictions and businesses that operate in more than one jurisdiction if implementation is harmonized.
- Input in how to engage stakeholders as evaluation process evolves

Additional policies for consideration:

- A description of the policy;
- The key issues to address or evaluate; and
- The potential benefits to harmonizing the policy across jurisdictions.

Draft Guidance for Developing WCI Partner Jurisdiction Allowance Budgets

November 25, 2009

Table of Contents

1 Purpose And Summary 1

2 Methodology For Calculating Preliminary Allowance Budgets 6

2.1 Preliminary Allowance Budget For 2012 6

2.2 Preliminary Allowance Budgets For 2013 And 2014 7

2.3 Preliminary Allowance Budget For 2015 7

2.4 Preliminary Allowance Budgets For 2016 Through 2020 8

3 Process For Reviewing, Finalizing, And Adjusting Allowance Budgets 8

3.1 Establishing Annual Budgets In 2010 8

3.2 Finalizing Annual Budgets Prior To The Start Of The First Compliance Period 10

3.3 Adjusting Annual Budgets Prior To The Start Of The Second And Third Compliance Periods 10

1 Purpose And Summary

The purpose of this document is to provide guidance for calculating, establishing, and reviewing annual allowance budgets for the WCI Partner jurisdictions, the sum of which is the regional cap. The *Design Recommendations for the WCI regional Cap-and-Trade Program* describe conceptually how these budgets should be developed.[1] Recognizing, however, that further technical analysis and regional coordination would be needed to develop the budgets properly and consistently across jurisdictions, the *WCI 2009-10 Work Plan* established the Cap Setting and Allowance Distribution (CSAD) Committee and charged the Committee with, among other things, proposing a methodology and/or guidelines for establishing and periodically reviewing Partner allowance budgets.[2]

The WCI Partner jurisdictions believe there is great value in developing a budget-setting process in advance of when budgets must be established and with public knowledge of how the process will be conducted. For this reason, the CSAD Committee is releasing this draft guidance well ahead of when allowance budgets must be established, recognizing that changes to the method or process described within this guidance may be necessary in response to federal developments, state and provincial implementation schedules, availability and results of mandatory reporting data, and updated emission inventories and forecasts.

The objectives of this guidance are to:

- Describe the responsibilities of WCI Partner jurisdictions, the CSAD Committee, and WCI contractors in the process of developing allowance budgets;
- Promote consistency across WCI Partner jurisdictions in establishing allowance budgets;
- Provide transparency to the budget-setting process such that WCI Partner jurisdictions and the public can be confident that budgets were determined correctly and fairly; and
- Establish a timeframe for the budget-setting process to work in concert with the development of jurisdictional regulations and the emergence of an allowance market.

The guidance is organized into three major sections, as follows:

---

[1] See http://www.westernclimateinitiative.org/the-wci-cap-and-trade-program/design-recommendations
[2] See http://www.westernclimateinitiative.org/component/remository/general/workplans/, CSAD Tasks 2.2 – 2.4.

Section 1

- Summarizes the proposed major activities, outcomes, and milestones for developing and reviewing allowance budgets, beginning with the calculation of preliminary allowance budgets by each Partner jurisdiction (Table 1);
- Shows how those budgets are calculated (Figure 1); and
- Provides a hypothetical illustration of a WCI Partner jurisdiction allowance budget (Figure 2).

Section 2

- Recommends the method for each WCI Partner jurisdiction to calculate preliminary allowance budgets.

Section 3

- Recommends an approach for establishing allowance budgets from the preliminary budgets; and
- Describes a process to finalize Partner budgets prior to the start each compliance period.

The guidance recognize the major factors in, and the procedures for, developing allowance budgets. They do not address how allowances within the budget may be distributed – for example, to address competitiveness and leakage issues – or seek to resolve all outstanding technical issues or policy decisions likely to have an effect on the allowance budgets, such as the best estimate of capped-source emissions in 2012 and 2015 or the results of the one-percent budget adjustment for 2012. The guidance identifies where such data and policy decisions would be incorporated into the calculation of allowance budgets and provides a roadmap for coordinating regional efforts over the course of the program.

Finally, the role of the CSAD Committee in the process of developing, reviewing, and finalizing allowance budgets is noted in several places in this guidance. Since the process would extend over several years, it is possible that the Committee's role may be filled by another regional committee or forum (e.g., a regional administrative organization) rather than the CSAD Committee in its current form.

The Committee will host a stakeholder conference call on this guidance on Tuesday, December 15 at 10:30 a.m. Pacific Standard Time (800-868-1837, participant code 659537#). Written comments can also be provided via the WCI website. Comments should be provided by Wednesday, January 13, 2010.

Table 1. Summary Of Budget Development And Review Process.

	Activity	Completion	Outcome	Purpose
Section 2	• Each Partner calculates a preliminary allowance budget, based in part on emission forecast methods developed by CSAD contractor. (See Figure 1.)	Q1 2010	Preliminary budgets	Form a consistent starting point to develop budgets that meet Partner and regional goals.
Section 3.1	• Partners present preliminary budgets and supporting information. • CSAD conducts a first review of budgets/info for consistent application of guidance and makes recommendations to improve. • Partners review recommendations and incorporate as appropriate. • CSAD conducts a second review of budgets/info and makes final recommendations. • Partner jurisdictions establish budgets, including any potential adjustments to address electricity generated in one jurisdiction but consumed in another.	Summer 2010	Established budgets	Basis for developing jurisdictional rules. Provide early and reliable market signal. Support any pre-2012 auctioning.
Section 3.2	• Partners inform CSAD of any adjustments to established budgets. • CSAD reviews emissions reporting and other data and makes recommendations for Partners' consideration. • Partner jurisdictions finalize budgets.	Q4 2011	Final budgets	Account for final program rules and available emissions and market data. Increase allowance market certainty, enable full distribution of allowances.
Section 3.3	• Similar process to above, but include assessment of the program's progress.	Summer 2014	Revised final budgets	Account for new data, program changes, and program performance.
	• Same process as in 2014.	Summer 2017	Revised final budgets	Account for new data, program changes, and program performance.

Figure 1. Calculation Of A Preliminary Allowance Budget.

2012 = 2012 emissions forecast for Phase I sources, determined with CSAD contract support to account for:

- Population growth*
- Economic growth*
- Mandatory emissions reductions*

"Best Estimate"

\+ 2012 forecast adjustments, determined by Partner jurisdictions to account for:

- Voluntary emissions reductions*
- Shut-down sources
- New sources

\+ 1 percent, 1 time adjustment

\+ Early Reduction Allowances to be awarded to emitters in accordance with Section 8.11 of the *Design Recommendations*

2013 = 2012 best estimate + 1 time adjustment - ROD_1

2014 = 2013 preliminary budget - ROD_1

2015 = 2014 preliminary budget - ROD_1 + 2015 best estimate of Phase II sources

2016 = 2015 - ROD_2

2017 = 2016 - ROD_2

2018 = 2017 - ROD_2

2019 = 2018 - ROD_2

2020 = 2019 - ROD_2

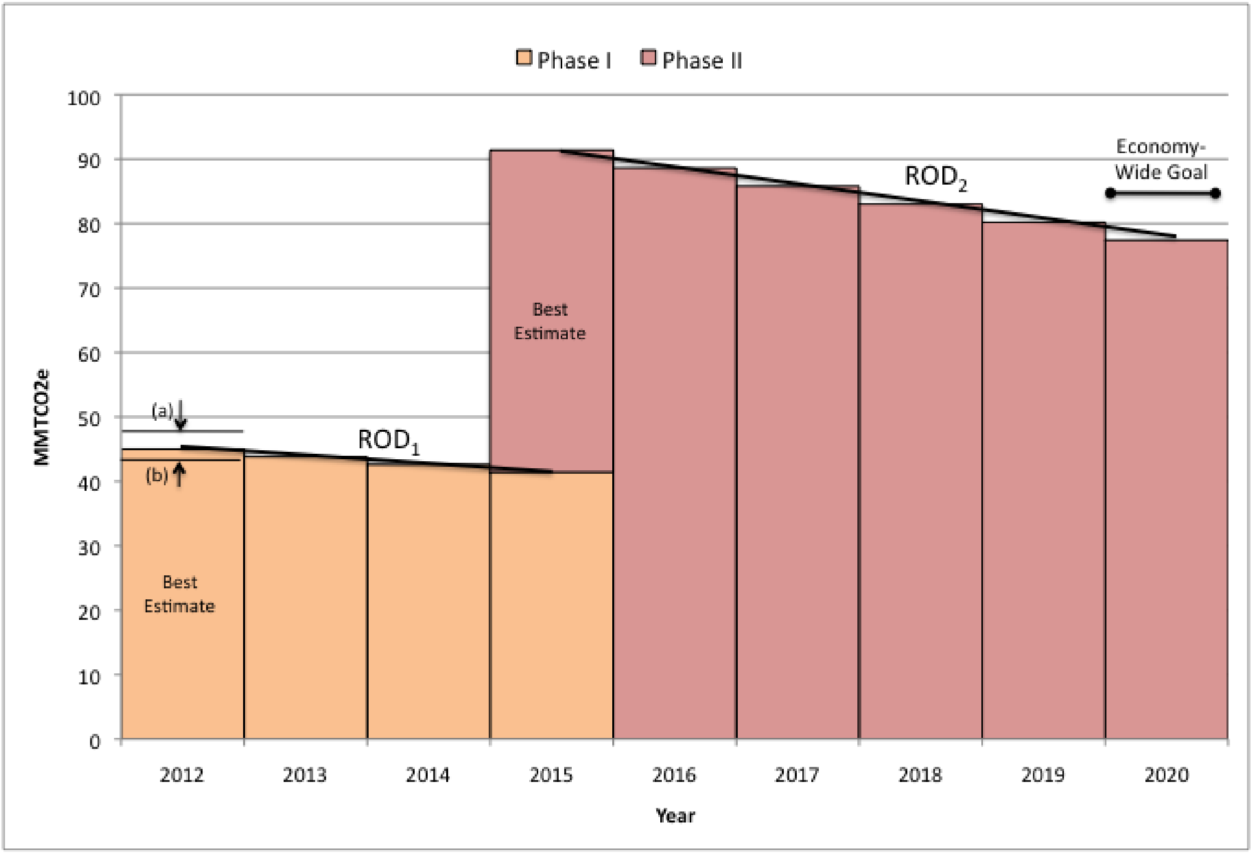
---

* = Factors also used to determine the 2015 best estimate for Phase II sources

ROD_1 = Rate of decline (in $MMTCO_2e$ per year) during Phase I

ROD_2 = Rate of decline during Phase II

Figure 2. Hypothetical Illustration Of A WCI Partner Jurisdiction Allowance Budget.



2 Methodology For Calculating Preliminary Allowance Budgets

2.1 Preliminary Allowance Budget For 2012

1. The Partner jurisdiction will calculate the best estimate of expected emissions for sources covered in the cap-and-trade program in the Partner's jurisdiction in 2012, accounting for population growth, economic growth (including new and shut-down sources), and voluntary and mandatory emission reductions through 2012. The best estimate will be an outcome of each Partner's application of the forecast methods developed by the CSAD Committee and contractor and is shown as the first colored bar in Figure 2. For the purpose of determining the best estimate of 2012 emissions:

    a. New sources are sources which are not included in the Partner jurisdiction's emission inventory but are expected to be emitting covered GHGs prior to January 1, 2013. The Partner jurisdiction will estimate, using any methods developed by the Committee to promote consistency, covered emissions from new sources and include these emissions in its 2012 best estimate.

    b. Shut-down sources are sources which are included in the Partner jurisdiction's emission inventory but are expected to be permanently shut down prior to January 1, 2012. The Partner jurisdiction will remove covered emissions from shut-down sources from its 2012 best estimate.

    c. Voluntary emission reductions are the emissions avoided in 2012 as a result of consumers or sources taking action which reduces GHG emissions and is not required by law or regulation. Such action must occur prior to 2012 and should have permanent emission benefits (e.g., persisting until 2020).[3] Voluntary emission reductions must include any reductions at sources which may be awarded with Early Reduction Allowances (ERAs) in accordance with Section 8.11 of the *Design Recommendations*.

2. The Partner jurisdiction will calculate the one-time, one-percent budget adjustment for 2012. This adjustment is the subject of Task 4 of the CSAD Committee and will be

[3] Actions first taken in 2012 can not necessarily be considered voluntary when Phase I producers are subject to the cap and when consumers face the cap's consequent price increase.

determined separately. If the one-time adjustment results in a greater amount of allowances for the Partner jurisdiction, then the 2012 preliminary budget will increase towards line (a) in Figure 2. If the one-time adjustment results in a lesser amount of allowances, then the 2012 preliminary budget will decrease towards line (b) in Figure 2.

3. The Partner jurisdiction will calculate the quantity of ERAs to be distributed to sources in accordance with Section 8.11 of the *Design Recommendations*. This quantity will increase the 2012 preliminary allowance budget towards line (a) in Figure 2.[4]

4. The Partner jurisdiction will calculate its 2012 preliminary allowance budget as the 2012 best estimate, plus (or minus) the one-time budget adjustment, plus the ERAs to be distributed to sources.

2.2 Preliminary Allowance Budgets For 2013 And 2014

1. The Partner jurisdiction will determine a rate of decline for the first phase of the cap-and-trade program (ROD_1). ROD_1 shall be expressed in units of million metric tons of CO_2 equivalents ($MMTCO_2e$) per year and shall be greater than zero.[5]

2. The Partner jurisdiction will calculate its 2013 preliminary allowance budget as the 2012 best estimate minus ROD_1.

3. The Partner jurisdiction will calculate its 2014 preliminary allowance budget as the 2013 preliminary allowance budget minus ROD_1.

2.3 Preliminary Allowance Budget For 2015

1. The Partner jurisdiction will calculate its 2015 preliminary allowance budget as the sum of the 2014 preliminary allowance budget minus ROD_1 plus the 2015 best estimate of expected emissions for sources first covered in the cap-and-trade program in the

---

[4] Early reductions are voluntary and, as such, should be included in, and therefore reduce, the 2012 and 2015 best estimates. This is important to assure that the distribution of ERAs does not create a surplus in the allowance market.

[5] The purpose of ROD_1 (and ROD_2 below) is to ensure, as stated in the Design Recommendations, that the trajectory for each WCI Partner jurisdiction's annual allowance budget for covered sectors will be a straight line from the year of initial coverage to 2020. This is the only way to ensure for planning purposes that the 2020 reduction goal is met. However, the actual annual trajectories of jurisdictional emissions and allowance distribution to specific sources will not necessarily follow a straight line reduction trajectory. For instance, any given Partner jurisdiction's emission reduction trajectory will depend on regional trading and the use of offsets by covered sources. In addition, the three-year compliance periods will allow covered sources to reduce emissions at various rates across the three-year period.

Partner's jurisdiction in 2015, accounting for population growth, economic growth, and voluntary and mandatory emission reductions. The best estimate of 2015 emissions will be an outcome of each Partner's application of the forecast methods developed by the CSAD Committee and contractor and is shown as the top half of the 2015 bar in Figure 2. For the purpose of determining the best estimate of 2015 emissions:

a. Voluntary emission reductions are the emissions avoided in 2015 as a result of consumers or sources taking action which reduces GHG emissions and is not required by law or regulation. Such action must occur prior to 2015 and should have permanent emission benefits (e.g., persisting until 2020). Voluntary emission reductions must include any reductions which may be awarded with Early Reduction Allowances (ERAs) in accordance with Section 8.11 of the *Design Recommendations*.

2.4 Preliminary Allowance Budgets For 2016 Through 2020

1. The Partner jurisdiction will determine a rate of decline for the second phase of the cap-and-trade program (ROD_2). ROD_2 shall be expressed in units of $MMTCO_2e$ per year. ROD_2, in conjunction with any reductions in non-covered emissions in the Partner's jurisdiction, shall be sufficient to achieve the Partner jurisdiction's 2020 economy-wide goal.

2. The Partner jurisdiction will calculate its preliminary allowance budgets for 2016 through 2020 by subtracting its ROD_2 from the prior year's preliminary allowance budget, starting with 2016 and continuing to 2020.

3 Process For Reviewing, Finalizing, And Adjusting Allowance Budgets

3.1 Establishing Annual Budgets In 2010

The purpose of this process is to compile and harmonize preliminary allowance budgets as much as possible for Partner consideration, revision, and agreement. The outcome of this process will be an "established budget" for each Partner jurisdiction in the summer of 2010.

The established budgets are intended to (a) provide a basis for each Partner jurisdiction in developing its regulations implementing the regional cap-and-trade program and (b) provide an early and reliable indication of the supply of allowances in the regional marketplace. Although established budgets may be revised when finalized prior to the start of the first compliance period (see Section 3.2), the limited and specific conditions under which such revisions would occur should preserve the value of established budgets as an early and reliable market signal.

1. The Partner jurisdiction will provide to the CSAD Committee:

    a. A preliminary allowance budget for each year in the period 2012-2020.
    b. A ROD for each phase of the cap-and-trade program.
    c. An explanation of how the RODs were determined.
    d. A presumptive ROD_1, determined as the product of:
        i. the ROD resulting from a straight-line reduction from the 2012 best estimate of Phase I and Phase II source emissions to the 2020 preliminary budget, and
        ii. the ratio of the best estimate of Phase I source emissions to the best estimate of Phase I and II source emissions in 2012.
    e. A best estimate of economy-wide emissions in 2005 and 2020, assuming emissions from capped sources in 2020 are equivalent to the preliminary budget for 2020.[6]

2. The Committee will compile and review the jurisdictional preliminary budgets and recommend changes for maintaining a regionally-consistent approach to achieving the regional goal.

3. The Partner jurisdiction will review recommendations and incorporate as appropriate, informing the Committee of any changes to its preliminary budget.

4. The Committee shall compile and review the jurisdictional preliminary budgets, including any revised preliminary budgets provided under 3 above, and recommend changes which may be important for maintaining a regionally-consistent and approach to achieving the regional goal.

5. Each Partner representative will seek the appropriate approvals from their respective jurisdictional authorities for a Partner's established budget after considering the compiled preliminary budgets and any changes recommended by the Committee. The established budget shall include any potential adjustments which are part of an equitable solution to electricity generated in one Partner jurisdiction but consumed in another.

[6] In British Columbia, the emissions from transportation and residential, commercial, and industrial fuels will be covered by a carbon tax in lieu of a cap. The carbon tax will be integrated with the cap-and-trade program.

3.2 Finalizing Annual Budgets Prior To The Start Of The First Compliance Period

The purpose of this process is to adjust, where necessary and according to Section 7.4 of the *Design Recommendations*, the established budgets from 2010. The outcome of this process will be a "final budget" for each Partner jurisdiction in autumn of 2011.[7]

1. The Partner jurisdiction will identify and inform the Committee of any potential changes to its established budget resulting from each of the following conditions:

    a. Changes in WCI membership.
    b. Changes in scope or threshold of the WCI regional program design.
    c. Differences in scope or threshold between the jurisdiction's final regulations and the sources included in the 2012 and 2015 best estimates.
    d. Incorrect or inaccurate data that were used to determine the established budgets of 2010, including new and permanently shut down sources not identified in Section 2.1.

2. The Committee will obtain from the WCI Regional Emissions Database the 2010 mandatory reporting data for capped sources in each Partner jurisdiction. The Committee will compare these data to the 2012 and 2015 best estimates of Phase I and Phase II sources and Partner allowance budgets, evaluate the necessity of any changes to the established budgets (taking into consideration the information identified in Section 3.2.1), and provide the Partner representatives with a summary of this evaluation.

3. Each Partner representatives will seek the appropriate approvals from their respective jurisdictional authorities for a Partner's final budget after considering the Committee's evaluation.

3.3 Adjusting Annual Budgets Prior To The Start Of The Second And Third Compliance Periods

The purpose of this process is to adjust, where necessary and according to Section 7.4 of the *Design Recommendations*, the budgets for Phase II of the program finalized in 2011. The

[7] This date would allow time for submittal and review of the mandatory reporting data collected according to the WCI essential requirements, which would first be submitted to the Partner jurisdictions by April 1, 2011 and verified by September 1, 2011.

potential outcome of this process would be a “revised final budget” for one or more Partner jurisdiction in the summers of 2014 and 2017.[8]

1. The Partner jurisdiction will identify and inform the Committee of any potential changes to its final budget resulting from each of the following conditions:

    a. Changes in WCI membership.
    b. Changes in scope or threshold of the WCI regional program design.
    c. Changes in scope or threshold of the jurisdiction’s regulations.
    d. Incorrect or inaccurate data that were used to determine the final budgets of 2011.

2. The Committee will obtain from the WCI Regional Emissions Database all available mandatory reporting data for capped sources in each Partner jurisdiction. The Committee will use these (and potentially other) data to assess the progress of the regional cap-and-trade program, the necessity of any changes to budgets in Phase II of the program (taking into consideration the information identified in Section 3.3.1), and provide the Partner representatives with a summary of this evaluation.

3. Each Partner representatives will seek the appropriate approvals from their respective jurisdictional authorities for a Partner’s budget after considering the Committee’s evaluation.

---

[8] Adjustments for Phase II budgets can occur earlier in the year than adjustments for Phase I budgets because verified data may be submitted earlier than September 1 for reporting years 2012 and later and because more mandatory data will be available in 2014 and 2017 than in 2011.

Draft Guidance for Developing WCI Partner Jurisdiction Allowance Budgets

An overview presented to stakeholders on December 15, 2009

Purpose of Document

- Provide guidance for calculating, establishing, and reviewing annual allowance budgets for the WCI Partner jurisdictions, the sum of which is the regional cap

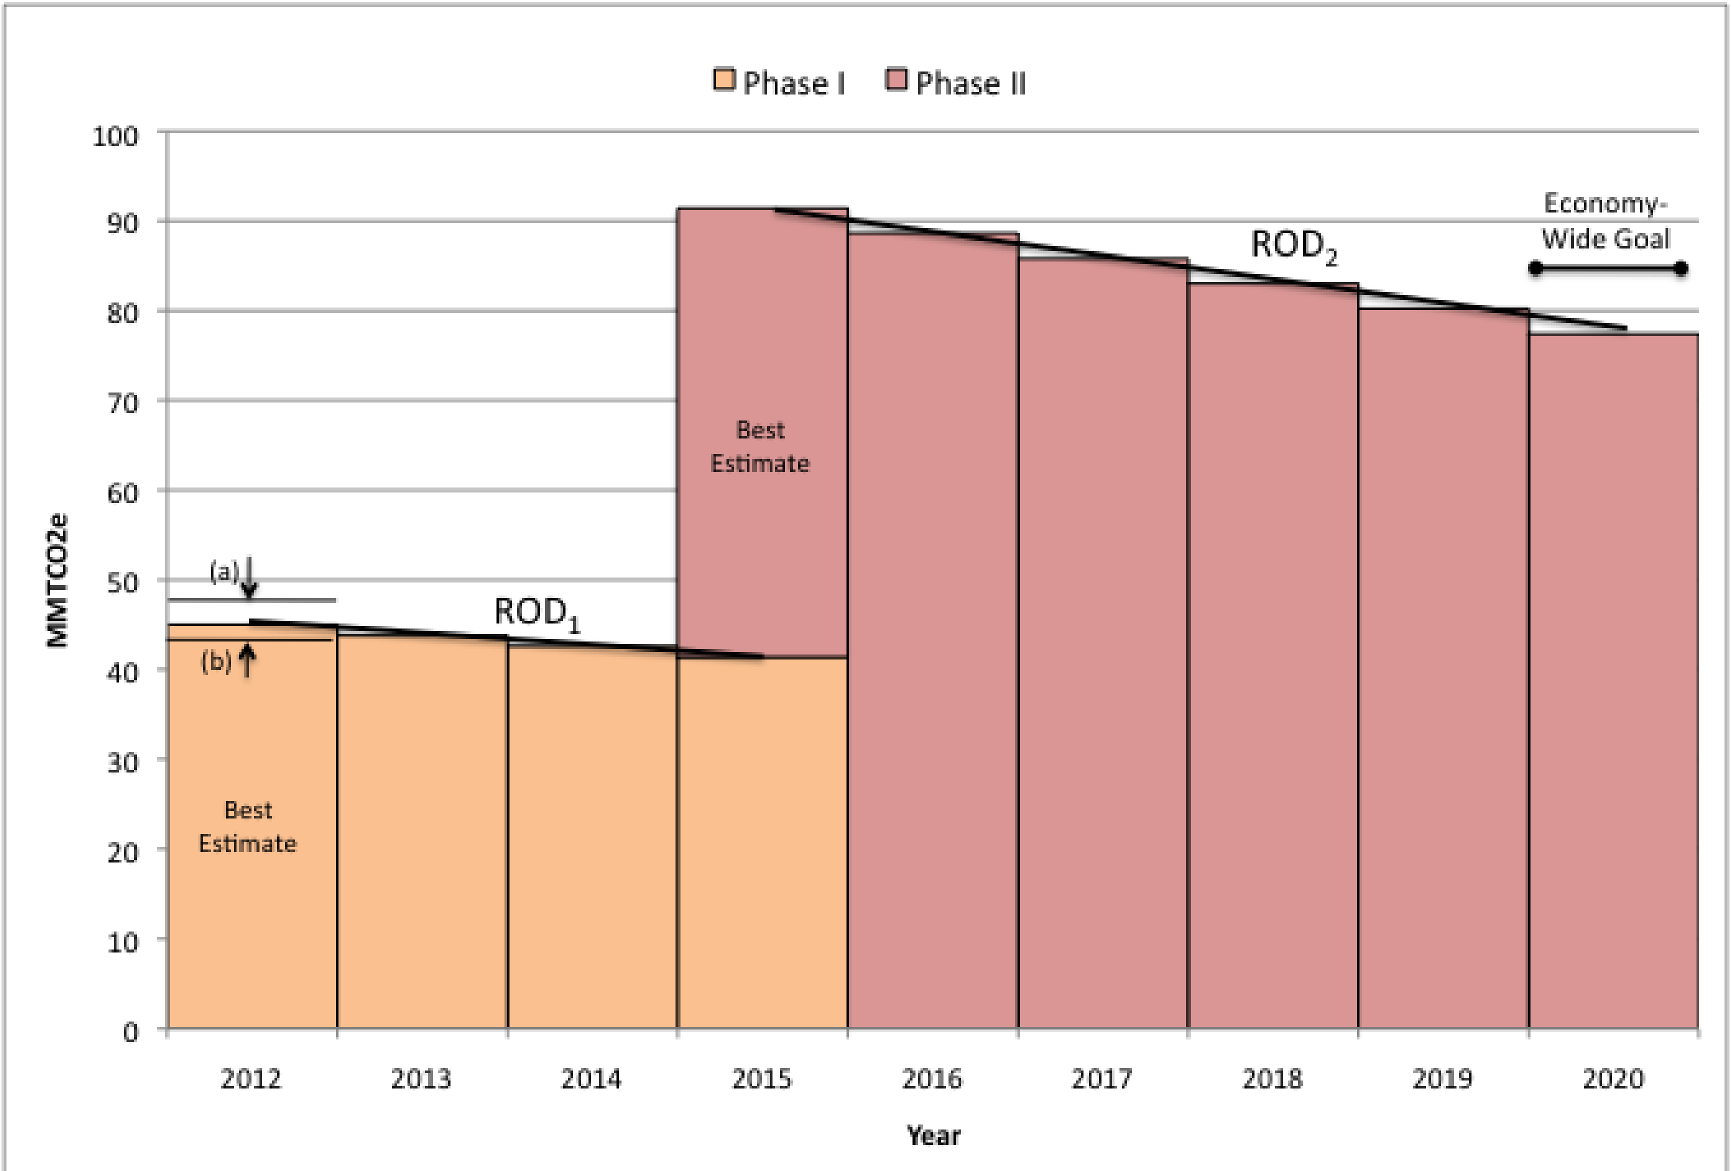
Objectives of the Guidance

- Describe roles and responsibilities of parties
- Promote consistency in establishing budgets across Partner jurisdictions
- Provide transparency to the budget-setting process
- Establish a timeframe for the process

Section 2 of the Guidance

- Methodology for calculating preliminary budgets
  - Consistent starting points for developing budgets that meet Partner and regional goals
- Best estimate of actual emissions from covered sources in 2012 and 2015 form the starting points of the annual budgets
- Rate of decline (ROD) forms the basis of subsequent year budgets
  - Determined individually by Partners to meet jurisdictional GHG reduction goals

Hypothetical Illustration of a WCI Partner Jurisdiction Allowance Budget



Section 3 of the Guidance

- Process for reviewing, finalizing, and adjusting budgets over time
- Budgets "established" in summer of 2010
- Budgets reviewed and finalized in fall of 2011
  - Adjusted as necessary to account for changes in WCI membership, changes in scope or threshold, or incorrect or inaccurate data used to establish budgets in 2010
- Budgets reviewed and revised as necessary in summers of 2014 and 2017 (essentially same criteria as above)

The Guidance Does Not …

- Specify numeric budgets or require Partner jurisdictions to follow a specific procedure in establishing them
  - But it does provide a coordinated, transparent path
- Indicate how allowances should be distributed to emitters (or others) from within a jurisdiction’s budget
  - But it does allow for harmonized methods among jurisdictions to address regional competitiveness, etc.

Next Steps

- Written comments should be provided via the WCI website by January 13, 2010
- CSAD Committee will continue collecting emissions data and developing forecast methods to support the best estimates of 2012 and 2015

California Air Resources Board Issues Preliminary Draft Cap and Trade Regulation

On November 24, 2009, the California Air Resources Board released a preliminary draft version of its greenhouse gas cap-and-trade regulation. This marks the beginning of the next phase of cap and trade rulemaking under AB32, the California Global Warming Solutions Act of 2006, which establishes a comprehensive program to achieve real, quantifiable, and cost-effect reductions of greenhouse gas emissions.

California collaborated with the other Partner jurisdictions in the Western Climate Initiative and solicited diverse stakeholder input to create a program with broad appeal. The program is designed to drive innovation and use market forces to find least-cost solutions to reducing greenhouse gas emissions. The proposed cap and trade program would cover 85 percent of California's emissions, including electricity generation, large industrial sources, transportation fuels, and residential and commercial use of natural gas and propane.

Once adopted, California's cap and trade program will link with of the collaborative is to expand discussion beyond the first jurisdictional approach to include how the industry may be affected by federal policy and other state/regional actions. Stakeholders are invited to attend in-person or via teleconference. To join by teleconference, dial 1-800-868-1837 (toll free), participant code 659537#. The agenda will be posted to the website and distributed via the WCI list server when available.

February 4, 2010: Stakeholder Update Call

The next WCI update call will be on February 4 at 12:30 p.m. Pacific. To join by teleconference, dial 1-800-868-1837 (toll free), participant code 659537#.

similarly rigorous programs implemented by partners of the Western Climate Initiative and include a stringent declining emissions cap along with trading and the limited use of offsets to provide flexibility for covered entities to comply. For more information, click here.

Québec Sets Ambitious Greenhouse Gas Emissions Reduction Target

On November 23, 2009 Premier Jean Charest and Minister of Sustainable Development, Environment and Parks, Line Beauchamp, unveiled a target to reduce GHG emissions by 20% below 1990 levels by 2020, a goal similar to the target established by the European Union. Nearly half of Québec's energy comes from renewable resources, and its industrial sector has already reduced emissions 7% below 1990 levels despite a 41% increase in GPD over the same period. At 11 tonnes per capita, Québec 's energy intensity is half the Canadian average. Québec 's energy intensity will become the lowest in North America under its new target. As part of its reduction strategy, the Québec government will soon be introducing light-duty vehicle emission standards equivalent to those in California. For more information, click here.

British Columbia Take Further Steps Towards Cap and Trade

On November 25, 2009, Environment Minister Barry Penner announced a new provincial regulation effective January 1, 2010 that will require all facilities in BC that emit over 10,000 tonnes of CO2e annually to publically report their emissions. It is expected that approximately 200 facilities will be required to report annually under this regulation. The regulation has been designed to allow for a single reporting window with Environment Canada and for reporting simplicity for the regulated entities. The regulation is also consistent with the WCI Essential Requirements for Mandatory Reporting and will facilitate the participation of BC in the regional cap-and-trade program. For more information click here.

Ontario Paves the Way for Cap and Trade System

Ontario's enabling legislation on cap and trade, the Environmental Protection Amendment Act (Greenhouse Gas Emissions Trading), was passed by the Ontario Legislature on December 3, 2009. The legislation, introduced by Ontario Environment Minister John Gerretsen earlier this year, provides the foundation to implement a cap and trade program in Ontario that can link to other jurisdictions and help industry reduce greenhouse gas (GHG) emissions at lowest cost.

The Ontario government also released a new reporting regulation and guideline on December 1, 2009 - another critical element to support the implementation of cap and trade and Ontario's participation in the Western Climate Initiative. The regulation comes into force on January 1, 2010 and specifies requirements for industry to report their GHG emission data to the government and public. The government anticipates that between 200 to 300 facilities will be affected. They will start reporting their 2010 emissions in 2011.

Ontario also released its second annual report which provides a comprehensive update on all the activities which Ontario has taken and the progress which has been made in 2008-09 towards achieving its GHG reduction targets.

WCI Markets Committee Issues Market Oversight White Paper

WCI's Market Oversight White Paper is the next step in developing recommendations for the architecture and oversight of its allowance and offset credit markets. It defines market architecture and oversight, and describes existing financial markets. It discusses market participation and types of transactions. It also briefly reviews market oversight in the U.S. and Canada, and oversight of the European Union's Emissions Trading Scheme, as well as proposals for carbon market oversight and financial market reform in the U.S. federal government. A stakeholder call was hosted by the Committee on December 2 to discuss the white paper. Written comments may be provided through December 18 via the WCI website.

WCI Complementary Policies Committee Issues White Paper

WCI's Complementary Policies Committee has begun to identify and evaluate policies that may address market barriers that can limit the use of low-cost GHG emission reduction options and examine opportunities to reduce emissions from a variety of sources, including from sources not covered by the cap-and-trade program. The Committee will recommend to the WCI Partner jurisdictions those policies which, if harmonized across multiple states and provinces - both within and outside the WCI Partner jurisdictions, would help achieve the regional emissions reduction goal and assist with the transition to a low-carbon economy. Stakeholder input on the white paper is sought on:

- The recommended evaluation criteria for complementary policies;
- The policies recommended for further evaluation;
- Key issues or barriers to harmonization; and
- The benefits that may accrue to jurisdictions and businesses that operate in more than one jurisdiction if implementation is harmonized.

A webinar to review and discuss the white paper was hosted by the Committee on December 7. Written comments can be submitted via the WCI website through January 29, 2010.

WCI Cap Setting & Allowance Distribution Committee Issues Draft Guidance for WCI Partner Jurisdiction Allowance Budgets

The WCI Partners believe there is value in developing a budget-setting process prior to establishing budgets. For this reason, the CSAD Committee is releasing this document to provide guidance for calculating, establishing, and reviewing annual allowance budgets for the WCI Partner jurisdictions ahead of when allowance budgets must be established, recognizing that changes to the method or process described within the guidance may be necessary in response to federal developments, results of mandatory reporting requirements, etc. A webinar to review and discuss the draft guidance will be hosted by the Committee on December 15 at 10:30 a.m. Pacific. Written comments can be submitted via the WCI website through January 13, 2010.

Harmonization of WCI Reporting Program with EPA Mandatory Reporting Rule

WCI Partner jurisdictions are currently in the process of adopting rules to implement the WCI's final Essential Requirements for Mandatory Reporting (ERs), which were issued on July 16, 2009. On September 22, 2009, U.S. EPA adopted its final Mandatory Reporting Rule (MRR) for greenhouse gas (GHG) emissions. Both programs require the filing of initial reports in 2011 for the 2010 reporting year. Many U.S. facilities in the WCI region will be subject to both reporting programs.

In order to avoid the imposition of duplicative or conflicting reporting obligations on facilities subject to both programs, the WCI Partners have directed the Reporting Committee to amend WCI's ERs to achieve harmonization with the EPA MRR. The harmonization effort will be guided by the following principles:

- A U.S. facility should be able to comply with both the MRR

and a WCI jurisdiction's reporting requirements by following a single set of monitoring, recordkeeping and reporting requirements.
- The quantification methods included in the amended ERs must be sufficiently reliable and accurate to be employed in a (GHG) cap and trade program. Because EPA has acknowledged that it did not develop the MRR with this goal in mind, the Reporting Committee must review each method included in the MRR to assure it meets this criterion.
- The amended ERs must remain suitable for use in Canadian WCI jurisdictions. For example, they must allow reporting in metric as well as English units and must where necessary include Canada-specific emission factors.

The WCI Partners recognize that the detailed analysis, redrafting and stakeholder review required to harmonize the existing WCI ERs with EPA's MRR cannot be accomplished in time for the 2010 reporting year. As an interim measure, the U.S. WCI Partner jurisdictions intend to include in their rules a provision that will allow facilities to comply with the jurisdiction's reporting rules for the 2010 reporting year by submitting a copy of the reports they file with EPA under the MRR. Although this approach may result in some inconsistencies in the data submitted for 2010, the Partners believe that is preferable to the potential imposition of duplicative or conflicting reporting obligations.

The WCI is also engaging with Environment Canada to harmonize reporting requirements.

The WCI's goal is to adopt ER amendments that achieve consistency across the region and with the MRR in time for the 2011 reporting year. Further details on the Reporting Committee's workplan to harmonize reporting requirements is available here.

Electricity Team Takes Steps to Improve Quantification of Imported Power

Through a contract with Open Access Technology International (OATI), the WCI Electricity Team has initiated an effort to collect and analyze data on power imports into each western WCI Partner jurisdiction during the period 2005-2008. When coupled with emission factors currently under development by the Electricity Team, these data will lead to quantitative estimates of emissions from historical electricity imports. Quantifying these emissions is an important step in establishing a cap which includes these emissions starting in 2012, as called for by the *Design Recommendations for the WCI Regional Cap-and-Trade Program*. The Electricity Team is receiving technical support from OATI to quantify power imports into WCI Partner jurisdictions in the Western Interconnection. Options to quantify power imports into Manitoba, Ontario, and Québec are currently under consideration.

Regional GHG Initiatives Hold Second Meeting

State and Provincial representatives of the three regional GHG initiatives met for the second time on November 9 in Washington, D.C. to continue sharing information on the status of their initiatives. Representatives of the Western Climate Initiative, Midwestern Greenhouse Gas Reduction Accord, and the Regional Greenhouse Gas Initiative discussed plans to collaborate in three specific areas - offsets, complementary policies, and identifying issues that would have to be addressed if the regions were to link their programs.

The group also discussed state roles under various federal action scenarios. This included meeting with EPA officials to discuss a plan for ongoing interaction with states as federal climate change programs are designed and implemented.

In a briefing hosted by the Senate Energy and Energy Resources Committee that afternoon, the three regional groups reiterated their support for federal action to implement comprehensive and rigorous programs to reduce greenhouse gases. The groups stated their intention to continue moving ahead with the development and implementation of their programs while working with Congress, EPA, and other federal agencies to ensure appropriate and effective state roles in the implementation of emerging federal programs and regulations. A video of the Senate Energy and Natural Resources Committee briefing is available here.

Presentations Available from November Partner Meeting and Oil & Gas Industry Collaborative

Material from the November 18 Partner meeting and November 19 oil and gas industry collaborative are available on the WCI website.

Presentations Available from Competitiveness Webinar

On November 12, the WCI Cap Setting & Allowance Distribution Committee hosted a webinar on competitiveness. Representatives from the European Commission and World Resources Institute presented the policies being developed for addressing competitiveness concerns of energy-intensive, trade-exposed industries, as well as the process for engaging industry in climate policy developments under the EU-ETS and proposed U.S. legislation. Their presentations are available on the WCI website.

Annex: Optional VRE Set aside Language in RGGI Model Rule 30

1 Executive Summary

Voluntary purchases of renewable energy products have played an important role in expanding the renewable energy market in many WCI jurisdictions. However, the voluntary renewable energy (VRE) market may be impacted by the implementation of a greenhouse gas cap-and-trade program. The impact on the VRE market depends in part on expectations that VRE consumers may have about the emission reduction benefits associated with their purchases. Renewable generators located in capped jurisdictions no longer contribute to greenhouse gas emission reductions once a cap is in effect because the level of allowable emissions is determined by the cap. In light of this, consumers motivated primarily by the desire to reduce greenhouse gases may choose to opt out of the VRE market or direct their purchases to uncapped jurisdictions. WCI Partner jurisdictions that wish to address potential impacts on the VRE market from the cap-and-trade program have the option to adjust their baseline allowance budget to reserve (or "set aside") a pool of allowances for retirement that ensures that emission reductions occur for VRE market purchases. This type of VRE policy (a "VRE set aside") has been implemented in the cap-and-trade system in the US Northeast (the Regional Greenhouse Gas Initiative, or RGGI), and has been proposed in Australia. Conversely, no such program exists in the European cap-and-trade system or proposed federal US programs.

The WCI Design Recommendations provide that WCI Partner jurisdictions have broad discretion in determining whether to reserve their allowances for designated purposes. In accordance with these recommendations, no program-wide recommendation is made as to whether all Partner jurisdictions should implement a VRE set aside. While it is important, if not necessary, for linked cap and trade programs to harmonize on certain elements, it is not important for all Partner jurisdictions to harmonize on the choice of whether to implement a VRE set aside.

This paper focuses on discussing the key design elements of VRE set asides and provides recommendations to those WCI Partner jurisdictions that do choose to implement a VRE set aside. Elements on which it is important for the WCI Partner jurisdictions to harmonize are highlighted. These draft recommendations are summarized below in Table 1.

Table 1: Summary of Draft Recommendations on VRE Set Aside Design Elements

Design Element	WCI Partner jurisdictions that choose to implement a VRE set aside should:	Importance of Harmonization
Accounting Mechanism for VRE Set Aside Program	Include a requirement that the measurement of voluntary renewable energy purchases that form the basis of any allowance retirement be based, first and foremost, on transactions verified through established REC tracking systems that span some or all of the WCI region (e.g., WREGIS). In addition, to account for those purchases that are not tracked through an established system (or for regions without such a system) provision should be made to accept transactions that are certified through a third-party verification system for voluntary renewable energy that includes, at a minimum, a requirement that the seller must attest to not having previously sold or otherwise transferred the greenhouse gas benefits of the renewable energy product.	High
Defining Eligible Renewable Energy Project Types	Define their own eligibility requirements for their VRE set aside programs. They may choose to mirror existing RPS or other statutory definitions or to define a separate list of qualifying project types.	Low
Jurisdictional Retirement Responsibility	Retire allowances using a generator-based approach in which allowances are retired whenever RECs from a facility in that WCI Partner jurisdiction's territory are purchased and retired by a customer in the VRE market with no limitation on the customer's location. Alternatively, the retirement should be based on VRE sales if RECs are not used.	High
Upper Limit on Retirement Amount	Choose whatever upper limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions must determine if they will cover shortfalls by either borrowing allowances from a future year or lowering the per MWh retirement rate.	Low
Time Limit on VRE Set Aside Program	Choose whatever time limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions may choose to base time limits on periodic reviews of the cost-competitiveness of the technologies supported by the set aside program.	Low
Emission Attribution for VRE Purchases	Work together to develop a rate based on a marginal dispatch analysis, such as the WCI Default Emission Factor Calculator, for each major grid region. However, use of this rate should be optional and specific assignment of emissions left to jurisdictional discretion.	Medium

2 Background

The WCI Partner jurisdictions committed to a set of principles when designing the WCI Regional Cap-and-Trade Program. A theme in those principles is the support of renewable energy by "diversifying energy sources" and "stimulating investment … in low carbon technologies"[1]. Therefore, increasing the amount of energy generated by renewable energy sources in the WCI region is a key goal of the WCI Partners. Much of the growth in renewable energy in the WCI region will happen through the economic incentives created by cap-and-trade, government mandates on load-serving entities to obtain renewable energy, and other complementary policies such as direct procurement or feed-in tariffs. Additional growth may come from energy consumers that make individual, voluntary decisions to purchase renewable energy in the voluntary renewable energy (VRE) market.

At present individual decisions to purchase renewable energy in the WCI region can potentially lead to reductions in greenhouse gas emissions.[2] Implementing a cap-and-trade program changes that dynamic because under a cap-and-trade program the amount of greenhouse gas emissions allowed in the region are pre-established by the cap level. As a result, decisions to purchase renewable energy – beyond what is cost-effective after imposition of a carbon price – free up emission allowances that would have been needed to generate electricity from fossil fuels, allowing other regulated entities to emit more than they could have otherwise. In essence, the voluntary purchase of renewable energy lessens the regulatory burden on greenhouse gas emitters. A large number of such VRE purchases has the potential to marginally decrease the cost of the program by eliminating the need for what may have otherwise been the most expensive[3] mitigation measure necessary to meet the cap. Therefore, in order for VRE purchases from facilities in the WCI region to deliver climate benefits beyond those achieved by the cap, those purchases must either lead to a reduction in the total number of allowances in the system or the emissions value of the allowances in the WCI system must be reduced.[4]

VRE consumers may be motivated to support renewable energy due to any one of various benefits renewable energy provides. These benefits include economic development ("green jobs"), reduced dependence on fossil fuels ("energy independence"), reduced use of nuclear

---

[1] Western Climate Initiative, "Design Recommendations for the WCI Regional Cap-and-Trade Program", September 23, 2008.

[2] This assumes that those decisions happen in the context of a program structure that can guarantee incremental increases in renewable energy generation. Without a firm program structure the same generation mix may simply be allocated differently; zero-carbon electricity may get diverted to interested customers while the energy mix to indifferent customers may become slightly more carbon intensive as zero-emission sources are stripped out.

[3] And therefore likely the price setting mitigation measure.

[4] For example, starting in 2010 the SO_2 allowances, which were allocated in perpetuity by the Acid Rain program, are worth less than a ton under EPA's more recent Clean Air Interstate Rule in order to reduce emissions more rapidly than envisioned when the Acid Rain program was established.

power, and numerous environmental benefits, including reduced (or avoided) greenhouse gas emissions.[5] If it is believed that a significant proportion of consumers in the VRE market are largely motivated by the desire to reduce greenhouse gas emissions, and they are aware that the presence of a cap and trade system will undermine those emissions benefits, then those participants may either stop purchasing VRE products or direct their purchases to sources in uncapped areas. As a result, the VRE market in the WCI region may be significantly impacted by the introduction of cap-and-trade. The extent of impact on the VRE market is difficult to predict. Central to this question is the degree to which consumers are primarily motivated by the desire to reduce greenhouse gas emissions when they purchase VRE products. If VRE consumers do not strongly prioritize reducing greenhouse gas emissions, then it is possible that the introduction of a cap-and-trade program may not have much impact on the VRE market.

If there is a strong relationship between consumer expectations of greenhouse gas reductions and voluntary purchases of renewable energy, support of the VRE market through a policy mechanism may be necessary if there is a desire to support a robust VRE market. This paper focuses on the key issues in deciding whether the VRE market should be actively supported by jurisdictions in the WCI cap-and-trade program and if so, how a policy mechanism that supports the VRE market should be designed and implemented.

3 Current Status of the Voluntary Renewable Energy Market

The VRE market started when some utilities began offering green power programs to their customers. These programs enabled their customers to support the development of "green power"—wind and other renewable energy generation—by paying the incremental cost of renewable energy above the cost of the conventional generation sources the utility would otherwise build. The utility in turn used the revenue to purchase electricity from renewable generators or to build renewable resources of its own. The introduction of renewable energy credits (RECs) which allowed the renewable attributes to be sold separately from the power enabled other players besides utility customers to participate by allowing buyers to pay for renewable energy generated anywhere in the United States. Renewable developers and utilities could sell RECs to anyone who wanted to be able to claim that in principle, large percentages of their electricity came from green resources.

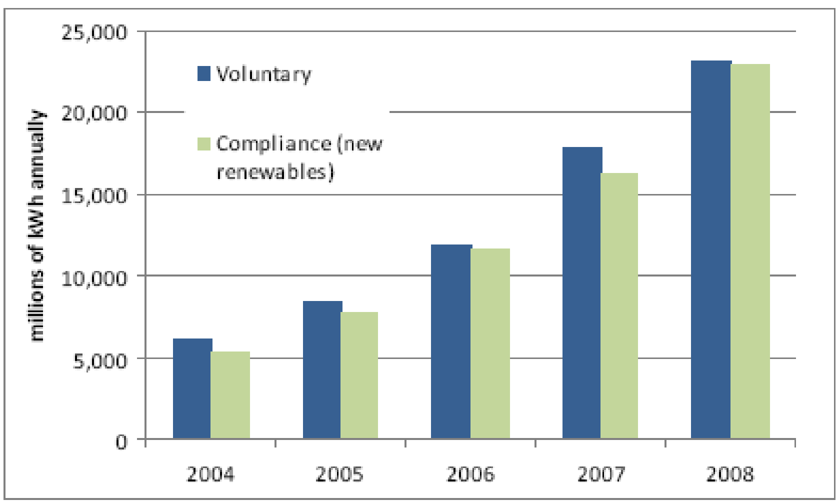
As climate change has become more salient as both a political and "values" issue, a voluntary carbon offset market has emerged in which carbon offset certificates denominating a unit of CO2 reduction are registered on an exchange (e.g. Chicago Climate Exchange) and issued by, among others, generators of renewable energy who can show that their increment of

[5] Another factor driving VRE purchase decisions is whether they are perceived as producing incremental growth to the renewable energy market. For purposes of this paper, it is assumed that the VRE market provides enough value to the renewable energy market to produce additional renewable capacity beyond business-as-usual levels.

renewable energy reduced greenhouse gases from the generation their energy replaced. In 2008, carbon offsets were sold from about 350 thousand Megawatt-hours (MWh) of electricity, a small fraction of the 25 million MWh VRE market.[6]

Today, green power programs are flourishing in the United States. More than 750 utilities offer them nationwide and 13 states mandate that their utilities offer them to customers, including Washington, Oregon, Montana, and New Mexico.[7] The average rate of participation in 2008 among eligible customers was 2.2% with the top ten programs reaching from 5% of customers up to a high of 21%. Actual energy sales amounted to almost 5 million MWh in regulated energy markets. In restructured markets, sales of green power tend to be in the form of RECs, which accounted for over 80% of VRE sales. Direct renewable energy sales in restructured markets and voluntary RECs combined amounted to almost 20 million MWh in 2008. Total VRE direct sales and RECs accounted for 0.7% of electricity sales nationally.[8] Residential customers dominated the markets for sales of energy while commercial customers dominated the REC markets, which have been growing much faster than the market for green energy products.

Figure 1: Comparison of Voluntary and Compliance Markets for Renewable Energy in the United States (Source: NREL)[1]



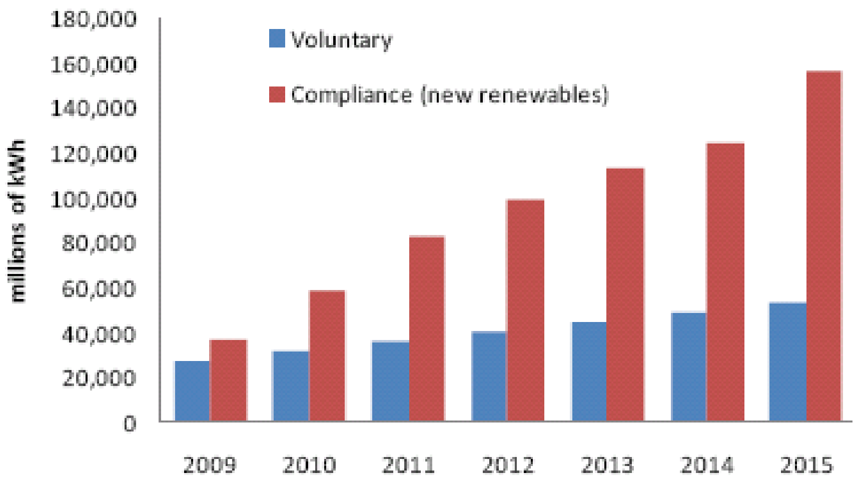
Note: Compliance market data sourced from Lawrence Berkeley National Laboratory (LBNL) (Barbose 2009)

Although green power programs have grown rapidly over the last ten years, renewable portfolio standards (RPS) in many states have served to drive a comparable amount of new renewable generation capacity (See Figure 1).

[6] Lori Bird, Claire Kreycik, and Barry Friedman, 2009. Green Power Marketing in the United States: A Status Report (11th Edition). National Renewable Energy Laboratory. http://www.nrel.gov/docs/fy09osti/44094.pdf
[7] See http://apps3.eere.energy.gov/greenpower/markets/state_policies.shtml.
[8] US. DOE/EIA, 2009. Electric Power Monthly – Retail Sales of Electricity to Ultimate Customers: Total by End-Use Sector. http://www.eia.doe.gov/cneaf/electricity/epm/table5_1.html

Twenty nine states plus the District of Columbia now have legislation requiring load serving entities to supply increasing percentages of their resource portfolios with renewable energy with targets ranging from 10-25% by the 2020s. It is projected that these amounts will soon overtake the voluntary market (See Figure 2).

Figure 2: Projected Voluntary Renewable Energy Market Relative to Compliance Market to 2015 in the United States (Source: NREL[1])



The voluntary market in Canada is relatively small compared to the US. A minority of provinces have utility green pricing programs or private green marketing programs. This reflects the fact that electricity generation already incorporates a large renewables component in most provinces. In addition, most provinces have adopted renewables procurement programs through government-owned utilities, with results similar to an RPS but without RECs, leaving limited opportunity for voluntary renewables. The degree of government ownership may also pose a barrier, in that private sector investment opportunities are limited in many provinces. Nonetheless a small number of retailers have been successful in establishing a voluntary market for renewable energy in some provinces. Voluntary renewables marketing has been most prevalent in the provinces with greater private ownership, including Ontario. The voluntary market for renewables in Canada today is estimated to be around 500,000 MWh/year[9].

4 Overview of VRE Support Policies under Cap-and-Trade

WCI Partner jurisdictions must decide whether to support the VRE market to ensure that it is not disadvantaged by the adoption of a cap-and-trade program or to put the burden on VRE

[9] Commission for Environmental Cooperation, *Fostering Electricity Markets in North America,* April 2007, http://www.cec.org/files/pdf/ECONOMY/Fostering-RE-MarketsinNA_en.pdf

market participants to ensure that some customers adapt to cap-and-trade programs. These two approaches are described and discussed in detail below.

4.1 Allowance Budget Adjustment Approach ("VRE Set Aside")

One possible policy response to support a VRE market would be to implement a VRE budget adjustment mechanism to allow the desired emission reductions to occur when VRE products are purchased from facilities subject to the cap. This is achieved by carving out a number of allowances from the Partner's base budget and setting those allowances aside to potentially be retired based on the estimated amount of voluntary renewable energy expected to either come on line in that Partner's state or province, or the amount of VRE products purchased by consumers in that state or province. Once the expected energy sales (in terms of MWhs) have been verified, allowances could be permanently retired. If there is a balance, those allowances could be released, or rolled over to the set aside for the following time period. The term used to describe this process is called an "off the top" approach to implementing this type of allowance budget adjustment to account for the sales of renewable energy in the VRE market.

Historically programs that reserve a portion of an overall budget of allowances for a certain purpose within a cap-and-trade system have been called a "set aside", referring to the fact that this portion of the allowances are reserved and literally set aside for the designated purpose. Once allowances are set aside they can be held, recycled for other uses, transferred, sold, or retired depending on how the program is designed. In the case of implementing a VRE budget adjustment mechanism for the purposes of ensuring that emission reductions accompany the VRE products in the marketplace, it is necessary that the allowances be retired, either immediately when the VRE products are consumed, or banked for future retirement at the appropriate time. Following this tradition, most of the literature on addressing the VRE market focuses on "VRE set asides" to describe the VRE budget adjustment mechanism described here. This paper will continue this tradition and refer to the policy option described in this section as a "VRE set aside". It is important to understand that the VRE set aside referred to in this paper is what is known as an "unallocated set aside" because the allowances are specifically intended to be retired (and not allocated to a programmatic use). Using the allowances set aside from the jurisdiction's overall budget for other purposes, such as selling them and using the revenue (except for any unused balance), would defeat the purpose of the VRE set aside program.

In order to implement a VRE set aside program market data and tracking systems can be used to estimate, track and verify voluntary renewable energy expected to come on line and enter the VRE marketplace. These estimates can assist WCI Partner jurisdictions in establishing the number of allowances to set aside for a given year. For example, the National Renewable

Energy Lab publishes a status report[10] that describes the status of the voluntary market in the US as compared to the compliance market. In addition, WCI Partner jurisdictions could also use data from their perspective energy agencies or organizations such as the Center for Resource Solutions[11]. The estimated generation should be verified before allowances are retired.

Verification of the estimated energy sales could be accomplished via tracking systems such as the Western Renewable Energy Generation Information System (WREGIS). WREGIS covers the Western Electricity Coordinating Council region (the western grid) and generates a REC for every MWh of renewable energy generation that is verified. In order to calculate the appropriate number of allowances, an emission factor is needed to represent the emissions of the electrical generation plant that would have operated if not for the additional renewable energy. The US EPA publishes these emission factors[12] for the US.

Table 2: Example of Voluntary Renewable Energy Set Aside Mechanism

Estimated VRE MWh sold in 2012	**Example Set Aside Emission Rate**	**Allowances in 2012 Reserve**	**Actual VRE MWh sold in 2012**	**2012 Allowances Retired by Jurisdiction**	**2012 Allowances Unused (and available for set aside in 2013)**
1,000,000	0.40 tCO2e	400,000	900,000	360,000	40,000

Table 2 provides an example of how a voluntary renewable energy set aside mechanism could work. Based on information provided by VRE vendors, the state or province estimates approximately 1,000,000 MWh of electricity (or a combination of direct energy sales and RECs) will be sold into the voluntary renewable energy market in 2012. The jurisdiction has determined that 0.40 metric tons CO_2e per MWh will be the emission rate used to retire allowances from the set aside for every MWh of voluntary renewable energy generated annually. Thus, the jurisdiction sets 400,000 allowances aside in the VRE reserve account. At the end of the year, the jurisdiction certifies that only 900,000 MWh of VRE were sold in 2012. In this case, only 360,000 allowances will be retired and the remainder is released or rolled over to 2013.

If a set aside is created for the VRE market, it may set an interesting precedent. Assuming that most VRE buyers are primarily motivated by a desire to reduce greenhouse gas emissions, the rationale for creating a VRE set aside could apply equally to other products and actions that reduce emissions. For example, many households and firms undertake measures to reduce their energy consumption. Without a set aside for energy efficiency, it could be argued that

[10] Lori Bird, Claire Kreycik, and Barry Friedman. Green Power Marketing in the United States: A Status Report (2008 Data). National Renewable Energy Laboratory; September 2009. http://www.nrel.gov/docs/fy09osti/46581.pdf
[11] Center for Resource Solutions; 2008 Green E Verification Report; http://www.green-e.org/docs/2008%20Green-e%20Verification%20Report.pdf
[12] http://www.epa.gov/cleanenergy/energy-resources/egrid/index.html

some of these households and firms may no longer implement efficiency measures knowing that if they do, total greenhouse gas emissions will not change.

A counterargument to this example is that energy efficiency is generally cost-effective, and those who implement efficiency measures benefit from their actions. Purchasers of VRE products, on the other hand, pay a premium for the superior environmental attributes of renewable energy, in effect providing a public good at their own expense. This difference may justify the creation of a set aside for VRE but not energy efficiency. However, there are other examples where consumers pay a premium for environmental attributes that are not cost-effective. Presumably, purchasers of hybrid vehicles do so largely for the environmental advantages that such vehicles provide because in most cases, these vehicles only recoup their price premiums over long time horizons (if ever). If a VRE set aside is established, vendors of hybrid vehicles may also ask for a hybrid-vehicle set aside using similar logic.

For these reasons, WCI jurisdictions that choose to implement a VRE set aside may need to provide some rationale for limiting such a set aside mechanism only to VRE products. Otherwise additional set asides for different classes of products may require tracking the sales of a wide variety of products and leading to an unacceptably large pool of unallocated allowances dedicated to set asides. Alternatively, a broader-based set aside that accommodates all of the types of greenhouse gas reduction products or actions discussed above (including the VRE market) may be established by the jurisdiction.

4.2 No Intervention Approach

If it is believed that most participants in the VRE market are not motivated primarily by the desire to reduce greenhouse gas emissions in their jurisdiction or region, or that no public policy is served by VRE once a cap and trade program is implemented, then an argument can be made that the VRE market does not need policy support, and no intervention in the VRE market is necessary. Some buyers may value other environmental or socioeconomic benefits more than greenhouse gas reductions and would continue to buy VRE from jurisdictions participating in a cap-and-trade system even if greenhouse gas reductions are not ensured. Other buyers may be more concerned with their personal “carbon footprints” than with the impacts that their purchase decision have on total greenhouse gas emissions. This is because buying VRE still reduces the carbon footprint of the individual buyer even if total emissions (at the jurisdictional or regional level) do not fall[13]. In short, the VRE market may continue to be viable for a number of reasons regardless of whether total greenhouse gas emissions reductions can be guaranteed to take place when purchases of renewable energy occur.

[13] This assumes the purchase is from a jurisdiction participating in the cap-and-trade program.

If most purchasers of VRE are not primarily motivated by total greenhouse gas reductions implementation of a VRE set aside may pull more allowances out of circulation than is necessary to ensure the continued viability of the VRE market. If jurisdictions auction allowances as part of their cap-and-trade program, a VRE set aside may also reduce the volume of allowances auctioned, and therefore total auction revenue. These allowances could be used for other purposes, including using the value of those allowances for other types of support programs for renewable energy (e.g., increased funds for existing public purpose funds supporting renewable energy projects). Even if permits are allocated for free, rather than auctioned, a VRE set aside reduces total permitted emissions and thus may raise the permit price while limiting the opportunity for firms that reduce their emissions to sell excess credits and offset compliance costs.

If WCI jurisdictions decide not to implement VRE set asides, VRE certifiers face the option of either de-certifying renewable generators from eligibility in their programs or changing the way they market VRE from capped jurisdictions. For example, generators or marketers of VRE products can obtain and retire a sufficient number of emission allowances within the cap-and-trade system to provide the emissions reduction advertised or otherwise conveyed to the buyer of those renewable energy products. It would be up to each seller in the VRE market to decide whether or not they want to package a given amount of greenhouse gas emission reductions with their renewable energy products, and they would purchase the appropriate amount of allowances and bundle or retire them to meet that claim.

If there is concern that some sellers of VRE products may claim emission reductions for which they have no basis, government intervention in the form of a requirement to obtain allowances before making those claims may be an option. Since it is likely that the provisions for this type of government-backed guarantee would happen in a legal or regulatory framework outside of the cap-and-trade system (e.g., consumer fraud rules) this approach would likely not involve including a program element specific to the VRE market in the cap-and-trade program. Moreover, it may not be necessary for the government to take any action in order for such a guarantee to exist based on existing consumer protection law at the state or provincial level.

It is important to note that an approach of requiring that allowances be obtained (either explicitly or implicitly through existing law) for VRE products sold to consumers would increase the price premium for VRE products and disadvantage renewable facilities in capped jurisdictions that seek to compete in the VRE market. Even if not required it is possible that many VRE sellers would include allowances as part of their VRE offering. As a result, the VRE market in the WCI region would be impacted, although it is difficult to predict the extent to which the overall market would be reduced.

5 Status of VRE Approaches in Other Trading Schemes and Proposed Federal Legislation

The following existing or proposed cap-and-trade programs were reviewed to identify how they address the VRE market prior to the development of the recommendations in this paper.

- Regional Greenhouse Gas Initiative (RGGI), the greenhouse gas emissions cap-and-trade program currently in place in the Northeastern United States.
- European Union Emissions Trading Scheme.
- American Clean Energy and Security Act of 2009 (H.R.2454), commonly referred to as Waxman-Markey, which was passed by the U.S. House of Representatives.
- Kerry-Boxer, the U.S. Senate version of American Clean Energy and Security Act of 2009 that is still undergoing debate and revision in the US Senate as this paper is written.
- The proposed Australian Carbon Pollution Reduction Scheme.

Table 3 below summarizes how these proposals or programs address the VRE market:

Table 3: Summary of Treatment of Voluntary Renewable Energy in Cap-and-Trade Systems and Proposals

Cap-and-trade program or proposed legislation	Voluntary Renewable Energy Market Directly Addressed?	Policy Mechanism Used to Address VRE Market	Potential Indirect Means of Addressing VRE Market
US Regional			
Regional GHG Initiative (RGGI)	Yes	Set aside as optional element of RGGI Model Rule.	Not necessary
European Union			
EU Emissions Trading System (EU ETS)	No	None	Unclear
US National Legislation and Proposals			
American Clean Energy And Security Act of 2009 (Waxman-Markey)	No	None	Allowances are distributed to states for renewable energy. States may use those allowances to implement a program like a VRE set aside at a state-by-state level.
Kerry-Boxer (Senate version of ACES)	No	None	Still in development, presumably similar to Waxman-Markey
Australia National Legislation			
Carbon Pollution Reduction Scheme (proposed for 2011)	Yes	By taking GreenPower (official VRE program) purchases above 2009 levels into account when setting program's emission caps.	Not necessary

5.1 Overview of the Australian VRE Market Approach

Australia's proposed GHG emission trading scheme is referred to as the Carbon Pollution Reduction Scheme (CPRS). This trading scheme would potentially reduce emissions from approximately 5 to 25 percent of 2000 levels by 2020, depending on the status of international treaty negotiations on a new binding global emissions reduction treaty.

The framework contains a provision for tightening the cap to recognize the contribution of additional renewable energy purchases[14,15]. The scheme sets a baseline for renewable energy purchases at the 2009 levels and factors renewable energy into setting the cap. If purchases go over that baseline the cap will be adjusted to recognize these contributions. If purchases fall below the baseline there will not be an adjustment of the cap.

On August 13, 2009 the Australian Senate voted against the set of bills that were to establish the program. On December 2, 2009 a renegotiated set of bills failed to pass the Australian Senate again by a vote of 41-33, and the scheme's future is currently uncertain.

5.2 Overview of the RGGI Model of a VRE Set Aside

The RGGI Model Rule contains a provision for a VRE set aside program. In RGGI the number of allowances retired is pegged to the CO_2 emissions that would have been avoided in the absence of the cap. This is calculated using two types of data:

- The amount of voluntary renewable energy purchased (typically in megawatt-hours, or MWh); and,
- The emissions rate of the electric generating source that would have run had the renewable energy not been purchased (expressed in tons CO_2/MWh).

Because the number of allowances reserved for the set aside is based on ex ante estimates of VRE sales, it is possible that the number may be too high or too low in any given year. The Model Rule contains provisions to adjust the size of the VRE set aside in subsequent years accordingly.

These set aside provisions are an optional part of the RGGI Model Rule, and therefore participating jurisdictions are not obligated to adopt them. However, at this time 9 of the 10 RGGI states have adopted them.

6 Implementation of VRE Set Asides in WCI Jurisdictions

A key decision made by the WCI Partner jurisdictions in the "Design Recommendations for the WCI Regional Cap-and-Trade Program" is that each jurisdiction has discretion over how the allowances apportioned to that jurisdiction are to be used. Other than agreeing that "some portion" of the apportioned allowances will be used for purposes like supporting renewable energy, which a VRE set aside would fit under, there is currently no common agreement among the Partner jurisdictions to require a VRE set aside in the design of each jurisdiction's cap and trade program. In keeping with the WCI design recommendations, it is therefore up to each individual WCI jurisdiction whether or not to implement a VRE set aside program in their jurisdiction. For those jurisdictions that do choose to put in place a VRE set aside program there are a number of design issues associated with implementing a VRE set aside program. The remainder of this paper focuses on those key design issues that will need to be examined by any of the WCI jurisdictions that choose to implement a VRE set aside program.

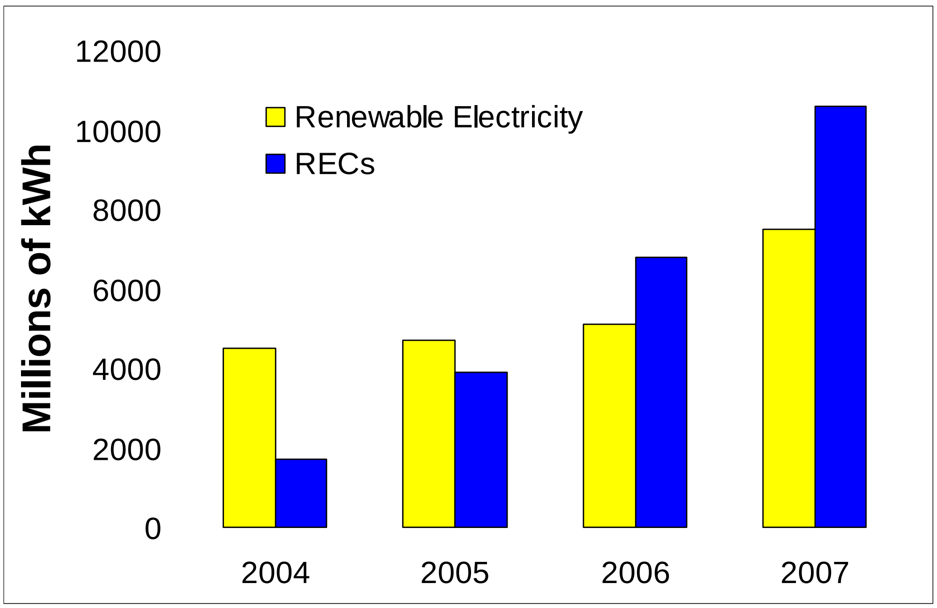
An important consideration in examining the design elements of a VRE set aside program is the extent to which certain elements need to be harmonized across participating jurisdictions. In other words, for each of the design elements examined below can each jurisdiction make its own policy choice without impacting the effectiveness of a VRE set aside program in either another WCI jurisdiction or the WCI region as a whole? Particular attention to this question is given as each design issue is addressed below. For comparison, the approach that RGGI took for each of these points of implementation is also summarized. Finally, a draft recommendation to WCI Partner jurisdictions for each design question is given.

6.1 Accounting Mechanism for the VRE Set Aside

There are two broad classes of products in the voluntary renewable electricity market: renewable electricity and renewable energy credits (RECs). RECs are the renewable attributes created by the generation of electricity from a renewable source and serve as proof of generation of (typically) one MWh of renewable energy generation. They can be sold bundled with the electricity underlying the REC or unbundled and bought and sold independently of the electricity produced. Unbundled RECs are often re-bundled with generic electricity to rebrand the generic electricity as green electricity. RECs may be defined solely by their primary attribute (i.e., that a MWh of renewable electricity was generated) or they may include reference to secondary attributes such as the greenhouse gas emissions avoided by displacing conventional generation. The inclusion of secondary attributes varies across states with respect to RECs used for compliance with renewable portfolio standards, but RECs used in the secondary market generally include reference to the secondary attributes.

When implementing a VRE set aside program, a decision has to be made as to what "currency" the program should use. One option is to base the program on actual renewable energy sales, and typically the basis for measuring VRE transactions are documents such as the sales receipt, sales contract, or other similar proof of the transaction. Another option is to use RECs as the currency to serve as the proof of renewable generation. This is convenient since the primary purpose of a REC is to serve as an easily transferable and trackable proxy for other legal documents (such as sales contracts) which provide the legal basis for ownership of the renewable energy in the voluntary renewable energy market. For this reason, renewable energy programs of all types (voluntary and mandatory) are increasingly using RECs.

Figure 3: Estimated Annual Green Power Sales 2004-2007[16,17]



RGGI Model Rule

The RGGI Model Rule only retires allowances for purchases of renewable electricity[18], and therefore does not accommodate sales of unbundled RECs. According to the National Renewable Energy Laboratory[19], about 95 percent of residential consumers purchased renewable electricity (typically through green power utility programs) instead of unbundled RECs in 2007. However, nonresidential customers clearly prefer unbundled RECs, which amount to over 90 percent of sales for these customers. This suggests that while the RGGI model is responsive to residential consumer demand, it does not match the purchase decisions

[16] Ibid.
[17] 2006 sale figures for renewable electricity may be underestimated because of data gaps (Ibid).
[18] Note that this means both renewable electricity purchased directly and bundled RECs (REC + electricity).
[19] Lori Bird, Claire Kreycik, and Barry Friedman. Green Power Marketing in the United States: A Status Report (11th Edition). National Renewable Energy Laboratory. http://www.nrel.gov/docs/fy09osti/44094.pdf

of nonresidential consumers. This is notable because REC sales (99% of which are to nonresidential consumers) account for nearly three-quarters of all voluntary renewable product sales in 2007. Therefore, the RGGI model may not be optimal for stimulating new renewable development.

Draft Recommendation

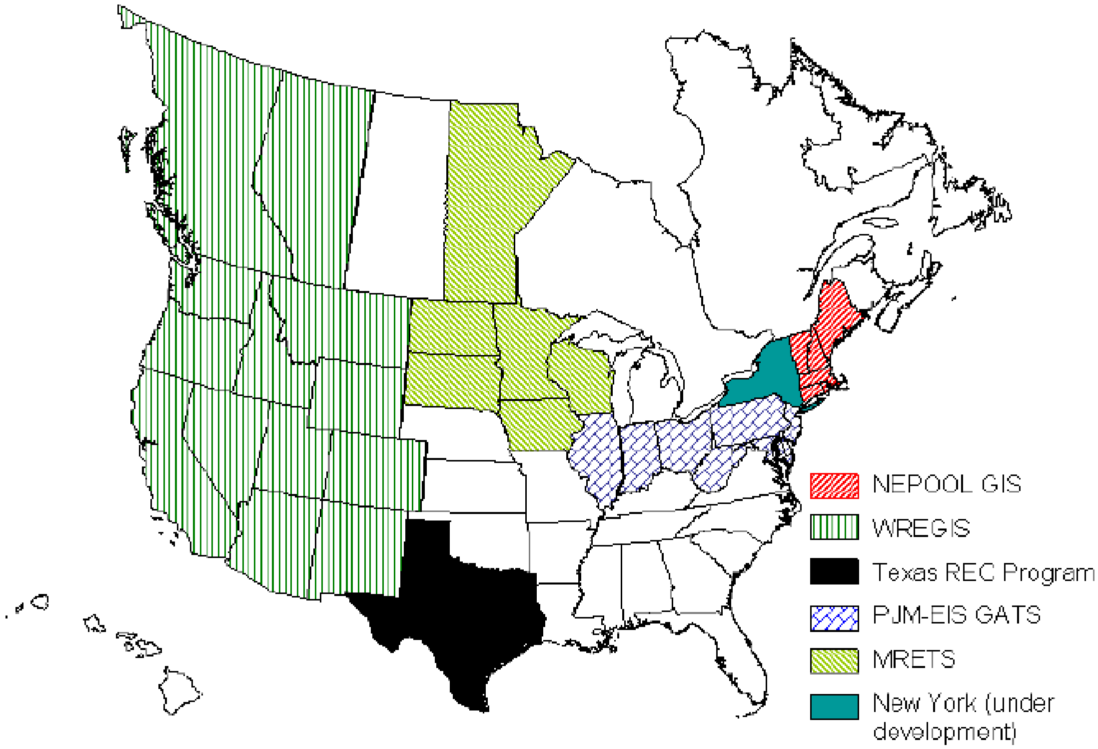
> *WCI Partner jurisdictions that choose to implement a VRE set aside should include a requirement that the measurement of voluntary renewable energy purchases that form the basis of any allowance distribution be based, first and foremost, on transactions verified through established REC tracking systems that span some or all of the WCI region (e.g., WREGIS). In addition, to account for those purchases that are not tracked through an established system (or for regions without such a system) provision should be made to accept transactions that are certified through a third-party verification system for voluntary renewable energy that includes, at a minimum, a requirement that the seller must attest to not having previously sold or otherwise transferred the greenhouse gas benefits of the renewable energy product.*

The decision as to whether to use RECs or the renewable electricity (i.e., using contracts as the proof of generation) as the principal mechanism for tracking the quantity of VRE applicable to the set aside is one design feature where harmonization across WCI jurisdictions is critical. Non-harmonization raises the potential for double-counting the renewable attribute because one jurisdiction may retire allowances for the electricity generated while another retires allowances for the RECs purchased for the same electricity. Harmonization ensures that each MWh of renewable energy in the voluntary market is claimed only once by a final user.

6.2 Defining Eligible Renewable Energy Project Types

WCI jurisdictions will need to decide which types of voluntary renewable energy projects should be encouraged through a VRE set aside. Establishing common criteria is challenging as jurisdictional RPS criteria vary, suggesting disparity about the types of renewable energy that each region wants to encourage.   Requiring that renewable projects meet RPS criteria where applicable may provide additional assurance that allowances are only retired for desired projects so long as those RECs can be retired in a regional tracking system (see Figure 4).

Figure 4 -- Map of Regional Tracking Systems (Source: NREL)[20]



In addition, VRE certifying organizations (typically independent non-profit organizations or government agencies) have their own eligibility criteria that they are likely to overlay on any state or jurisdictional eligibility criteria.[21,22] In both cases, the eligibility criteria are likely to address not only the types of eligible renewable energy, but also provide some assurances that the renewable projects used for voluntary program purposes are authentic and also meet additional criteria which consumers may find desirable. For example, both the Canadian EcoLogo and the Green-E certification program for VRE certify that the projects that meet their requirements are "additional", i.e., that those projects were not required by government mandate and that the VRE purchase is helping to advance the renewable energy market above and beyond what would be happening without the purchase.

One issue worth noting, which is an ongoing concern with tracking and verification systems used in both the mandatory and voluntary renewable energy markets, is some of the market barriers that small-scale "behind the meter" renewable energy systems (typically residential

---

[21] Green-e certification criteria can be found at http://www.green-e.org/docs/energy/Appendix%20D_Green-e%20Energy%20National%20Standard.pdf

[22] An example of this can be found in Green-e's RGGI update http://www.resource-solutions.org/pressreleases/2008/120508-2.htm.

solar photovoltaic systems) have encountered in entering the VRE marketplace. In some cases the additional administrative costs or process issues associated with either (or both) the REC tracking systems used for the mandatory renewable market or the certification programs in the voluntary market have prevented the owners of these installations from becoming VRE market participants. If the VRE set aside policy option is focused solely on addressing the traditional VRE market, which is focused on VRE products, than the VRE set aside option may not be of direct assistance to all entities that voluntarily produce renewable energy. Nonetheless, the decisions to install these smaller systems may be driven by similar motivations as in the VRE product market (i.e., ghg emission reductions). Therefore it may be worth including behind the meter distributed resources, such as residential systems, in the list of eligible resources for the VRE set aside to further encourage their growth. Since these systems are generally not registered with generation information systems like WREGIS and may not be configured to report output data at all, quantifying these systems for inclusion in the VRE set aside can be a challenge. WCI Partner jurisdictions that include small-scale solar or wind systems among their VRE set aside eligible resources will have to determine whether to limit eligibility to systems with metered output or whether to accept generation estimates for unmetered systems.

RGGI Model Rule

The RGGI Model Rule limits eligibility for retirement from the VRE set aside to electricity generated from biomass, wind, solar thermal, photovoltaic, geothermal, hydroelectric facilities certified by the Low Impact Hydropower Institute, wave and tidal action, and fuel cells powered by renewable fuels. However, this particular definition was intended to be optional. Several states have adopted it, while others have limited eligibility to renewables that meet their own RPS standards.

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should define their own eligibility requirements for their VRE set aside programs. They may choose to mirror existing RPS or other statutory definitions or to define a separate list of qualifying project types.*

Unlike the choice of accounting mechanism, jurisdictional consistency on eligibility criteria is less important. Marketers of VRE products will adapt to whatever eligibility criteria jurisdictions adopt. If a facility is eligible for set aside retirements, marketers will know that emission reduction claims are supported and can market energy or RECs from the facility accordingly. A modest advantage to harmonization is that potential project developers would not have to keep track of eleven different sets of eligibility criteria when financing and developing projects in WCI jurisdictions.

6.3 Jurisdictional Retirement Responsibility

Another variable to consider when designing a VRE set aside is whether the jurisdiction responsible for retiring allowances is determined by the location of the purchaser or the generator. For example, when a renewable facility in a WCI jurisdiction produces RECs that are used in the VRE market and then retired by an entity in another WCI jurisdiction, which jurisdiction bears the responsibility for retiring allowances? Either approach is feasible, but the underlying rationale and effect differ. The purchaser-based approach serves to assure consumers in the jurisdiction where the VRE set aside is based that emission reductions occur regardless of the location of the renewable electricity facility. The generator-based approach supports renewable energy development in the jurisdiction where the VRE set aside is based by allowing emission reduction claims in the marketing of the VRE product to customers.

RGGI Model Rule

The RGGI Model Rule uses a purchaser-based responsibility in which each state retires allowances for VRE purchases occurring in the state. The RGGI Model Rule provides for the retirement of allowances for in-state sales regardless of where the REC is generated. Because these RECs may come from uncapped states, the RGGI Model Rule may be retiring too many allowances for in-region purchases. However, some RGGI states have adopted VRE set aside provisions that only retire allowances for in-region generation, which avoids this problem.[23]

6.3.1 Purchaser-Based Responsibility

Under the purchaser-based approach, a WCI jurisdiction retires allowances whenever a retail customer, utility, or VRE aggregator serving customers in the jurisdiction retires RECs[24] from the VRE market from a facility in a capped jurisdiction. The application of the set aside could be limited by various geographic criteria. If the goal is to both protect in-jurisdiction consumers and promote renewable development in the jurisdiction, the set aside could be limited to purchases from in-jurisdiction generators. If adoption of the set asides is widespread in the WCI, Partner jurisdictions may opt to apply the set aside to purchases from sources in any WCI jurisdiction. Alternatively, this reciprocity could extend further to apply the set aside to purchases from any capped source (assuming that the capped source selling RECs in the VRE market is not already supported by a generator-based set aside).

[23] RGGI State Set-Aside Provisions for Voluntary Renewable Energy (VRE). Draft October 25, 2008. Ed Holt & Associates, Inc. http://www.epa.gov/greenpower/documents/events/rggi_status_table.pdf

[24] Or otherwise documents a VRE purchase if the accounting mechanism is not based on RECs.

This system is relatively simple where there is a direct connection between the in-jurisdiction person or entity retiring the RECs (or purchasing the electricity) and the facility. However, the fact that some VRE products consist of RECs purchased from a large number of facilities by VRE marketers complicates matters. If, for example, a REC retailer buys 5,000 RECs from capped jurisdictions and 5,000 RECs from uncapped jurisdictions, and then sells 5,000 RECs to customers in uncapped jurisdictions and 5,000 RECs to customers in a capped jurisdiction with a purchaser-based set aside, how many RECs should the set aside jurisdiction count when it retires allowances?

One option would be to assume that all customers receive the same share of RECs from each facility, that is, that all of the RECs are thoroughly mixed and then sold to customers. If the set aside jurisdiction assumes that all customers receive the same mix of renewables, then the jurisdiction would apply 2,500 RECs toward its set aside on the basis that half of the 5,000 RECs used by customers in the jurisdiction came from capped areas and half came from uncapped areas. However, that would entail that 2,500 RECs from a capped area were sold to customers in uncapped jurisdictions, necessitating that those RECs could not be associated with claims of emission reductions.

Another option would be to allow REC marketers to specify the renewable generators used to supply RECs to their various customers. Under this approach, REC marketers in a purchaser-based model are likely to direct the maximum amount of RECs from capped areas to those jurisdictions that implement a set aside to ensure that no RECs are left without credible emission reduction claims.

The participation of large organizations with locations in multiple jurisdictions may add further complication to accounting under the purchaser-based approach. For example, if the headquarters of a large corporation is located in a set aside jurisdiction, and the headquarters coordinates the purchase of several hundred thousand RECs for its facilities throughout North America, a VRE marketer might report all of those RECs as being consumed in the set aside jurisdiction. If the jurisdiction does not believe that it should have responsibility for retiring allowances for all of the RECs in this example, either the marketer or the customer could provide information on the customer organization's consumption within the jurisdiction.

If the rationale for the set aside is to protect consumers in WCI jurisdictions, WCI VRE consumers could simply buy RECs from uncapped jurisdictions. However, to the extent that demand for VRE is driven by customers primarily motivated by contributing to absolute GHG reductions, this "no action" solution to protecting consumers will push investment in renewable facilities serving the voluntary market toward uncapped jurisdictions. Purchaser-based retirement responsibility would not cover sales of RECs from facilities in the jurisdiction to VRE consumers in uncapped areas or capped areas without a set aside.

Because the RGGI Model Rule provisions do not retire allowances for exported renewable products, renewable energy generated inside the RGGI region will not have an emissions benefit when sold outside the RGGI region unless allowances are purchased and retired by the renewable energy marketers. This has led Green-e to announce that they are no longer certifying renewable energy generated inside the RGGI region and sold outside the RGGI region.[25] It is not clear whether this will have practical implications for the RGGI states in the short-term. High REC prices inside several RGGI states indicate that in-region supply of certain types of renewables is already struggling to meet demand. This may be an indicator that the RGGI states are not currently strongly situated as net exporters of renewable energy products.

Purchase and generation data for WCI partner states available from Green-e and the National Renewable Energy Laboratory suggest that WCI Partner US States on the whole appear to generate more renewable products for sale on the voluntary market than they purchase from it, meaning that they are a net exporter of voluntary renewable energy products. Constraining retirement to in-region purchases could disrupt the market for renewable generation in WCI Partner jurisdictions.

Unfortunately, comparable data does not appear to be available for the Canadian WCI Partner jurisdictions, making it challenging to determine whether constraining retirement to in-region purchases would disrupt the market for renewable generation.

6.3.2 Generator-Based Responsibility

Under the generator-based approach to retirement responsibility, a WCI jurisdiction would retire allowances whenever RECs from a facility in its territory were retired by customers in the voluntary market. Like the purchaser-based approach, the set aside could be limited to purchases by customers in the same jurisdiction, other WCI jurisdictions, other capped jurisdictions, or to apply regardless of the customer's location. One advantage to a generator-based approach with no limitation on the customer's location is that it enables renewable generators in the jurisdictions to be certified for the VRE market without any further need to track where VRE sales ultimately occur (i.e., where RECs are retired). If set aside jurisdictions impose a geographic limitation, then generators participating in the VRE market risk having some portion of their output being decertified (or marketed as a different "no avoided emissions" product) based on the purchaser's location. All other options introduce an additional complication of having to track either where the RECs used in each jurisdiction were generated or where the purchasers of RECs from generators in each jurisdiction are located[26].

[25] Green-e Energy Policy Update: RGGI State Set-Aside Provisions for Voluntary Renewable Energy Sales and Green-e Energy Eligibility. Green-e. December 5, 2008. http://www.resource-solutions.org/where/pressreleases/2008/120508-2.htm

[26] Or where the renewable energy is generated if the accounting system for the VRE set aside is not based on RECs.

Renewables from uncapped regions do not require allowance retirement because their generation does avoid additional fossil-based electric generation. Renewables from other capped regions present the same issue as RECs from within the capped WCI region. The only other capped region at this time is RGGI, which does not contain provisions to retire allowances for exports of renewables outside the RGGI region (i.e., to the WCI). However, given the current supply and demand balance in North America, failure to retire allowance for REC imports from the RGGI region may not have any practical implications for WCI. Voluntary renewable products imported from the Midwestern Greenhouse Gas Reduction Accord (Midwestern Accord) region[27] could be made whole through allowance retirement by the Midwestern Accord or the WCI. The question that remains is who should bear the financial costs of allowance retirement. Exporting states may wish to do so in order to encourage new renewable development within their borders, while importing states may wish to do so in order to encourage renewable development outside their borders in effort to make these products more affordable to their citizens.

Table 4: Comparison of Options for Geographic Treatment of Voluntary Renewable Energy

Limitation→ ↓ Responsibility	Purchased from/sold to own jurisdiction	Purchased from/sold to any WCI jurisdiction	Purchased from/sold to any capped jurisdiction	Purchased from/sold to any jurisdiction
Purchaser-Based	Equivalent to gen-based, need to account for number of RECs from in-jurisdiction sources	Need to account for number of RECs used from in-WCI sources	Need to account for number of RECs used from all capped (e.g. RGGI) sources	N/A (no need to have purchaser-based version because purchases from uncapped jurisdictions do not need set aside)
Generator-Based	Equivalent to purchaser-based, need to track where RECs are retired	Need to track where RECs are retired	Expands application to sales to entities in other capped jurisdiction such as RGGI or Midwestern Accord jurisdictions, need to track where RECs are retired	Generators receive one certification, good for sales to all jurisdictions, no need to track where RECs retired

6.3.3 Implications of Geographic Treatment Options

The options for treatment of VRE products are summarized above in Table 4. In short, in-region renewable development may be maximized under a purchase approach by retiring allowances only for renewable energy generated in the region, and under a generator approach by retiring

[27] Assuming the Midwestern Accord results in an active cap-and-trade regime.

allowances for all renewable generation including exports. Retirement for out-of-region generation is only necessary when renewables are located in a capped state, and then the question is which program should bear the responsibility for the retirement.

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should retire allowances using a generator-based approach in which allowances are retired whenever RECs from a facility in that Partner jurisdiction's territory are purchased and retired by a customer in the VRE market with no limitation on the customer's location. Alternatively, the retirement should be based on VRE sales if RECs are not used.*

Harmonization on the jurisdictional responsibility is essential to avoid introducing considerable and unnecessary confusion into the VRE market. Consider two WCI states, one with a purchaser-based set aside (State A) and the other with a generator-based set aside (State B). If RECs from a generator in State B are retired by an entity in State A, then both states would retire allowances for the same MWhs. If RECs from a generator in State A are retired by an entity in State B, then neither state would retire allowances.

This draft recommendation has some interesting implications for both the WCI and RGGI. There is considerable variation among the RGGI states in how they treat voluntary purchases of renewable energy generated outside their borders. While some states only retire allowances for renewable energy generated within the RGGI states, others do not constrain geographic scope in this manner. The RGGI voluntary renewable energy program is purchaser-based. Therefore, no RGGI state retires allowances to account for in-state renewable generation that meets out of state voluntary renewable energy demand. As a result, the RGGI rule does not contemplate a scenario under which allowances have already been retired to account for renewable energy sold into the voluntary market. Therefore, it is not clear whether those states would retire allowances for WCI-based renewable energy sold into the RGGI market if a WCI jurisdiction has already retired allowances to account for that electricity. While there is an environmental benefit to retiring more allowances than is warranted for an individual purchase of voluntary renewable energy, the RGGI and WCI jurisdictions have a financial interest in not retiring more allowances than is warranted. Therefore, it could be advantageous for any WCI jurisdictions that plan on adopting a generation-based VRE program to work with the RGGI states that retire allowances for generation outside the RGGI region to collaboratively determine an appropriate path forward.

6.4 Retirement Limits

Because establishing a VRE set aside involves removing allowances that could be used for other purposes, such as funding energy efficiency or R&D, jurisdictions may wish to limit the amount of allowances placed in the VRE reserve. In addition, jurisdictions may consider limiting the number of compliance periods the program will remain in effect.

6.4.1 Upper Limit on Retirement Amount

As described in Section 4.1, a key component to establishing a VRE set aside is determining the total allowances that would be dedicated for retirement to support the VRE market. However, the need to access allowances for compliance purposes may lead covered entities to resist dedicating a large number of allowances to support one sector of the economy. For that reason WCI Partner jurisdictions may choose to limit the amount of allowances that are dedicated to supporting the VRE market.

Given the regional strength as an exporter of voluntary renewable products, if the WCI adopts VRE set aside provisions that acknowledge out-of-region purchases of in-region renewable generation, then a larger set aside might be appropriate (as a fraction of electricity emissions). However, it is important to note that WCI is an economy-wide program and therefore its base budget is much larger than electric sector emissions. This means that more VRE sales can be supported with 1% of the budget from the economy-wide WCI program than 1% of the budget from the RGGI program, which only covers the electric sector.

Establishing limits does provide planning certainty to regulated entities. However, while short-term predictions may be reasonably accurate, uncertainty increases substantially the further out in time predictions are made. Some RGGI states have dealt with this by establishing provisions that allow them to increase the size of the set aside over time. Rather than exclude some VRE transactions from set aside eligibility after the fact, a jurisdiction that does reach the retirement limit in a given year could borrow some allowances from a future period or avoid borrowing by pro-rating the reductions by lowering the per MWh rate at which allowances are retired. This would give the jurisdiction time to re-evaluate the retirement limits and avoid having some transactions disqualified from the set aside eligibility assumed by parties at the time those transactions were arranged. If a jurisdiction has hit its limit for several years and compensated by adjusting the de facto retirement rate downward, it is possible that VRE certifiers may respond by decertifying facilities located in or serving customers in that jurisdiction.

RGGI Model Rule

The VRE set aside provisions in the RGGI Model Rule provide for states to retire enough allowances to make all voluntary renewable energy purchases whole. However, all nine states that have adopted a VRE set aside have limited the total number of allowances that may be retired to around 1% to 2% of the state allowance budget. Most states adopted these limits expecting that this limit would be adequate to satisfy demand for the next several years.

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should choose whatever upper limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions must determine if they will cover shortfalls by either borrowing allowances from a future year or lowering the per MWh retirement rate.*

It is not important for jurisdictions to harmonize on the issue of limits to allowances in the set aside. Because there is significant disparity in member jurisdictions' renewable capacity, then if retirement limits are pursued, each jurisdiction may wish to calculate its own.

6.4.2 Time Limit on VRE Set Aside Program

In determining whether or not a set aside is necessary, consideration may be given to how long a set aside for this purpose should be available. Stakeholders have expressed concern that a cap-and-trade program could dampen the dramatic increase in VRE sales in recent years. A justification for a set aside could be to initially provide a bridge for this market while they adjust their promotion message to reflect an economy that is now factoring in the cost of carbon. As technology improves, the cost of renewable energy goes down and allowance price stabilizes, Partners may want to be able to adjust a program accordingly.

If the price premium is the justification for a VRE set aside (or any other set aside), then it will face a problem in the longer-term. Cap and trade programs work by putting a price on the right to emit GHGs, thereby incentivizing conservation, efficiency, and alternative sources of energy. As a price signal propagates through the economy, additional investments in energy efficiency and alternative energy become cost-effective. Thus, over time there is greater prevalence of low-carbon investments and purchases because such decisions are economically beneficial, as well as environmentally beneficial. If the price of allowances is low and/or renewable energy technology has not progressed enough to make renewable energy cost-competitive, a VRE set aside could be justified to encourage those willing to pay a premium to cover the spread between conventional and renewable energy. But what happens when renewable energy technology advances and rising allowance prices make renewable energy cost-competitive? In other words, if the rationale used to justify a VRE set aside is that VRE consumers are willing to pay a premium to provide a public good, what happens when a premium is no longer needed?

If the public goods aspect of the VRE market serves as the primary justification of a set aside, then WCI jurisdictions that choose to implement them should consider making them contingent on a continued price premium for the technologies supported by the set aside. The set aside program should be re-evaluated periodically to determine whether the technologies supported by the set aside have attained price parity with conventional alternatives. Presumably, with the combination of rising costs for fossil fuels (as a result of the cap and trade price signal) and technological progress many sources of renewable energy will be cost-competitive in the next ten to fifteen years. As renewable technologies become cost-competitive, they would be removed from the list of eligible sources.

<u>RGGI Model Rule</u>

At present, there is no time limit on the VRE set aside program in any RGGI jurisdiction.

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should choose whatever time limit (if any) that is found appropriate for that jurisdiction. Partner jurisdictions may choose to base time limits on periodic reviews of the cost-competitiveness of the technologies supported by the set aside program.*

This is not an area where harmonization among WCI jurisdictions is important.

6.5 Attributing Emissions to Voluntary Renewable Energy Purchases

A central feature of designing a VRE set aside is determining the rate at which allowances will be retired for every MWh of verified eligible VRE. If the goal of the VRE set aside is to preserve the right to make legitimate emission reduction claims comparable to the claims that could be made before implementation of a cap, that suggests basing the allowance retirement rate on the emissions that would have been avoided by VRE facilities in the absence of a cap. However, estimating the emissions avoided by renewable electricity requires a complex analysis of the resources serving the grid region where the facility is located.

Power from many generating units is dispatched to meet fluctuating demand, and the impact of a given renewable energy facility could cause any of a number of operating plants to curtail its generation, prevent a different plant from generating at all or some combination of the two. This effect is referred to as the “operating margin.” In the longer term, investment in renewable energy capacity could displace the construction of a new fossil-fired plant altogether. This effect is referred to as the "build margin."[28] With interconnected electricity markets, the problem becomes even more complex. A VRE purchase in one jurisdiction from another may then cause the second jurisdiction to import less fossil-fired generation from a third jurisdiction.

Since the exact units affected by the output from a renewable energy facility cannot be known at every moment, estimated avoided emissions rates are necessary. One method of estimating the emissions rate is to use the average emissions rate for the jurisdiction in which the VRE purchase is made or the jurisdiction where the renewable energy was generated. This calculation is straightforward, but it is unlikely to be very accurate.[29] Marginal emission factors better reflect the generation sources displaced by output from renewable energy facilities. Use of an emission factor for the region where the electricity was generated would be consistent with the generator-based responsibility recommended in section 6.3.

One option may be to use the Default Emissions Factor Calculator that the WCI Electricity Team is currently developing for the purpose of attributing emissions to electricity imported into the WCI region. The Calculator is designed to calculate marginal emission factors based on operating margins

RGGI Model Rule

The RGGI Model Rule defines the benefit of a voluntary renewable energy purchase as the marginal CO_2 emissions rate (lbs CO_2/MWh) in the control area where the generation occurred. However, if the data necessary to determine the marginal emissions rate is unavailable, then the average emissions rate should be used.

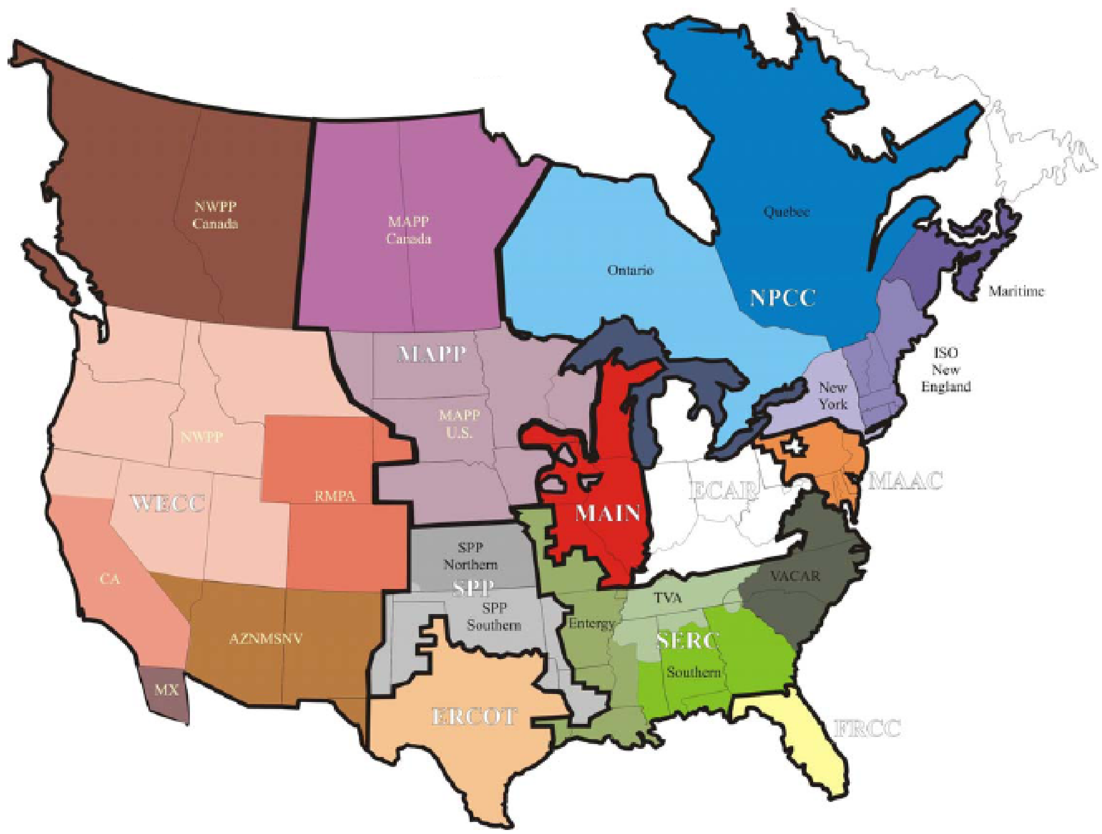
The RGGI Model Rule simply refers to a "control area." The interconnection of electric grids seems to make state and provincial borders less relevant than NERC regions (e.g., WECC) and NERC sub-regions (e.g., AZNMSNV) (See Figure 5). If allowance retirement is tied to use of renewable energy products, then a broader region may be desirable as RECs are likely to come from sub-regions different than where they are "used." However, if allowance retirement is tied to generation, than smaller sub-regions may be useful. At this time, it is not yet clear whether marginal emissions rates are calculated for each NERC region and sub-region.

Several of the RGGI states intend to use the marginal emissions rate calculated by their NERC Sub-region, ISO New England (ISO-NE). ISO New England (ISO-NE) began calculating marginal

[28] Derik Broekhoff, 2007. *Guidelines for Quantifying GHG Reductions from Grid-Connected Electricity Projects.* World Resources Institute/World Business Council for Sustainable Development. http://www.wri.org/publication/guidelines-quantifying-ghg-reductions-grid-connected-electricity-projects
[29] Ibid.

emissions rates in 1994 in order to analyze the impact of Demand Side Management programs. This analysis continues today, though the methodology has changed over time. Currently, ISO-NE calculates the marginal emissions rate using the actual hourly generation and monthly air emissions rate[30] of marginal fossil units, which are defined as all units whose primary fuel is oil or natural gas.

Figure 5: NERC Regions and Sub-Regions (Source: NERC)



Previously, the ISO-NE marginal emissions rate was based on the emissions rate of units that would have run had demand been higher. This employed a production simulation model developed to replicate system operations for the previous year. The marginal emissions rate was calculated as the difference between modeled historical emissions and modeled emissions when load was 500 MW higher in each hour. According to the 2006 Marginal Emissions Rate Analysis, ISO-NE moved away from the production simulation model because "the reference case never exactly matched the previous year's unit level energy production because of

[30] The emission rates are mainly based on actual emissions reported in the EPA Clean Air Markets database, along with some data from the NEPOOL Generation Information System (GIS), and some rates from EPA's eGRID.

numerous modeling reasons including market dynamics, specific outages and deratings." [31] Additional communications with ISO-NE indicate that prior to switching methods, a comparison of the two methods was performed and yielded "very similar" results, and therefore, they decided to go with the "more straightforward" approach of evaluating actual emissions from oil and gas fired units.[32]

Draft Recommendation

> *WCI Partner jurisdictions that choose to implement a VRE set aside should work together to develop a rate based on a marginal dispatch analysis, such as the WCI Default Emission Factor Calculator, for each major grid region. However, use of this rate should be optional and specific assignment of emissions left to jurisdictional discretion.*

Harmonization on the allowance retirement rate is not essential, and in the current market, avoided emissions rates are either not quantified or vary by location. It may be desirable, however, to use one rate across the WCI region to simplify transactions in the VRE market.

7 Stakeholder Involvement and Next Steps

The WCI Partner jurisdictions invite stakeholders to provide written comments on the discussion and analysis in this paper. We encourage stakeholders to structure their comments around the draft recommendations (summarized in Table 1 at the beginning of this paper) for those WCI Partner jurisdictions that do choose to implement a VRE budget adjustment program (VRE set aside) as part of their cap-and-trade program.

We invite stakeholders to discuss with us and provide their comments during the WCI Electricity Collaborative on January 21, 2010 in Phoenix, AZ. Details on the collaborative and stakeholder participation options will be distributed via the WCI list serve and posted on the Western Climate Initiative website (www.westernclimateinitiative.org).

Written comments on this paper can be submitted via the Western Climate Initiative website until February 19, 2010.

A paper with final recommendations which incorporates stakeholder comments on this paper will be produced and posted after the comment period closes.

Annex: Optional VRE Set aside Language in RGGI Model Rule[33]

Voluntary renewable energy purchase. A purchase of electricity from renewable energy generation or renewable energy attribute credits by a retail electricity customer on a voluntary basis. Renewable energy includes electricity generated from biomass, wind, solar thermal, photovoltaic, geothermal, hydroelectric facilities certified by the Low Impact Hydropower Institute, wave and tidal action, and fuel cells powered by renewable fuels. The renewable energy generation or renewable energy attribute credits related to such purchases may not be used by the generator or purchaser to meet any regulatory mandate, such as a renewable portfolio standard.

(d) Voluntary renewable energy market set-aside allocation. For each control period, the REGULATORY AGENCY shall allocate to the voluntary renewable energy market set-aside account a certain number of tons, calculated as set forth in this subdivision, from the NAME OF RELEVANT RGGI STATE CO_2 Budget Trading Program base budget set forth in section XX5.1, as applicable. The REGULATORY AGENCY shall administer the voluntary renewable energy set-aside in accordance with this subdivision.

> (1) The REGULATORY AGENCY will open and manage a general account for the voluntary renewable energy market set-aside for each control period.
>
> (2) The number of tons that will be allocated to the voluntary renewable energy market set-aside account in a specific control period will be determined as set out in this paragraph.
>
>> (i) Any person may submit data to the REGULATORY AGENCY documenting purchases of voluntary renewable energy that meet the requirements of this subdivision by no later than the July 30 prior to the beginning of a control period. Such data must be from reputable sources, which may include retail electricity providers, organizations that certify renewable energy products, and other parties as determined by the REGULATORY AGENCY. To be considered, data must be verifiable and document the following for voluntary renewable energy purchases.
>>
>>> (a) Documentation of voluntary renewable energy or renewable energy attribute credit purchases by retail customers, by customer class, in the State during the most recent three-year period for which data are available.
>>>
>>> (b) Documentation that the renewable energy or renewable energy attributes related to voluntary renewable energy or renewable energy attribute credit sales was procured by the retail provider.
>>>
>>> (c) Time period when the retail purchase(s) was made.
>>>
>>> (d) State where the electricity was generated or the renewable energy attribute credit was created, including documentation of facility name, unique generator identification number, and fuel type.
>>>
>>> (e) Time period when the electricity was generated or the renewable energy attribute credit was created.
>>
>> (ii) Subject to the timely receipt of adequate data pursuant to subparagraph (i) of this paragraph, and based on such data, the REGULATORY AGENCY shall project the

[33] Regional Greenhouse Gas Initiative Model Rule. 1/5/07 Final with Corrections. http://rggi.org/docs/model_rule_corrected_1_5_07.pdf

voluntary renewable energy purchases in the State during a control period that represents renewable energy generation in one or more participating states. The megawatthours (MWh) of projected voluntary renewable energy purchases in a control period shall be multiplied by the marginal CO_2 emissions rate (lbs. CO_2/MWh) in the control area where the generation occurred, as determined by the REGULATORY AGENCY. If data to determine the marginal emissions rate is unavailable, the average emissions rate shall be used, as determined by the REGULATORY AGENCY.

(iii) The CO2 tons to be allocated to the voluntary renewable energy set-aside account shall be calculated as follows:

CO2 tons = MP x EF

where:

CO2 tons, rounded down to the nearest whole ton, is the number of allowances to be placed in the reserve account.

MP is the projected MWh of voluntary renewable energy purchases in the State during the future control period that meets the requirements of this subdivision.

EF is the CO2 emissions factor for the control area where the electricity represented by the sale was generated.

(iv) If following the end of a control period, the number of CO2 allowances allocated to the voluntary renewable energy set-aside account is less than the number of CO2 tons represented by the actual MWh of voluntary renewable energy purchases during the control period, the REGULATORY AGENCY will add the difference between CO2 tons represented by actual purchases, as calculated in accordance with subparagraph (iii) of this paragraph, and CO2 allowances held in the set-aside account to the projection for the following control period, pursuant to paragraph (2) of this subdivision. If following the end of a control period, the number of CO2 allowances allocated to the voluntary renewable energy set-aside account is greater than the number of CO2 tons represented by the actual MWh of voluntary renewable energy purchases during the control period, the REGULATORY AGENCY will subtract the difference between CO2 tons represented by actual purchases, as calculated in accordance with subparagraph (iii) of this paragraph, and CO2 allowances held in the set-aside account from the projection for the following control period, pursuant to paragraph (2) of this subdivision. In no event shall the size of the voluntary renewable set-aside exceed ___________ tons.

(3) As of the December 31 that is after the end of a control period for which an allocation has been made to the voluntary renewable energy set-aside account, the REGULATORY AGENCY shall determine the actual MWh of voluntary renewable energy purchases that occurred during the control period. The REGULATORY AGENCY shall retire CO2 allowances in the voluntary renewable energy set-aside account in an amount up to the number of tons of CO2 represented by actual voluntary renewable energy purchases, based on actual MWh purchases and the emissions factor determined pursuant to paragraph (2) of this subdivision.

Algae-Based Biofuels and Bioproducts

Brief Overview

Milton Sommerfeld and Qiang Hu

Laboratory for Algae Research and Biotechnology (LARB)

Department of Applied Sciences and Mathematics

ASU Polytechnic Campus, Mesa, AZ 85212

Western Climate Initiative

Tempe Mission Palms Hotel

Tempe, Arizona

January 20, 2010

Laboratory for Algae Research and Biotechnology

LARB's Mission:

To conduct fundamental and applied research on algae to accelerate the use of algae as a cost-affordable and sustainable source of fuels and chemicals and for improving the environment through algae-based bioremediation.

LARB provides innovative training for the next generation of scientists and engineers for the biotechnology workforce, collaborates with industry and research institutions, and develops international partnerships for research and education to promote algae-based opportunities and solutions.

LARB's Research Areas

Algae Biology

- Strain selection and characterization
- Lipid metabolism
- Carotenoid synthesis
- Carbon partitioning
- Oxidative stress and stress response

Biofuels

- Bioreactor
- Algal mass culture
- Downstream rocessing
- Oil production
- Fuel conversion
- Co-products recovery

Carbon Capture

- CO_2 removal from power plant gas emissions

Water/wastewater bioremediation

- Nutrient and heavy metal removal from water and wastewater

High-value products

- Omega-3 fatty acids
- Carotenoids and other pigments
- Polysaccharides and starch
- Biologically active substances

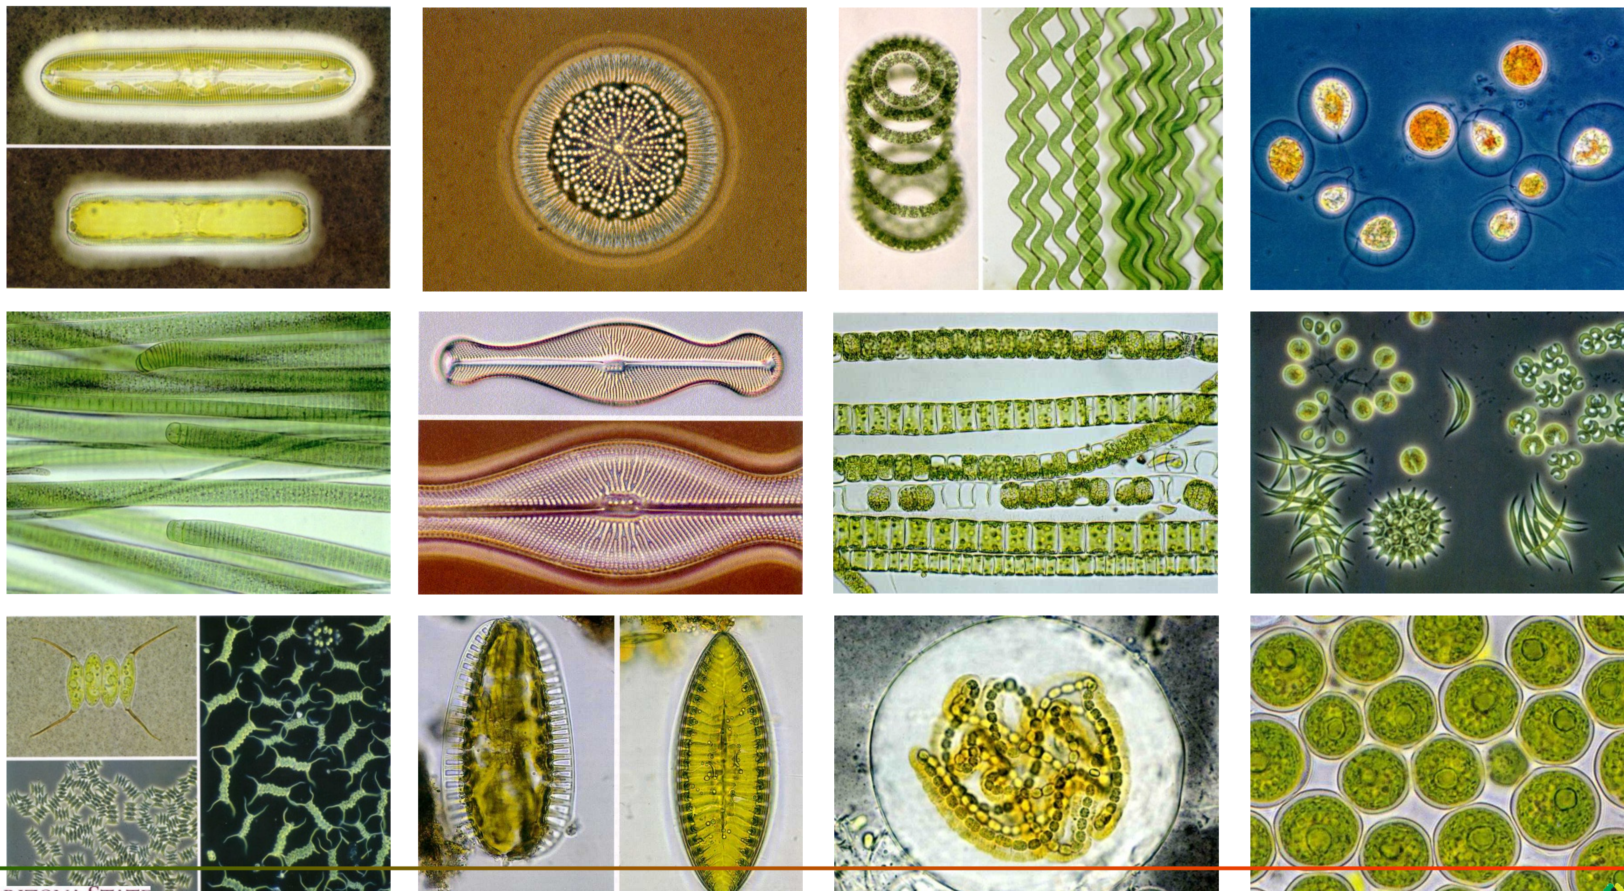
What are Algae?

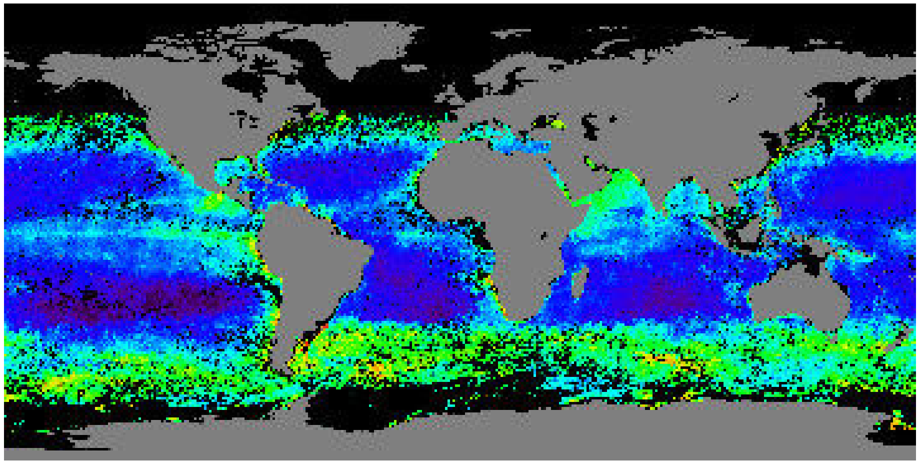
- Photosynthetic organisms
- Range from giant seaweeds to microscopic unicellular organisms
- Lack specialization associated with typical terrestrial plant life
- Widely distributed

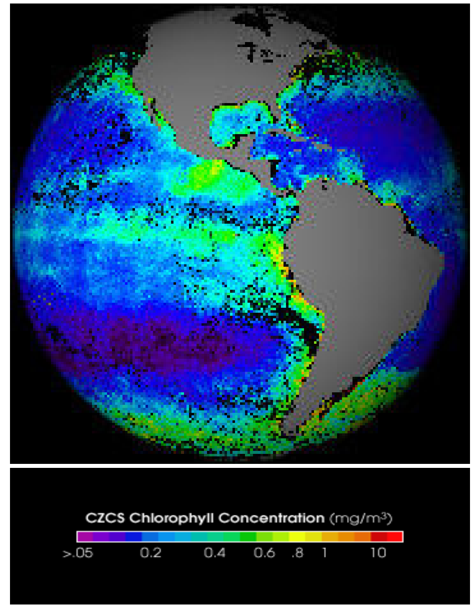
Macroalgae

Microalgae

Prokaryotic: **cyanobacteria (blue-green algae)**
Eukaryotic: **diatoms, green algae, red algae, brown algae, golden algae, dinoflagellates, etc**



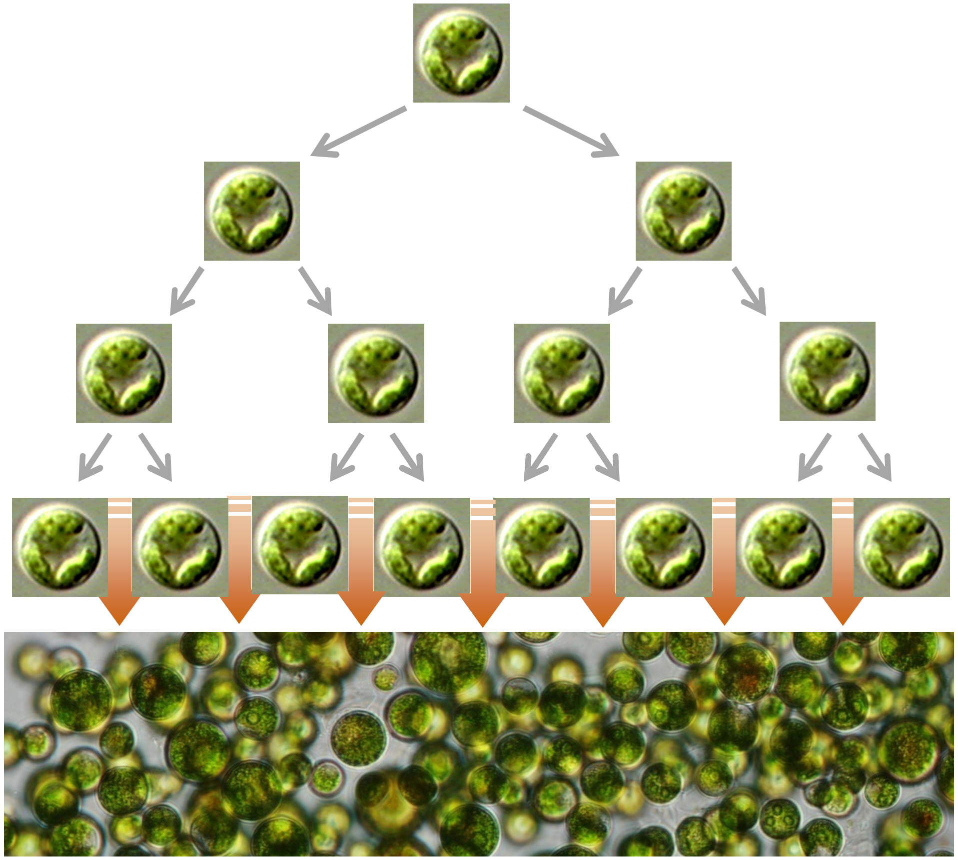




Some Facts about algae:

- > 40,000 described species
- ~ 1-2 % of the total global plant carbon
- Fix about 40 % the total carbon annually (30~50 billion metric tons of carbon/yr)
- Rapid biomass doubling time (1-6 days)

Growth Potential: Algae *vs* Plants



Biomass Yields of Algae *vs* Terrestrial Crops

Crops	Biomass yield (tons ha^{-1} y^{-1})
Sugar cane	54 - 125
Sweet sorghum	35 - 70
Soybean	1.1- 4.0
Sweet potato	10 - 40
Forest plants	20 - 50
Microalgae	100 - 300

Algae for Fuel?

"The identification or development of microalgal strains that will meet the performance criteria of high productivity, high lipid content, and wide ranges of environmental tolerance is the single most critical research requirement for the economic viability of microalgal fuels technology."

- sulfated polysaccharides
- destrin
- carrageenans

Minerals
- zinc
- iron
- selenium
- calcium, boron

Polyunsaturated fatty acids
- eicosapentaenoic acid (EPA, 20:5ω3)
- docosahexaenoic acid (DHA, 22:6ω3)
- γ-linolenic acid (GLA, 18:3ω6)
- arachidonic acid (AA, 20:4ω6)

Pharmaceuticals
- antibiotics
- antitumour/cancer metabolites
- antineoplastic metabolites
- anti-HIV substances
- anti-viral compounds

Pigments
- lutein
- ß-carotene
- zeaxanthin
- astaxanthin
- phycobiliproteins

Advantages of Microalgal Feedstock Production

- High growth potential (>1 doubling time a day)
- High cellular oil content (20~60% of dry weight)
- 5~10-fold higher yield potential than oilseed plants
- Wealth of natural products and chemicals
- Thrive in saline/brackish (non-potable) water
- Couple with wastewater treatment
- Couple with carbon capture
- Flexibility in land requirement: desert and arid lands
- Opportunities for strain improvement
- Not a food crop

Western Climate Initiative

Summary of Comments on Draft Guidelines for Developing WCI Partner Allowance Budgets

www.westernclimateinitiative.org

Commenters

- Approximately 50 comments from 10 submitters / letters
  - Arizona Public Service
  - BC Forestry Climate Change Working Group
  - Pacific Gas & Electric
  - Puget Sound Energy
  - Southern California Edison
  - Southern California Public Power Authority
  - Power Workers' Union
  - WEST Associates
  - Utah Business Climate Change Coalition
  - Western Climate Advocates Network

Nature of Comments (1)

- Increase transparency and stakeholder input
  - Contractor methods / results regarding emissions forecast
  - Economic modeling results
  - Proposed budgets
- Provide greater explanation / detail
  - Relationship between capped emissions, uncapped emissions, and regional goal
  - Developing a rate of decline
  - Voluntary reductions and early reduction allowances
  - Accounting for recession / recovery
  - One percent 2012 adjustment

Nature of Comments (2)

- Maximize accuracy of 2012 / 2015 best estimates
  - Avoid use of economic/emissions forecast (too uncertain)
  - Consider using 2005-07 or 2009-2011 reported emissions
- Minimize risk of over /under allocation
  - Maintain flexibility in establishing / adjusting budgets
  - Consider mandatory reporting data
  - Develop criteria for when adjustments are warranted
  - Avoid overestimation of new source emissions (retire new source allowances if sources not built)

Nature of Comments (3)

- Consider improving budget-setting method by:
  - Setting a single rate of decline from 2012 to 2020
  - Assessing actual vs forecasted data in 2011
  - Improving 2005 emission inventory
  - Actively engaging industry to improve emissions/forecasts

Nature of Comments (4)

- Schedule / process
  - Establishing preliminary budgets this summer unrealistic, especially if public review / input is expected
  - What if a Partner jurisdiction rejects CSAD recommend-ations, or if program not fully implemented by 2012
- Other
  - Allocation methods should be developed as early as possible and more heavily centralized or harmonized
  - Economic/pop growth should not be factors in forecast
  - Economic/pop growth should not be underestimated due to current recession

Nature of Comments (5)

- Other (continued)
  - Budgets should be based on on electricity consumption
  - Linear decline could create high costs
  - All sectors should be included in 2012

Western Climate Initiative

An Update on CSAD Competitiveness Work (task 3)

WCI Partners Meeting
Phoenix, AZ
January 20, 2009

Background

WCI Design Recommendations (Section 8.5):

Analyze competitiveness for like facilities

- Sectors such as: aluminum, steel, cement, lime, paper and pulp, and oil refining. Other big sectors include iron, copper, glass, and basic chemicals*****
- Analysis of competitive factors in the electricity sector

*****Identified in *Leveling the Carbon Playing Field* (2008)

Milestones

- Stakeholder discussion in Seattle (May 2009)
- Release of principles (Aug 2009)
- Review of other programs (Aug 2009)
- Outlined process and guidance (Nov 2009)
- Provide first analysis and identify methods for further assessment (Mar 2010)
  - Guidance to partners by April 2010
- Evaluate mechanisms to address competitiveness (April 2010)

Number of facilities in WCI*

FOR DEMONSTRATION ONLY

Sector	Hypothetical Partner	WCI (most partners)	Nationally (U.S.)
Aluminum	4	~10	55
Cement	2	~50	300
Glass	2	~20	695
Lime	2	~20	80
Steel	2	~10	740

Obama Competitiveness Report

Dec 2, 2009: Obama Administration releases report on competitiveness provisions of HR 2454*

- **Without** output based rebates to identified manufacturing sectors and allocations to LDCs, total annual emissions leakage to countries without C&T in the order of ~10 million MTCO2e.
- **With** rebates to mfg sectors and allocations to LDCs, leakage of emissions from identified sectors estimated at ~1 million MTCO2e.

Next steps

- **Task 3.1:** Carry out the initial WCI competitiveness analysis and identify methods for additional assessment (April 2010)
- **Task 3.2:** Evaluate mechanisms to address competitiveness based on competitiveness principles (April 2010)
- **Task 3.3:** Sponsor a workshop on benchmarking of GHG emissions from industrial sectors (May 2010)

Western Climate Initiative

An Update on the CSAD Committee's Emissions Inventory and Forecast Work

WCI Partners Meeting
Phoenix, AZ
January 20, 2009

Acknowledgements

- E. H. Pechan & Associates
  - Andy Bollman, Project Manager
  - Steve Roe, Brad Strode, and Viola Glenn
- Multiple jurisdictional staff
  - Collecting and submitting emissions data
  - Reviewing proposed forecast methods, preliminary results, and this presentation

Project Background

- WCI Design Recommendations
  - "For 2012, each Partner's allowance budget will be based on the best estimate of expected emissions for sources covered in the cap-and-trade program in the Partner's jurisdiction in 2012."
  - "For 2015 each Partner's allowance budget will be set by adding the best estimate of expected actual emissions in 2015 from transportation fuels and RCI fuels to the emissions trajectory for the sources first included in 2012."

2020

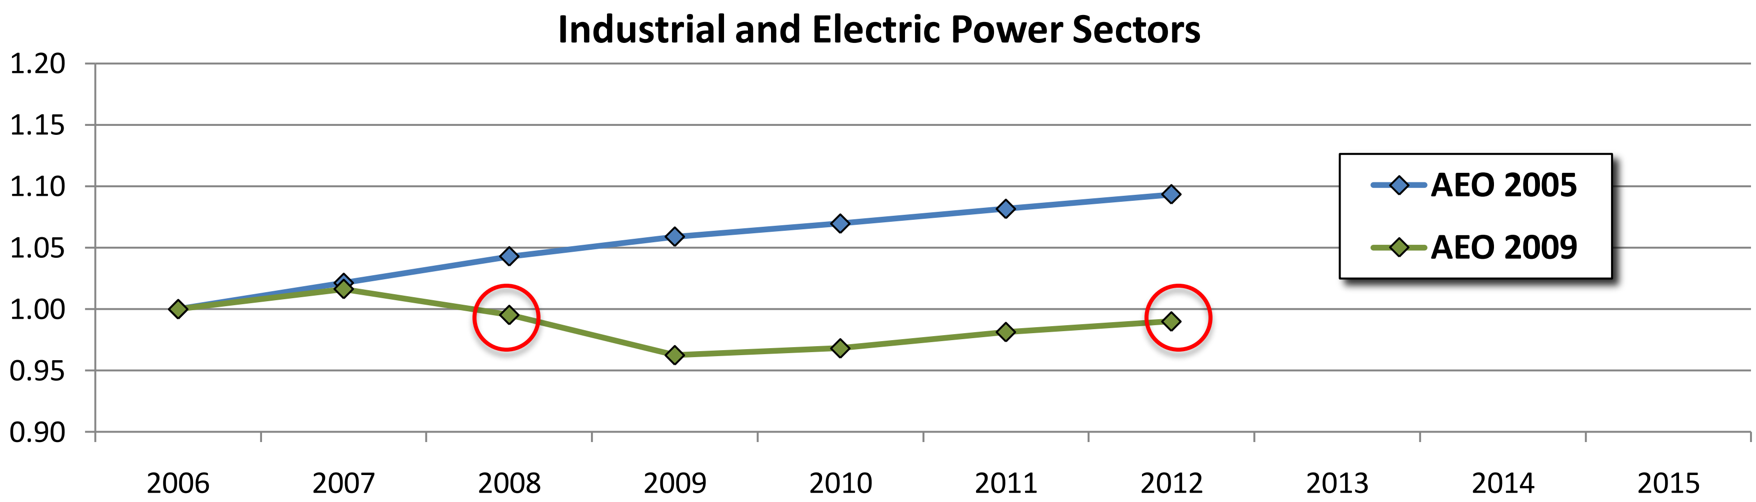
Project Background

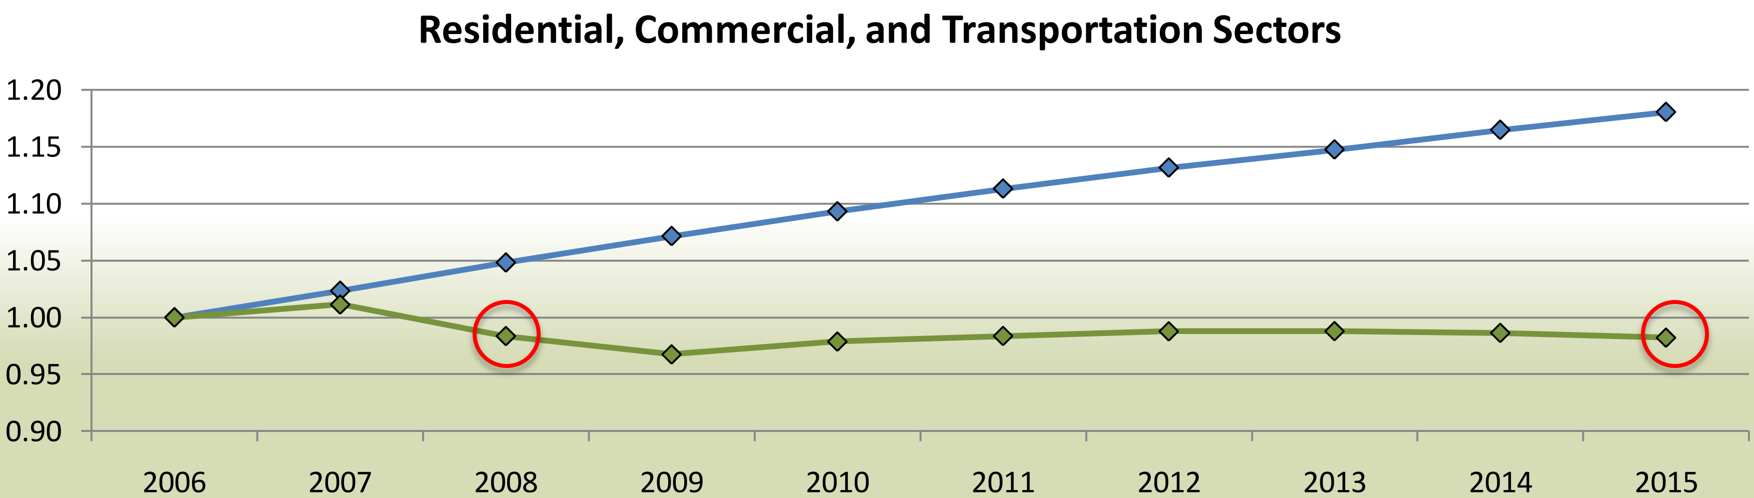
- Project objectives
  - Collect the most recent emissions data from Partners
  - Identify and compare forecast methods that can produce “best estimates” of 2012 and 2015 emissions consistently across Partner jurisdictions
  - Build a regional database that can be used by Partners throughout the budget setting process
- Project history
  - RFP released June 19, 2009
  - Pechan selected on July 29, 2009
  - Project funded at $50,000

Project Background

- Notes
  - This inventory necessarily differs from prior inventories (e.g., state action plans and the Task 0 data) in that it must include only those emissions which would be subject to the cap (e.g., facilities > 25,000 tpy for which sufficient monitoring protocols have been developed)
  - Emissions associated with electricity imports are not yet included in this analysis (the necessary data are being collected by the Electricity Team)
  - Accounting for the 2008-09 recession, recovery, energy efficiency improvements, and renewable energy standards is important for avoiding over allocation

Normalized Growth in CO_2e Emissions
U.S. DOE Annual Energy Outlook 2005 vs 2009





Basic Approach

1. Identify emission forecast methods
   - Appropriate for purpose of project
   - Provide growth factors at no additional cost
2. Collect "base year" emissions data from each Partner jurisdiction
   - As recent as possible
   - At a resolution that matches / takes advantage of the resolution in the forecast methods

Basic Approach

3. Apply emissions "growth factors" from each forecast method to the base year data and compare results

Example: WA Paper Manufacturing (NAICS 3221)								
	Base Emissions		ENERGY 2020			AEO		
Fuel/Process	Year	CO_2e	Surrogate	GF	2012	Surrogate	GF	2012
Natural Gas	2007	534,032	WA - EI Industry - Energy Use	0.85	453,927	National - Paper - NG Consumption	0.97	518,011
Waste Oil	2007	108,124	WA - EI Industry - Energy Use	0.85	91,905	National - Paper - Renewable Consumptior	0.95	102,718
Natural Gas	2008	98,886	WA - EI Industry - Energy Use	0.89	88,009	National - Paper - NG Consumption	0.99	97,897
Waste Oil	2008	73,539	WA - EI Industry - Energy Use	0.89	65,450	National - Paper - Renewable Consumptior	0.96	70,597

Emission Forecast Methods

Method Number	Energy		Industrial Processes	
	Canada	United States	Canada	United States
1	ENERGY 2020 energy use projections		ENERGY 2020 GHG emissions, fuel, and economic output projections	
2	*Canada's Energy Outlook* energy projections	*Annual Energy Outlook* energy projections	EPA non-CO_2 GHG projections and growth projected based on analysis of historical emission trends	
3	*Canada's Energy Outlook* socioeconomic projections	*Annual Energy Outlook* socioeconomic projections	*Canada's Energy Outlook* socioeconomic projections	*Annual Energy Outlook* socioeconomic projections

- Task 1a and Task 1b memos on SharePoint
  - Describe each method and compares them across five evaluation criteria
- The Task 2 memo on SharePoint
  - Describes a crosswalk linking growth factors from each method to base year emissions by jurisdiction, sector, and fuel/process

Method Comparison: Transparency

ENERGY 2020	AEO	CEO
• Major assumptions documented. • Extensive history of application/review by many clients. • Algorithms and functions deriving emission estimates are not identified in WCI documentation. • Calibration to historical emissions data not clear.	• Major assumptions very well documented. • Algorithms very well documented. • Undergone extensive review, including peer reviews.	• Much less well documented than AEO, however, CEO models are derived from AEO models.

Method Comparison: Scope

ENERGY 2020	AEO	CEO
• Comprehensive 2012 and 2015 emission forecasts provided for all Partner jurisdictions.	• Provides 2012 and 2015 energy sector and socioeconomic projections by regions. • Does not project industrial process activity/emissions.	• Provides 2010 and 2015 projections for energy sectors by province, and 2010/2015 national economic projections for a limited number of sectors. • Reports industrial sector projections by fuel type only for combustion sources. • Projects CO_2-equivalent total industrial sector "non-energy" emissions by province for 4 GHGs.

Regions Modeled by the AEO

Census Region

Electricity Market Module Regions

Method Comparison: Resolution

ENERGY 2020	AEO	CEO
• Primary fuel energy forecasts for each Partner jurisdiction. • Industrial processes not categorized at level of preferred detail. • U.S. power sector generation and emissions are modeled at the plant level, and by "model" plants in Canada. • US energy data are from 2004. The vintage of Canadian energy data is not documented.	• Primary fuel demand forecasts by region. • Power generation and emissions are forecast by NERC region, although modeled at plant-level. • RCI and transportation primary fuel use forecast at Census division level. • Incorporates data up through 2007	• Primary fuel demand forecasts for each sector reported by province. • Some growth factors available by province, others at national level. • Forecasts total CO_2e emissions by pollutant (no process-specific data are reported). • Does not specify the vintage of source data, however CEO projections were last published in 2006.

Method Comparison: Method Design and Foundation

ENERGY 2020	AEO	CEO
• Robustness of model difficult to assess (proprietary nature). • Does not explicitly assume learning curves over the period for most building end uses. • Price elasticities are modeled endogenously. • Electricity imports /exports between jurisdictions are simulated. • Impacts of numerous state/federal policies included.	• Built on a strong theoretical foundation and includes rich detail of energy technologies. • Develops 4 sets of alternative forecasts (low/high economic growth, and low/high oil prices). • Models learning-by-doing effect on tech costs. • Price elasticities, and their associated rebound effects, are modeled. • Impacts of numerous state/federal policies included.	• Provides cursory information on MAPLE-C model (derived from NEMS used in AEO) • Provides cursory information on the governmental policies for which impacts are estimated.

Method Comparison: Historical Performance

ENERGY 2020	AEO	CEO
• The range of differences between the 2006 model forecast and Partner base year emissions is generally modest, but some anomalies for a few jurisdictions. • Prediction of 2006-2007 growth in electricity sales and generation in Illinois was mixed.	• Provides historical performance evaluations in an annual Retrospective Report, indicating modest differences relative to actual EIA estimates.	• CEO does not document a retrospective comparison of its projections against historical estimates.

Base Year Emissions:
Two Major Types of Data

- “Bottom-up” data
  - Emissions reported for each facility based on emission measurements, fuel consumption, or other throughputs
  - Basis for 2012 forecast
- “Top-down” data
  - Emissions calculated for an entire sector and jurisdiction based on its fuel use or other activity data
  - Basis for 2015 forecast

Base Year Emissions: Data Collection Process

- In Aug-Sep, staff from each WCI jurisdiction were contacted to determine:
  - availability of bottom-up data
  - preferences for top-down data
  - estimates for voluntary reductions

See Task 3 memo on SharePoint

- In October, templates were sent to each jurisdiction to collect bottom-up data in a common format
- Sufficient data were collected for purposes of comparing forecast methods, but additional data will be needed for budget-setting purposes

Base Year Emissions:
Data Sources

	Bottom-Up	Top-Down
BC, MB, ON	Federal Large Final Emitters Database (2008)	Federal National Inventory Report (2007)
QC	Provincial GHG reporting rule (2006)	
CA, NM	State GHG reporting rule (2008)	U.S. State Energy Data System (2007)
AZ, OR, WA	State/local air quality permits and some voluntary industry data in WA (2008 for AZ and 2007/2008 for WA)	
MT, UT	Mostly power plant data from EPA, with some industry data from MT (2008)	

Model Results

- Recently received, under review by staff
- Socioeconomic growth factors provide a useful reference but are not recommended as surrogates for forecasting GHG emissions
  - Do not account for significant changes in efficiency, renewable energy generation, demand response to price
  - Emissions growth surrogate not always appropriate (e.g., power sector employment)
- ENERGY 2020 generally predicts a wider range of changes than AEO/CEO

Next Steps

- Partner review and feedback
- Additional data collection and analysis
  - Include electricity imports
  - Improve base year emissions data
- Decide on forecast approach
- Stakeholder review
- Additional funding required for all the above
- Prelim annual budgets from Partners by April?

Additional Data Collection/Analysis

- Top-down emissions data
  - Update data for U.S. and Canada from 2007 to 2008
- Bottom-up emissions data
  - Two states could not complete bottom-up inventory
  - Some states missing or have incomplete process emissions
  - Three provinces missing most sources in the 25-100kt range
  - Most U.S. power plant emissions for 2009 available by April
- Forecast data
  - New AEO and CEO expected this spring (last CEO was 2006)

Possible Forecast Approaches

1. All Partners use same method
2. Each Partner chooses most appropriate method or blend of methods
3. Investigate alternative methods
   - A third multi-sector equilibrium model
   - Single-sector method (electricity)
     - Partner-level data/knowledge (utility forecasts/IRPs)
     - Regional forecasts/model (NERC forecasts and utility production-cost modeling)

Possible Forecast Approaches

The following two approaches place a stronger emphasis on empirical data and Partner knowledge of local, near-term economic development and emission trends

4. Use methods above to portray the likely range of 2012 and 2015 best estimates while Committee continues improving inventory through 2011

   … as new data become available on economy, new sources, shutdowns, process emissions, and mandatory reporting.

5. Each Partner submits "best estimate"
   - Methodological results used as a check in this process

Western Climate Initiative

Next steps for WCI Offset Protocols

WCI Partners Meeting
Phoenix, AZ
January 20, 2009

Overview

Today, we are seeking Partner guidance on:

1. Completing the final DNV report
2. Options for adapting existing protocols to meet WCI's criteria
3. Options for stakeholder engagement on the DNV report and the adaptation of existing protocols

DNV Report

- DNV has completed the draft Report on Existing Offset Protocols.
- The Offsets Committee is awaiting Partner feedback prior to tasking DNV to complete the Report.
- On what timeline can we expect Partner feedback?

Options for adapting existing protocols to meet WCI criteria

We have discussed three different options for moving forward, which have different timing and cost implications.

1. **Staff complete required modifications for the existing protocols to meet WCI criteria**

   Time: Slow – high time commitment from WCI staff

   Cost: Low

   Considerations:

   - Do WCI Partner jurisdictions have the expertise and are they willing to dedicate staff time to this project?
   - Are there copyright issues with using existing protocols as the base?

Options for adapting existing protocols to meet WCI criteria, con't

2. WCI issues RFP to hire contractor(s) to complete the required modifications for the existing protocols to meet WCI criteria

Time: Fast

Cost: High

Considerations:

- Does WCI have the budget to complete this work via contractors?
- Are there copyright issues with using existing protocols as the base?

Options for adapting existing protocols to meet WCI criteria, con't

3. **WCI partners with the organizations that created the protocol to create a version that meets WCI criteria**

   Time: Fast

   Cost: Medium

   Considerations:

   - What if there are different organizations that are best for different project types?
   - Are the organizations willing to partner with WCI?
   - Are the organizations willing to put their resources into the partnership with WCI?
   - Should WCI select a single organization for all protocol adaptation work?
   - What financial contribution would WCI have to make?

Options for engaging the public

- Provide DNV's final report for public release to:
  1. provide public input on protocols evaluated by DNV;
  2. seek public comment on DNV's evaluation of the protocols;
  3. make suggestions on way forward.

Options for engaging the public, con't

- Involve public in protocol adaptation work:
  1. Involve experts in the protocol adaptation process;
  2. Involve the public directly in adaptation of protocols (subcommittee structure);
  3. Provide draft adapted protocols for public review and comment.

Options for engaging the public, con’t

- Seek public feedback on adapted protocols:
  1. Post final recommended protocols for comment;
  2. Hold stakeholder workshops/webinars for final protocols;
  3. Incorporate final protocols into Offset Essential Elements with final Committee recommendations.

Western Climate Initiative

Preliminary 2010 Work Plan Proposals

WCI Partners Meeting

Phoenix, AZ

January 20, 2009

Cap Setting and Allowance Distribution

- Task 1: Data Review and Collection
  - Assumes data collection by Committee will be used to assess issues, guide improvements, and promote transparency, but not as ***the*** data for setting budgets
  - Products and timing:
    - In process: Assemble regional emissions spreadsheet
    - In process: Draft recommendations for forecast methodologies
    - Ongoing: Spreadsheet revised every 3-6 months
    - March: Recommendations for harmonizing historic emissions data and applying forecast methodologies
    - April: Stakeholder call and comment on regional emissions data and projection methodologies
    - June – October: Compare and assess differences between inventory methodologies and reporting methodologies
  - Resources: Approximate budget is $95,000

Data Needed to Establish Annual Partner Allowance Budgets

Data sources in red to be provided by Partners
Data sources in blue to be provided by Partners and/or CSAD/contractors

+ New Sources
– Shut Downs
– Vol. Reductions ← **Forecasted Emissions** ← **Base Year Emissions (inc. electricity imports)**

CSAD Task 1

2001 – 2005 Econ-Wide GHG & **MWh Produced MWh Consumed** & **Population Growth**

CSAD Task 4

CSAD Task 2

2012 = **2012 B.E.** + **1% Adjustment** + **ERAs**

2013 = 2012 B.E. + 1% Adjustment - **ROD_1**

2014 = 2013 - ROD_1

2015 = 2014 - ROD_1 + **2015 B.E.**

2016 = 2015 - **ROD_2**

Etc

.

<u>Other factors potentially affecting budgets:</u>

- Results of mandatory reporting data in 2011
- Number of participants in C&T program in 2012
- Bilateral agreements on electricity generated in one Partner jurisdiction / consumed in another

Data Needed to Evaluate Reductions Against Regional Goal

- To determine if regional emissions are likely to be 15% lower in 2020 relative to 2005, the following data will be needed for each Partner jurisdiction:
- **2005 Economy-Wide GHG Emissions**
  - Could use the 2001-2005 data from the 1% adjustment
- **2020 Best Estimate of Uncapped Emissions**
  - Would be added to 2020 budget to determine economy-wide emissions
  - Waste, wastewater, non-combustion agriculture/forestry, and miscellaneous industrial process emissions
    - Process emissions without sufficient monitoring protocols
    - Process emissions with sufficient monitoring protocols but at facilities whose total emissions are less than 25,000 tpy CO_2e

CSAD *Cont.*

- Task 2: Cap and Budget Setting
  - Principal work involves potential revision to draft guidance document and implementation of guidance by Partners and Committee
  - Products and timing:
    - March: Approve any revisions to guidance document
    - April: Submit/review "preliminary" budgets
    - June: Partner jurisdictions agree to "established" budgets
    - October 2011: Partner jurisdictions agree to "final" budgets
  - Resources: No additional needs are currently identified

CSAD *Cont*

- Task 3: Competitiveness Analysis
  - CSAD will work closely with the Electricity Team to assess competitiveness issues in the electricity sector
  - Products and timing:
    - Jan – March: Data analysis for competitiveness impacts, and evaluate mechanisms to address
    - March: Stakeholder call and comment
    - April: Options papers - methods for additional assessment , and mechanisms to address competitiveness
    - TBD: Stakeholder workshop
  - Resources: No additional needs are currently identified

CSAD *Cont.*

- Task 4: 2012 One-time Budget Adjustment
  - Products and timing:
    - February: Draft criteria recommendations
    - March – April: Data set for the budget adjustment
    - May: Final adjustment recommendation
  - Resources: $10,000 for gathering data and initial calculation
- Task 5: Offset Compliance Limit
  - Products and timing:
    - February : Offset Compliance Limit Recommendations
    - March: Stakeholder call
  - Resources: No additional needs are currently identified

CSAD *Cont.*

- Task 6: Early Reduction Allowances (ERA)
  - Products and timing:
    - February: Draft recommendations on ERA criteria and process
    - March: Draft ERA design recommendations (with a background document)
    - April: Stakeholder call and comments
    - June: Final ERA design recommendations
  - Resources: No additional needs are currently identified

Markets Committee

- Task 1: Coordinate Development of Cap-and-Trade Essential Elements
  - 2009 Status: Moved out of Markets Committee to be under overall responsibility of Partners through Co-Chairs
- Task 2: Recommend Compliance Verification and Enforcement Requirements
  - 2009 Status: Work deferred as part of mid-year prioritization
  - Products: **Partner input requested on what specific products are needed from this task to support 2010 WCI priorities**
  - Timing: TBD based on guidance received
  - Resources: Partner staffing support needed

Markets Committee, *Cont.*

- Task 3: Recommend Market Oversight
  - 2009 Status: Objectives defined, white paper released, and stakeholder call and workshop held
  - Products, timing and resource needs:
    - March: Draft recommendations (budget TBD, no additional staffing needs)
    - March-June: Options paper on quantity limits ($25,000)
    - April: Stakeholder call and comments
    - May-June: Final recommendations

Markets Committee, *Cont.*

- Task 4: Recommend Tracking Systems and Related Infrastructure
  - 2009 Status: Work deferred as part of mid-year prioritization
  - The task group recommends two tracks for 2010:
    - Tracking system policy recommendations (to be completed in time to feed into the model rule)
    - Approach to tracking system procurement (timing TBD)
  - Resources: Budget TBD. Partner staffing support needed.

Markets Committee, *Cont.*

- Task 5: Design Regional Administrative Body
  - 2009 Status: Work deferred as part of mid-year prioritization
  - Products: **Partner input requested on whether interest in broadening RAO work beyond cap and trade to support complementary policies (e.g. LCFS)**
  - Resources: Budget TBD. Partner staffing support needed.
- Task 6: Recommend Auction Design for Allowances
  - 2009 Status: White paper drafted, circulated for peer review
  - Products and timing: White paper and draft/final recommendations (Feb-June 2010)
  - Resources: Budget TBD. Partner staffing support needed.

Offsets Committee

- Task 1: Recommendations for Offset System Essential Elements
  - Products and timing - Offsets Definition and Criteria
    - Jan : Draft recommendations, release for stakeholder comment
    - March – April: Draft Final recommendations, release for stakeholder comment
    - June: Final recommendations, release for stakeholder comment
  - Products and timing – Offsets Process
    - Feb: White paper, release for stakeholder comment
    - March-April: Draft recommendations, release for stakeholder comment
    - May: Draft Final recommendations, release for stakeholder comment
    - July: Final recommendations, release for stakeholder comment
  - Resources: No additional needs are currently identified

Offsets Committee, *Cont.*

- Task 2: Recommendations for accepting offsets credits and allowances from systems other than the WCI
  - On hold: Develop white paper and recommendations
  - Current work:
    - Monitor ongoing development of international offset mechanisms and the linking of emission trading systems on an ongoing basis.
    - Prepare comments for WCI as needed.
  - **Partner input requested: is specific work required on this task to support June WCI priorities.**

Offsets Committee, *Cont.*

- Task 3: Offset Protocols
  - Products and timing:
    - Feb: Evaluation Report on Existing Protocols, release for stakeholder comment
    - March – December: Adapt existing protocols (timing TBD based on resources – possible additional resources from 3 regional initiatives collaboration):
    - July onwards: Recommend protocols where no suitable protocol exists
    - October – December: Release final WCI protocols for WCI Partner jurisdiction adoption
  - Resources:
    - $50,000 per protocol for significant modifications of an existing protocol
    - $100,000 per protocol for new protocols where no suitable protocol exists

Reporting Committee

- Task 1: Harmonization of WCI Essential Requirements for Mandatory Reporting (ERs) with EPA Mandatory Reporting Rule (EPA Rule)
  - Products and timing
    - In process: Committee technical work to review EPA Rule and identify changes needed for:
      – WCI program
      – Conformance to Canadian regulatory norms
    - March-April: First present final recommendations, stakeholder call and comments
    - April: Final ERs
  - Resources: No additional needed

Reporting Committee, *Cont.*

- Task 2: Develop Essential Requirements for Mandatory Reporting for Oil and Gas Exploration and Production and Natural Gas Processing
  - Products and timing:
    - In process: Ongoing calls/workshops with stakeholder Technical Working Group
    - March: WCI comments to US EPA on re-proposed Subpart W of their mandatory reporting rule
    - December: First present harmonized ERs for Mandatory Reporting for Oil and Gas, stakeholder comment period
    - January 2011: Approve final ERs
  - Resources: No additional needed

Electricity Team

- Task 1: Attributing emissions for electricity imports
  - Products and timing
    - In progress: Default emissions calculator to determine emission factors for imports (tied to CSAD Task 1 & 2, will be discussed at Collaborative)
    - In progress: OATI report and analysis, and eastern provinces data collection, to quantify historical imports (tied to CSAD Task 1 & 2 and Reporting, will be discussed at Collaborative)
    - In progress: Recommendation on treatment of RECs
    - March – July : Recommendation on conditions for specified imports
  - Resources: No additional needed

Electricity Team, *Cont.*

- Task 2: Estimate Eastern Leakage potential
  - Products and timing
    - In progress: Contractor study to estimate Eastern Leakage potential
    - January: Initial results will be presented at Collaborative
    - March: Report complete, will be used as input for eastern Provinces decision on FJD
  - Resources: No additional needed

Electricity Team, *Cont.*

- Task 3: Recommend Administrative Option Design
  - Products and timing:
    - January – Feb: Issues will be discussed at Collaborative
    - March - June: Draft and final Administrative Option recommendations
  - Resources: Support staff assistance on analysis and drafting

Electricity Team, *Cont.*

- Task 4: Voluntary Renewable Energy
  - Products and timing:
    - January – Feb: Draft options and recommendations paper will be presented at Collaborative, released for stakeholder comment
    - April: Final recommendations
  - Resources: Support staff assistance
- Task 5: Competitiveness and Reliability Issues Related to Distribution of Allowance and Allowance Value
  - Support CSAD Task 3 on competitiveness issues associated with the electricity sector – Team will provide analysis and recommendations as required.
  - Resources: Possible support staff assistance

Complementary Policies

- Task 1: Selection of Complementary Policies for Preliminary Analysis
  - Almost complete:
    - Stakeholder comment period on Complementary Policies White Paper closes Jan 29, 2010.
    - Committee will then amend and finalize paper.
- Task 2: Stakeholder input and dialogue
  - The committee will continue to work to identify and pursue ways to obtain stakeholder views and engage additional partners
  - Additional resources not anticipated

Complementary Policies, *Cont.*

- Task 3: Analyze Workforce Issues and Develop Recommendations
  - Products and timing: To be developed based on Partner guidance
  - Resources: Additional needs will depend on approach developed and ability to access state/provincial experts

Complementary Policies, *Cont.*

- Task 4: Recommend Complementary Policies for Regional Harmonization
  - Products and timing:
    - June: Draft white paper on policies for regional harmonization
    - June: Stakeholder review and comment
    - July: Final recommendations for harmonized policies
  - Resources: Additional needs will depend on policies selected
- Task 5: Inventory of inter-jurisdictional adaptation work groups, committees and other collaborations
  - Work deferred in 2009 as part of mid-year prioritization
  - Partner input requested on priority of this task for 2010

Western Climate Initiative

Administrative approach to covering imported electricity in the WCI cap and trade system

Electricity Collaborative
Phoenix, Arizona

January 21, 2010

Background

- September 2008 Design Recommendations recommend First Jurisdictional Deliverer (FJD) as point of regulation for electricity sector including imported electricity
- July 2009 recommendation to use individual boundary approach
- September 2009: Electricity team asked to propose an administrative option

Rationale

- Some jurisdictions may import only small amounts of fossil-fuel-fired electricity and it may be more cost effective to take an administrative approach to those very small emissions
- The environmental integrity of the cap (total number of allowances in 2012 and declining amounts through 2020) should be considered in the alternative approach
- The effect of the price signal for buyers and consumers of imported electricity GHG emissions created by the cap should be considered in the alternative approach

Concept

Step 1: Jurisdiction determines 2012 forecast emissions for imported electricity

Step 2: Jurisdiction creates allowances equal to the forecast emissions and places them in a the jurisdiction’s reserve account

Step 3: Jurisdiction tracks emissions attributable to imported electricity consumed in the jurisdiction

Step 4: Jurisdiction retires allowances in an amount equal to emissions attributable to imported electricity

Possible Results

- FJD has no direct compliance obligation under jurisdiction’s cap and trade system
- Price advantage for importers of fossil-fuel-fired electricity may be contained if the amount of imports are small or if the type of imports is regulated by another regulator under an approach such as a Renewable Portfolio Standard
- Negative impacts on GHG and electricity markets could be mitigated if electricity is imported under a specified contract and generation information is tracked by the jurisdiction to calculate annual reserve pool amounts.

Challenges

1. Forecasting the reserve pool
   - What if the reserve pool is insufficient to cover emissions from imports?
     - Are allowances taken from other compliance entities?
     - Does the jurisdiction purchase allowances on the market?
   - What if the reserve pool contains more allowances than are needed to cover emissions from imported electricity?
     - Are excess allowances retired?
   - Reserve pool would not affect integrity of cap so long as 2010 baselines are not inflated.

Challenges

2. Creating a price signal for deliverers of power from outside the jurisdiction.
   – Administrative option may create incentive to shift emissions out of region (leakage).
   – Administrative option imposes no carbon price on electricity from outside jurisdiction, while putting a price on in-jurisdiction generation
3. Creating a price signal for purchasers and consumers of power from outside the jurisdiction.
   – Administrative option creates price differential for electricity suppliers (and their consumers) in same jurisdiction based on regulation coverage and not on emissions

Summary questions

- Can an administrative approach be designed to achieve the environmental objective while also sending a consistent price signal to deliverers, buyers and consumers of imported electricity?
  – How important is the price signal to importers/traders?
  – How can the design be modified to reduce or eliminate leakage?
  – How important is the price signal to consumers?
  – How can the design be modified to emulate the price signal of the cap and trade coverage

Tempe Mission Palms Hotel

60 East 5th Street
Tempe, AZ 85281

Remote access: Call 1-800-868-1837 toll free in the U.S. and Canada
(1-404-920-6440 for outside the U.S. and Canada)
Participant code 659 537#

Thursday, January 21, 2010

8:30 am Welcome and Introductions (Palm Conference Room)

8:40 am Status of WCI program development
Overview of WCI design as it relates to the electricity sector

9:00 am Industry and Environmental Perspectives on Status of Carbon Regulation

Panelists:

- Ed Fox, Vice Pres. & Chief Sustainability Officer, AZ Public Service Co.
- David Butters, President, Association of Power Producers of Ontario
- Steven Kelly, Dir. of Policy, Independent Energy Producers Assoc., CA (invited)
- Suzanne Leta Liou, Renewable Northwest Project

10:30 am Break

10:45 am Moderated discussion with panel and WCI Partners followed by audience Q&A

11:30 am Wrap-Up and Next Steps – Discuss opportunities for ongoing collaboration

12:00 pm Lunch

1:00 pm WCI Electricity Team

General introduction to the issue of addressing emissions from imported electricity, including status of OATI work on historical emissions

1:30 pm Default Emissions Calculator

- Electricity Team will present and discuss default emission rates suggested by their work on an updated calculator.

2:00 pm Eastern Leakage Study

- The WCI's contractor for the Eastern Leakage Study (Navigant Consulting) will provide an update on their analysis.

3:00 pm Break

3:15 pm Voluntary Renewable Energy Market

- The WCI Electricity Team will present its white paper on this topic, including recommendations.
- Response from environmental representative

4:15 pm Administrative Option

- The Electricity Team will present a description of the administrative option and call for comments.

5:00 pm Adjourn

WCI Greenhouse Gas Analysis for Ontario, Quebec and Manitoba
DRAFT

Prepared for

Western Climate Initiative

January 21, 2010

Disclaimer

Status of Report

The results summarized in this report are the results of Navigant's analysis and as such as are draft and are subject to review and acceptance by WCI

Copyright

Confidentiality

The following report represents an analysis of the impacts of potential carbon regulation in Quebec, Ontario and Manitoba by Navigant Consulting and contains confidential information belonging solely to Navigant Consulting. Any person acquiring this report agrees and understands that the information contained in this report is confidential and, except as required by law, will take all reasonable measures available to it by instruction, agreement or otherwise to maintain the confidentiality of the confidential information of Navigant Consulting. Such person agrees not to release, disclose, publish, copy or communicate this confidential information or make it available to any third party, including, but not limited to, consultants and financial advisors, other than employees, agents and contractors of such person and its affiliates and subsidiaries who reasonably need to know it in connection with the exercise or the performance of such person's business.

Such person agrees that any disclosure of Navigant Consulting's confidential information in a manner inconsistent with the above provisions may cause Navigant Consulting irreparable harm for which remedies other than monetary relief may be inadequate, and such person agrees that Navigant Consulting shall be entitled to receive from a court of competent jurisdiction injunctive or other equitable relief to restrain such disclosure in addition to other appropriate remedies.

No Warranties or Representations

Any person acquiring this report agrees and understands that Navigant Consulting makes no representations or warranties as to the accuracy or completeness of the information contained in this report.

Some of the assumptions used in the preparation of Navigant Consulting's power market forecast, although considered reasonable at the time of preparation, inevitably will not materialize as forecasted as unanticipated events and circumstances occur subsequent to the date of the forecast. Accordingly, actual power market prices will vary from the power market price forecast and the variations may be material. There is no representation that our Ontario power market price forecast will be realized. Important factors that could cause actual power market prices to vary from the forecast are disclosed throughout the report.

Limitation of Liability

In no event will Navigant Consulting be liable for any direct, indirect, special, consequential or incidental damages, costs or expenses, including but not limited to damages for loss of business profit, information, use of the report or resulting products or services arising from use or inability to use the report or any information contained therein, whether in tort, negligence, contract or otherwise even if Navigant Consulting has been advised of the possibility of such damages.

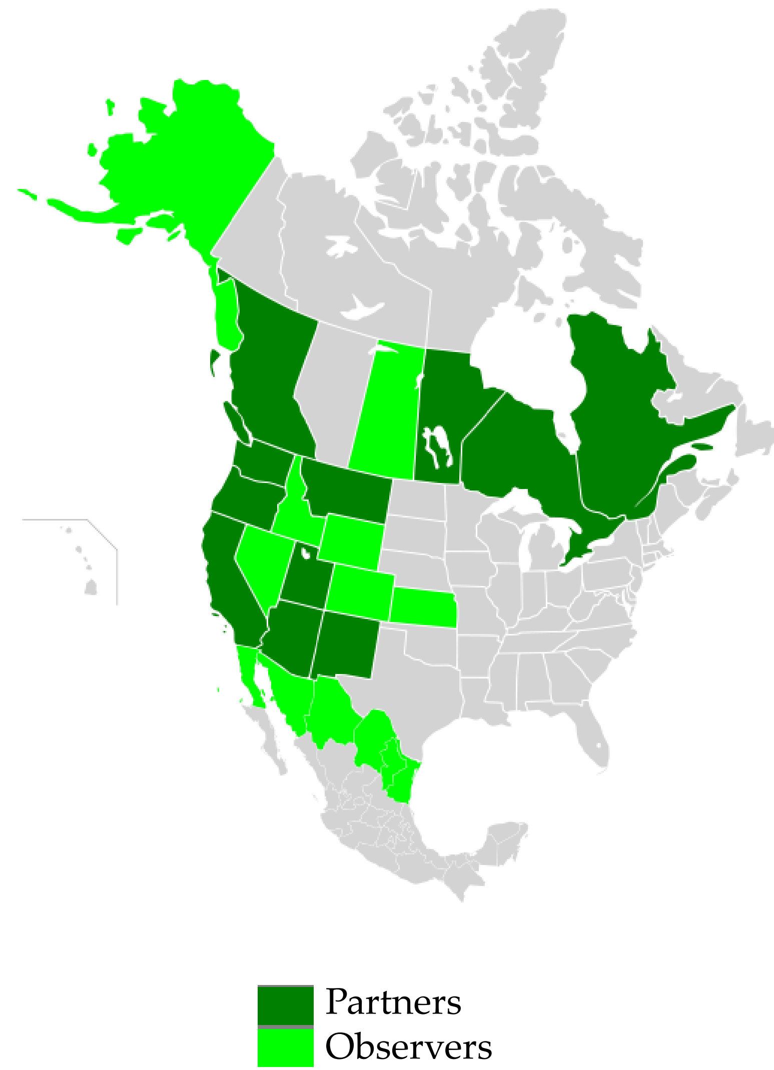
NAVIGANT CONSULTING

Study Scope

- WCI retained Navigant Consulting to analyze how electricity system operation would change if the Eastern Canadian WCI members (Manitoba, Ontario and Quebec) put a price on carbon
  - In particular, Navigant was to look at 'leakages' – whether reductions in WCI emissions would be offset by increases in non-WCI emissions
- The analysis was based on a series of hourly simulations of the electricity system in eastern Canada and the eastern U.S.
  - With and without carbon emission charges in Quebec, Ontario and Manitoba
  - With and without deemed charges on importing electricity into Quebec, Ontario and Manitoba

Western Climate Initiative Participants



Who We Are

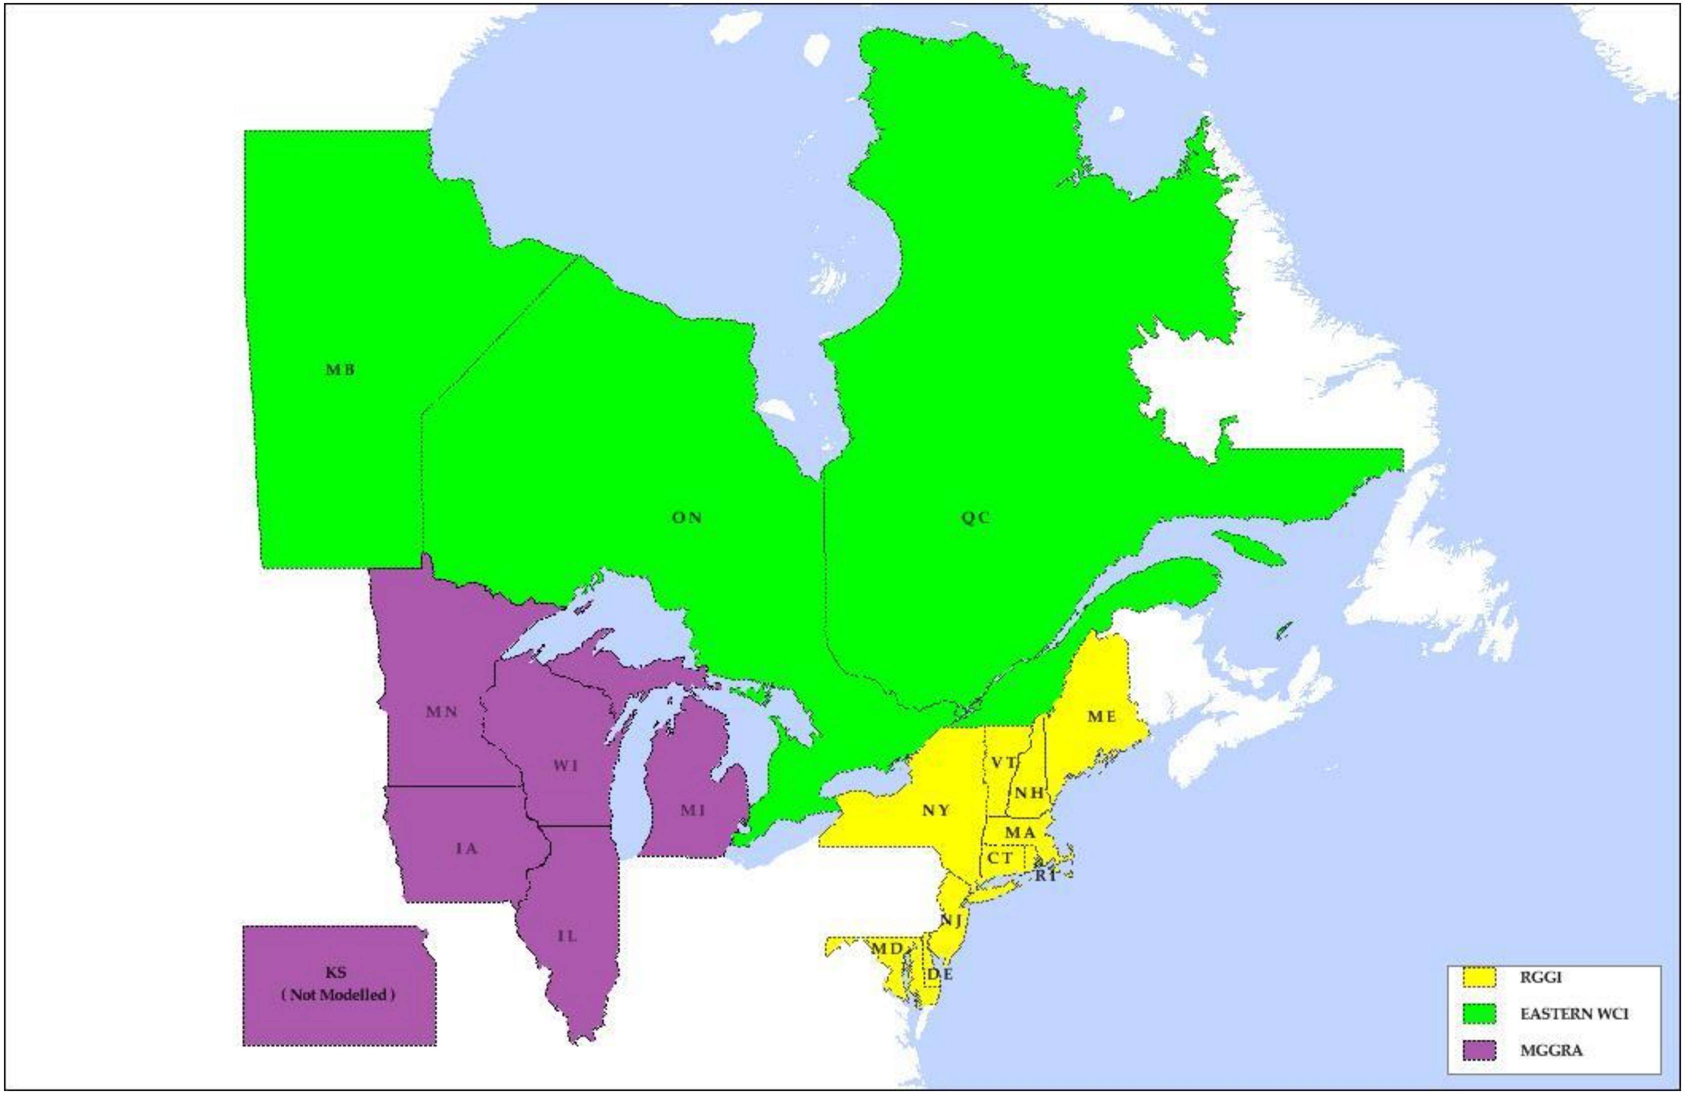
Navigant Consulting ("NCI") is a specialized independent consulting firm providing professional services to assist clients in identifying practical solutions to the challenges of uncertainty, risk and distress.

- NCI has over 1800 professionals in 30 cities
- The Energy Practice, hired by the WCI for this analysis, is 250 professionals and provides a full range of advisory services for energy sector clients
- Particular expertise in clean energy, renewables and greenhouse gas issues

Questions Addressed

- This study was intended to address the following questions:
  - Expected reduction in WCI emissions with various carbon and import charges
  - Offsetting increases in non-WCI emissions
  - Changes in generation and flows
  - Average carbon content of induced imports
  - Impact of exempting non-fossil generation outside WCI from import charges
  - Impact of aligning with RGGI (Regional Greenhouse Gas Initiative) and MGGRA (Midwestern Greenhouse Gas Reduction Accord)

WCI – MGGRA – RGGI Geography



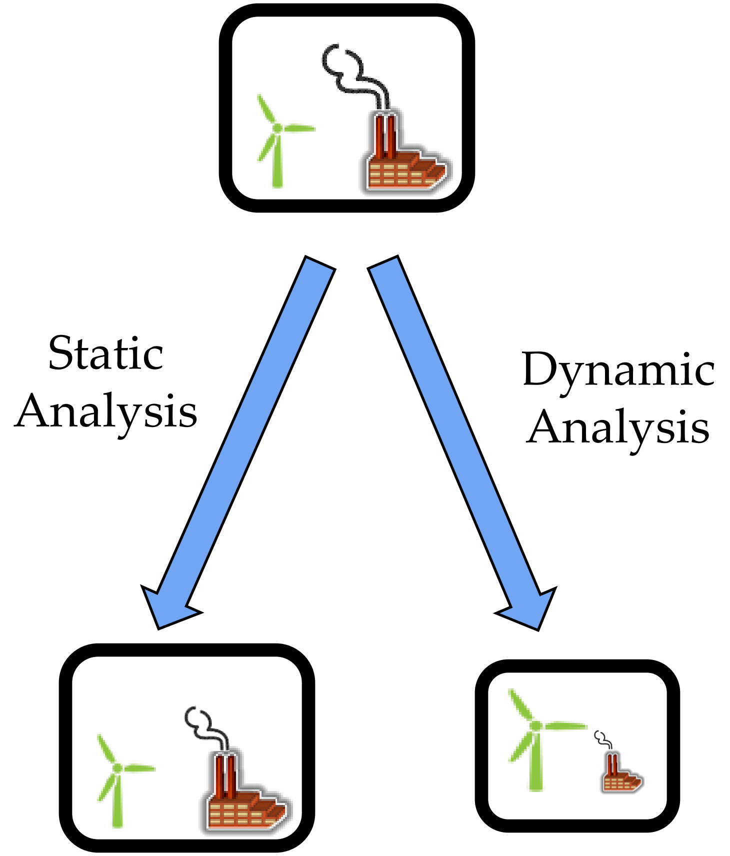
NAVIGANT CONSULTING

Static Analysis Only

- Important caveat: this is a STATIC analysis
  - Available power plants are fixed – the only change is how they operate
  - Demand is fixed – no change in total generation
  - Annual output of non-fossil plants is fixed – only fossil output can change
  - Carbon charges in WCI

    => less fossil generation in WCI

    => more fossil generation in non-WCI areas
  - Expect shifting of carbon emissions but no significant overall reduction
- Dynamic analysis (NOT considered here) would involve different expansion plans in each scenario.
  - Higher carbon prices would lead to less fossil and more non-fossil capacity
  - Potentially different demand
  - This was beyond the scope of this study



Assume no change in demand or generation *capacity*; expect less fossil generation *output*.

Expect lower demand due to higher prices, less fossil generation capacity, more non-fossil generation capacity.

5 RGGI and MGGRA

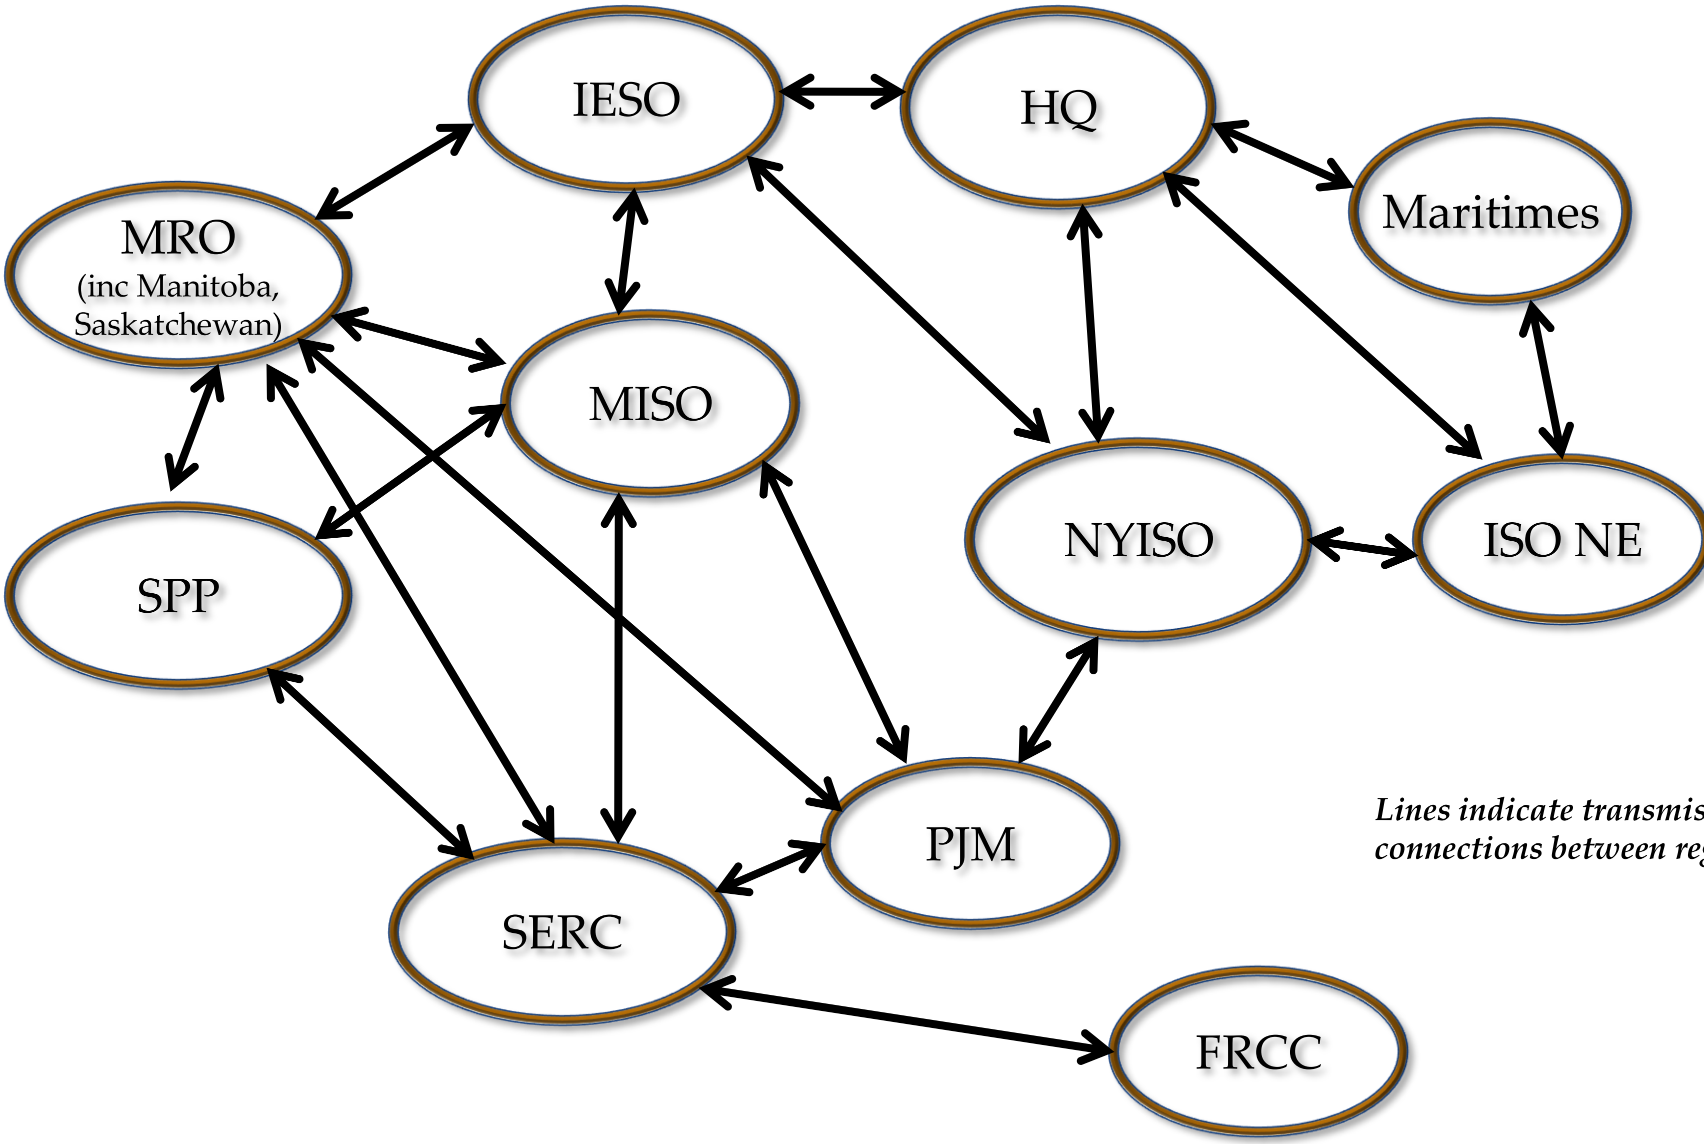
6 Modeling Conclusions

PROMOD IV

- PROMOD IV is a commercial software package that simulates the hourly operation of electricity markets:
  - Widely used in the U.S. by utilities, energy consulting firms and ISOs including WECC, PJM and MISO
  - PROMOD typically used to forecast future electricity prices and generation, revenue and costs for units
- PROMOD represents the US using three regional models:
  - WECC, the Western Electricity Coordinating Council, which covers the western U.S., Alberta and British Columbia
  - ERCOT, the Electricity Reliability Council of Texas, which covers most of Texas
  - Eastern Interconnect, the generation and transmission system that extends from Eastern Canada to Florida into the Midwest
- For the WCI analysis Navigant used the Eastern Interconnect model:
  - For Canada, this includes Quebec, Ontario, Manitoba, Saskatchewan and the Maritime provinces
  - For the US, this includes the ISO NE, NYISO, PJM, MISO markets and regulated areas in the Midwest/southeast U.S.

NAVIGANT CONSULTING

Eastern Interconnect Pool Structure



Lines indicate transmission connections between regions

PROMOD IV – Methodology

- PROMOD is a chronological optimization model that simulates the hourly operation of generation and transmission across the markets/regions included
- For each hour, PROMOD commits and dispatches units in order of increasing generation cost until hourly demand is met, while taking into account unit operating constraints and transmission limits:
  - The unit operating constraints represent real system parameters such as outages, unit minimum up and down times, ramp rates, heat rate structures
  - The transmission line limits and interface limits represent the operating restrictions that apply to the physical transmission system
- PROMOD's commitment and dispatch solution corresponds to least cost across the Eastern Interconnect, subject to the constraints defined by the user
- PROMOD output includes – hourly, monthly, annual, peak/off peak as necessary:
  - Prices at specific generators, load buses and zonal averages
  - Generation, cost and revenue data for units
  - Estimated emissions - SO_2, NO_X, CO_2 and Mercury if applicable - for units
  - Flows on transmission lines

PROMOD Assumptions

- To set up the Eastern Interconnect WCI runs for 2012 and 2020, Navigant provided assumptions for:
  - Existing and planned generation, based on published sources
  - Peak and annual energy forecasts, based on published ISO forecasts
  - Expected wind and hydro generation, based on published sources
  - Fuel prices – oil, gas, coal – based on the NCI Fall 2009 fuel forecasts
  - The likely transmission system in 2012 and 2020, based on FERC load flows and ISO transmission expansion plans
- These assumptions covered all regions in the Eastern Interconnect
  - Data assumptions for the WCI eastern Canadian provinces were reviewed by Manitoba, Ontario and Quebec

US – Canada Transmission Connections

- For the WCI analysis, PROMOD was run as a **nodal** model which includes a detailed representation of individual transmission lines in the Eastern Interconnect
- There are significant transmission interfaces that permit import and export of power into the eastern Canadian WCI provinces

  Quebec – New Brunswick [~1080 MW]

  Quebec – ISO NE [~1670 MW, expected to increase to ~2870 MW]

  Quebec – NYISO [~1625 MW]

  Ontario – NYISO [~1825 MW]

  Ontario – MISO [~2540 MW]

  Manitoba – MISO [~2175 MW]
- These transmission links create the possibility for leakage, where US generation and CO_2 emissions increase in response to WCI CO_2 regulation
- Quebec and Manitoba have substantial hydro generation and generation in excess of demand
  - Hydro Quebec has indicated intentions to increase exports to the northeast US to reach ~15-20 TWh annually
  - This assumes planned hydro and wind developments occur

WCI Modeling Methodology

- WCI Allowance Prices:
  - For some scenarios, PROMOD was set up to allow the inclusion of a CO_2 cost for carbon-emitting units in the WCI provinces, according to the proposed regulations
  - For some scenarios, a similar cost was added for thermal units in certain MGGRA states – Illinois, Wisconsin, Minnesota, Iowa, Michigan – based on that proposed legislation
- FJD Charges
  - WCI scenarios typically assumed that power imported from regions outside the WCI would attract a charge based on the assumed carbon content of the imported power
  - This is a mechanism to reduce 'leakage'
  - Referred to as FJD, First Jurisdictional Deliverer
  - Defined in PROMOD by setting tariffs between external pools to WCI provinces
- Key Assumptions:
  - Scenarios considered effects of WCI allowance and FJD charges assuming no change in demand and generating capacity from Base Case
  - Implies total generation across Eastern Interconnect is unchanged, ignoring slight difference in losses and pumped storage
  - Hydro and wind generation are unchanged as these are defined in PROMOD on the basis of annual expected generation
  - **Result is that in each scenario the balance of thermal generation changes in terms of coal/gas and US/Canadian share, taking into account transmission limits between the US and Canada**

Details of WCI Scenario Parameters - Regulatory

- Base Case
  - CAIR SO_2, NO_x in US
  - No national CO_2 in US but RGGI CO_2 in 10 north eastern US states
  - No mercury regulation
  - Ontario NO_X and SO_2
  - US regulations apply to units > 25 MW
- WCI allowance cases
  - Scenarios with $15, $30, $60 /metric tonne [US $]
  - Applied to carbon-generating units in Quebec, Ontario, Manitoba that generate more than 25,000 metric tons of CO_2 annually
  - Biomass units defined to be non-carbon generating
  - Nuclear units although thermal are non-carbon generating
- MGGRA
  - Similar legislation proposed for MGGRA
  - Five US states – Illinois, Wisconsin, Minnesota, Iowa, Michigan - plus Manitoba
  - For some scenarios, WCI and MGGRA allowance price aligned
- FJD charges
  - Defined on basis of assumed carbon content of imported power – 500 kg/MWh, 1000 kg/MWh
  - In terms of $/MWh adder, translates to 50% or 100% of WCI allowance price for each scenario
  - Depending on PROMOD setup, can be applied to all power imported into WCI provinces form non-WCI regions or can be applied to just imports from carbon-producing units

WCI Modeling - Simple Scenarios

First set of simulations considered scenarios with:

- CO_2 regulation for generating units in the eastern WCI provinces – Quebec, Ontario, Manitoba
- No corresponding CO_2 regulation in MGGRA states – Illinois, Wisconsin, Minnesota, Iowa, Michigan. [Kansas was not included in this analysis to reduce modeling complexity, and Manitoba is in the WCI]
- RGGI regulation in NE US **not** aligned with WCI regulation in terms of CO_2 allowance price
- FJD charges applied to all flows into Quebec, Ontario, Manitoba from other provinces/states – no distinction made on basis of carbon content of imported power

Scenario #	Years	WCI Allowance Price *$/tonne*	MGGRA Allowance Price *$/tonne*	RGGI Allowance Price *$/tonne*	FJD Charge *kg/MWh*	*$/MWh*
1 [Base Case]	2012, 2020	0	0	2.06	0	0
2	2012, 2020	30.00	0	2.06	0	0
3	2012, 2020	30.00	0	2.06	500	15
3a	2020	60.00	0	2.06	500	30
4	2012, 2020	30.00	0	2.06	1000	30
5	2012, 2020	15.00	0	2.06	0	0
6	2012, 2020	15.00	0	2.06	500	7.5
7	2012, 2020	15.00	0	2.06	1000	15
8	2012, 2020	15.00	0	15	500	7.5

Notes

1. In this table, RGGI allowance prices from the auction result - $1.87/short ton - have been converted to metric tonnes

2. In these scenarios the FJD charge applies only to imports from all units

NAVIGANT CONSULTING

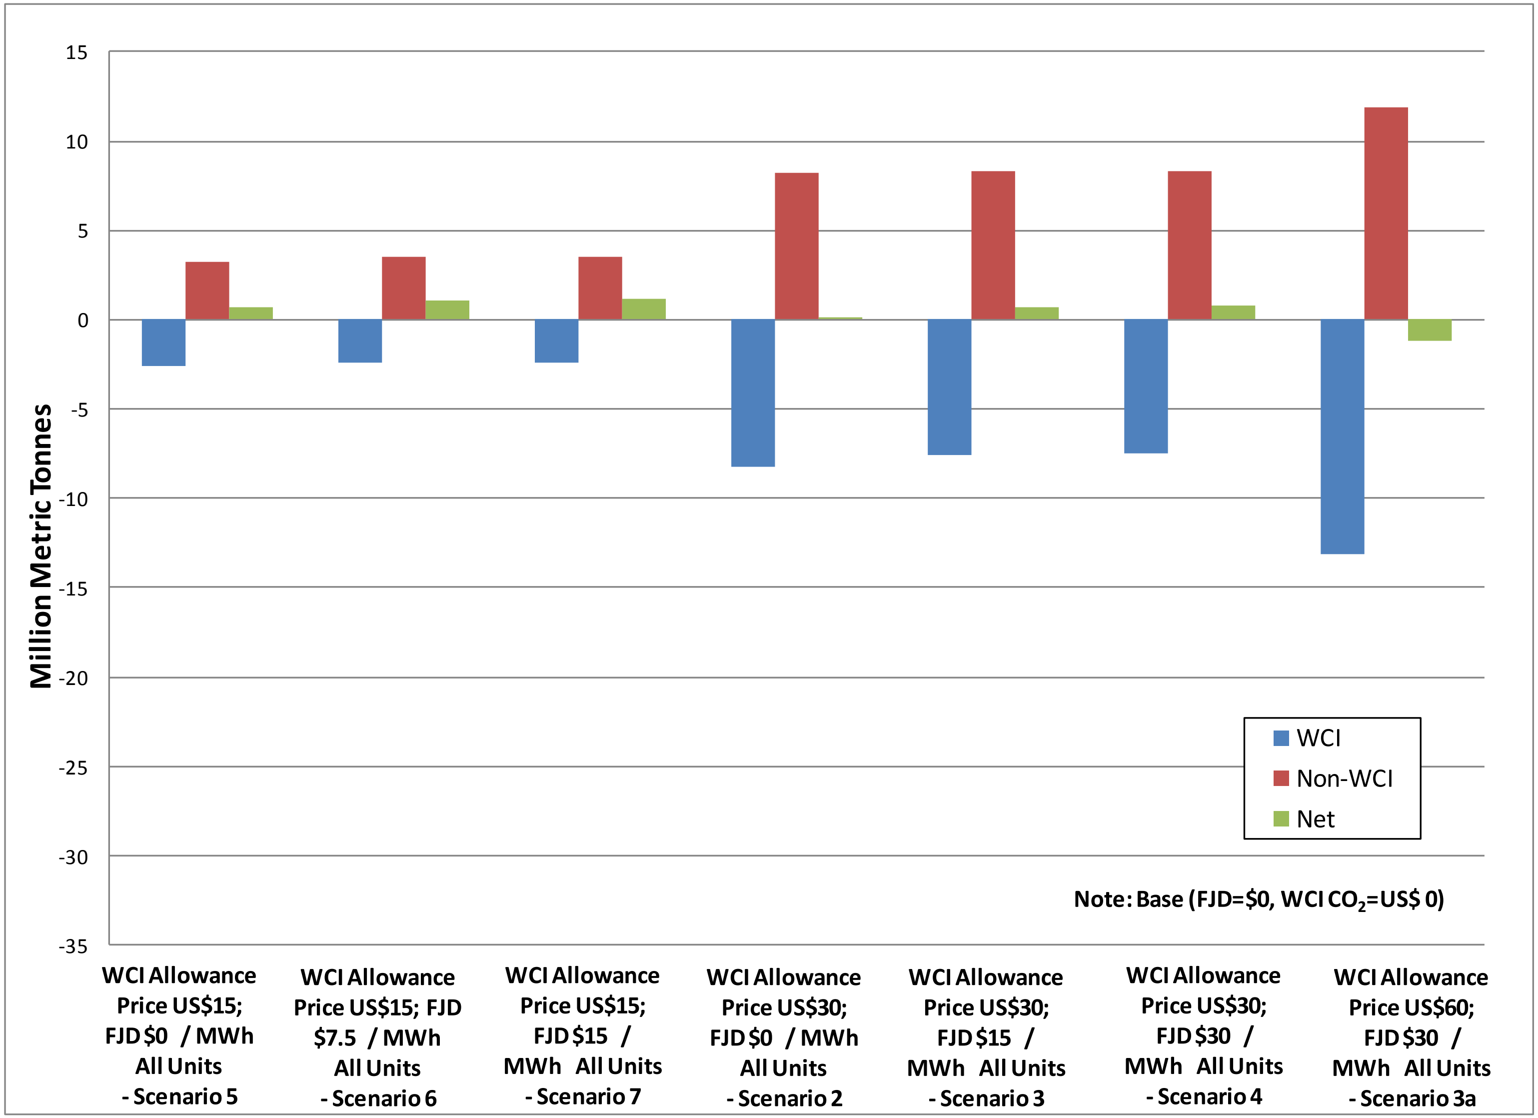
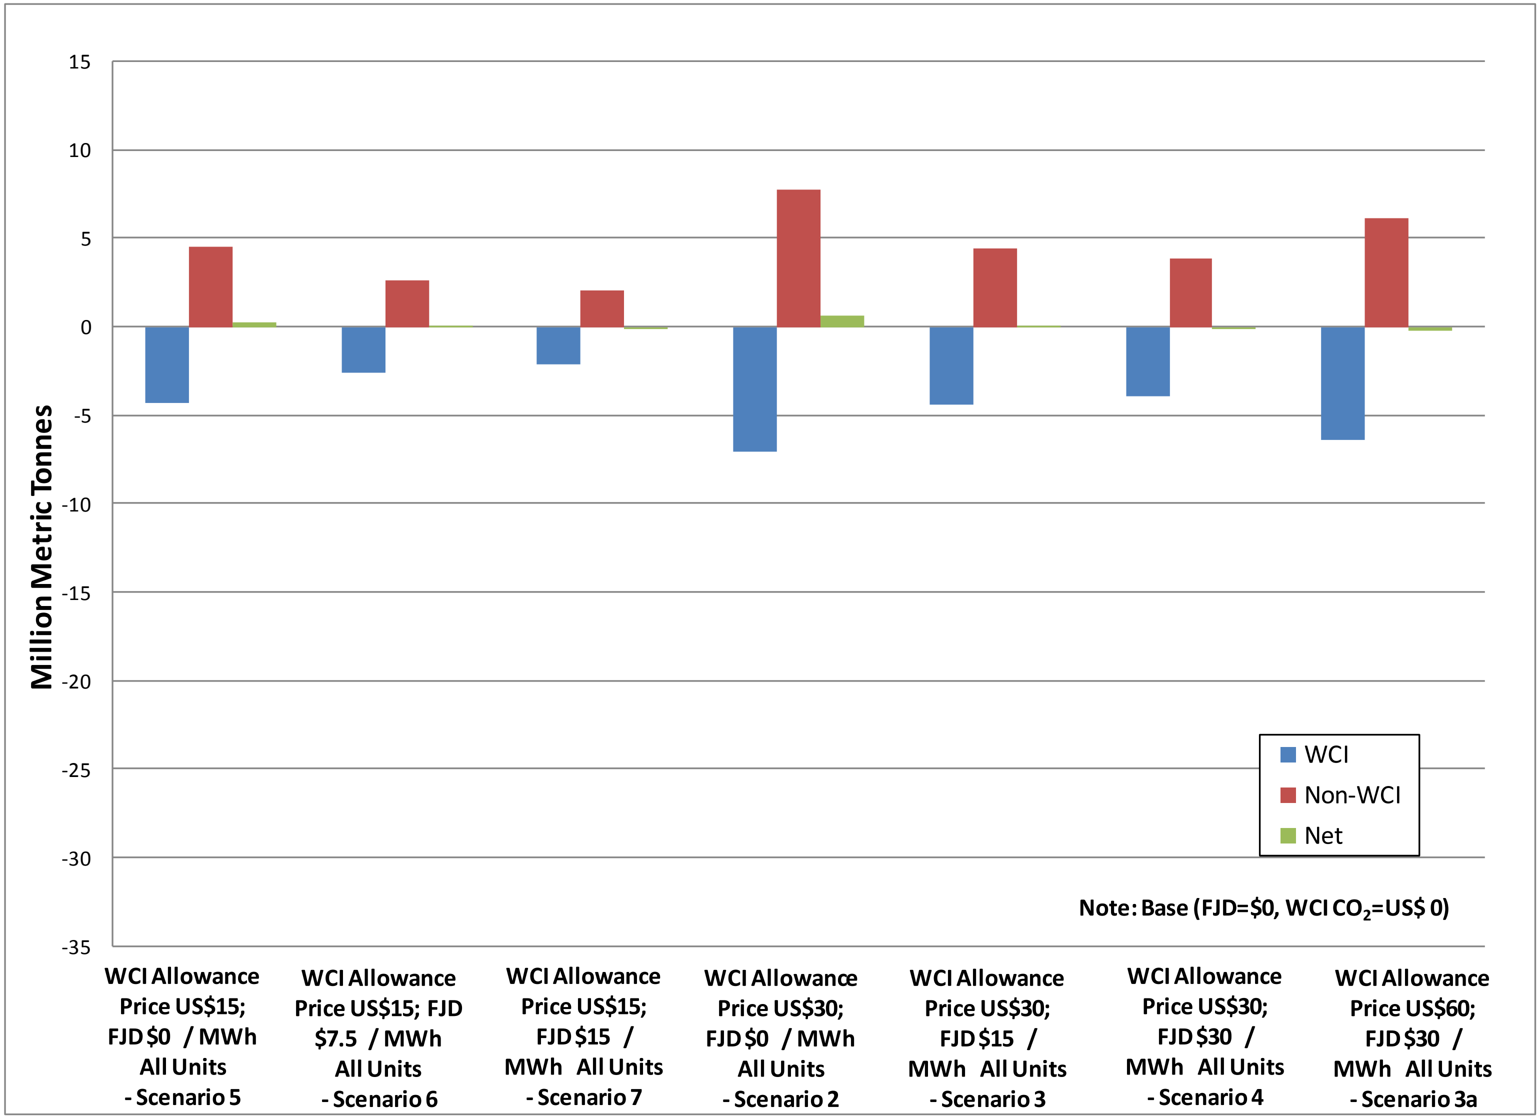
Change in Total Eastern Interconnect CO_2 Emissions - 2012



NAVIGANT CONSULTING

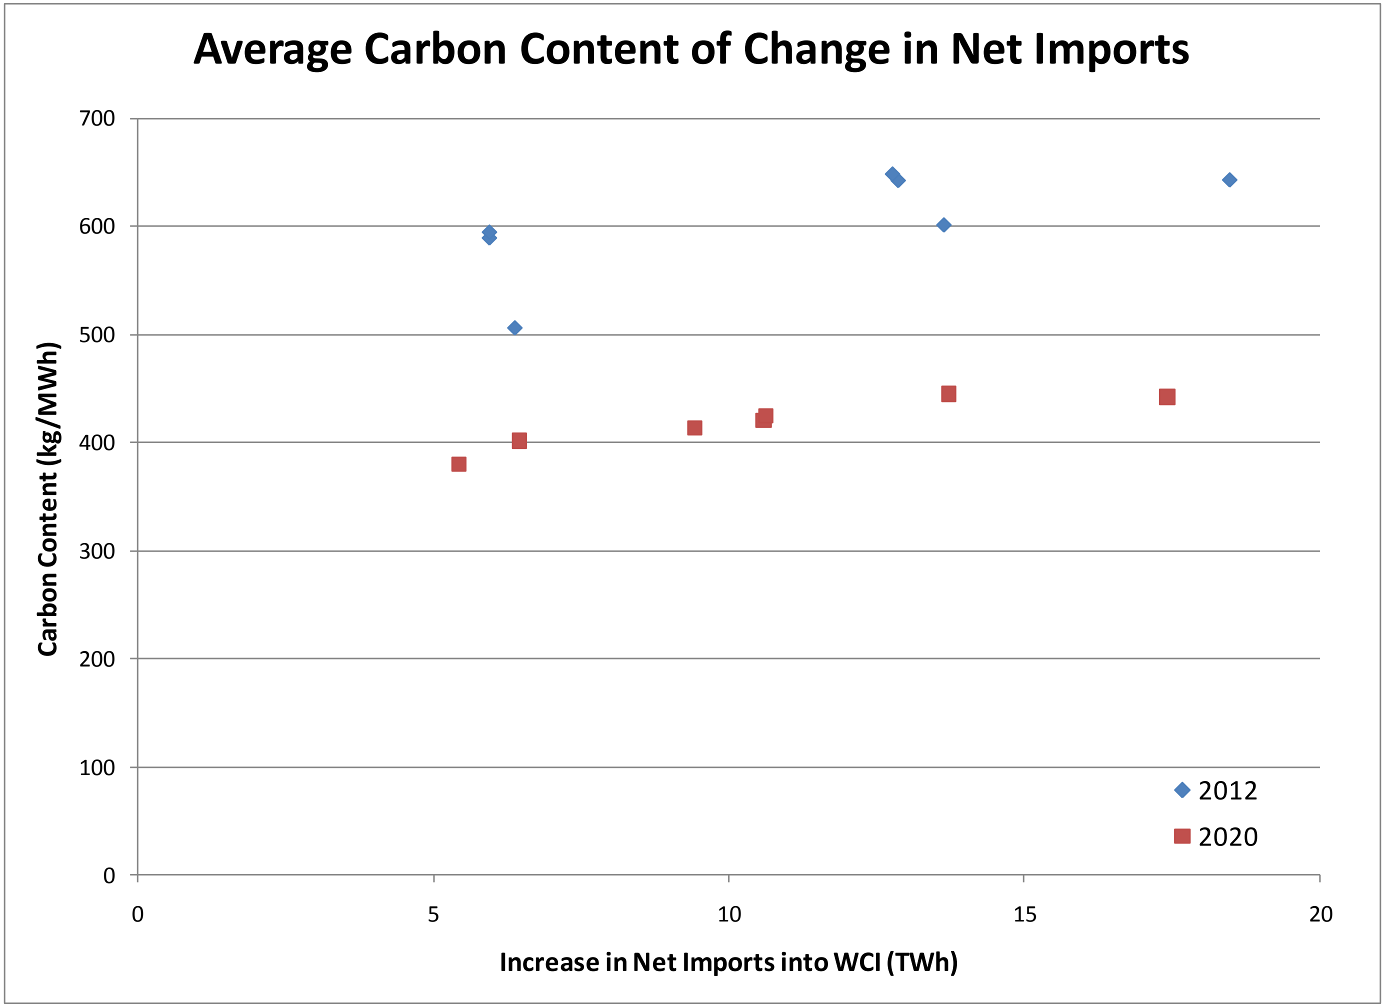
Change in Total Eastern Interconnect CO_2 Emissions - 2020



Carbon Content of Non-WCI Generation

- Carbon allowance costs in eastern WCI lead to
  - Reduction in Ontario fossil generation
    - Little change in Quebec and Manitoba generation because they do not have significant fossil capacity
  - More imports from Quebec, Manitoba and non-WCI regions into Ontario
  - Reduced exports from eastern WCI to non-WCI regions
  - More fossil generation in non-WCI regions
- For purposes of setting the FJD charge, it would be useful to know the average carbon content of imports from non-WCI regions
  - The best indicator is the CHANGE in non-WCI emissions divided by the CHANGE in NET flows (imports minus exports)
    - Looking only at imports misses most of the effect; the reduction in exports is much larger than the increase in imports

Carbon Content of Non-WCI Generation



- Average carbon content is around 600 kg/MWh in 2012 and around 400 kg/MWh in 2020. It increases slightly as the change in net imports increases (due to higher allowance costs and/or lower FJD charges).

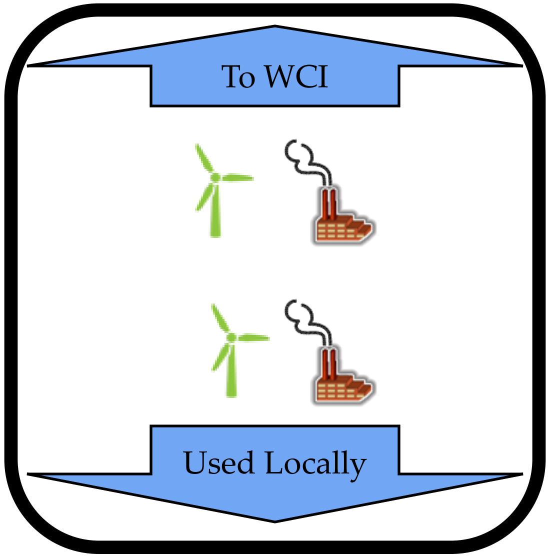
6 Modeling Conclusions

NAVIGANT CONSULTING

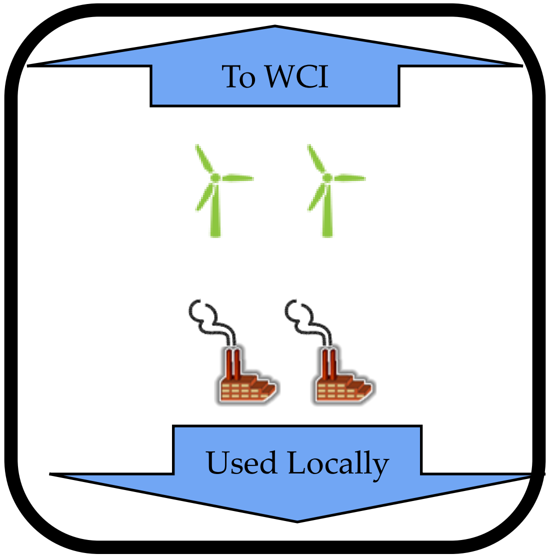
Contract Shuffling Defined

- Under WCI rules, non-fossil generation outside WCI can be exempt from import (FJD) charges if it is specified as no or low-carbon
  - This can lead to “contract shuffling”, as non-fossil generation is deemed to serve WCI load and fossil generation is deemed to serve local (non-WCI) load, with no change in total generation, fossil generation, flows, or emissions
- WCI rules regarding renewable attributes have not been finalized. For this analysis it was assumed that renewables can “double-dip”:
  - Sell renewable attributes to U.S. states – count toward meeting Renewable Portfolio Standards AND
  - Sell electricity to WCI provinces exempt from FJD charges
  - Impact of contract shuffling would be slightly less if renewables couldn’t double-dip, because most wind (but not nuclear or hydro) is tied to Renewable Portfolio Standards

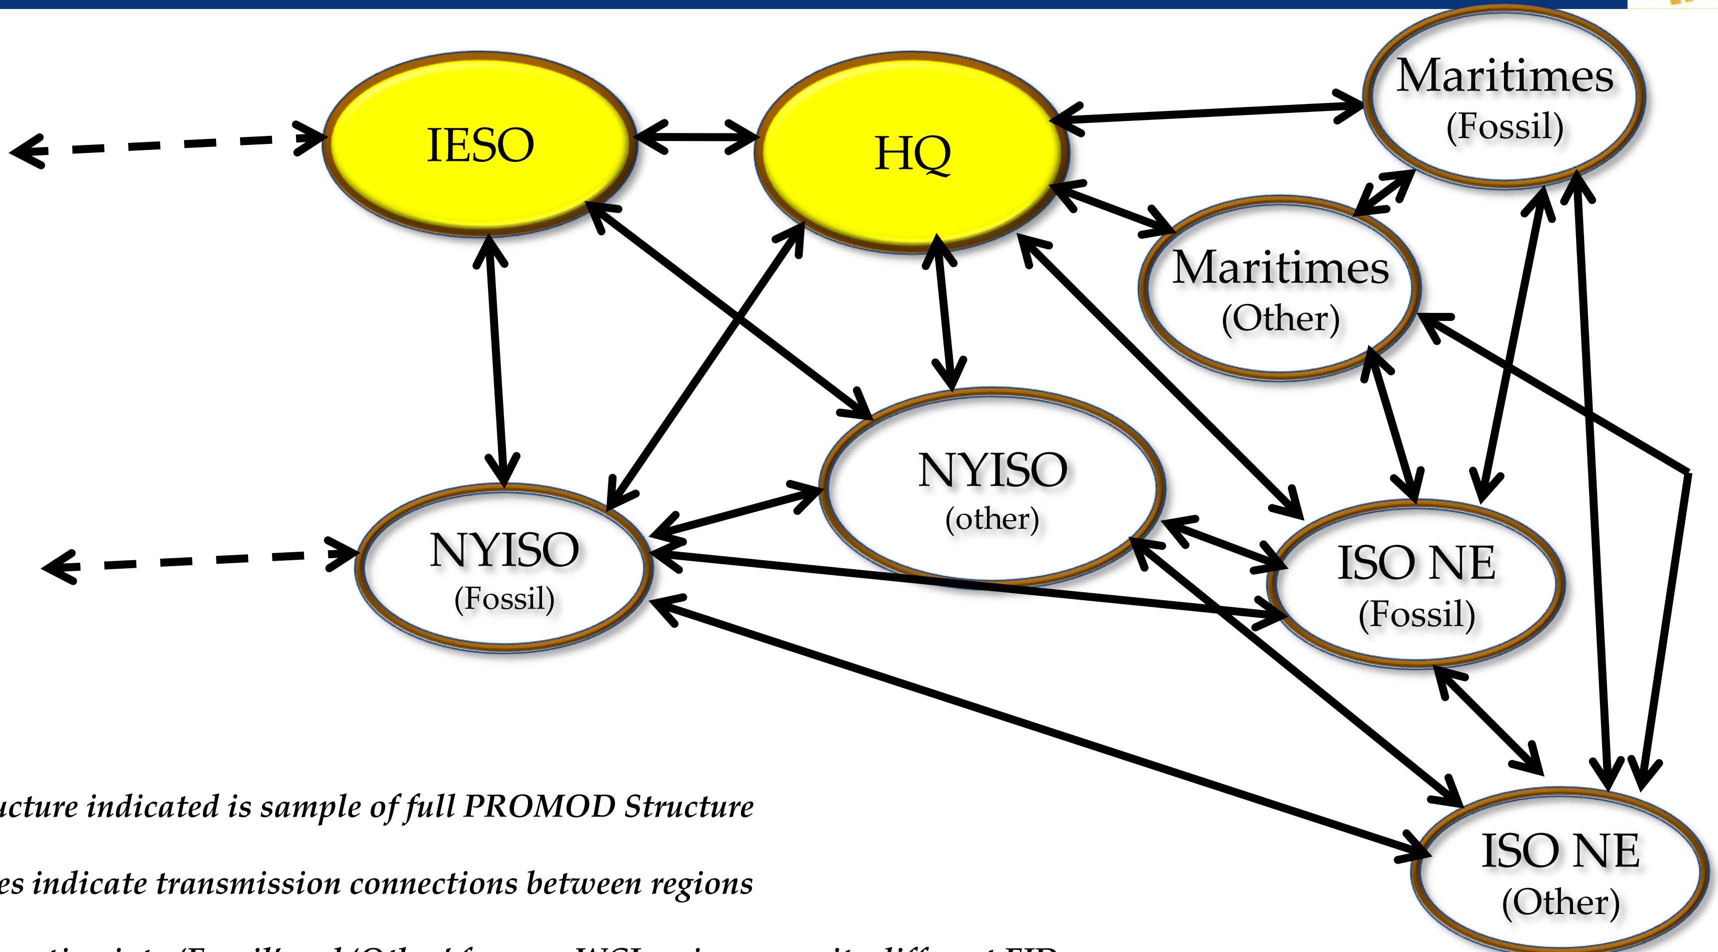
Non-WCI Generation Without Contract Shuffling



Non-WCI Generation With Contract Shuffling



Contract Shuffling – PROMOD Methodology



Structure indicated is sample of full PROMOD Structure

Lines indicate transmission connections between regions

Separation into 'Fossil' and 'Other' for non-WCI regions permits different FJD tariffs for different unit types based on carbon content

Contract Shuffling Methodology

- In PROMOD, transmission charges are based on pools not individual plants
- Generation in each non-WCI pool was divided into two pools: fossil and non-fossil
  - Demand was attached to non-fossil pool
  - FJD charge + transmission charge between fossil pool and eastern WCI pools
  - Zero FJD charge (normal transmission charge only) between non-fossil pools and eastern WCI pools
  - No charge between local fossil and non-fossil pools
- Significant increase in simulation time
  - Simple scenarios: each run took ~2 days elapsed time for one simulated year
  - Complex scenarios: each run took ~ two weeks elapsed time for one simulated year
  - The number of runs/scenarios was greatly reduced

Scenario #	Years	WCI Allowance Price	MGGRA Allowance Price	RGGI Allowance Price	FJD Charge	
		$/tonne	*$/tonne*	*$/tonne*	*kg/MWh*	*$/MWh*
9	2020	0	0.00	2.06	0	0
10	2020	30.00	0.00	2.06	1000	30.00
10a	2020	30.00	0.00	2.06	500	15.00
12	2020	30.00	30.00	30.00	1000	30.00

Notes

1. In this table, RGGI allowance prices from the auction result - $1.87/short ton - have been converted to metric tonnes

2. In these scenarios the FJD charge applies only to imports from carbon producing units

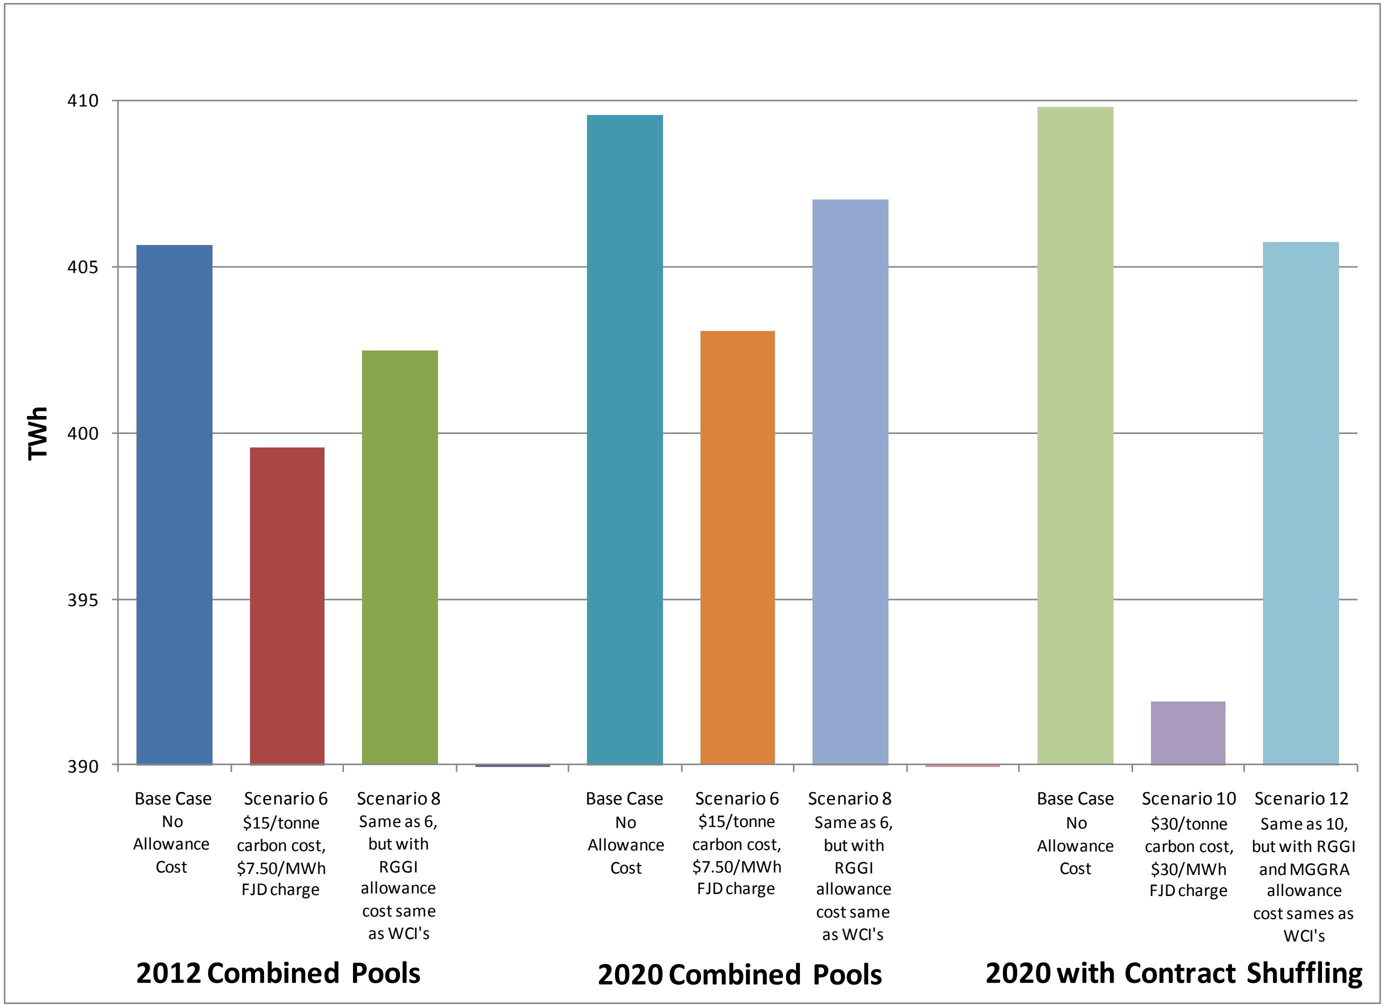
1 Introduction
2 Modeling Methodology
3 Modeling Results
4 Contract Shuffling
5 RGGI and MGGRA
6 Modeling Conclusions

NAVIGANT CONSULTING

Coordination with RGGI and MGGRA

- In the base case, RGGI (New England, New York, New Jersey, Delaware, Maryland) was assumed to have a low ($2.06/metric ton) carbon price, and MGGRA (Illinois, Wisconsin, Minnesota, Iowa, Michigan) was assumed to have no carbon pricing. Both were subject to FJD charges where appropriate
- Several scenarios explored what would happen if eastern WCI, RGGI and/or MGGRA worked together to adopt similar carbon pricing regimes, and were therefore exempt from each other's FJD charges
  - For scenarios with RGGI and MGGRA allowance prices aligned with eastern WCI, FJD charges applied to flows into WCI and MGGRA rather than just into WCI

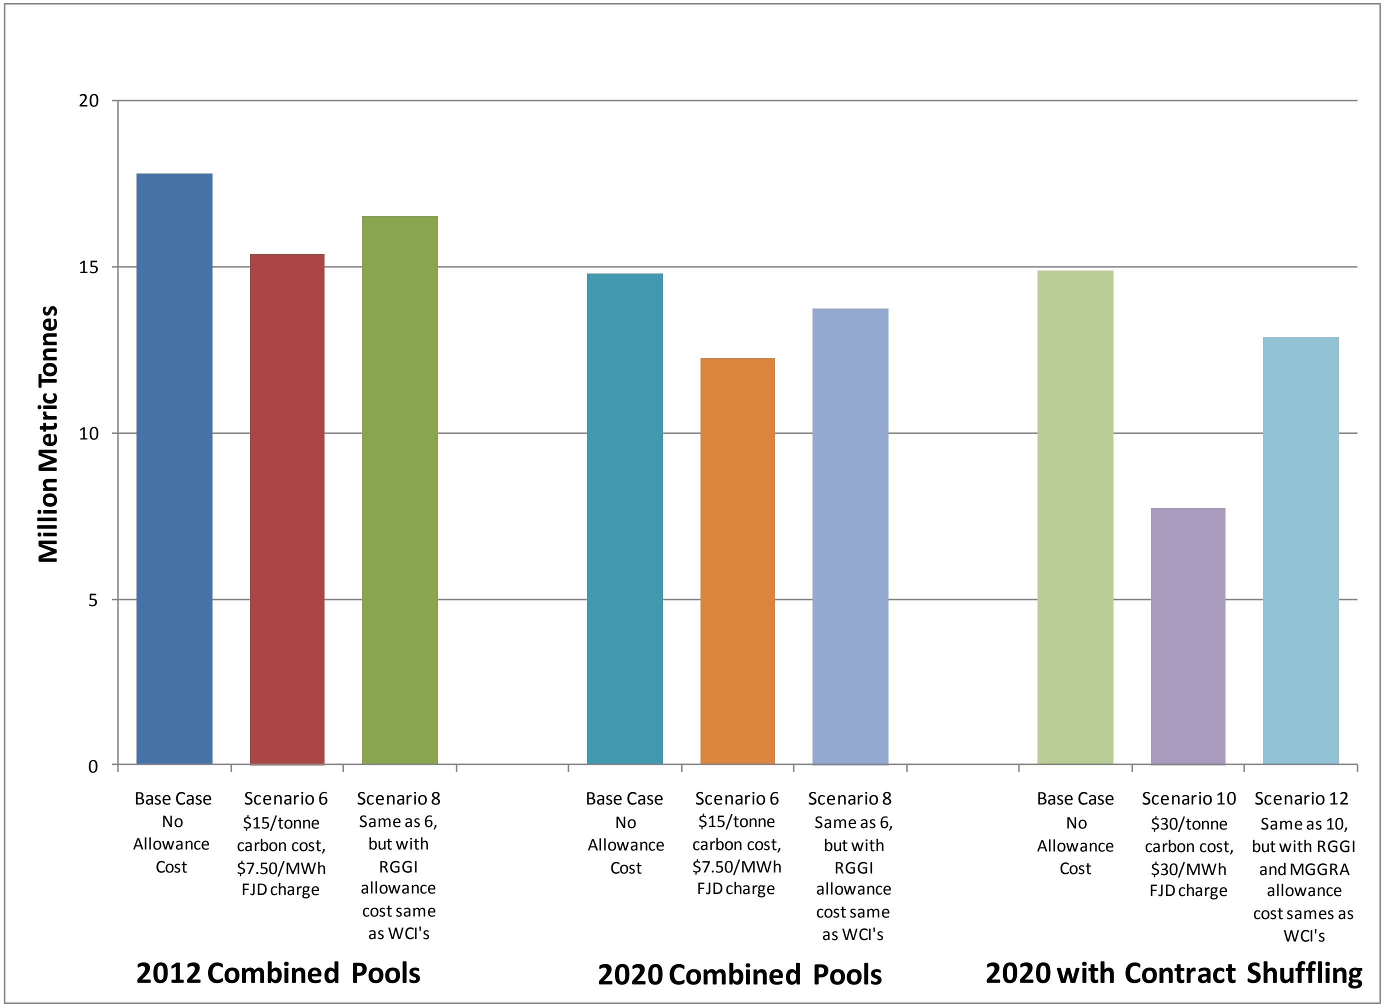
WCI Generation with RGGI and MGGRA Coordination



- Reduction in eastern WCI generation due to allowance costs is smaller if WCI coordinates with RGGI and/or MGGRA.

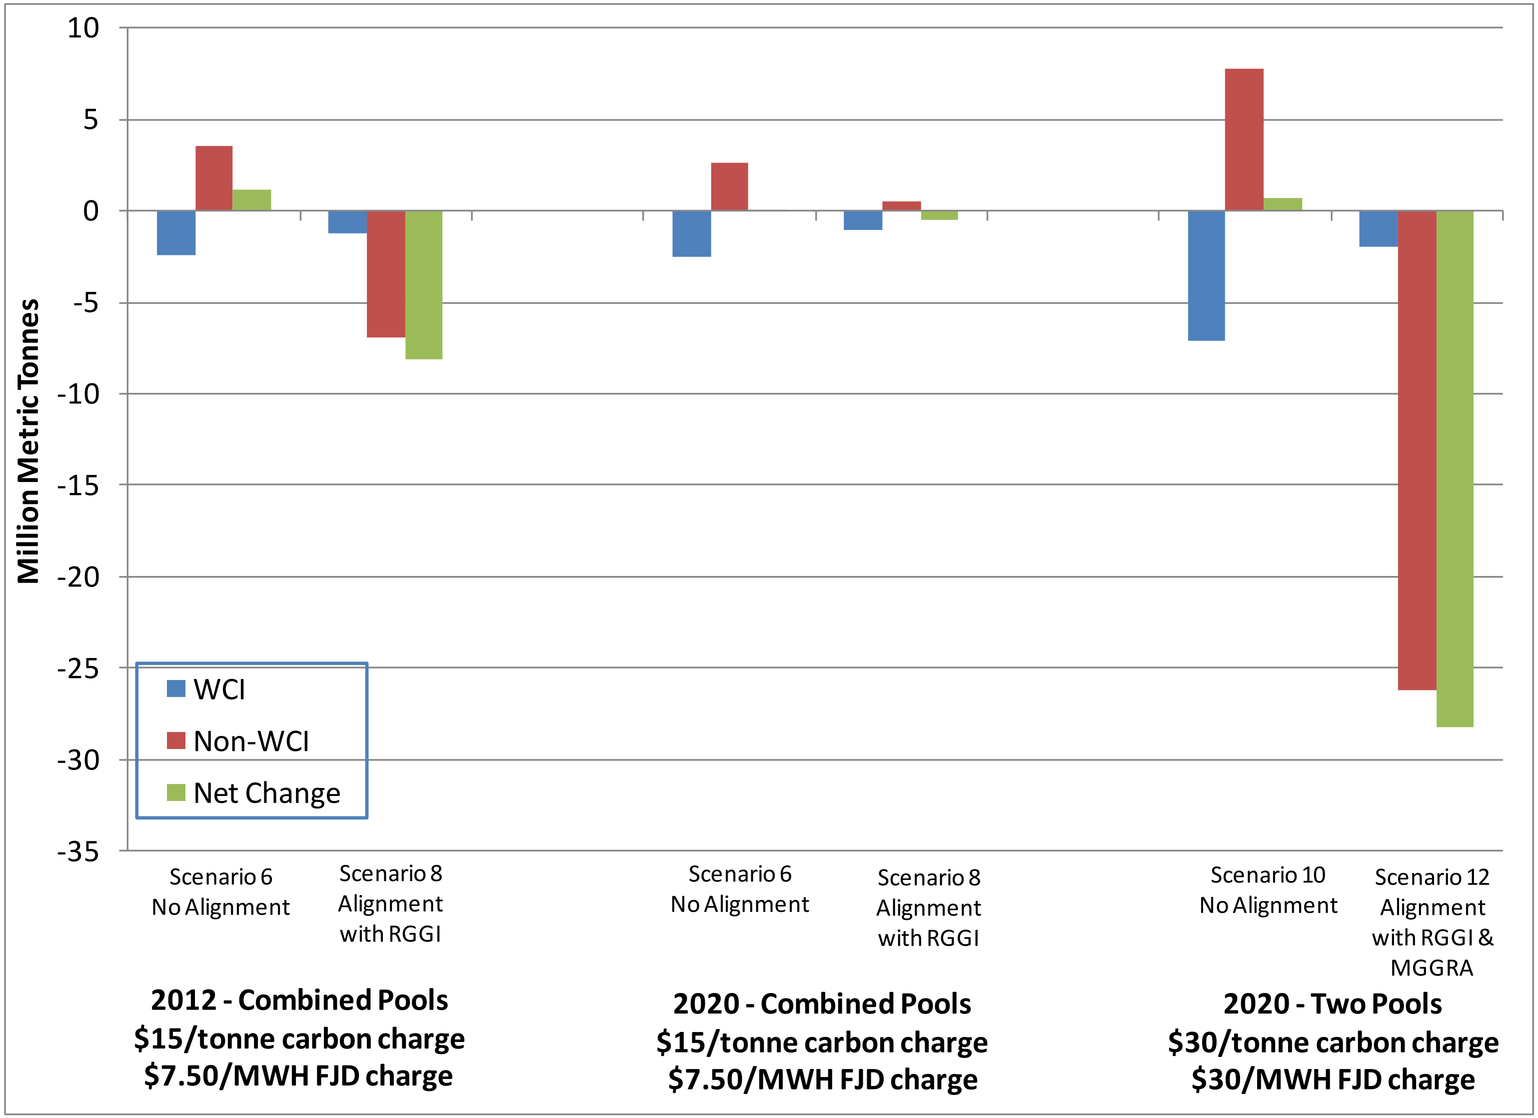
NAVIGANT CONSULTING

WCI Emissions with RGGI and MGGRA Coordination



- Higher allowance prices in RGGI and/or MGGRA mean less incentive for eastern WCI to use imports instead of their own generation.

Change in Total Eastern Interconnect Emissions with RGGI and MGGRA Alignment



1 Introduction

2 Modeling Methodology

3 Modeling Results

4 Contract Shuffling

5 RGGI and MGGRA

6 Modeling Conclusions

Modeling Conclusions - Summary

- As expected, given the static demand assumption, each scenario has almost the same total generation across the Eastern Interconnect. There are minor differences in total generation from the PROMOD loss calculations and the operation of pumped storage plants.
- However, the pattern of generation shifts between eastern WCI and non-WCI regions in response to the assumed eastern WCI allowance price and FJD charge
  - WCI emissions are reduced by between 13% and 50% depending on the scenario. Higher emission charges and lower FJD charges mean greater reductions.
  - This is almost exactly offset by increases in non-WCI emissions. The total level of CO_2 emissions across the Eastern Interconnect changes by less than 1% in most scenarios.
- These changes in CO_2 emissions from individual regions are the result of changes in the total generation from those regions interacting with the dispatch of different types of thermal units in the individual regions.
- The average carbon content of the increase in non-WCI generation is around 600 kg/MWh in 2012 and 400 kg/MWh in 2020.
  - This is calculated as the increase in non-WCI emissions divided by the change in net imports (imports minus exports) into WCI.

NAVIGANT CONSULTING

Modeling Conclusions – Eastern WCI

- The changes in eastern WCI generation and eastern WCI CO_2 emissions levels are strongly affected by the eastern WCI CO_2 allowance price, with increases in non-WCI generation and in non-WCI CO_2 emissions as the WCI allowance price increases.
- For a given eastern WCI Allowance price, increasing the FJD charge on power imported from non-WCI regions lessens the reduction in WCI generation and CO_2 emissions.
- However, with the FJD charges used there is still a significant reduction in eastern WCI generation and CO_2 emissions regardless of the level of FJD charges.
- Although not reported in detail, most of the changes in eastern WCI emissions would occur in Ontario, the location of the majority of thermal generation in the eastern WCI.
- Overall, scenarios with non-zero eastern WCI allowance prices lead to leakage and this is not eliminated by imposing FJD charges.

.

NAVIGANT CONSULTING

Modeling Conclusions – Contract Shuffling and Regulatory Structure

- Where contract shuffling was permitted, there was a further ~ 25% reduction in eastern WCI CO_2 emissions compared to the equivalent scenarios with no shuffling.
- Where similar allowance prices were assumed across eastern WCI, MGGRA and RGGI, the changes in eastern WCI generation and eastern WCI CO_2 emissions were much reduced.
- Effectively, a combined regulatory/allowance price structure across eastern WCI, MGGRA and RGGI would appear to reduce leakage potential.

NAVIGANT CONSULTING

Western Climate Initiative

Western Climate Initiative: Electricity Sector Overview

WCI Electricity Collaborative
Phoenix. AZ
January 21, 2010

The Challenge

- WCI is a regional entity in an interconnected electricity market
  - Addressing electricity imports and exports
- WCI is inter-jurisdictional
  - Wide range of generation and emissions
  - Differing market structures
- WCI is international
  - Varying reporting conventions
  - Different legislative and legal frameworks

Cap-and-Trade:
What Has To Be the Same

- **Basic reporting requirements**
- *Sectors, gases and thresholds (generally)*
- **Points of regulation**
- *Quantification methods*
- *Setting regional caps*
- **Establishing partner budgets**
- *Compliance periods; banking; borrowing*

Items addressed by the Electricity Team

WCI Design: Electricity Imports

- Fundamental design decision: Jurisdictions to be responsible for emissions associated with electricity imports.
- Understanding the issues
  – Two studies to examine leakage potential
    - Electricity Leakage Study covering WECC presented October 16, 2008
    - Eastern Leakage study underway – discussion today

WCI Design: Electricity Imports

- Analysis and consultation on First Jurisdictional Deliverer design
  - Decision announced July 15, 2009
- Administrative Option
  - Analysis underway – discussion today

WCI Design: Reporting

- Essential Elements for Reporting for the Electricity Sector
  - Completed and released as part of the Final Essential Requirements for Mandatory Reporting
- Outstanding issues:
  - Assigning emissions to imports: Default Emissions Calculator – discussion today

WCI Design: Budgets

- Forecasting 2012 budgets requires data on base years.
- Outstanding items:
  - Establish baseline data for electricity imports
    - OATI analysis for WECC – discussion today
    - Default emissions calculator – discussion today
    - Specified imports
    - Eastern provinces data

WCI Design: Competitiveness

- Outstanding item: The Electricity Team will support the Competitiveness group on electricity issues

WCI Design: Special Items

- Voluntary Renewable Energy: how to accommodate the voluntary market under Cap and Trade
  - Draft recommendation paper released January 15, 2010 – discussion today
- Treatment of Renewable Energy Certificates under Cap and Trade
  - analysis underway

Western Climate Initiative

Emissions from Imported Electricity: Default Factors and Historical Imports

Presented at the Electricity Industry Collaborative

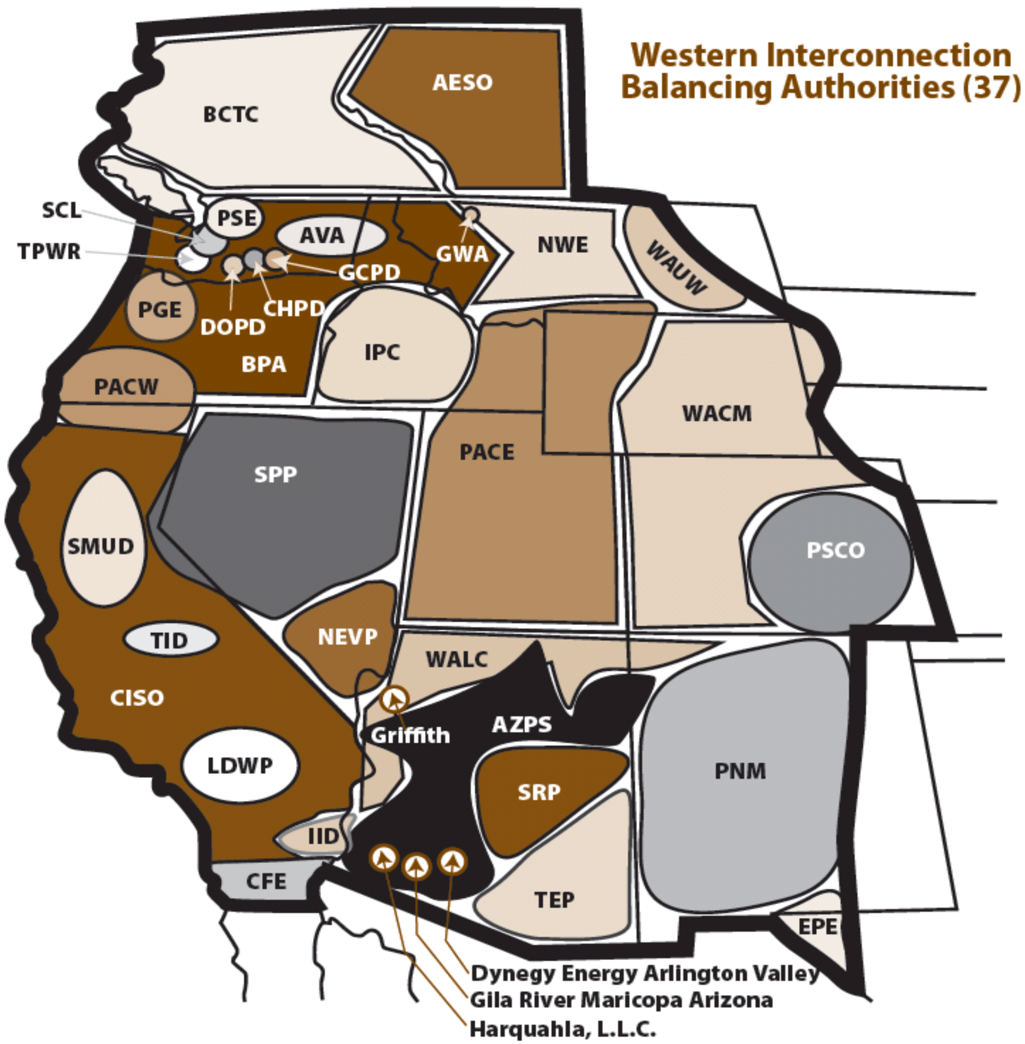
Phoenix

January 21, 2010

OATI Analysis of E-Tagged Transactions in WECC

- OATI, which manages the e-tag database for WECC, was hired to analyze inter-balancing authority transactions from 2005 to 2008
- This information will inform WCI's allowance budget setting process
- Balancing authorities in the eastern provinces are conducting their own analysis

WECC Balancing Authorities



Alberta Electric System Operator (AESO)
Arizona Public Service Company (APS)
Avista Corporation (AVA)
Bonneville Power Administration – Transmission (BPAT)
British Columbia Transmission Corporation (BCTC)
California Independent System Operator (CISO)

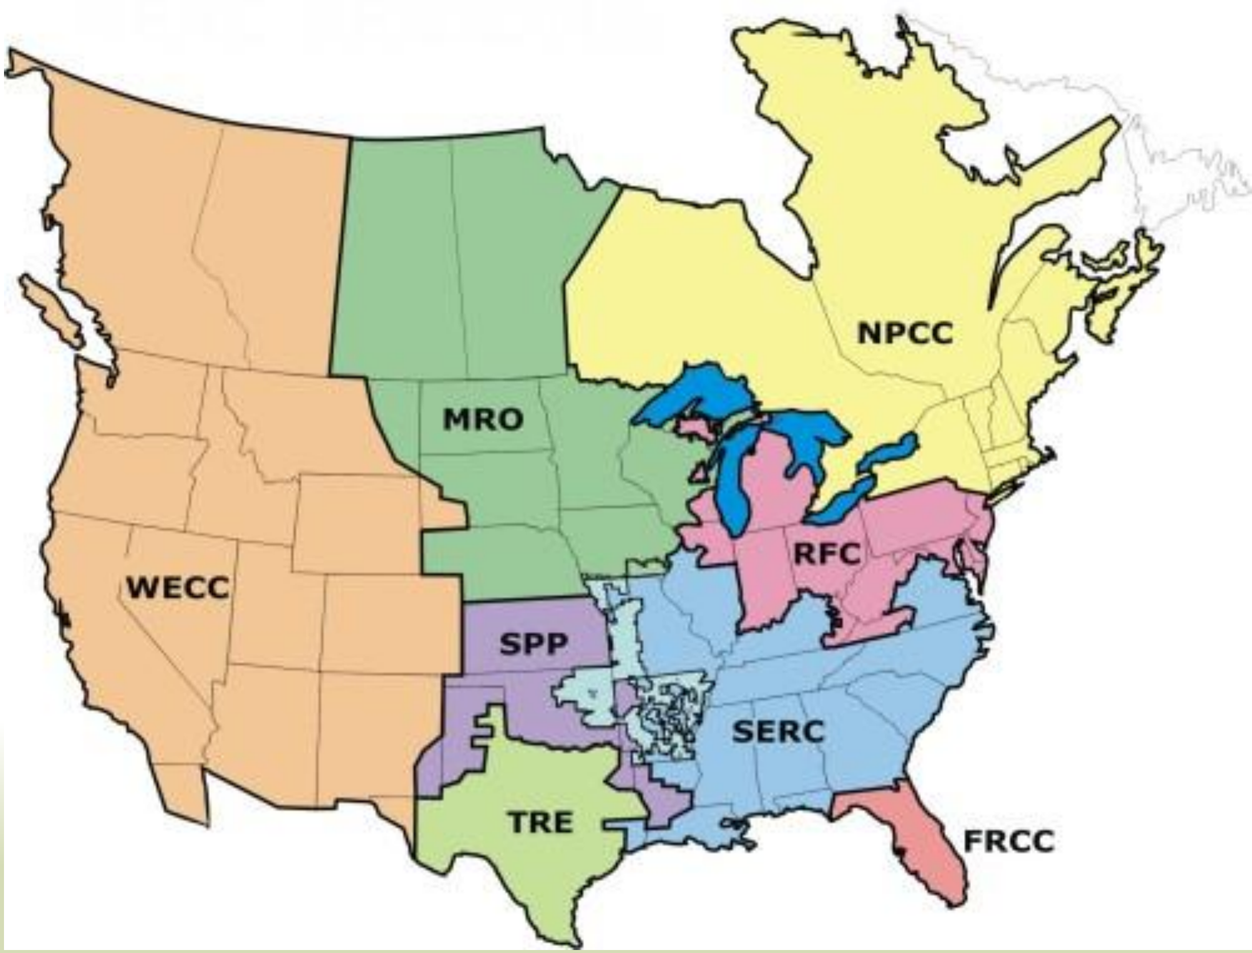
E-Tag Questions for Stakeholders

- Can we identify all specified imports for WCI members?
- From 2008 on, are all dynamically scheduled plants now tagged? Can we fill in data for previous years?
- Are intra-Balancing Authority transactions now consistently tagged? (relevant for BPA and PACE)
- How should BPA-SYS transactions be accounted for?

Updates on the Default Emissions Factor Calculators

- Draft version of the DEF Calculator have been completed for 2006 and 2007
- EIA data for 2008 were not yet available but should be released soon
- Draft DEF Calculators include additional NERC regions and an adjustment for transmission losses

NERC Regions



FRCC - Florida Reliability Coordinating Council
MRO - Midwest Reliability Organization
NPCC - Northeast Power Coordinating Council
RFC – Reliability First Corporation
SERC - SERC Reliability Corporation
SPP - Southwest Power Pool
TRE - Texas Regional Entity
WECC - Western Electricity Coordinating Council

Draft DEF Calculator Results

Assumes 2% Transmission Losses, non-WCI sources only

	50% Capacity Factor		60% Capacity Factor		70% Capacity Factor	
NERC Region	**2006**	**2007**	**2006**	**2007**	**2006**	**2007**
MRO	**0.905**	**0.795**	**0.963**	**0.975**	**1.039**	**1.016**
NPPC	**0.581**	**0.557**	**0.570**	**0.548**	**0.569**	**0.581**
RFC	**0.895**	**0.836**	**0.949**	**0.923**	**0.947**	**0.944**
WECC	**0.461**	**0.489**	**0.456**	**0.456**	**0.597**	**0.641**

DEF Questions for Stakeholders

- How often should the factor be updated?
- How far in advance should it be finalized?
- How many years' worth of data should be used? One year or an average of 2 or 3 years?
- How are losses handled on e-tags and what is the appropriate transmission loss factor? Does the loss factor only need to account for losses from actual sources to first Point of Receipt?

DEF Questions for Stakeholders

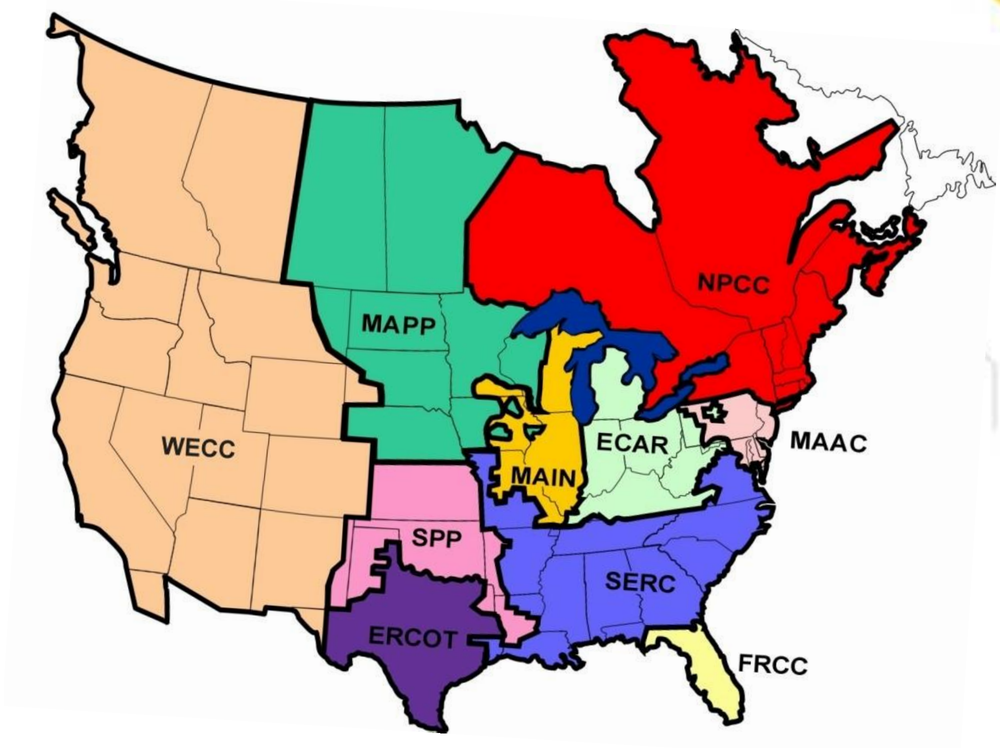
- Should capacity factors be based on nameplate capacity or net summer capacity?
- Should CEMS data reported to EPA be used instead of calculated emissions from reported fuel consumption?

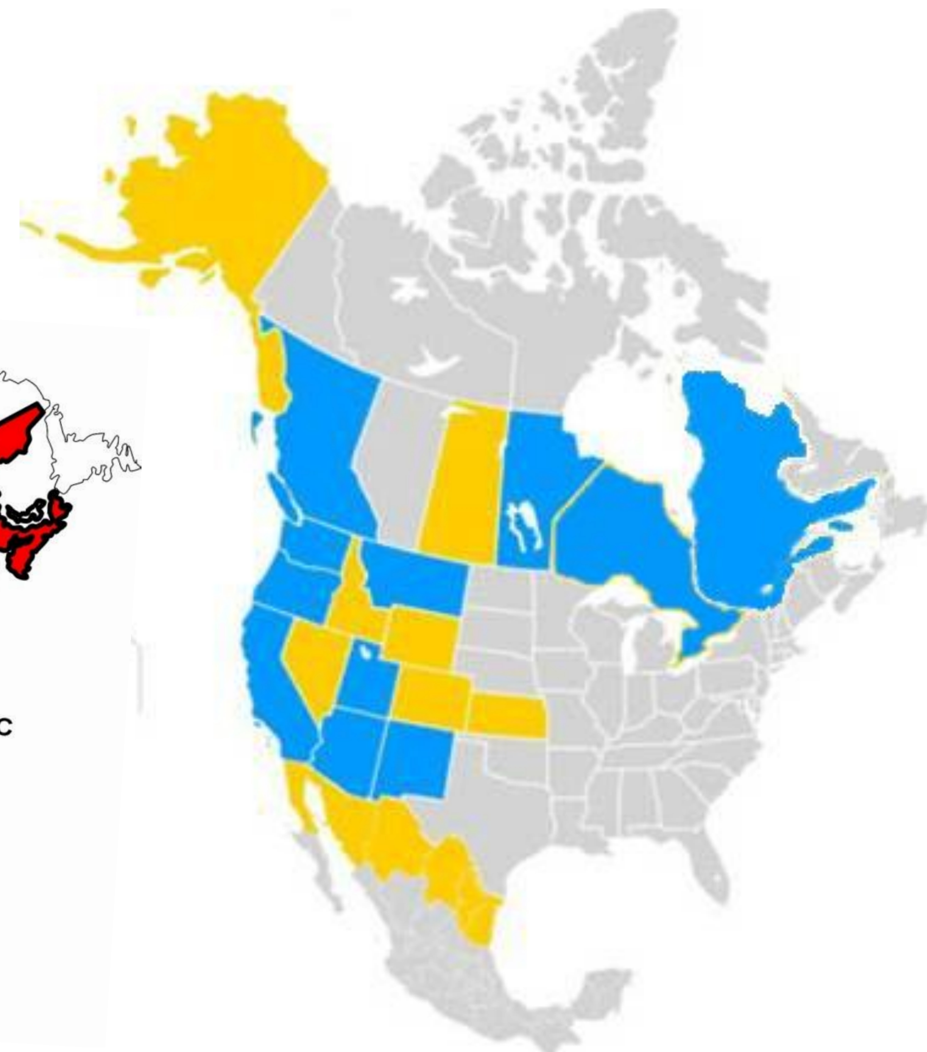
Western Climate Initiative

Introduction to the Electricity Team Items

WCI Electricity Collaborative
Phoenix. AZ
January 21, 2010

Boundaries: Electricity and WCI





Quantifying Leakage Potential

- An essential element of understanding leakage
- Requires market analysis
- WECC system reviewed in E3 Electricity Leakage Study
  - Found limited potential for leakage from coal, some potential for gas
  - FJD approach limited leakage

Quantifying Leakage Potential

- Eastern grid is fundamentally different from WECC for WCI jurisdictions
  - Greater use of market pools (New York, Ontario, PJM) and less use of contracts
  - Coal is more frequently the marginal source
  - Ontario phasing out coal
  - Quebec and Manitoba are predominantly hydroelectric
  - WCI jurisdictions are net exporters
- Eastern leakage study by Navigant to analyze market and leakage potential

Assigning Emissions to Imports

- Need these elements to quantify emissions associated with imports:
  - Level of imports from identified generation (MWh)
    - Apply known specific emission factor from reporting
  - Level of imports from unknown generation (MWh)
    - Aggregated by source region
    - Apply emissions factor for marginal generation in source region
      - role of Default Emissions Calculator

Addressing Imports: Establishing a Baseline

- WCI design calls for the 2012 cap to be based on the best estimate of emissions.
- Proposed process starts from established emissions in a baseline year.
- Emissions from imported electricity must be included in the baseline level.
- Need to identify specified imports and unspecified imports by source region:
  - OATI analysis for WECC
  - Jurisdictional review for Eastern Provinces

Addressing Imports: Administrative Option

- The full First Jurisdictional Deliverer approach may not be appropriate in all jurisdictions:
  - Low levels of imports may not warrant the administrative burden
- Emissions associated with imports must still be accounted for by the consuming jurisdiction
- Examining Administrative Option alternative to account for emissions under the cap

Voluntary Renewable Energy

- The market for voluntary renewable energy has been identified by stakeholders as potentially vulnerable under a greenhouse gas cap and trade system.
- The Electricity Team has reviewed the issue and prepared an issues paper with recommendations for jurisdictions who may wish to address the market for voluntary renewable energy.

Western Climate Initiative

Voluntary Renewable Energy Market: Issues and Draft Recommendations

WCI Electricity Collaborative
Phoenix. AZ
January 21, 2010

Voluntary Renewable Energy (VRE) Market Issues Addressed in Paper

- VRE market (green power programs) has been important for growth of renewable energy.
- With cap and trade (C&T), level of allowable emissions in region is determined by the cap.
- Individual decisions to purchase VRE products may not lead to emission reductions since purchases free up allowances for others.
- VRE market may be impacted if consumers expect emission reduction benefits to be associated with their VRE product purchases.

VRE Market Policy Alternatives

- WCI Partner jurisdictions that wish to address potential impacts from C&T have the option to adjust their baseline allowance budget to reserve (or “set aside”) a pool of allowances for retirement that ensures that emission reductions occur for VRE market purchases.
- Alternatively, WCI Partner jurisdictions may choose not to intervene in the VRE market and let VRE marketers guarantee emission reductions through allowance purchases.

How a VRE Set Aside Might Work

Estimated VRE MWh sold in 2012	Example Set Aside Emission Rate	Allowances in 2012 Reserve	Actual VRE MWh sold in 2012	2012 Allowances Retired by Jurisdiction	2012 Allowances Unused (e.g. for 2013 Set Aside)
1,000,000	0.40 tCO_2e	400,000	900,000	360,000	40,000

1. VRE product sales estimated in advance.
2. Emission reductions from sales estimated.
3. Allowances are "set aside" from budget.
4. Actual sales trued up and allowances retired.
5. Unused allowances rolled over or used for ??.

Treatment of the VRE Market in Other Existing or Proposed Cap and Trade Systems

Cap-and-trade program or proposed legislation	Voluntary Renewable Energy Market Directly Addressed?	Policy Mechanism Used to Address VRE Market
USA – Regional GHG Initiative (RGGI)	**Yes**	Set aside as optional element of RGGI Model Rule.
Europe – EU Emissions Trading System (EU ETS)	**No**	None
USA – American Clean Energy And Security Act of 2009 (Waxman-Markey)	**No**	
USA – Kerry-Boxer (Senate version of ACES)	**No**	
Australia – Carbon Pollution Reduction Scheme (proposed for 2011)	**Yes**	By taking GreenPower (official VRE program) purchases above 2009 levels into account when setting program's emission caps.

Context for VRE Market Issues Paper

- WCI design recommendations provide broad discretion to WCI Partner jurisdictions to reserve allowances for designated purposes.
- Therefore, no recommendation is made as to whether all WCI Partner jurisdictions should implement a VRE set aside program.
- Focus is on recommendations for the key design elements of VRE set asides for those WCI Partner jurisdictions that do choose to implement a VRE set aside program.

Recommendation on Accounting Mechanism for VRE Set Aside Program

- VRE set asides should be based, first and foremost, on transactions verified through established REC tracking systems.
- In addition, where RECs aren't an option, certification through a third-party verification system for voluntary renewable energy that includes, at a minimum, a method of attesting to not having previously transferred the greenhouse gas benefits of the VRE product.
- Harmonization across WCI is important.

Recommendations on Defining Eligible Renewable Energy Project Types

- Jurisdictions should define their own eligibility requirements for their VRE set aside programs. They may choose to mirror existing RPS or other statutory definitions or to define a separate list of qualifying project types.
- Important to recognize that REC tracking systems and VRE certifying organizations also will likely have eligibility criteria that will be applicable to VRE products used for set aside.

Comparison of Options for Geographic Treatment of Voluntary Renewable Energy

Limitation→ ↓ Responsibility	Purchased from/sold to own jurisdiction	Purchased from/sold to any WCI jurisdiction	Purchased from/sold to any capped jurisdiction	Purchased from/sold to any jurisdiction
Purchaser-Based	Equivalent to gen-based, need to account for number of RECs from in-jurisdiction sources	Need to account for number of RECs used from in-WCI sources	Need to account for number of RECs used from all capped (e.g. RGGI) sources	N/A (no need to have purchaser-based version because purchases from uncapped jurisdictions do not need set aside)
Generator-Based	Equivalent to purchaser-based, need to track where RECs are retired	Need to track where RECs are retired	Expands application to sales to entities in other capped jurisdiction such as RGGI or Midwestern Accord jurisdictions, need to track where RECs are retired	Generators receive one certification, good for sales to all jurisdictions, no need to track where RECs retired

Recommendation on Jurisdictional Retirement Responsibility

- Retire allowances using a generator-based approach in which allowances are retired whenever RECs from a facility in that WCI Partner jurisdiction's territory are purchased and retired by a customer in the VRE market with no limitation on the customer's location. Alternatively, the retirement should be based on VRE sales if RECs are not used.
- Need to have harmonized WCI-wide approach on retirement responsibility.

Recommendations on Limits for VRE Set Aside Program

- Jurisdictions should choose whatever upper limit on the allowance retirement amount (if any) and/or program time limit (if any) that is found appropriate for that jurisdiction.
- Need policy to deal with allowance shortfalls.
- Jurisdictions may choose to base time limits on periodic reviews of the cost-competitiveness of the technologies supported by the set aside program.

Recommendation on Emission Attribution for VRE Purchases

- Work together to develop a rate based on a marginal dispatch analysis, such as the WCI Default Emission Factor Calculator, for each major grid region. However, use of this rate should be optional and specific assignment of emissions left to jurisdictional discretion.
- Clearly this work ties in closely with the overall default emission rate work of the WCI.

Next Steps for VRE Issues Paper

- Comments and discussion at today's session.
- Written comments via WCI website.
- Deadline for comments is February 19, 2010.
  - Comments should be directed at draft recommendations to be most useful.
  - All comments get posted on WCI website.
- Final recommendations will be written up once stakeholder comments have been received and processed by the VRE group.

Reflections on the WCI Document

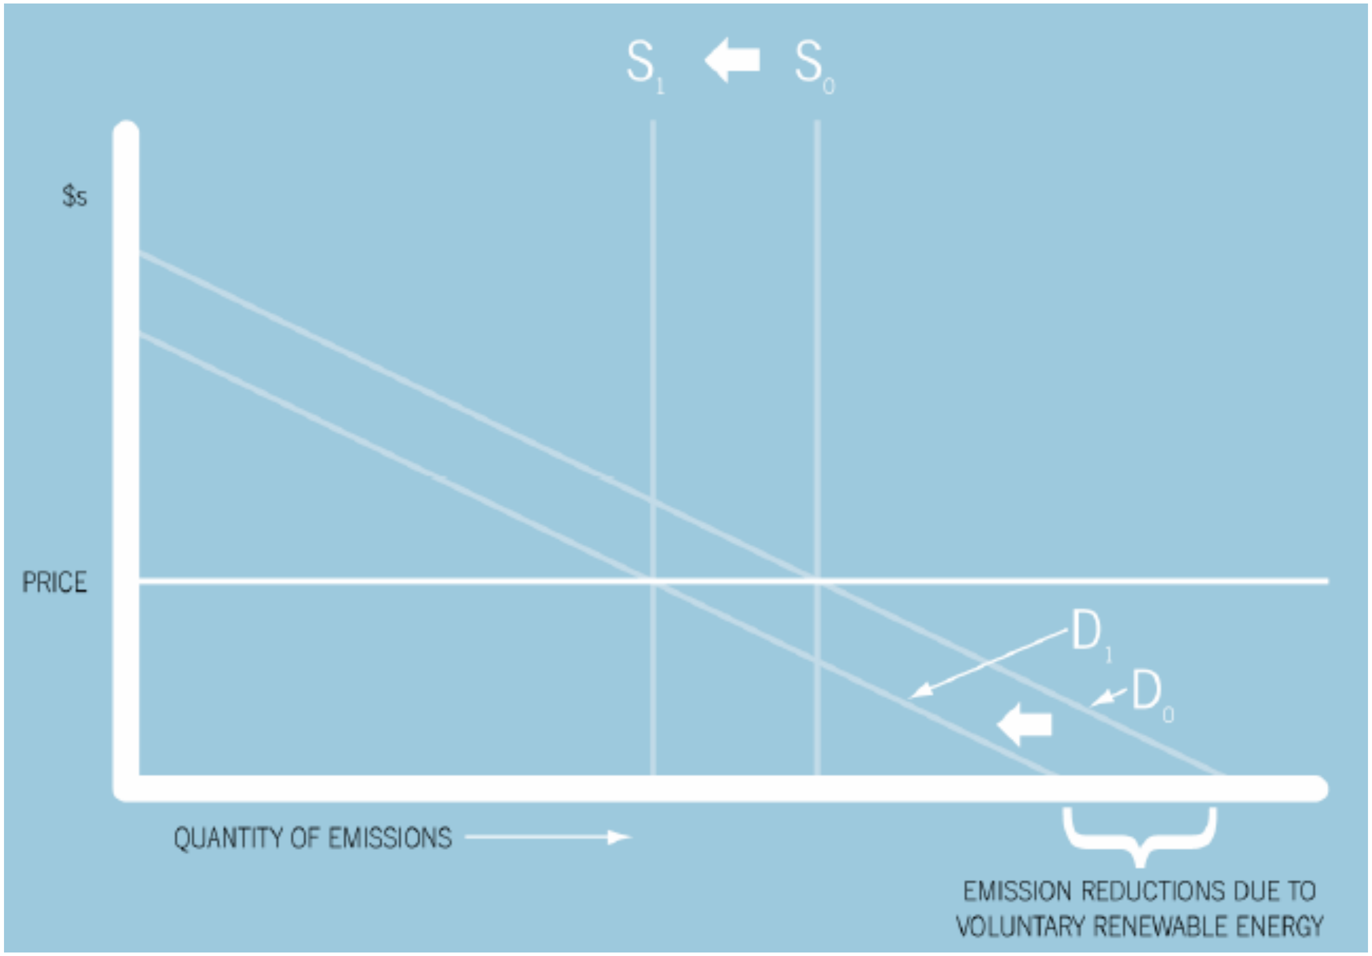
Interaction of supply and demand:

Example of an off-the-top scenario that leaves allowance prices unaffected



CRS center for resource solutions

Observations relevant to the "no intervention" approach

Not yet a foregone conclusion that others besides capped entities will have access to allowances (as is implied).

Savvy corporate and other larger purchasers have driven much of the growth in recent years.

- The top 50 largest green power purchases combined amount to nearly 11.8 billion kilowatt-hours annually (70% of EPA Green Power Partner purchases, EPA data April 2009)

- Carbon claims have been important.

Figure 1. data on real (actual) explosive market growth.

Figure 2. an uncertain forecast of future voluntary market trends.

California Releases Preliminary Draft Regulation

On November 24, 2009 California released a preliminary draft regulation (PDR) that conveys, at a conceptual level, how a broad-based multi-sector cap-and-trade program will work with complementary measures to reduce greenhouse gas emissions to meet the 2020 statewide emissions limit as required under California law (AB 32). The PDR is consistent with the September 2008 WCI program design recommendations, and describes the mechanism for linking to the cap-and-trade programs implemented by the WCI partners.

Manitoba Makes Commitment Towards Cap-and-Trade Legislation

On December 15, 2009, Premier Greg Selinger committed the provincial government to moving forward with legislation enabling the creation of a cap-and-trade system to reduce greenhouse-gas emissions in Manitoba. He said the system will be subject to public consultations in 2010.

"Manitoba is playing a constructive role in focusing on commitments, goals and targets that we and other leading sub-national governments can take," Selinger said. "Market mechanisms like cap-and-trade will play a large role in the global collaborative will be held at the same location at the Hyatt Regency Hotel in Vancouver, BC. Stakeholders are invited to attend in-person or via teleconference. If you plan to attend in-person, please register here. To join by teleconference, dial 1-800-868-1837, participant code 659537#. (Outside the U.S. and Canada, dial 404-920-6440.) The agenda will be posted to the website and distributed via the WCI list server when available.

April 14: WCI Partners Meeting in San Francisco, CA

Details for this meeting will be posted to the WCI website and distributed via the list server when available.

effort to address climate change in a cost-effective manner. Cap-and-trade legislation will complement Manitoba's participation in regional climate-change strategies like the Western Climate Initiative and Midwestern Greenhouse Gas Reduction Accord." For more information, click here.

Québec Adopts California Greenhouse Gas Emission Standards for Vehicles

On December 29, 2009 Line Beauchamp, Minister of Sustainable Development, Environment and Parks, announced that Québec's regulation to adopt California greenhouse gas emission standards for cars and light trucks will come into force in mid-January, 2010, making Québec the first Canadian province to apply North America's strictest standards. At approximately 40% of total emissions, transportation is the largest sector of greenhouse gas emissions in Québec. For more information, click here.

Material Available from WCI Partners and Electricity Collaborative Meetings

Material and presentations from the January 20 Partners meeting and January 21 WCI Electricity Collaborative are available on the WCI website. The first half of the Partners meeting focused on the 2010 work plan for the WCI and the several technical and policy products expected in the coming months.

WCI Electricity Team Issues Draft Recommendations for the Voluntary Renewable Energy Market

Voluntary purchases of renewable energy products have played an important role in expanding the renewable energy market in many WCI jurisdictions. The Electricity Team has examined how the voluntary renewable energy (VRE) market may be affected by the implementation of a greenhouse gas cap-and-trade program. The Electricity Team's draft recommendations describe the issue in greater depth and offer key design elements for a VRE allowance set-aside program for WCI Partner jurisdictions who choose to implement one. Comments on the draft recommendations should be submitted by February 19. To download a copy of the recommendations and submit comments, click here.

WCI and Federal Governments Continue Coordination on Mandatory Reporting Procedures

Several WCI Partner jurisdictions are participating on a team convened by the U.S. EPA to develop data exchange mechanisms between facilities, the EPA, and the states. The team includes Canadian observers and is intended to help harmonize the implementation of state and federal greenhouse gas emission reporting requirements. Similarly, the WCI provinces are working with Environment Canada on the data infrastructure required for mandatory reporting in the provinces.

Comment Period on WCI Complementary Policies White Paper Closing

The WCI Complementary Policies Committee has requested that public comments on its white paper be submitted by January 29, 2010. Any stakeholders still interested in submitting comments should do so as soon as possible. To download a copy of the document or submit comments, click here.

Issue Paper – Vented and Fugitive Compressor Emissions

Issue:

Compressors are used in the production, processing and transportation of natural gas. Typically, either gas-fired reciprocating compressors (85% of compressor population) or centrifugal compressors (turbines) are used to increase and maintain gas pressure as natural gas is moved from point of production to end-users.

These compressors and associated components are subject to thermal, pressure and mechanical stresses which result in fugitive leaks and loss of natural gas. Additionally, operational practices such as compressor start-up and blowdown also result in vented emissions of natural gas. While numerous studies indicate that these fugitive and vented emissions are a major source of methane and represent a significant economic loss, there are also many leak mitigation technologies available which have been proven to dramatically reduce these emissions. Fugitive emissions sources include: 1) valve leaks – from pressure relief valves, closed blow-down and unit isolation valves, 2) continuous leaks from rod-packing (either wet or dry seals) both during operation and when the unit is in pressurized/standby mode, 3) wet-seal oil degassing and, 4) miscellaneous leaks from fittings, pump and valve seals.

Western Regional Air Partnership (WRAP)/The Climate Registry (TCR) Approach:

The voluntary TCR draft Oil and Gas Production Protocol does not provide methodologies specifically designed to address compressor station emissions. The TCR draft includes compressor fugitive emissions under Fugitive Emissions from wellhead and Oil and Gas Production Installation or Facility. This section of the Protocol lists four methods which reporters may use to estimate these fugitive emissions:

<u>Fugitive Emissions</u>

1). Direct measurement approach where the composition of the processed natural gas is measured, mass emission rates are determined using bagging techniques, hi-volume samplers, or a screening and correlation method.

2). Use of facility level default emission factors (EFs) (EFs for valves, pump seals, connectors etc for three facility types - offshore facilities, oil and gas production facilities, and gas plants).

3). Use of default emission factors for large equipment types (e.g. small and large compressors, separators)

4). Use of facility default emission factors (e.g. off-shore oil production, gas processing)

TCR provides two methods for the determination of blowndown and start-up vented emissions.

Blowdown and Start-Up
1). Use of engineering approach to calculate vented volume for each blowdown or start-up, and record the number of blowdowns and start-ups per reporting period.
2). Record number of blowdowns and compressor starts and use a generic default EF.

EPA Approach: The draft EPA Subpart W requires that reporters screen the following components with an Infrared detection instrument, and then subsequently use a high-volume sampler to quantify emissions from these components:

1) centrifugal compressor wet and dry seals,
2) compressor fugitive emissions,
3) reciprocating compressor rod packing, and,
4) fugitive emissions from open-ended pipes, pump seals, and processing facilities.

EPA allows the use of calibrated bags or meters when high volume samplers cannot capture all fugitive emissions from the sources listed above.

WCI Options:

Option	Pros	Cons
A: Use default emission factors (e.g. 15 Mcf/blowdown)	Easiest of the methods	Data not of sufficient accuracy for cap-and-trade
B: 1) Screen all compressor station gas service components – use EFs to estimate emissions, and 2) quantify major compressor component emissions using Hi-Vol or calibrated bag sampling 3) calculate blowdown and start-up volumes and record number of compressor start-ups and blowdowns	Site specific measurements result in more accurate data. Provides facility operators with the data essential for the design of a mitigation strategy.	More extensive monitoring and sampling involved. Fugitive emissions data generated using EFs would not be cap-and-trade quality. Vented emissions data measured using Hi-Vol or bagging would be cap-and-trade quality.

Table 1. Methodology Options

WCI Reporting Subcommittee Comments and Recommendations:

Because of the significance of both fugitive and vented compressor emissions, a reporting regulation explicitly focused on the identification and quantification all major compressor GHG emissions is the most effective manner to address these fugitive and vented emissions. Studies by both Gas Research Institute (GRI) and Pipeline Research Committee International (PRCI) indicate that compressor components are responsible for more than 80% of the total leakage at compressor stations. In a typical compressor station there may be thousands of components, however only a small fraction of these components contribute significantly to total fugitive emissions from the facility. Thus, WCI recommends the use of Option B which is discussed in detail below.

1) Component screening of all gas carrying components shall be conducted using a handheld device (e.g. OVA, TVA, or IR instrument). Default emissions factors would then be used to estimate fugitive emissions. Because default EF's are by their nature not facility or compressor specific, these emission estimates would not be of cap-and-trade quality. This data would however, provide the site operator with the information necessary to design a mitigation plan to address these fugitive leaks – screening identifies leaks and provides actionable semi-quantitative information concerning leak magnitude. Screening should be conducted on an annual basis.

2) In the case of the major compressor related vented emission sources listed in Table 2 below, emissions should be measured using high-volume sampler and bagging techniques which are much more accurate and quantitative. This data will be sufficiently accurate for inclusion in a cap-and-trade program. The WCI Subcommittee is proposing that emissions sampling and quantification be conducted twice annually – approximately every six months. Because major station maintenance turnarounds are scheduled well in advance, it should be possible for reporters to conduct sampling shortly after station maintenance turnarounds and thereafter at approximately six month intervals. For the purposes of emissions calculation, we assume a linear increase in leak rate during the approximately six month interval between measurements. For instance, if a blowdown valve was found to have a zero leak rate when last sampled, and an emission rate of 500 scf/hr during the present sampling period, a leak rate of 250 scf/hr would be used to calculate emissions over the time interval between these two sampling efforts.

Component	**Compressor Status**		
	Running	Idle/Pressurized	Blowdown/ Pressurized
Rod packing seals	X	X	
Blowdown valve	X	X	
Pressure relief valve	X	X	
Unit isolation valve			X
Wet-seal oil degassing	X		

vent			
Centrifugal compressor seals	X	X	

Table 2. Sampling Matrix - Component and Compressor Status

For most components, measurements must be conducted both when compressors are running and when they are idle and pressurized (see Table 2 for details). Compressor rod seals leak during normal operations but leak rates can increase four-fold when the compressor is idle but remains pressurized. It is interesting to note that the EPA Gas Star Program has found that leaving a compressor pressurized results in lower emissions than the practice of blowing down a compressor when it is placed in idle or standby mode. In the case of unit isolation valves, sampling is required only when compressors are blowdown but remain pressurized.

For vented emission sources listed in Table 2, the WCI Subcommittee is considering establishing a compressor horse-power threshold (200 hp) below which reporters could simply screen the compressor and associated components and use a default EF to estimate emissions for most of their smaller (<200 hp) compressors. Seventy-five percent of compressors below the 200 hp threshold could use a default EF to estimate emissions. For the remaining 25percent of compressors, reporters would be required to carry out the more extensive sampling and quantification measurements. This approach will allow WCI to evaluate the effectiveness and accuracy of this approach. The WCI Subcommittee is seeking comment and data concerning the horse-power distribution of field and processing facility compressors to better evaluate the most effective threshold. Canadian data suggests that a threshold of 250 hp would capture approximately 75% of the compressors in service.

This threshold will not be applied in the case of blowdown and start-up emissions because the start-up and blowdown volumes remain constant. Reporters will be required to use an engineering approach to calculate blowdown and start-up emissions regardless of compressor size.

WCI Quantification Methodology:

Compressor Blowdown and Start-up Emissions - The following methodology (based on CAPP, 2002) shall be used to calculate blowdown and start-up emissions for all compressors, regardless of size.

a). Use engineering approach to calculate the volume of gas released during compressor start-up and blowdown,
b). Record temperature and pressure of gas prior to blowdown,
c). Correct volume of gas released to STP (standard atmospheric temperature and pressure),
d). Record number of blowdowns and start-ups,
e). Determine gas composition (carbon content) semi-annually using standard methods approved by WCI jurisdiction.

<u>Step 1.</u> Calculate the compressibility factor (Z) for natural gas to account for deviation from ideal gas behavior. Z must be calculated for both initial conditions (temperature and pressurize prior to blowdown) and standard temperature and pressure (20°C and 1 atmosphere)

$$Z = a + bP + cT + dP^2 + eT^2 + fPT$$

Where:

- Z= compressibility factor
- P = gas pressure (kPA) – (standard pressure = 101.325kPa)
- T = gas temperature (°C) – (standard temperature = 20°C)
- a,b,c,d,e, and f are correlation coefficients (see Table below)

Correlation Coefficient	Value
a	9.9187E-01
b	-3.3501E-05
c	6.9652E-04
d	6.3134E-10
e	-8.6023E-06
f	2.3290E-07

Table 3 – Correlation Coefficients for Estimating Compressibility Factor for Natural Gas

Step 2. Gas volume released during blowdown is corrected to atmospheric temperature and pressure in the following manner:

$$V_{STP} = V_{BD} \left(T_{STP} / P_{STP} \right) \left(P_C / Z_i * T_C - P_{STP} / Z_{STP} * T_C \right)$$

Where:

- V_{STP} = blowdown volume at standard temperature and pressure (scf)
- V_{BD} = compressor blowdown volume (cf)
- T_{STP} = standard temperature (293.15 °K)
- P_{STP} = standard pressure (101.325 kPa)
- P_C = compressor pressure prior to blowdown (kPa)
- Z_i = natural gas compressibility factor (initial conditions – unit-less)
- T_C = temperature of gas prior to blowdown (°K)
- Z_{STP} = natural gas compressibility factor at STP (unit-less)

<u>Step 3.</u> Emissions are calculated as follows:

$$E_{CH4/CO2} = \sum_{1}^{2} \sum_{1}^{N} V_{STP-B,S} * 1/MVC * MW_{CH4/CO2} * MF_{CH4/CO2} * 0.001$$

Where:

- $E_{CH4/CO2}$ = emissions of methane or carbon dioxide (MT/yr)

N= number of start-ups or blowdowns per sampling interval (semi-annual)
$V_{STP-B,S}$ = blowdown or start-up volume of gas released (volume at STP, V_{STP})
MVC = molar volume conversion factor
$MW_{CH4/CO2}$ = molecular weight of carbon dioxide or methane
$MF_{CH4/CO2}$ = molar fraction of methane or carbon dioxide in gas
0.001 = conversion factor (kg to metric tons)

<u>Compressor Component Emissions</u> – For all compressors greater than 200 hp and 25% of compressors less than 200 hp reporters must conduct quantitative measurements of emissions from the sources listed in Table 2. Hi-volume sampler and/or bagging techniques shall be used to measure gas emission rates.

Emissions shall be calculated in the following manner:

$$E_{CH4/CO2} = \sum_{1}^{2}\sum_{1}^{N} \left(ER_{Ci-F} - ER_{Ci-i}\right)/2 * MF_{CH4/CO2} * 1/MVC * T * 0.001$$

Where:

$E_{CH4/CO2}$ = emission of methane or carbon dioxide (Mt/yr)
N = number of components (see Table 2)
ER_{Ci-F} = gas emissions rate at time of current (final) sampling (scf/d)
ER_{Ci-i} = gas emission rate at time of prior (initial) sampling (scf/d)
$MF_{CH4/CO2}$ = molar fraction of methane or carbon dioxide in gas
MVC = molar volume conversion factor
T = time between sampling periods (decimal days)
0.001 = conversion factor (kg to metric tons)

WCI Monitoring Methodology:

see methodology discussed above.

1) individual components are screened annually,
2) emissions from components list in Table 2 would be quantified using Hi-Vol or bagging techniques semi-annually,
3) gas composition would be determined at least semi-annually.

Issue Paper -- Contractor Emissions

Note to those reviewing issue paper for the first time:

The contractor emissions issue paper has been developed sequentially by the WCI Reporting Subcommittee over the last months with input from the Oil and Gas Technical Working Group (consisting of industry and environment group representatives). The foundation for this issue paper was the technical discussion that occurred for the development of the WRAP/Climate Registry Oil and Gas Protocol. Those reviewing the issue paper for the first time may want to first focus their reading on the first and last sections: (i) Issue; and, (ii) WCI Subcommittee Discussion and Recommendation prior to looking through the sections on the background and stakeholder comments.

Issue:

Oil and gas installation operations may be conducted by owners/leaseholders or service providers who act as contractors. At some installations there may be fractional owners of wells, each owner having a slightly different ownership group. One company will often be assigned operational control and either performs the exploration and extraction operations itself, or contracts them to a service provider. In these instances, the question arises as to which entity is responsible for reporting emissions: the owner/leaseholder with operational control or the contracted service provider ("contractor").

Owners and leaseholders have raised concerns that reporting contractor emissions could cause significant burden as such emissions are not currently reported in any form. New contractual obligations may be required if the owner/lease holder were to obtain emissions data from the contractor for reporting purposes.

A significant issue could arise from facility splitting if firms were to contract out oil and gas installation operations to avoid both greenhouse gas reporting and a future cap and trade system. In addition, an equity issue is raised as Canadian operators contract out significantly less in the way of equipment such as compressors than their American counterparts. Also significant is the WCI's goal of capturing 90 percent of emissions from each source category. Without capture of contractor emissions it is doubtful that 90 percent of oil and gas production installation emissions will be captured.

Western Regional Air Partnership (WRAP)/ The Climate Registry Approach:

The reporting of emissions from contractor activities was discussed in depth in the WRAP/Climate Registry process, and the technical working group came to the consensus that, as defined by the GHG Protocol Corporate Standard for voluntary reporting, contractor emissions are the Scope 3 indirect emissions of the owner/leaseholder. Although it should be noted that some working group participants felt that certain categories of contractor emissions should be required to be reported by The Climate Registry's voluntary program because those activities were seen to be significant, central and necessary to the production of oil and gas. However, in The Climate Registry's voluntary program Scope 3 emissions are not required to be reported. The WRAP/Climate Registry working group did identify that emissions such as venting are in general considered to be the responsibility of the owner/leaseholder to report and are therefore not contractor emissions. That left contractor activities related primarily to combustion from portable (e.g. mobile drill rigs) or stationary sources as the categories of Scope 3 sources typically found in this sector.

Whether to include contractor emissions under a mandatory reporting program was not addressed in the WRAP/Climate Registry process.

EPA Approach:

In the Mandatory Reporting Rule (MMR), EPA's definition of a facility would not preclude contractor equipment at an installation from being considered a separate facility subject to the MRR and reportable by the owner or operator, or as part of the larger facility. The EPA definition would include in the facility all equipment under "common ownership or common control"; therefore, specifics of the contractual arrangement might determine whether contracted equipment was under the control of the party contracting to purchase services. However, the EPA excludes portable equipment from coverage under MRR Subpart C (General Stationary Combustion), and defines portable equipment to include equipment which is easily transportable and located at a given site for less than twelve months. Portable contractor equipment is often located at a site for periods less than a year, and therefore much of contractor combustions emissions would be excluded from reporting under Subpart C. EPA deferred on the issues of defining the reporting entity for oil and gas production sources and of reporting vented and fugitive emissions from oil and gas sources.

We also note that EPA has addressed policy issues related to contractor emissions in the context of PSD and Title V programs. In several guidance letters, EPA has consistently stated that "contractor-operated units [must] be included as part of the source with which they operate or support" (Ref. 1). Although this policy is not necessarily binding on Subpart W of the Mandatory Reporting Rule, EPA's rationale for this policy is relevant: "the contracting entity can control the relevant aspects of the contract operator's performance through terms of the contract (e.g., the level of production, the requirement to implement and maintain emission control measures, the requirement to comply with all applicable environmental regulations, etc.)" (Ref. 2).

WCI Options:

Option	Pros	Cons
A. Not require reporting of contractor emissions. Neither the oil and gas producer nor the contractor report emissions.	Simple	Facility splitting could be a problem Would capture fewer emissions than other options. Does not match WRAP/Climate Registry approach to leaseholder emissions. Inequitable coverage: creates a two-tier system of facilities with and without contractors. Could result in underreporting contrary to WCI design principle.
B. Require contractors to report if aggregated emissions exceed threshold. Require contractors to report all emissions associated with the operations they are contracted to perform (if in total they exceed the threshold.)	Creates responsibility for contractors to report emissions Would be the simplest scenario for emissions from combustion and portable sources	Added administrative burden for the regulator as emission sources could be covered by several operators and contractors, at a single installation. Does not match WRAP/Climate Registry approach to leaseholder emissions. Facility splitting could create administrative difficulties. Would create a new class of 'facility'.
C. Include venting, fugitive and flaring emissions from a contractor in the emissions of the owner or operator. The oil and gas producer reports all emissions associated with the contractor operations excluding combustion emissions.	Would cover a significant portion of emission sources. Reduces facility-splitting potential through intentional use of contractors. All emissions are generally considered part of a typical oil and gas installation. WRAP/Climate Registry approach identified that these emissions are the responsibility of the leaseholder.	Does not include what could be substantial combustion emissions from contractor activities. Inequitable coverage: potentially creates a two tier system of facilities with and without contractors (for other emission sources).

Option	Pros	Cons
D. Include all emissions in Option C (above) and combustion emissions from contractors, other than portable combustion emissions. The oil and gas producer reports all emissions associated with contractor operations including combustion emissions, other than portable combustion emissions.	Creates equitable coverage. Would cover all emission sources that are typically considered as part of an oil and gas installation. Producer consumption is a significant emission source. Reduces facility-splitting potential through intentional use of contractors. Requirements to track combustion emissions from contractors could be included within contracts.	May require phasing in due to standing contractual obligations. (Could require owners/leaseholders to estimate combustion emissions in the first years to allow importance to be established and to phase in new contractual obligations) More rigorous than WRAP/Climate Registry approach to leaseholder emissions.
E. Include all emissions in D and portable combustion emissions from contractors. The oil and gas producer reports all emissions associated with contractor operations including portable combustion emissions occurring on- site.	Would cover the largest portion of emission sources.	Portable combustion emissions (e.g., onsite emissions from a mobile drilling rig) in the oil and gas industry likely would prove hard to track, creating an administratively burdensome system. More rigorous than WRAP/Climate Registry approach to leaseholder emissions.

Stakeholder Input (from both initial and revised issue papers):

Natural Resources Defense Council (NRDC), Wild Earth Guardians, Western Environmental Law Center

Initial comments on November, 2009 version of issue paper:

- Contractor emissions are significant and must be included in reporting.
- Operators can make GHG emissions data collection part of contracts.
- Operators should be required to report contractor emissions, including combustion (portable and stationary), venting and fugitive emissions.
- Contractor sources should be considered for inclusion on same technical criteria as operator sources (significant emissions in aggregate, availability of cost-effective emissions reduction method).
- Supports Option E.

Subsequent comments are on January, 2010 version of issue paper:

- In the January 21, 2010 teleconference WCI explained that having the owner/operator report contractor emissions harmonizes with EPA's historical approach of reporting contractor emissions at a facility under the Clean Air Act. Owner/operators are in a unique position to select and hire contractors that chose to run low emission units. And, because contractor emissions can be a significant portion of the oil and gas GHG emissions, it is important for the owner/operator to take ownership and have a solid understanding of the full environmental impact of its operation and work collaboratively to select and reward environmentally progressive contractors.
- The main difference between Option D and Option F1/F2 is who does the reporting. In Option D the owner/operator must report all contractor emissions. In Option F1/F2 the owner/operator would report venting, fugitive and flaring emissions, and the contractor would report combustion emissions. We do not see any advantage to the split reporting. We agree with WCI that owner/operator reporting would be preferable, over the split reporting Option F1/F2. Option E, that we support, also requires owner/operator reporting.
- During the January 21, 2010 work group meeting, we inquired how WCI handled contractor emissions within the other WCI GHG Reporting Protocols. WCI explained that contractor emissions at the owner/operator facility were included and reported by the owner/operator. We pointed out that WCI's past precedent for handling contractor emissions was consistent with Options D and E, but not Option F1/F2. We recommended that this fact be listed as a "con" in the proposed Option F1/F2, because Option F1/F2 would not be consistent with the approach taken on other established WCI GHG reporting protocols.
- The difference between our preferred Option E and WCI's new Option D is that all contractor emissions from combustion sources using gasoline, diesel and other liquid fuels provided by a commercial fuel supplier would be excluded. This would essentially eliminate tracking of GHG emissions from all portable/mobile combustion sources [e.g. fleet vehicles, vessels, drill rigs, workover rigs, etc.] that operate on liquid fuels. WCI clarified that it was proposing this exclusion, because WCI has plans to capture GHG emissions from commercial fuel suppliers in a separate protocol (Fuel Supplier's Protocol) under development for 2012.
- We would like to better understand the rationale for including fleet combustion source emissions under the Fuel Supplier's Protocol. It is not clear to us tracking contractor combustion emissions from fleet units under the Fuel Supplier's Protocol will ultimately lead to the GHG emission reduction solutions WCI seeks.
- Since the ultimate goal is to quantify GHG emissions and then identify cost-effective emissions reduction strategies to reduce emissions it seems necessary to track emissions generated by Fuel Suppliers (generated in the fuel production and delivery itself) and by Contractors/Owners/Operators that generate GHG emissions by combusting the liquid fuels in portable/mobile sources.
- We think it would be better to include contractor fleet emissions under the Oil & Gas GHG Reporting Protocol where the owners/operators and contractors have more direct influence on future emission reduction opportunities. We are concerned that if the GHG emission reporting obligation is transferred to the Fuel Supplier's Protocol, the Fuel Suppliers will not have any control over future

emission reduction opportunities for Oil & Gas Contractor equipment, other than controlling the amount and carbon content of fuel sold.

- In Option D, we don't understand why a more rigorous reporting approach is listed as a "con"; we recommend that this comment be placed in the "pro" section of the analysis.

Canadian Association of Petroleum Producers (CAPP)

Initial comments on November, 2009 version of issue paper:

- Supports Option C: Include venting, fugitive and flaring emissions from contractor in the emissions of the owner or operator.
- Canadian rules require metering and reporting of venting and flaring associated with well drilling and servicing activities.
- Emissions associated with operation of drilling and servicing rigs are best reported by operators of that equipment (such as contractors).
- Combustion emissions from operation of well drilling and service rigs in Canada account for about 1.5 percent of upstream O&G emissions. These emissions should be excluded. The level of effort required for well owners/operators to gather the contractor data necessary to estimate these emissions is out of proportion with the benefits achieved of capturing these emissions.

Subsequent comments on January, 2010 version of issue paper:

- Verification of contractor combustion emissions would be difficult because well owners do not have access to the necessary data. Well owners/operators typically do not have access to the data necessary to make the emission estimates and have no power to compel their drilling/servicing contractors to have verifiable data collection systems in place nor to provide the required data.
- Supports Option F1 and F2 because emissions associated with the operation of a production well should be the responsibility of the owner/operator as they have access to the data required to determine the GHG emissions associated with the activity.
- In the case of well drilling and servicing activities, GHG emission sources include flaring and venting associated with gas returned during drilling, well cleanouts and drill-stem tests. In Canada, volume associated with these activities are currently metered and reported to the regulator.
- On the other hand, other GHG emissions associated with the operation of drilling and servicing rigs are best reported by the operators of that equipment. Drilling and servicing contractors are best equipped to estimate and report GHG emissions as they have access to the necessary activity data, which the well owner/operator would not.
- The level of effort required by drilling and servicing contractors to report their GHG emissions would be significantly less than if the owner/operator were to report the GHG emissions from each well. The contractor would merely report their total emissions based on total fuel consumed, in contrast to having to allocate fuel consumption to each well drilled during the year, which is what the owner/operator would be required to do.

Chevron (CVX)

Comments on November, 2009 version of issue paper:

- Support WCI efforts to include significant contractor emissions
- Limit this reporting to fields/basins where these emissions contribute to 95 percent of total.
- Contractors often work on multiple sites in workday; may be difficult to allocate total fuel use among well sites/operators.

American Petroleum Institute (API)

Initial comments on November, 2009 version of issue paper:

- Support Option C (operator reports venting, fugitive and flaring emissions from contractor, but not contractor combustion emissions).
- Producer does not have access to data on contractor fuel use, device specifications, hours of operation.
- WCI could devise simplified methods for reporting of combustion emissions from portable equipment used by field service contractors, as in Option B, to cover such equipment emitting more than threshold amount per year.

Subsequent comments on January, 2010 version of issue paper:

- It is clear that contractors have an important role to play in Oil & Gas operations and they – as independent entities – should have the responsibility to report emissions that are under their operational control.
- Supports in principle Option F1/F2 thus splitting the reporting responsibility between owners and service contractors. Such a reporting split should rest with the owners reporting of emissions from their operations including venting and/or flaring from compression, workover and well completion. Combustion emissions along with fugitive emissions from equipment leaks associated with contractors operations should be included under the F2 option.
- Both oil and gas companies and field service contractors should be required to report GHG emissions from the equipment that is under their operational control whether it is owned or leased.
- Does not concur that this approach would create a new type of “facility” since it is recommending that the reporting boundaries be set at the jurisdiction level with either field operators or field service contractors reporting their applicable emissions for listed sources that exceed certain threshold applicability criteria. Such an approach will simplify data tracking and reporting for contractors by enabling them to integrate accounting for their activities when servicing multiple operators in the same jurisdiction.
- It is essential to minimize confusion and reduce reporting burden by ensuring that the option selected be consistent with EPA’s owner and/or operator approach and the flexibility it has afforded in its GHG mandatory reporting rule (MRR) for joint ownership reporting by a designated official that is acceptable to the applicable parties.
- WCI should retain consistency with its stated policy of harmonizing their reporting requirements

with the EPA MRR rule and should therefore adopt EPA's definition of owner/operator to establish the reporting obligations of both field owners and field service companies reporting obligations.

- WCI should also ensure harmonization with the EPA MRR definition of portable equipment that is exempt from reporting, where such equipment includes emergency generators and mobile and/or easily transportable devices.
- The use of the term 'non-commercial fuels' is open to widely varying interpretations. API views these fuels as field generated fuels prior to the respective 'custody transfer' points where they enter into commerce. WCI ought to confirm and expound on what is meant by this term.

Suncor

Comments on January, 2010 version of issue paper

- Whatever option is chosen, you have to realize that the quality of data that Operators will get from contractors is lower, and at least initially we will have to accept best estimates until long-term contracts can be written requiring better data. Similarly, it will be effectively impossible to get a "reasonable" level of assurance from third-party data sources, so we may have to accept a "limited" assurance level for contractor emissions.

WCI Subcommittee Comments and Recommendation:

The WCI Reporting Subcommittee acknowledges the Technical Work Group comments on contractor emissions. Based on the discussion and the need to capture combustion emissions from contractors, there are two feasible alternatives – a combined Option B and C (termed Option F1/F2), and Option D. They are presented below for clarity. Due to the coverage of portable combustion emissions (e.g. diesel fuel use at a drilling rig) under fuel suppliers in the WCI design, Option E was discarded. Option A was viewed as not covering a sufficient portion of emissions.

The difference between options D and F1/F2 is whether a producer would be responsible for combustion emissions at equipment owned by a contractor, or if a contractor would be responsible for these specific emissions. Both would cover a similar amount of emissions and meet the WCI goal of covering a significant portion of emissions for each industry. Option D would have fewer entities reporting than Option F1/F2.

Due to the control that owners/leaseholders have over production, processing and transmission operations, and given that it would cover all sources normally considered as part of the oil and gas operation, Option D is recommended by the subcommittee. As it is understood that standing contractual agreements may need to be revised, phasing in of reporting may be required. Owners/leaseholders may need to estimate combustion emissions in the first year(s) to phase in new contractual obligations.

For Option D, the reporting requirements for each of the three sectors – production, processing, and transmissions are shown the final Table.

Revised WCI Options (based on stakeholder feedback from November, 2009 version of issue paper):

Option	Pros	Cons
D. An owner or operator would include all venting, flaring, fugitive and combustion emissions (from fuels not obtained by a commercial supplier) from contractors, other than portable combustion emissions. The oil and gas producer reports all emissions associated with contractor operations including combustion emissions from fuels not obtained from a commercial supplier (fuels obtained from a commercial supplier would be covered under a future WCI fuel supplier Essential Requirement quantification method.)	Creates equitable coverage. Would cover all emission sources that are typically considered as part of an oil and gas installation. Producer consumption is a significant emission source. Reduces facility-splitting potential through intentional use of contractors. Requirements to track combustion emissions from contractors could be included within contracts. Contractors would likely quickly install necessary meters and be responsible to the owner/operator.	May require phasing in due to standing contractual obligations. (Could require owners/leaseholders to estimate combustion emissions in the first years to allow importance to be established and to phase in new contractual obligations). Requires administrative steps by the owner/operator to ensure data is received from the contractor. More rigorous than WRAP/Climate Registry approach to leaseholder emissions.

Option	Pros	Cons
F1. Include venting, fugitive and flaring emissions from a contractor in the emissions of the owner or operator. **F2. Require contractors to report combustion emissions (from fuels not obtained from a commercial supplier) if aggregated emissions exceed threshold.** The oil and gas producer reports all emissions associated with the contractor operations excluding combustion emissions (the producer would include their own combustion emissions, from fuels not obtained from a commercial supplier). The contractor reports all combustion emissions (from fuels not obtained by a commercial supplier) (except flaring) associated with the operations they are contracted to perform (if in total they exceed the threshold).	Would cover a significant portion of emission sources. Covers emissions generally considered part of a typical oil and gas installation. WRAP/Climate Registry approach identified that the non-combustion emissions are the responsibility of the leaseholder. Creates responsibility for contractors to report emissions. Would be simplest scenario for a facility to report combustion emissions. Contractors would likely quickly install necessary meters.	Does not include potentially substantial contractor combustion emissions with the classic owner/operator. Inequitable coverage: potentially creates a two tier system of facilities with and without contractors (for other emission sources). Facility splitting could create administrative difficulties. Added administrative burden for the regulator as emission sources could be covered by several operators and contractors. Does not match WRAP/Climate Registry approach to leaseholder emissions. Would create a new class of "facility". Does not match traditional EPA handling of contractor emissions within the total emissions for a facility.

Reporting Requirements (by sector) Under Option D

Sector	Who Reports	What Emissions are Reported
Production	Oil and Gas Producer	All stationary combustion emissions from produced gas and other fuels (with the exception of fuels brought on site by contractors). All fugitive, flaring and venting emissions where methods are provided.
Processing	Oil and Gas Processor (operator of the processing facility)	All stationary combustion emissions for gas and other fuels. All fugitive, flaring and venting emissions where methods are provided.
Transmission	Operator of the transmission facility	All stationary combustion emissions for gas and other fuels. All fugitive, flaring and venting emissions where methods are provided.

Dear Stakeholder:

The Western Climate Initiative (WCI) Reporting Subcommittee on Oil and Gas has developed draft recommendations for quantifying certain emissions in the upstream oil and gas sector. These recommendations will serve as the basis for the WCI's comments to U.S. EPA on their revised draft reporting rules for the sector (Subpart W). We anticipate EPA will release these draft rules sometime this month. The recommendations will also serve as the basis for the WCI essential mandatory reporting requirements for the upstream oil and gas sector which we hope to complete this calendar year. After EPA has released their final version of Subpart W, the WCI Reporting Committee will develop a set of recommended Essential Requirements for Mandatory Reporting for this sector which will be harmonized with the final EPA rule.

Many of the draft recommendations have been reviewed by a technical workgroup consisting of representatives from the oil and gas industry and the environmental community and are now ready for broader review and input.

The WCI has developed and posted draft recommendations covering eight issues: contractor emissions, compressors, glycol dehydration, sour gas treatment, well unloading, storage tanks, instrument gas and vented methane, and reporting entity and threshold. Comments on these papers should be submitted by March 30 for the Reporting Entity and Threshold Issue Paper and March 16 for the others. The subcommittee may post additional papers in the future.

Please let me know if you have any questions.

Western Climate Initiative

Issue Paper -- Defining the Reporting Entity and Threshold

Issue:

Greenhouse gas emission sources in the oil and gas industry often consist of small sources distributed over a broad geographic area that, when taken together, can contribute significantly to total GHG emissions in their regions. Large numbers of these emissions sources are typically owned and/or operated by the same company, although ownership (and operation) is not necessarily determined exclusively on the basis of geographic proximity. While many of the oil and gas emission sources in the oil and gas sector are small, some individual oil and gas facilities are large enough to be captured under the current reporting and verification thresholds. To ensure that a comparable portion of emissions is captured in the oil and gas sector as in other sectors, individual small oil and gas sources may need to be aggregated into oil and gas reporting entities for the purposes of reporting GHG emissions to WCI jurisdictions.

In discussions of this issue, it should be noted that the oil and gas industry in Canada can be vertically integrated (i.e. the producing company can also own the natural gas plant and/or the transmission company), while in the United States such vertical integration is prohibited by Federal Energy Regulatory Commission regulations.

Western Regional Air Partnership (WRAP)/The Climate Registry (TCR) Approach:

The WRAP/TCR approach recommends that emissions be aggregated and reported from small individual oil and gas sources which are owned and/or operated by a company at the field level. Large sources that meet the traditional definition of a standalone facility must be reported separately to maintain transparency. Reporting thresholds would be established at the field level for small sources and at the facility level for sources meeting the traditional definition of a facility. Companies have the option to aggregate multiple fields together up to the state-level for reporting convenience.

EPA Approach:

Not applicable – deferred to final Subpart W.

WCI Options:

The basic option would be to follow the general WRAP/TCR approach (defining the reporting entity as outlined in the first option table below), adding the following detail needed for a mandatory reporting program:

1. Use the WCI (or EPA) facility definition, including the clause: ”are under common control of the same owner(s) or operator(s)” for aggregation purposes. Discard clause b “Are located on one or more contiguous or adjacent sites” and part of clause d of the same definition for aggregation purposes.

For oil and natural gas entities, the "facility" definition would thus be:

"Oil and Natural Gas Facility" means all buildings, plants, structures, installations, and equipment that:

(a) Emit or may emit GHG(s);

(b) Are under common control of the same owner(s) or operator(s);

(c) have the first three digits "211" or "221", or the six digit codes "213111" or "213112" of the North American Industry Classification System (2007), excluding natural gas distribution and (potentially) transmission systems

(d) Operate within a single geologic basin, or process or receive oil or natural gas from the said geologic basin

2. Apply thresholds (as outlined in the second option table below) to the aggregated emissions to create an 'Oil and Gas Reporting Entity'.

3. Jurisdictions may choose to aggregate emissions to a broader level than the WCI determines.

4. Apply to all oil and gas emissions sources covered under EPA Subpart W and those emissions sources not included in Subpart W but to be included in the WCI Oil and Gas Essential Requirement. Apply similarly to all emission sources involved in the transfer of carbon dioxide from one location to another, whether it be for carbon capture and storage, release in another location, enhanced oil recovery, or other purposes.

Defining the Reporting Entity:

Option	**Pros**	**Cons**
A. Do not aggregate emissions. Apply existing facility definition to oil and gas installations	Simple, follows current WCI facility definition.	May not meet WCI principle of covering a significant portion of emissions.
B. Aggregate emissions to the field level	Consistent with WRAP/TCR approach Emission factors likely similar at field level	May not meet WCI principle of covering a significant portion of emissions unless lower thresholds are used. Fields vary in size, potentially creating inequity between leaseholders in different field.
C. Aggregate emissions to the basin level	Extend WRAP/TCR approach to a scale potentially more suitable for a mandatory	Appropriate thresholds would need to be determined.

	program. With appropriate thresholds would likely meet WCI design principle of covering a significant portion of emissions with as few facilities and reporting entities as possible.	Variable emission factors may need to be used in different fields.
D. Aggregate emissions to the jurisdictional level.	Extends WRAP approach to a scale potentially more suitable for a mandatory program. With appropriate thresholds would likely meet WCI design principle of covering a significant portion of emissions with as few facilities and reporting entities as possible.	Appropriate thresholds would need to be determined. Variable emission factors may need to be used in different fields.

Reporting Thresholds:

Option	**Pros**	**Cons**
A. Existing WCI thresholds: 10,000 metric tons reporting, 25,000 metric tons verification.	Follows current WCI standards. Easy to communicate	May not meet WCI principle of covering significant portion of emissions. May need more detailed reports form a reporting entity to understand the distribution of emission sources.
B. Lower thresholds	Would capture a higher portion of emissions and may meet the WCI principle of covering a significant portion of emissions. May not require more detailed reports from a reporting entity to understand the distribution of emission sources.	May or may not meet WCI principle of covering a significant portion of emissions with as few facilities and reporting entities as possible. May increase reporting burden for small companies.

C. Higher thresholds	May reduce reporting burden for small companies. Potentially could meet WCI principle of covering a significant portion of emissions with as few facilities and reporting entities as possible.	May not meet WCI principle of covering a significant portion of emissions. May need more detailed reports from a reporting entity to understand the distribution of emission sources.
D. Base threshold on a similar amount of barrels of oil equivalent	May be easier to determine obligations for the oil and gas industry.	Deviates from WCI emissions threshold approach for reporting and verification.

Note: There is a relationship between how the reporting entity is defined and the appropriate thresholds to use. A broader reporting entity may mean a higher threshold could be used. A smaller reporting entity may mean a lower threshold is needed. The optimum combination of reporting entity definition and threshold to meet the design principle may not be known until one or more years of reported data is available at a finer scale than that ultimately required for the long-term.

Screening:

Some industry representatives are concerned that potential reporting entities may need to undertake significant effort to determine whether or not they meet the reporting threshold. One solution is to specify a screening approach to determine whether a potential reporting entity is obligated to undertake an emissions estimate of its facilities. Screening would involve a simplified approach that provides reasonable clarity that a potential reporting entity has emissions below the reporting thresholds.

Several different screening approaches are possible:

i) A threshold set by the sum of total horse power (hp) capacity for compressors and heat capacity for heater/treaters operated by a reporting entity in a basin with a projected emissions from these activities (based on average activity level) and added to this estimated emissions from venting and flaring. The table below provides some examples. These examples represent only approximate sized equipment that would meet these thresholds.

Threshold Examples for Equipment Types:

Threshold	Engines	Boiler/Heaters/Flares	Vents/Leaks/Blowdowns/Pneumatics
10,000 TPY	2365 hp	21.3 mmBtu/hr heat input (HHV)	47.2 scfm of methane

Emissions from all types of equipment combined could be estimated for comparison to the threshold using the following equation:

$E = [V \times 212 \times (1 - 0.9X)] + [C \times 4.23 \times (1 + X)] + [B \times 470 \times (1 + X)]$

Where:
E = GHG emissions, $MTCO_2e/yr$
B = cumulative boiler, flare, heater burner capacities, mmBtu/hr
C = compressor engine capacities, hp
V = cumulative vented field gas rate, scfm
X = fraction of CO_2 in field gas

ii) A threshold set by the total production volume of a reporting entity in a basin. Specific thresholds could be set for natural gas and different thresholds for crude oil depending on its recovery process, so for example, thermally recovered oil would have a lower production threshold. Studies that have estimated average emissions per unit of output from natural gas or different types of oil production could be used to calculate an expected production cut-off. This approach might be difficult to implement because of the variety of production processes in WCI jurisdictions and the manner in which they change over time.

iii) Where necessary data is available and of good quality (e.g. for some emission sources in Canada), it may be possible to use pre-existing data on natural gas lease fuel use, flaring and venting reported by individual oil and gas facilities pursuant to current regulatory requirements such as those related to conservation or royalty payments. These data can be combined with emission factors to estimate a reporting entity's total emission levels from its facilities. Reporting entities with estimated emission below the reporting cut-off (based on calculations from data reported under oil and gas regulatory requirements) would be exempt from emission reporting.

Screening thresholds would be based on average expected emissions, but set at a conservative level, to allow a margin of error for possible underestimation of actual emissions..

Possible Quantification Methodology:

'Oil and Gas Reporting Entity' emissions could be calculated using the following general approach:

i. Include all oil and gas sources covered by EPA Subpart W, those other sources deemed appropriate and included in the WCI Oil and Gas Essential Requirement and all WCI and/or EPA source categories (e.g. stationary combustion).

ii. Include, exclude, or extend applicability for contractor emissions as determined by the WCI through this process.

iii. Apply emission factors to emission sources at the well, gathering location or field level (as appropriate in the jurisdiction) for true upstream sources. Apply emission factors as otherwise used in EPA Subpart W or the WCI metric ERMR (for use in Canada).

iv. Sum all oil and gas emission sources under common control of the same owner(s) or operator(s) to the field, basin or jurisdiction (as determined by the WCI) level

v. To provide sufficient information to understand distribution of emission sources, to determine potential facility splitting and to determine whether equitable coverage is occurring, provide at a minimum disaggregated reporting for each individual facility within the aggregated 'Oil and Gas Reporting Entity'. Determination of reporting and verification thresholds would be from the aggregated 'Oil and Gas Facility' total, including the facilities reported individually.

vi. Some emission sources that are required to be reported may be determined not appropriate for market trading in combination with the WCI Cap Setting and Allowance Distribution work.

Attention will need to be paid in the compliance and policies of jurisdictions to change of ownership/leasehold, possible facility splitting and/or outsourcing of emissions to contractors.

Stakeholder and Technical Working Group Input:

Natural Resources Defense Council (NRDC), Wild Earth Guardians, Western Environmental Law Center

- Start decision making with assumption of 10K and 25K thresholds.
- Optimum reporting entity may not be known until after 1-2 yrs of collecting fine-scale data.
- Jurisdiction level approach has merit.
- Goals are to ensure capture of cumulatively large emissions from individually small sources, and to avoid unreasonable burdens on individual small operators.
- Operator should be reporting entity.

Canadian Association of Petroleum Producers (CAPP)

- Aggregation to field, basin or jurisdiction level will require operators to estimate emissions for thousands to tens of thousands of small dispersed sources, which will be excessive effort to quantify small portion of emissions.
- Verification of emissions for large number of small dispersed sources will be challenging. Discussions with verifiers indicates that they would be challenged to provide a "reasonable level of assurance" for the estimated emissions from the multitude of small sources within a reasonable level of effort and cost. Verifications to a "limited level of assurance" under the Alberta GHG reduction regulation (entitled the Specified Gas Emitters Regulation) cost in the region of $15,000 CDN to $20,000 CDN per facility with ten to fifteen major sources and a few minor sources.
- Estimate level of effort and cost will increase 100-fold from current Alberta requirements.
- The level of effort required to estimate emissions of these small disperse sources is out of proportion with the magnitude of the emissions.

Chevron (CVX)

- Supports reporting at field level, possibly at basin level.
- Avoid term "aggregation" to reduce unintended triggering of other regulations or permitting requirements.

American Petroleum Institute (API)

- Supports aggregation at the jurisdictional level for reporting purposes provided it is coupled with simplified reporting methodologies, minimizes reporting burden and ensures resources and technological know how available for data collection.
- A clear distinction should be made between the definition of reporting entity and reporting threshold and the meaning of "facility" as used in other regulatory programs or facility permits for the oil and gas industry
- Reports will include listing of the field sites included with the sources being listed by source categories and number of devices in each of these categories at the jurisdiction level. For example, 400 glycol dehydrators of 1 MMBtu/hr each, 10 compressors > 500hp etc.
- Simplified applicability criteria, or a screening tool, should be developed for each source type to determine exceedances of a reporting threshold. Criteria for applicability screening could be based on throughput, capacity or actual emissions, and would be developed collaboratively as part of the rule development process.
- Screening criteria should be selected to capture all significant contributors to GHG emissions and prevent burdensome reporting on immaterial sources such as office heaters, lawnmowers and emergency generators.

WCI Subcommittee Comments and Recommendation:

The WCI Oil and Gas Subcommittee appreciates the Technical Working Group and other stakeholder comments, in particular the potential burden of calculating emissions from a producer's entire operation, in particular as they are not located in a single geographic location, as are the emission sources for a traditional facility. To capture a sufficient portion of emissions from the oil and gas production sector, however, it will be necessary to sum the discrete emission sources into a larger reporting entity. Given that field level reporting was accepted through the WRAP/TCR approach and given the jurisdictional boundaries within the WCI, a minimum would be to determine applicability for a producer at the combination of field and jurisdiction. Given the practical difficulty in determining field boundaries, and the multitude of potential fields, a basin/jurisdiction level approach to determining applicability is recommended. Total emissions for an owner/operator would be summed to the geologic basin level within a jurisdiction to determine reporting and verification obligations.

There is an interaction between the specific emission sources that would be covered by the WCI and the appropriate reporting and verification thresholds. We wish to ensure equity with other sectors, including 90 percent sector coverage, and considering that some emission sources in the oil and gas sector may not be included in market trading because they are not quantifiable to a sufficient level of accuracy. Therefore, the WCI is currently examining the interaction of a basin/jurisdiction level reporting entity definition and the current WCI Essential Requirements of Mandatory Reporting reporting and verification thresholds for this sector. It is possible that a recommendation may emerge that the existing thresholds (10,000 and 25,000 metric tons CO_2e) be used until such a time as reported data demonstrates (in combination with any emission sources not captured in the quantification) that more than 90 percent of emissions are covered. A threshold in units of barrel of oil equivalent is not recommended due to the different levels of emissions at different sources with the same total production or throughput. In addition, given the number of emission sources at disparate locations, the WCI recommends that the WCI Verification Subcommittee address means of ensuring efficient verification of oil and gas reporting entities.

A screening approach is recommended to specify whether a potential reporting entity is obligated to undertake an emissions estimate of its facilities. Screening approaches (i) and (iii) above will be investigated further for possible use.

Issue Paper – Glycol Dehydration

Issue:

Glycol based dehydration units are used in the natural gas industry to remove water from natural gas. Industry estimates that roughly 40,000 glycol dehydration units are in operation. Dehydrators are most typically found at production sites (e.g. storage tank batteries), natural gas processing facilities and natural gas storage and transmission facilities. EPA has identified dehydrator vent stacks as a major source of fugitive emissions for the oil and gas production sector.

Glycol dehydrators function in a manner very similar to amine treaters. The wet natural gas stream is contacted with an absorber solution (glycol) where water (and some hydrocarbons) is removed. The absorber solution (wet/rich glycol) is then regenerated in a reboiler where contaminants are thermally desorbed and separated from the treated glycol (lean glycol) which is then recycled back to the absorber. A flash tank may be installed between the absorber and the reboiler still. A flash tank removes a large fraction of absorbed hydrocarbons by pressure reduction. Flash tank emissions may be released to the atmosphere or captured and used as supplemental fuel or destroyed in a flare or thermal oxidizer. Figure 3.1 depicts one of the more common dehydrator configurations. Emissions of methane in uncontrolled systems will occur at the flash tank (if present) and at the reboiler (still) vent. Stripping gas (e.g. natural gas) may be used in the reboiler to enhance the glycol regeneration process. This stripping gas is subsequently released to the atmosphere if emissions from the reboiler are not controlled.

Glycol circulation pumps (e.g. a Kimray pump) may be natural gas driven. In this case there will be gas emissions associated with the operation of these pumps. The spent Kimray pump gas is usually dumped into the rich glycol stream, and thus will be flashed off up-stream of the reboiler if a flash tank is installed or in the absence of a flash tank, it will be flashed off in the regenerator and vented through the still column to the atmosphere. If this is the case, there is the potential for double-counting these pump emissions – here as part of the flash tank or reboiler emissions and in the regulation section dealing with vented gas-powered pneumatic devices and pumps. One way to address this issue would be to require reporting of Kimray pump emissions using the pneumatic device methodology if the pump emissions are vented directly to the atmosphere. If the Kimray pump gas is routed to the rich glycol stream and, reporters would not be required to meter Kimray pump gas consumption because these emissions would be captured by measurements made at the flash tank or reboiler vent.

If all (or a portion of) dehydrator emissions are controlled, that is pump gas, stripping gas and flash tank and still gas off-gas emissions are sent to a destruction device, they should not be reported here to avoid double counting.

Western Regional Air Partnership (WRAP)/The Climate Registry (TCR) Approach:

The Climate Registry Draft Oil & Gas Production Protocol discusses three methods for the determination of dehydrator methane and carbon dioxide emissions: 1) direct measurement of vent emissions, 2) modeling software, and 3) use of industry default emissions factors.

EPA Approach:

The EPA Draft Subpart W directed reporters to use "simulation software packages, such as GLYCalc™" to calculate dehydrator vent stack emissions.

WCI Options:

Option	Pros	Cons
A: Use industry default emissions factors	Simplest and least labor intensive method	Large degree of error associated with default emission factors – data not rigorous enough for cap and trade
B: Engineering estimation using simulation software (e.g. GLYCalc™)	May be less labor and resource intensive than direct measurement.	There is uncertainty as to the accuracy of simulation software. Method does require that reporters determine a suite of variables such as wet gas temperature, pressure, and composition. Method may be sufficiently accurate for smaller dehydrators.
C: Direct measurement – measure volume (mass) and composition of all vented emissions (reboiler and flash tank)	Most accurate of the methods if sampling accurately reflects standard operating conditions. (Requires site specific sampling and analysis.)	Requires site specific sampling and analysis. Measurements must be made during "normal operation". Changes in dehydrator operational parameters may trigger additional sampling.

WCI is seeking comment as to the advisability of establishing a dehydrator through-put threshold 25 MM scf/d) below which reporters may use simulation software. We are currently seeking information on the distribution of dehydrator through-put capacity (MM scf/d). Above the threshold, direct measurement would be required. Below the threshold, reporters may us Option B – simulation software - to calculate emissions. In the case of Option C additional sampling may be required if dehydrator operational parameters change significantly.

WCI Subcommittee Comments and Recommendation: The WCI subcommittee recommends the use of most accurate methodology, Option C where direct measurements of vented dehydrator emissions are made. A dehydrator throughput threshold of 25 MM scf/d would be established. Emissions from dehydrators above 25 MMscf/d capacity would calculate emissions using Option C methodology. Emissions from dehydrators below this threshold would be calculated using Option B, simulation software. WCI is seeking comment on the accuracy and applicability of GLYCalc and other publically available software applicable to this emissions source.

WCI Quantification Methodology: Methane and carbon dioxide emissions from dehydrators with a gas processing capacity of 25 MM scf/d and greater will be calculated in the following manner:

$$E_{CH4/CO2} = H / MVC * MW_{CH4/CO2} \left(V_{ft} * MF - ft_{CH4/CO2} + V_{rb} * MF - rb_{CH4/CO2} \right) * 0.001$$

Where:

- $E_{CH4/CO2}$ = methane or carbon dioxide emissions (metric tons/year)
- H = hours of dehydrator operation
- MVC = molar volume conversion factor
- $MW_{CH4/CO2}$ = molecular weight of methane or carbon dioxide (kg/kg-mole)
- V_{ft} = emissions flow rate from flash tank vent (scf/hour)
- MF-ft = molar fraction of methane or carbon dioxide in flash tank emissions
- V_{rb} = emissions flow rate from reboiler/still vent off-gas (scf/hr)
- MF-rb = molar fraction of methane or carbon dioxide in reboiler/still gas vent off-gas
- 0.001 = conversion factor (kg to metric tons)

Methane and carbon dioxide emissions from dehydrators with a gas processing capacity of less than 25 MM scf/d will be calculated using simulation software.

Stakeholder Input:

Stakeholders have not yet commented on this Issue Paper.

Issue Paper – Instrument Gas and Vented Methane Emissions

Issue:

Pneumatic control devices employing pressurized natural gas or field gas are commonly used in the natural gas industry. In the production sector these devices perform tasks such as the control and monitoring of gas and liquid flows and levels in dehydrators and separators, temperature in dehydrator regenerators, and pressure in flash tanks. In the processing sector high and low bleed pneumatic devices are used for compressor and glycol dehydration control in gas gathering and booster stations and isolation valves in processing plants. In the transmission sector these devices actuate isolation valves and regulate gas flow and pressure at compressor stations, pipelines, and storage facilities.

Pressurized natural gas or field gas is used as the motive agent and is routinely vented, either continuously or periodically. Many factors influence pneumatic device venting rates and volumes. Important variables are: the gas supply pressure, actuation frequency, and the age, condition and maintenance history of the equipment.

Consequently, these pneumatic devices are a major source of methane emissions from the natural gas industry. In most cases instrument gas is not routinely metered. In a Background Technical Support Document addressing *Fugitive Emissions Reporting from the Petroleum and Natural Gas Industry* EPA states that emissions from natural gas driven pneumatic valve and pump devices are know to be major contributors to fugitive emissions from the oil and gas production sector, accounting for emissions of about 21 million metric tons CO_2e in 2006.

Western Regional Air Partnership (WRAP)/Climate Registry (TCR) Approach:

TCR recommends that oil and gas producers who voluntarily report GHG emissions use the method and emissions factors found in the API Compendium (See below).

EPA Approach:

EPA has not published an emissions calculation methodology specific this vented source.

WCI Options:

Option	Pros	Cons
A. Use Original Equipment Manufactures (OEM) information	Easiest of the methods	Data consistency and reliability questionable.
B. API Compendium (2009) – use available emission factors	Simple methodology	Large uncertainty in the emission factors.

Option	Pros	Cons
C. Measure individual device emissions	Accurate methodology	Labor intensive and expensive. Instrument modification and changes in operating conditions would trigger additional measurements.
D. Meter instrument gas	Most accurate method	Requires installation of piping and meters. Does not provide consumption information for individual devices.

Background on available methodologies:
The options are discussed below.

A. Use of Original Equipment Manufacturers (OEM) data.

In many cases manufacturers' data for equipment bleed rates is available. There are several issues which suggest that significant errors in estimated emissions may result when one uses OEM data. First, there is no industry standard concerning the reporting of instrument bleed rates and thus manufacturers report information in a wide range of units and under varying operating conditions. In addition the data reported by manufacturers has not been independently verified. USEPA has found large discrepancies between OEM bleed rate data and actual field data. As stated above, factors not reflected in available OEM data, such as gas pressure and maintenance history, significantly influence emissions rates. While the American Petroleum Institute API (2009) states that the use of manufactures' data is "the most rigorous approach" the Compendium also acknowledges that manufactures emission rates "tend to be lower than emissions observed."

B. American Petroleum Institute (API) Methods:

API offers several approaches for the calculation of "emissions from a high or continuous bleed device" based on an equation from a Gas Processors Suppliers Association 1987 publication (see API Compendium, Section 5.6 Other Venting Sources, page 5-66). However, this equation is applicable only to high or continuous bleed devices and does not consider factors such as device maintenance history. Emission factors (EFs) for pneumatic devices have been developed. Many of these EFs were published in the 1997 GRI/EPA Report, Methane Emissions from the Natural Gas Industry. The API Compendium compiles these and other EFs (see Table 5-15, pages 5-68 and 5-69) and estimates uncertainties in some cases. Where specified, reported uncertainties range from ±33% to ±407%. This indicates that use of EFs would result in very unreliable estimates of vented methane emissions. In general, the use of EFs may result in relatively accurate emission estimates on a large scale (e.g. for an annual national inventory) but at the facility level EFs which are not site or equipment specific can introduce significant error.

C. Use of site specific measurement:

Actual site specific measurement of vented emissions from low and high bleed pneumatic control devices is accepted to be the most accurate method to quantify methane (and CO_2 if present in the gas) emissions. There are two approaches one may take when conducting site specific measurements.

One may characterize emissions from each pneumatic device at a facility using a bagging technique (or other method) where emissions from the device are captured and the volume of released gas is measured. Gas analysis then allows one to calculate actual CH_4 and CO_2 emissions. This technique is time consuming, labor intensive and expensive. In addition emissions may subsequently change as the result of factors such as maintenance activities and gas pressure changes.

D. Meter Instrument Gas Consumption:

Actual metering of instrument gas consumption and periodic measurement of gas composition will provide a much more accurate determination of GHG emissions. Changes in instrument gas plumbing and installation of one or more gas meters may be required initially and this will result in upfront material and labor costs. However, reporting in subsequent years will be very simple and easy, especially given the fact that periodic gas analysis will be required for other GHG emission calculations (e.g. stationary combustion emissions). In addition, changes in system operating conditions (e.g. line pressure, maintenance activities, instrument modifications) designed to reduce emissions will be reflected in the volume of instrument gas consumed and thus will be easily quantified. Facility operators receive immediate feedback on their efforts to reduce emissions and can also monitor instrument gas consumption in real time.

Stakeholder Input:

Natural Resources Defense Council (NRDC), Wild Earth Guardians, and Western Environmental Law Center

- Recommend allowing reporter choice of either Option C (measure device emissions) or Option D (meter instrument gas).
- Frequent calibration of measurement devices should be required.

Canadian Association of Petroleum Producers (CAPP)

- Supports Options A (use OEM emissions factors) and B (use API emissions factors).
- Fuel gas supply to pneumatic often comes from common fuel line supplying combustion devices; installing meter would require time-consuming and costly re-piping.
- CAPP states that these emissions account for only 5.5% of emissions from oil and gas operations in the Province of British Columbia.

Chevron (CVX)

- Direct measurement is impractical and cost prohibitive given the age and number of these devices in the field.
- Supports the use of Option B (use API emissions factors).
- Absolute volume of emissions from this source will decrease over time as more companies are using low-bleed devices in new installations.

American Petroleum Institute (API)

- Support Option B (use emission factors from API Compendium 2009).
- On-site measurement of emissions vented from these devices requires substantial effort and would not be sufficiently accurate for cap and trade programs.
- API suggests using engineering and industry standard approaches to estimate these emissions.

SunCor

- SunCor states that installing individual meters on each device would be prohibitively expensive.

WCI Subcommittee Comments and Recommendation:

The WCI Reporting Committee Oil and Gas Subcommittee recognizes that methane emissions from natural gas driven pneumatic devices represent not only a significant greenhouse gas source but also significant lost revenue to industry and lost royalties to the regulating jurisdiction. It is estimated that in the production and transmission sectors there are 400,000 pneumatic devices used to monitor and control liquid levels and flows, gas flows and levels in dehydrators, and control pressure in flash tanks (EPA – Options for Reducing Methane Emissions from Pneumatic Devices in the Natural Gas Industry). In addition, there are currently available many methodologies and technological fixes to effectively and economically reduce or eliminate these emissions (and save money). Many mitigation options identified by EPA have pay-back times of less than one year. Whether this GHG emission source ultimately is covered as part of a cap-and-trade program or addressed through an offset approach, it is essential that emissions be accurately quantified.

The magnitude and importance of this GHG source and the myriad of available emissions reduction strategies, suggest that direct measurement of these emissions is required. Where default emissions factors are available (from OEM or API) the accuracy and applicability of these EFs to real world operational conditions is questionable at best (see API Compendium, 2009). These EFs do not and cannot accurately reflect current emissions or emission reductions achieved through such procedures as enhanced maintenance, cleaning and tuning, repair/replacement of leaking gaskets, tube fittings and seals, or adjustments made to control loops to lower emissions.

Only direct measurement of pneumatic device emissions (Options C and D) will provide the rigor required for either cap-and-trade or offset programs. Option C, the direct measurement of emissions from individual devices, is both time consuming and costly. Furthermore, the accuracy of periodic single measurements in assessing long term emissions is questionable and additional measurements would be required to accurately assess the efficacy of emission reduction efforts.

Thus Option D is deemed to be the most accurate methodology to 1) accurately measure current emissions from pneumatic devices and 2) quantify emission reductions resulting from mitigation and control measures. The subcommittee recognizes that requiring metering of all pneumatic devices would, in some cases, require significant upfront costs associated with materials and labor needed to re-plumb and instrument large facilities with many pneumatic devices. The present WCI recommendation does not require a meter be installed for each device – only that pneumatic device and pump gas consumption be metered. In addition, the subcommittee recommends that metering not be required for low bleed devices and instead engineering calculations would be accepted. Although engineering calculations are not the most accurate mechanism to measure emissions from low bleed devices, the error would be small since the total emissions from these sources are small. In addition, the subcommittee also recommends a phased-in approach where, in year one, 50% of all high bleed and continuous bleed devices must be metered. In year two, all gas consumption for all pneumatic devices and pumps shall be metered excluding low bleed or no bleed devices. While low bleed and no bleed devices would be exempt from direct metering requirements, emissions should be estimated using default EFs. The subcommittee does not recommend requiring installation of a dedicated meter for each pneumatic device. In most cases it should be possible to meet the requirements by plumbing all or multiple pneumatic device gas supply lines through a single meter. In year one, emissions from all unmetered devices must be quantified using available EFs (API or OEM). Methane and CO_2 emissions shall be calculated in the following manner:

$$E_x = V_g * MW_x / MVC * F_x * 0.001$$

Where:

Ex = CO_2 or CH_4 emissions (metric tonnes/year)

V_g = volume of instrument gas consumed (scf/year)

MW_x = molecular weight of CO_2 (44.01kg/kg-mole) or CH_4 (16.04 kg/kg/mole)

MVC = molar volume conversion (scf/kg-mole)

F_x = molar fraction of X (X= CO_2 or CH_4)

0.001 = conversion factor (kg to metric tonnes)

Issue Paper – Sour Gas Treatment

Issue:

Produced gas may contain high concentrations of corrosive acid gas species - sulfur species such as H_2S and CO_2. These gases are removed in acid gas removal units (AGR) or sulfur recovery units (SRU). These units typically use an amine compound to strip sulfur containing gases and carbon dioxide from field gas. Amine treaters have components similar to those used in gas dehydrators – an absorber, liquid circulation pump, and absorber regenerator. Carbon dioxide emissions occur 1) at the absorber regenerator (reboiler vent) where most absorbed CO_2 is emitted and 2) as a result of tail gas treatment where incineration in a flare or destruction device converts any remaining carbon containing species to CO_2. Methane emissions also occur at the absorber regenerator (reboiler vent) where methane absorbed in the amine is released to the atmosphere. See Figure 1.

In some parts of the US and Canada, greenhouse gas emissions vented from sour gas treatment units can be significant. New Mexico has two coal bed methane gas sweetening plants that each reported vented CO_2 emissions close to 1.0 MMT in 2008.

Western Regional Air Partnership (WRAP)/ The Climate Registry (TCR)

Approach: The August 2009 Draft TCR Oil and Gas Production Protocol provides four methods for determining GHG emissions. These methods are shown in the table below (Options A thru D).

EPA Approach: In Subpart W – EPA proposed that reporters use simulation software such as ASPEN™, AMINECalc™, or TSWEET (Option D below).

WCI Options:

Option	Pros	Cons
A. Mass balance approach – measure carbon content and volume of incoming acid gas and treated sweet gas.	Accurate method if sampling is conducted at intervals that accurately characterize annual emissions picture.	Sampling acid gases such as H_2S can be dangerous. Sampling frequency may need to be quarterly or semi-annually. Not as accurate as the direct measurement approach (Option B)

B. Determine CH_4 and CO_2 content of reboiler vent emissions and volume of gas vented from reboiler.	Accurate method if sampling is conducted at intervals that accurately characterize annual emissions picture. This option appears to be the most accurate of the four methods.	Sampling acid gases such as H_2S can be dangerous.
C. Use default emissions factors (API, 2009)	Least labor and resource intensive method	Very high uncertainty associated with available EF's. Resulting data is not cap-and-trade quality
D. Use a model (API AMINECalc™ ,ASPEN™, or TSWEET)	Data collection requirements can be less burdensome.	Models also require reporters to gather input data. Accuracy questionable - models may significantly underestimate emissions. The AMINECalc model is designed to output VOC data which must then be converted to methane using the gas methane content or a default factor.

Option B, where reporters quantify both the volume (or mass) and composition of vent gases, appears to be the most accurate of the methods presented here. If emissions from a flash tank and/or a reboiler vent are captured, used and/or destroyed elsewhere (e.g. tail-gas which is incinerated or vented gas used as a supplemental fuel) these emissions would be reported elsewhere and not thus not reported using this methodology to avoid double-counting.

WCI Reporting Subcommittee Comments and Recommendation:

The WCI Subcommittee recommends using the direct measurement (Option B) methodology. Direct measurement of emissions should provide the most accurate data for this important GHG source. The number of sources that will require direct measurement in the US is manageable. A Gas Research Institute study suggests that most acid gas removal operations are located at approximately 400 gas processing plants nationally. These sources should be capable of conducting gas measurements, if they are not already doing it currently. Option A (the mass balance approach) also involves direct measurement – however the Option B measurement regime should better constrain the emissions calculation and thus provide better data. The WCI Subcommittee proposes that emissions sampling be conducted on a quarterly basis.

There are indications that modeling approach (Option D) using software modules such as AMINECalc™, GLYCalc™, and TSWEET may underestimate emissions. The Colorado Department of Public Health and Environment, Air Pollution Control Division in their Guidance Document –

Form APCD-206, Amine Sweetening Units states that "*experience indicates that AMINECalc 1.0 significantly underestimates still vent emissions from amine sweetening units. Therefore, the Division discourages the use of this modeling software*." Option C, the use of default Emission Factors, would not provide data of sufficient quality for a cap-and-trade program.

WCI Quantification Method:

Emissions of CO_2 and CH_4 from amine treaters will be calculated in the following manner:

$$E_{CH4/CO2} = \sum_{1}^{n} [(V_{FG} * MF_{FG-CH4/CO2} * MW_{CH4/CO2} \div MVC) +$$
$$(V_{OG} * MF_{OG-CH4/CO2} * MW_{CH4/CO2} \div MVC)] * 0.001$$

Where:

$E_{CH4/CO2}$ = emissions of CH_4 or CO_2 (MT/yr)
n = quarterly sampling interval (1-4)
V_{FG} = volume of flash gas emitted per quarter (scf)
$MF_{FG-CH4/CO2}$ = molar fraction of CH_4 or CO_2 in flash gas
$MW_{CH4/CO2}$ = molecular weight of CH_4 or CO_2
MVC = molar volume conversion factor
V_{OG} = volume of reboiler off-gas emitted per quarter (scf)
$MF_{OG-CH4/CO2}$ = molar fraction of CH_4 or CO_2 in still vent off-gas
0.001 = conversion factor – kg to metric tons

WCI Monitoring Methodology:

Quarterly samples of flash tank and still vent off-gas from the amine reboiler should be collected and analyzed for methane and carbon dioxide content. If accurate measurement of flow volume from amine treater flash tank and/or the amine reboiler are available, reporters should use this data. If flow is not monitored, reporters may use an engineering calculation to determine volume of mass flow. In either case volume should be determined with an accuracy of ±5%. Reporters should exercise car to avoid double-counting as flash tank emissions may be capture and used as a fuel and emissions from the reboiler may be directed to a flare or incinerator.

Stakeholder Input:

Stakeholders have not yet seen or commented on this issue paper.

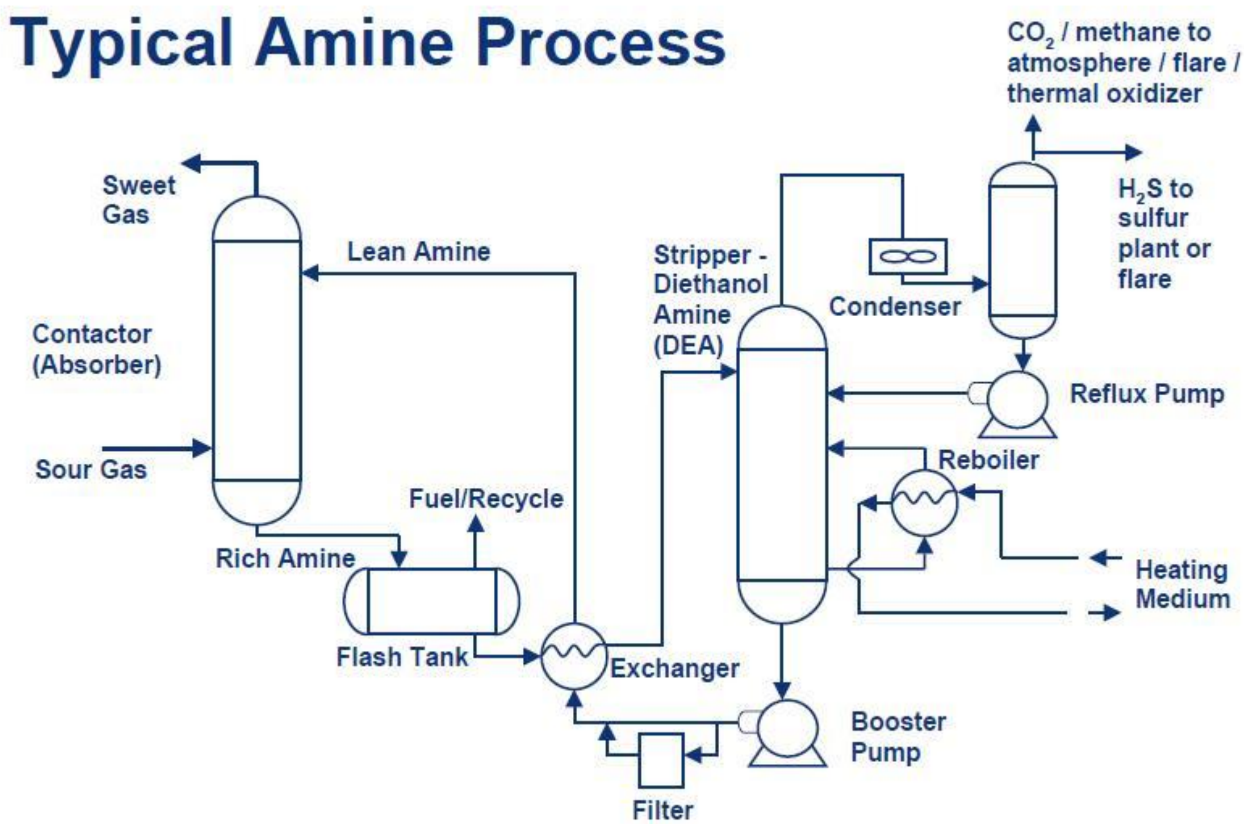

Figure 1: A Typical Amine Process Diagram

Issue Paper -- Storage Tanks

Issue:

Storage tanks provide temporary storage of liquids prior to the point when produced liquids are moved off site in a pipeline or mobile tanker for processing. Emissions of methane (and CO_2 if present in significant quantities in produced liquids) occur through several mechanisms.

Flashing losses occur when the produced liquid experiences a change in pressure. For instance as produced oil is pumped from the well it experiences a pressure drop as it exits the pipe and enters the tank. Dissolved gases such as methane and carbon dioxide may flash off as the pressure is reduced.

Working losses occur as a result of the filling and emptying of the storage tank. Tank headspace gases containing methane and carbon dioxide are emitted from the tank as the tank fills. As the tank is emptied the reverse process occurs, outside air is drawn into the tank. The liquid in the tank then re-equilibrates with this introduced air.

Breathing losses of headspace air containing methane and carbon dioxide occur as the tank gas volume expands and contracts in response to environmental conditions such as ambient temperature, solar insulation, and atmospheric pressure.

Flashing, breathing and working losses must all be characterized to insure an accurate estimation of storage tank GHG emissions.

Storage tank emissions occur when produced liquids are sent to atmospheric storage at the following locations:

1. wellhead sites
2. tank batteries
3. compressor stations
4. gas plants
5. where liquids in a gas line are “pigged”

EPA estimates that Storage Tank venting emits on the order of 9 Bcf (billion cubic feet) of methane annually, which is approximately 1 million metric tons CO_2e. EPA states that emissions from crude oil and condensate storage tanks are known to be a “major contributor(s) to the total petroleum and natural gas production segment fugitive emissions”.

Western Regional Air Partnership (WRAP)/The Climate Registry (TCR) Approach:

WRAP has not specifically addressed the issue of accurately determining GHG (CH_4 and CO_2) emissions from storage tanks in the up-stream oil and gas sector. A method using the EPA TANKS Model was included in the WCI Essential Requirements for the Refinery sector.

EPA Approach:

EPA has not officially published an emissions calculation methodology specific for this source. A method was published in Subpart W of the Draft Reporting Rule (see §98.233(d)(8) – page 1167). Subpart W was subsequently withdrawn prior to release of the EPA Final Rule.

Briefly, the EPA Subpart W method requires that reporters:

a) Measure the volume of vapor escaping each storage tank over a representative period of operation.

b) Determine the vapor composition by chemical analysis.

c) Calculate fugitive emissions using this data.

The details of this method are shown below:

1. Calculate the total annual hydrocarbon vapor fugitive emissions using Equation W-7

$$E_{a,h} = Q \times ER \qquad \text{(Eq. W-7)}$$

Where:

$E_{a,h}$ = hydrocarbon vapor fugitive emissions at actual conditions Q = storage tank total annual throughput

ER = measured hydrocarbon vapor emissions rate per throughput (e.g. cubic feet/barrel) determined from §98.234(j)(2) (page 1181).

ER is measured using a flow meter described in paragraph (h) for a test period that is representative of the normal operating conditions of the storage tank throughout the year and which includes a complete cycle of accumulation of hydrocarbon liquids and pumping out of hydrocarbon liquids from the storage tank.

2. Estimate hydrocarbon vapor volumetric fugitive emissions at standard conditions using calculations in paragraph (e).

3. Estimate CH_4 and CO_2 volumetric fugitive emissions from volumetric hydrocarbon emissions using Equation W-8 (page 1168).

$$E_{s,i} = E_{s,h} \times M_i \qquad \text{(Eq.W-8)}$$

Where:

$E_{s,i}$ = GHG i (CH_4 and CO_2) volumetric fugitive emissions at STP

$E_{s,h}$ = hydrocarbon vapor volumetric fugitive emissions at standard conditions

M_i = mole percent of GHG i in the hydrocarbon vapors; the hydrocarbon analysis shall be conducted using ASTM D1945 03

4. Estimate CH_4 and CO_2 mass fugitive emissions from GHG volumetric emissions using the calculations in paragraph (g)

$$Mass_{s,i} = E_{s,i} \times \rho_i \qquad \text{(Eq. W-11)}$$

Where:

$Mass_{s,i}$ = GHG i (CH_4 or CO_2) mass fugitive emissions at STP

$E_{s,i}$ = GHG i volumetric fugitive emissions at STP

P_i = density of GHG i; 1.87 kg/m^3 for CO_2 and 0.68 kg/m^3 for CH_4

Background on Available Methodologies:

A recent study commissioned by the Texas Commission on Environmental Quality (TCEQ) provides an in-depth analysis of available methods for the determination of storage tank emissions. The following modeling methods were compared with actual measurements of storage tank emissions which were conducted in a manner very similar to the EPA Subpart W method detailed above.

1. TANKS 4.09 (EPA model)
2. Vasquez-Beggs + TANKS 4.09
3. GOR + TANKS 4.09
4. Valko-McGagn + TANKS 4.09
5. Hysis VOCs
6. E&P Tank – RVP VOCs
7. E&P Tank – GEO/RVP VOCs
8. AP-42 LPO VOCS
9. GRI-HAPCalc VOCs

The final report concluded that "each model reviewed has limitations and shortcomings. No one model resulted in the extremely strong correlation to measured data." Measurements were made at thirty-six production sites. The models also required measurement of input variables such as GOR (gas oil ratio). The GOR is a difficult measurement given that the recovered liquid/gas mixture from a well must be collected and maintained at pressure prior to analysis. The report states that the TCEQ considers direct measurement the most accurate method to quantify storage tank fugitive emissions. A copy of this report, Upstream Oil and Gas Storage Tank Project Flash Emissions Models Evaluation Final Report, July 16, 2009 is available on the WCI Reporting Committee SharePoint website.

The API Compendium (2009) also contains a discussion of several of the models available (see Section 5.4 Storage Tank Emissions, page 5-40). API states that direct measurement provides accurate emissions estimates but "this approach is generally expensive and time consuming for large numbers of tanks."

WCI Options:

The WCI subcommittee recognizes that direct measurement of the volume and composition of fugitive emissions emitted from storage tanks is the most accurate quantification method. While volumetric emissions at a storage tank can be completed in as little as 24 hours, questions remain concerning the accuracy of a single or several emissions measurements when applied to calculate annual emissions.

Modeling approaches require input data (such as GOR, API, separator pressure, stock tank gas molecular weight and specific gravity, oil gravity, etc.) which may require extensive gas and oil analysis. These models do not appear to provide a higher level of accuracy than direct measurement of GOR does.

Stakeholder Input:

Natural Resources Defense Council (NRDC), Wild Earth Guardians, and Western Environmental Law Center

- Direct measurement of volume and composition is the most accurate method, and is preferred. NRDC does support use of the proposed GOR methodology.
- Requirements should state that testing must be done during representative operating conditions.
- Propose testing quarterly, or when operating conditions change.
- Would consider some logical thresholds for mandatory direct measurement, perhaps including:
    - mandatory direct measurement on quarterly basis for all tanks over a size/emissions threshold;
    - for tanks under the threshold, initial direct measurement to obtain site specific data for calibration of a tank model; four quarterly tests to calibrate, then can model if modeling shows reasonably accurate results;
    - reduced frequency of direct measurement based on a showing that actual tank emissions do not vary significantly;
    - return to direct measurement if operating conditions change.

SunCor

- SunCor supports the use of the GOR method for “live” (as opposed to “stabilized”) fluids at storage tanks where no vapor recovery takes place.

Canadian Association of Petroleum Producers (CAPP)

- Prefer the use of modeling to estimate emissions.
- Direct measurement is complicated because of technical difficulties.

- Direct measurement is not guaranteed to be more accurate than modeling because it would have to cover wide range of possible operating modes; uncertainty is estimated to be about ± 20-25%.
- CAPP states that in British Columbia, storage tanks account for only 0.1% of up-stream oil and gas sector emissions.

Chevron (CVX)

- Given the large number of tanks and operating modes, a requirement to use direct measurement on all tanks would be extremely burdensome and would raise worker safety issues.
- Many modeling methods would be adequate for most application.
- Chevron is currently reviewing the modeling methods and will have more specific recommendation after Jan. 1.

American Petroleum Institute (API)

- Proposed Subpart W method should not be used. It is overly prescriptive, burdensome, costly, and problematic.
- Most tanks are very small; distribution of size/throughput has a long tail.
- Measurement across a complete cycle of operation would require sampling throughout entire year.
- Emissions flow rates and compositions for flashing tanks can be reliably determined using process simulation models such as HySys or ProSim. These are used by industry in facility design and are becoming method of choice for regulatory purposes.
- Sampling of emissions from a fixed roof tank is impractical on a routine basis. For external floating roof tanks it is impossible to obtain a representative sample.
- Many tanks have either vapor recovery or thermal control of VOCs, to meet regulatory requirements or for operational or safety reasons.
- At many sites, particularly offshore production platforms, tank vents cannot be safely accessed to enable direct measurement.
- The Subpart W method is not feasible for tanks in the hull of floating facilities due to the nature of the tank's service and the inaccessibility of the tank vent.
- API Recommendations:
  - Tanks with low throughput (< 10 bbl/day): allow use of E&P Tanks to determine flow and vapor composition.

- Since the emissions estimation is for CH_4, determination of standing and breathing losses is not necessary.
- Allow process simulation model approaches as an alternative to direct measurement.
- Tanks with VRU are not significant GHG sources and should be excluded from reporting, especially since they would emit CO_2 rather than CH_4 from the thermal control unit. Process simulation models could be used to determine flow and composition to the control device.
- Tanks where the vent cannot be safely accessed should be excluded from the requirement to quantify and report emissions.
- Storage tanks in the hull of floating offshore vessels should be excluded from reporting.
- Tanks handling hydrocarbon liquids with little or no CH_4 content (e.g., diesel fuel, stabilized oil) should be excluded from reporting.

- API recommends the use of the GOR measurement method on a formation wide basis, rather than at individual production sites where production is 10bbl/d or greater.

WCI Subcommittee Comments and Recommendation:

After reviewing stakeholder comments and considering the many available models and methodologies, the subcommittee recommends that the results of a periodic laboratory determination of GOR (Gas Oil Ratio) from a pressurized liquid sample (2009 API Compendium, #2 on p. 5-41) be used to quantify methane and carbon dioxide emissions at storage tank batteries where daily production exceeds a threshold value (>10 bbl/day). Semi-annually a pressurized liquid sample will be collected at a point downstream of all field separators and prior to the point where produced liquid is flashed to atmospheric pressure (that is, where it enters the storage tank). In the laboratory, the sample is allowed to equilibrate to atmospheric pressure, the volume of gas generated measured (i.e. GOR determined) and a sample of the evolved gas collected and analyzed for methane and carbon dioxide content. Additional testing is required when a well is connected to or disconnected from the battery, or changes in separator operational parameters are made. Emissions calculated in this manner assume that the methane generated in this measurement is ultimately released to the atmosphere (where there is no vapor recovery in-place). At storage tank batteries where production is below the threshold (<10 bbl/day) E&P TANKS would be used to determine flow and vapor composition.

The assumption implicit with this approach is that only flashing losses are important for methane emissions from storage tanks. While small amounts of methane and carbon dioxide will be emitted during subsequent storage and handling, all the methane emissions quantified by this method will be attributed to the initial depressurized storage tank. Storage tanks equipped with vapor recovery units (VRU) required by permit or rule are exempt. It should not be necessary to limit measurements to land-based storage tanks containing condensate and crude oil. At off-shore production platforms, collection of pressurized samples for determination of GOR should be straightforward as it does not require access and sampling of the tank itself (platform legs may be used as temporary storage at off-shore facilities). The method is not affected by the sampling and safety limitations associated with the initially proposed EPA Subpart W method.

Methane and CO_2 emissions at storage tank batteries where the oil production rate is 10 barrels per day or greater shall be calculated in the following manner:

$$E_{CH4/CO2} = \sum_{1}^{n} GOR * PR * 1/MVC * MW_g * MF_{CH4/CO2} * 0.001$$

Where:

$E_{CH4/CO2}$ = methane or carbon dioxide emissions (metric tonnes/year)

n= number of measurement periods in the reporting period (n=2)

GOR = Gas Oil Ration (scf/bbl)

PR = oil production rate (bbl/measurement period)

MVC = molar volume conversion

MWg = molecular weight of the gas (kg/kg-mole)

$MF_{CH4/CO2}$ = mass fraction of methane or carbon dioxide in gas (kg CH_4/kg gas)

0.001= conversion factor (metric tonnes/kg)

Methane and carbon dioxide emissions at storage tank batteries where the oil production rate is less than 10 barrels per day shall calculate methane emissions using the E&P TANKS Model.

Western Climate Initiative

Issue Paper – Well Unloading (Well Blowdowns)

Issue:

The accumulation of liquids in mature gas wells reduces gas production rates and may stop gas production entirely. This fluid must be removed to maintain gas production. To eliminate accumulated fluids, a well may be “blowndown”, - vented to atmospheric pressure to purge liquids from the well. The practice of blowing down a well can occur on a weekly basis, last anywhere from a few minutes to hours and thus may result in significant methane emissions. The magnitude of gas released is a function of wellhead pressure and temperature, event duration, size of the vent line, and produced gas and liquid properties. There is discrepancy about the significance of this emission source in the oil and gas sector, highlighting the need for accurate reporting. Although, in the Background Document for the draft Subpart W regulation, EPA estimated the methane emissions from this source to be 9 billion scf/yr in 2006, the EPA also reported that they thought that this source was underestimated.

Western Regional Air Partnership (WRAP)/The Climate Registry (TCR) Approach:

The Climate Registry (TCR) Draft Oil & Gas Production Protocol provides reporters with an engineering methodology to calculate well blowdown emissions. This method was derived from the API Compendium (2009) and calculates unloading duration (rather than using a measured value) “based on field conditions (formation, depth, etc.)”.

EPA Approach:

The draft and final EPA Mandatory Reporting of Greenhouse Gases rule did not contain a methodology for the determination of emissions resulting from well unloading.

WCI Options:

Option	Pros	Cons
A: Estimation based on GRI/EPA emissions factor	Simplest method. Assumes that the integrated average flow over the blowdown period is 56.25 percent of full well flow.	Data quality questionable. Duration of blowdown not measured.
B: TCR/API	More accurate than Option A	Does not determine individual blowdown event emissions but assumes that all events are of the same duration.
C: CAPP (2002)	Appears to be the most	Requires sampling and site

1) calculate mass flow rate of gas and liquid 2) correct for mass of produced liquid 3) calculate mass flow rate of gas, multiply by event duration.	accurate methodology. Calculates emissions for each blowdown event.	specific data collection.

Option B – Detail:

TCR and American Petroleum Institute (API) present the following calculation methodology for the determination of well blowdown emissions:

$$E_{CH4/CO2} = 9{,}781x10^{-7} * 1/Z * \left(D_{casing}\right)^2 * (Depth) * P * f_{CH4/CO2} * MW_{CH4/CO2} * N/yr * 1/2204.62$$

Where:

$E_{CH4/CO2}$ = emissions of CH_4 or CO_2 (tonnes/yr)

Z = compressibility factor (assumed to be 1 for an ideal gas)

D_{casing} = casing diameter (inches)

Depth = well depth (feet)

$MW_{CH4/CO2}$ = molecular weight of CH_4 or CO_2 (lb/lbmole)

$f_{CH4/CO2}$ = molar weight of CH_4 or CO_2 (lb/lb-mole)

N = number of blowdowns per year

2204.62 = conversion factor (lbs to tonnes)

This method does not calculate emissions from individual well blowdown events or include the well blowdown duration in the calculation, but rather assumes that emissions are the same for each blowdown event regardless of the duration.

Option C – Detail:

1) The Canadian Association of Petroleum Producers (CAPP) approach models the vent process as isentropic flow of an ideal gas through a nozzle:

$$m_t = A^* * P_0 / \sqrt{T_0} * \sqrt{k/R} * 1/\left(k+1/2\right)^{(k+1)/(2*k-2)} * 1000$$

Where:

m_t = total mass flow rate of gas and water vapor from the unloading (kg/s)

A^* = cross sectional area of the unloading valve or vent pipe (m^2)

P_0 = wellhead pressure (kPa)

T_0 = wellhead temperature (K°)

K = specific heat ratio – 1.32 for natural gas

R = universal gas constant (kJ/kg K) (8314.5/gas molecular weight)

2) The quantity of water produced is then calculated:

$$m_w = V * \rho_w / t$$

Where:

m_w = mass flow rate of water produced by the unloading event (kg/s)

V = volume of liquid water produced by the unloading event (m^3)

P_w = density of liquid water (1000 kg/m^3)

t = duration of the blow down event (s)

3) The mass flow rate of gas released is then calculated by subtracting the water mass flow rate from the total mass flow rate:

$$m_v = m_t - m_w$$

Where:

m_v = mass flow rate of gas released

4) The total volume of gas released is then calculated:

$$V = m_v * t / W_v * 23.6449$$

Where:

V = volume of gas released (m^3)

W_v = molecular weight of the vapor released (kg/kg-mole)

23.6449 = the volume (m^3) occupied by one kg-mole of an ideal gas at 15°C and 101.325 kPa.

5) Methane and carbon dioxide emissions are then calculated:

$$E_{CH4/CO2} = \sum_{1}^{n} V_g * MW_{CH4/CO2} * 1/MVC * MF_{CH4/CO2} * 0.001$$

Where:

$E_{CH4/CO2}$ = mass of methane or carbon dioxide released (metric tons/yr)

n= number of blowdown events per year

V_g = volume of gas released for each event

$MW_{CH4/CO2}$ = molecular weight of methane or carbon dioxide

MVC = molar volume conversion factor

$MF_{CH4/CO2}$ = molar fraction of methane or carbon dioxide (20% = 0.20)

0.001 = conversion kg to metric tons

WCI Reporting Subcommittee Comments and Recommendation: The WCI Subcommittee recommends the use of Option C**.** Option C appears to be the most accurate of the available methods. This method calculates emissions for each blowdown event (Option B does not). This ability is critical if reductions in emissions resulting from operator initiated changes in well operational parameters are to be assessed. Method A does not result in data quality sufficient for cap-and-trade.

WCI Quantification Methodology: See Option C.

WCI Monitoring Methodology: See Option C above.

Stakeholder Input:

Stakeholders have not yet provided comment on this Issue Paper.

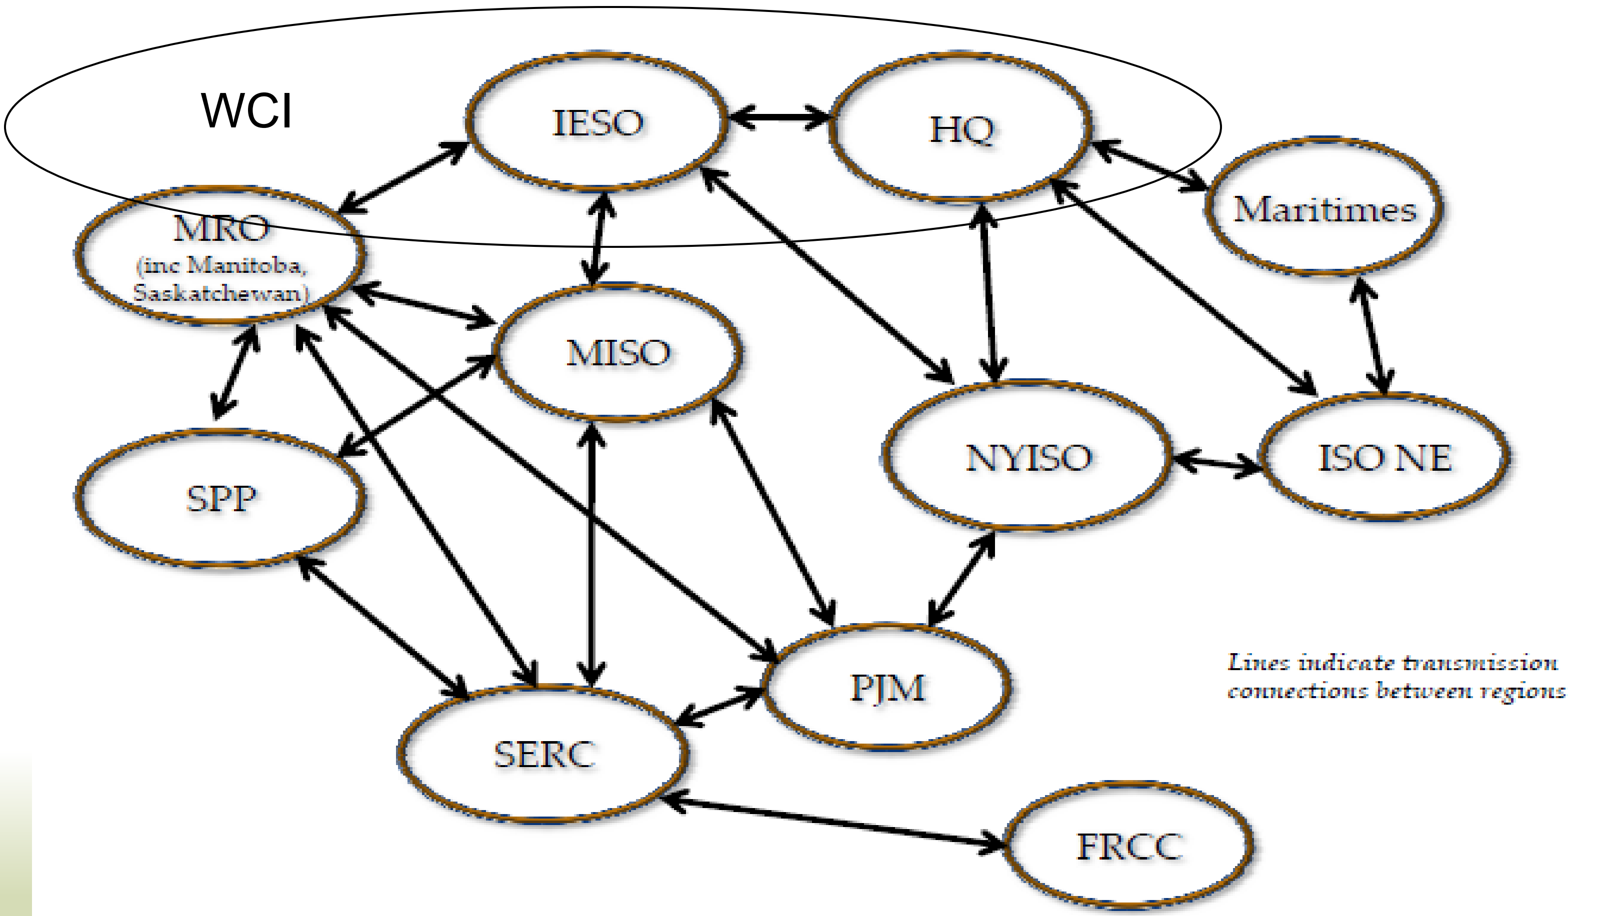
Eastern Leakage Study

Update and Preliminary Results

Eastern Interconnection



Navigant Modeling

- Navigant presented results of modeling to WCI Electricity Industry Collaborative Meeting in Phoenix on January 21.
- Posted on public WCI website at:

  http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/Jan-21-2010-Electricity-Collaborative-(Phoenix)/Update-on-Eastern-Leakage-Study/
- Key questions the study addresses for the eastern WCI partners:
  - Expected reduction in WCI generation and emissions with various carbon and import charges
  - Offsetting increases in non-WCI generation and emissions
  - Impact of exempting non-fossil generation outside WCI from import charges (potential for shuffling)
  - Impact of aligning with RGGI and MGGRA

Navigant Modeling

- PROMOD simulates the hourly operation of generation and transmission across the markets/regions
- For each hour, PROMOD commits and dispatches units in order of increasing generation cost until hourly demand is met, while taking into account unit operating constraints and transmission limits

Limitations

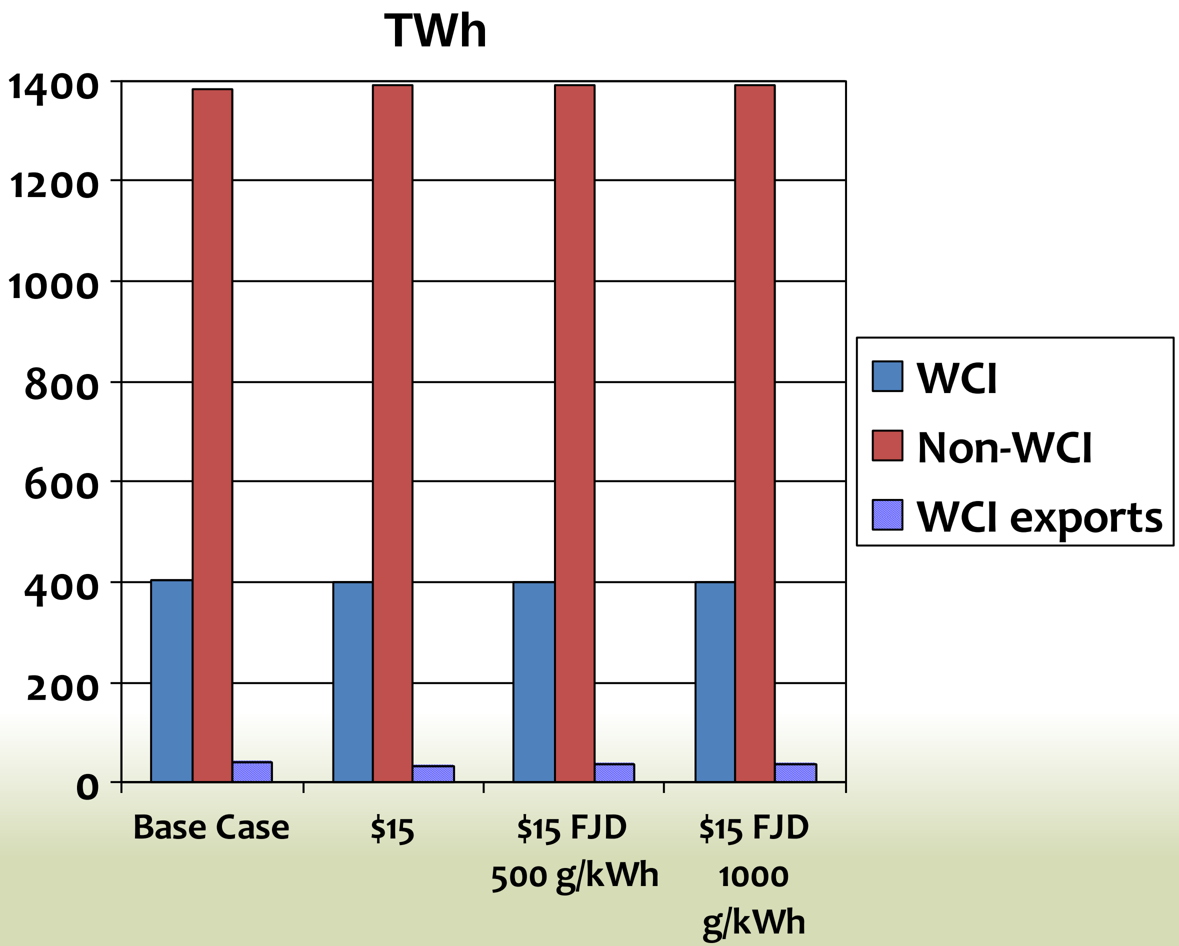
- Static analysis
- Available power plants are fixed
  - Annual output of non-fossil plants is fixed
  - Only fossil output can change
- Demand is fixed

Scenarios Defined

- Scenarios with \$15, \$30, \$60/metric tonne [US\$]
- Applied to carbon-generating units in Quebec, Ontario, Manitoba that generate more than 25,000 metric tons of CO_2 annually
- FJD charges
  - Defined on basis of assumed carbon content of imported power – 500 kg/MWh, 1000 kg/MWh
  - In terms of \$/MWh adder, translates to 50% or 100% of WCI allowance price for each scenario
  - applied to all power imported into WCI provinces from non-WCI regions (simple scenarios) or just to imports from carbon-producing units (contract shuffling scenarios)

Modeling Results – Simple Scenarios

2012 Projection with $15 Allowance Price



WCI eneration	TWh
Base	405.6

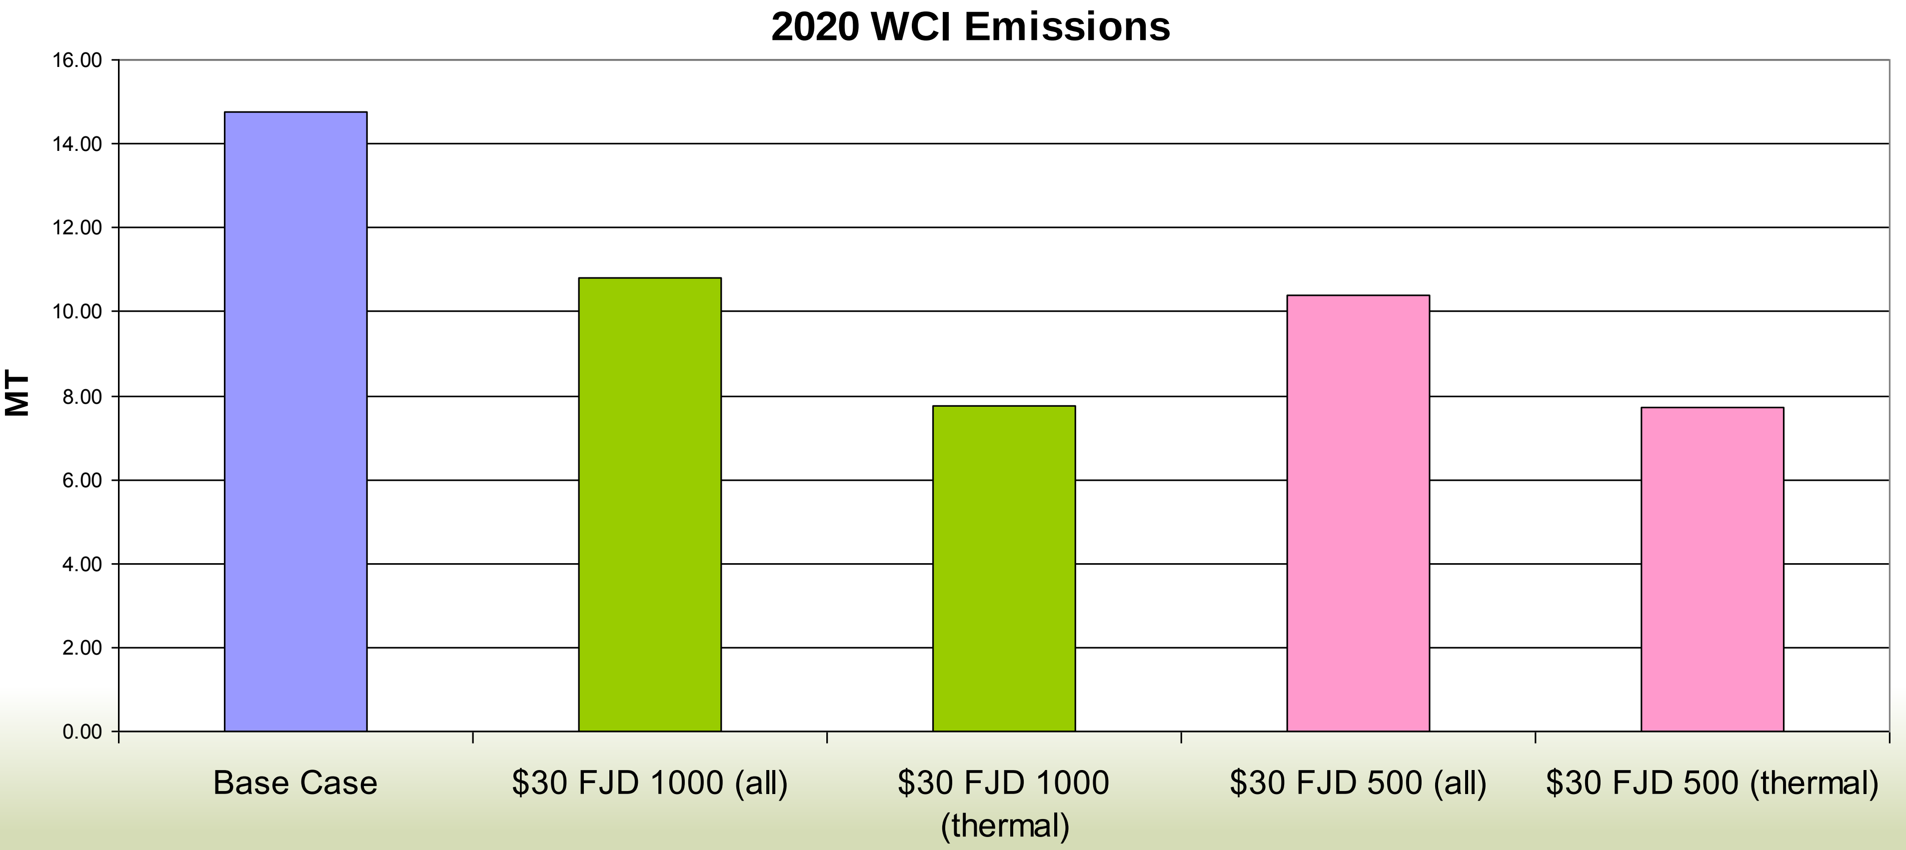
Allowance Price $30 FJD 0	391.8	8.2	6.1
Allowance Price $30 FJD 1000 g/kWh (all units)	400.1	11.2	1.0
Allowance Price $30 FJD 1000 g/kWh (thermal units)	391.9	8.3	6.0
Allowance Price $30 FJD 500 g/kWh (all units)	398.9	10.8	1.8
Allowance Price $30 FJD 500 g/kWh (thermal units)	391.9	8.3	6.0

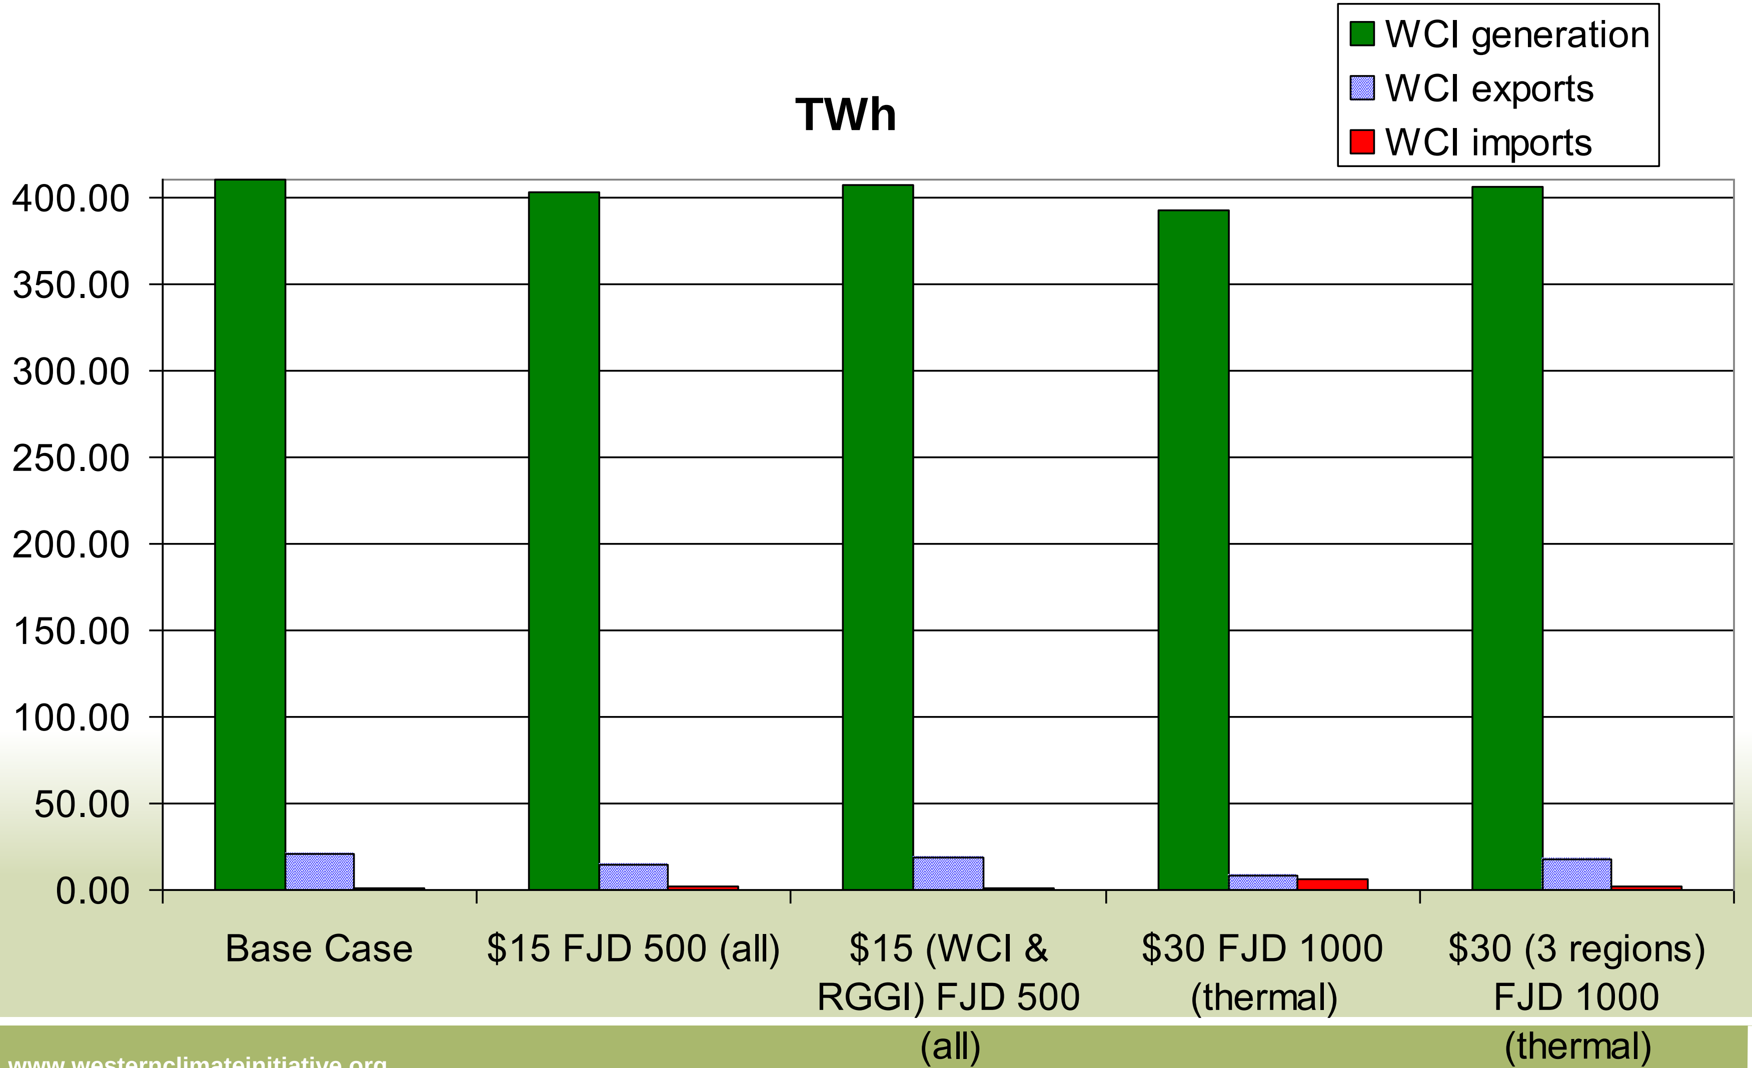
2020 Projection Emissions - Complex



RGGI/MGGRA Coordination

- Base case scenarios assume:
  - RGGI allowance price $2.06 per metric ton; MGGRA no carbon pricing. Both were subject to FJD charges where appropriate.
- Three scenarios explored what would happen if WCI, RGGI and/or MGGRA worked together to adopt similar carbon pricing regimes, and were therefore exempt from each other's FJD charges.
  - For scenarios with RGGI and MGGRA allowance prices aligned, FJD charges applied to flows into WCI or RGGI/MGGRA rather than just into WCI.

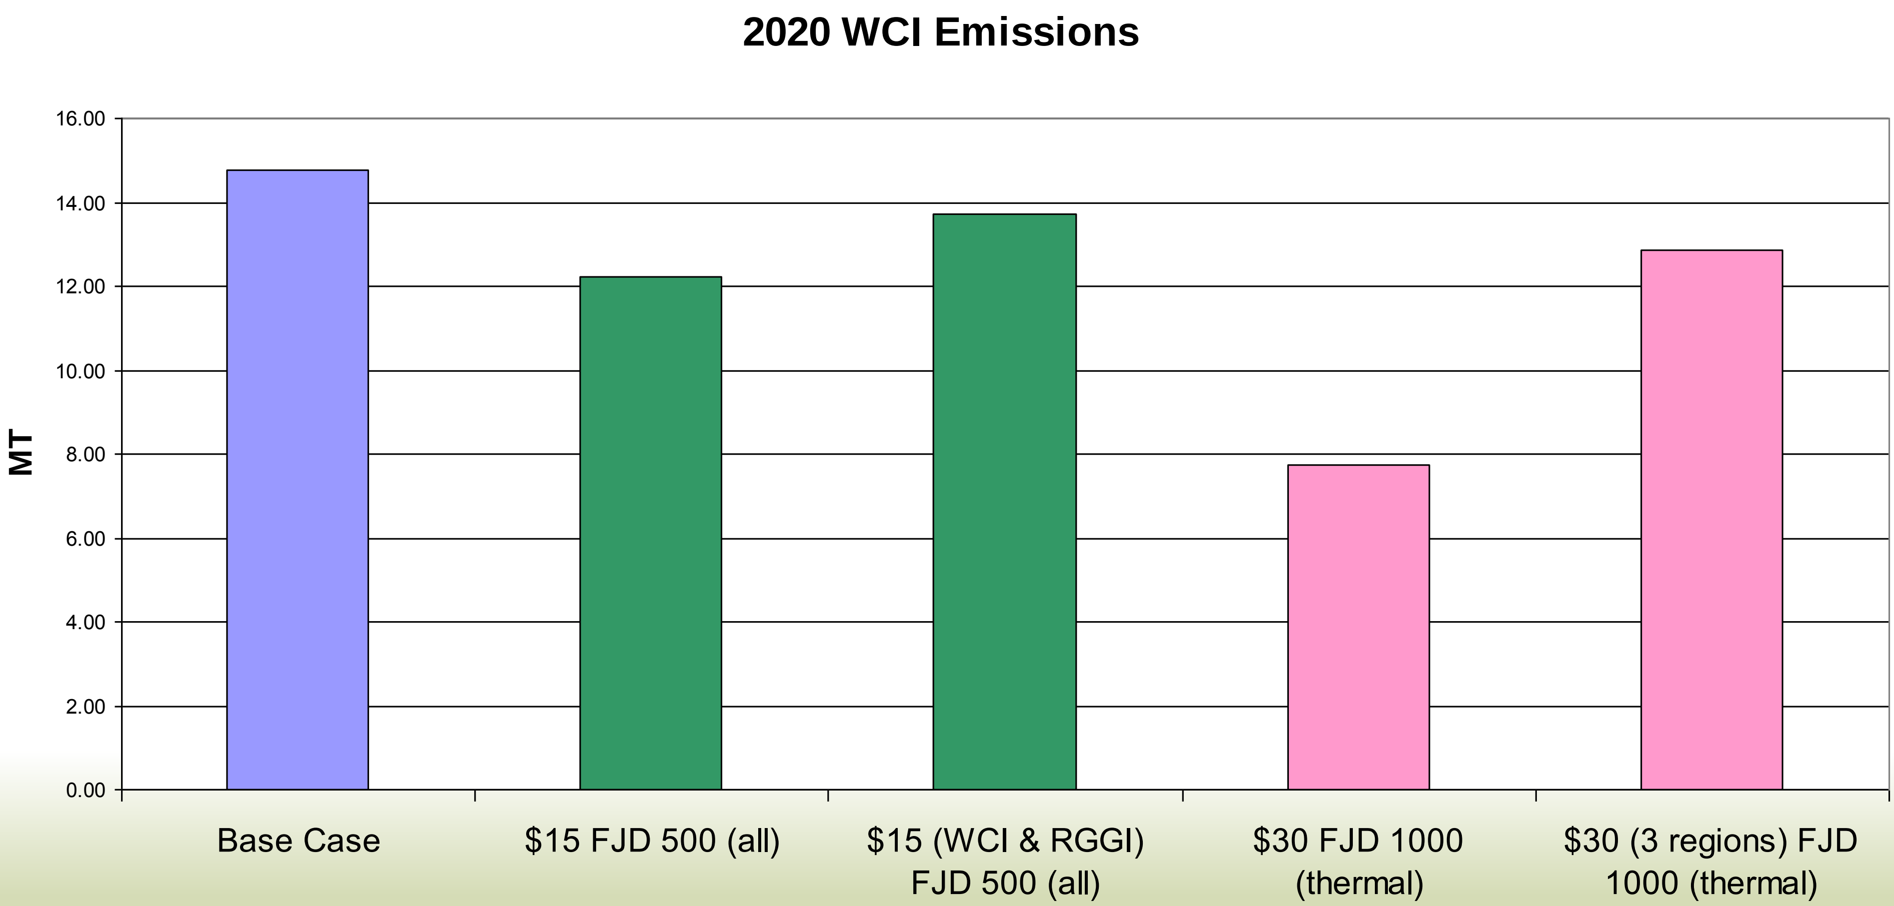
2020 Projection – RGGI/MGGRA



2020 Projection – RGGI/MGGRA

	WCI Generation (TWh)	WCI Exports (TWh)	WCI Imports (TWh)
Base	409.6	21.1	1.5
Allowance Price $15 (WCI) FJD 500 g/kWh (all units)	403.0	14.9	1.8
Allowance Price $15 (WCI and RGGI) FJD 500 g/kWh (all units)	407.0	18.7	1.4
Allowance Price $30 (WCI) FJD 1000 g/kWh (thermal units)	391.9	8.3	6.0
Allowance Price $30 (WCI, RGGI, MGGRA) FJD 1000 g/kWh (thermal units)	405.7	18.1	1.9

2020 Projection Emissions – RGGI/MGGRA



Modeling Conclusions

- WCI generation and eastern WCI CO2 emissions levels are strongly affected by the eastern WCI CO2 allowance price
  - WCI generation and WCI emissions decrease as the WCI allowance price increases
  - At a given allowance price, increasing the default emissions factor only slightly affects imports / exports and WCI generation
  - Most generation change occurs in Ontario
- Where contract shuffling was permitted, there was a further ~ 25% reduction in eastern WCI CO2 emissions. WCI imports are higher in these cases.
- Where coordination of WCI/RGGI/MGGRA occurs, imports into the WCI are reduced relative to scenarios where contract shuffling occurs, meaning there is less incentive for WCI to use imports rather than their own generation.
- Significant (-2%) total emission (WCI and non-WCI) reductions occurred only in the scenario where coordination of WCI/RGGI/MGGRA occurs. In all other scenarios, total emission changes are 0.1% or less.

Next Steps

- Final report being drafted by Navigant and will be reviewed by WCI.
- Final report will be posted on WCI website

  http://www.westernclimateinitiative.org/

Western Climate Initiative

Market Oversight
Draft Recommendations

Partner Meeting, Vancouver, British Columbia

March 3, 2010

Market Oversight Objectives

- "The recommended design will provide opportunities to obtain low-cost emission reductions through emission trading, allowance banking, and inclusion of an offsets component."

WCI Design Recommendations, September 23, 2008

- "The WCI Partner jurisdictions and stakeholders want appropriate safeguards and oversight of the allowance and offset credit trading markets and want them to function efficiently."

Materials for Markets Workshop, April 9, 2009

Principles

- **Efficiency**: The market is designed to operate efficiently so that greenhouse gas (GHG) emission reductions can be achieved at the least cost. An efficient market means that allowance and offset credit prices reflect supply and demand, and accurately reveal the value of allowances and offset credits.

- **Effective Oversight**: The design and oversight of the market is effective in preventing or minimizing fraud, manipulation, and speculative excess.

Oversight Recommendations Process

- Public workshop April 9, 2009
- White Paper November 18, 2009
- Stakeholder call December 2, 2009
- Draft Recommendations paper
- Stakeholder call
- Final Recommendations paper
- Detailed Program Design contributions

Draft Recommendations

- Allowances, Offset Certificates, and Derivatives
- Market Participants
- Holdings and Transfers
- Market Monitoring

Allowances, Offset Certificates, and Derivatives

- #1: Treat Allowances as Commodities for Market Oversight Purposes
  - Implies primary regulation of derivatives by provincial securities commissions and US federal regulators
- #2: Information on Derivatives Positions
- #3: Treat Allowances and Offset Certificates Identically for Market Oversight Purposes

Market Participants

- #4: Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System
- #5: Do Not Limit Market Participation to Compliance Entities
- #6: Require Registration of Intermediaries as Market Professionals

Holdings and Transfers

- #7: Holdings Limits
- #8: Require Use of a Centralized Quotation System for Transactions
- #9: Require Reporting of Beneficial Ownership
- #10: Information Required for Compliance Instrument Transfer
- #11: Holdings and Transfer Information Disclosed to Public

Information on Derivatives Positions

- Mirror information to derivatives regulators for real-time monitoring
- Forensics
- Support for “providing appropriate technical and other compliance assistance” (Design Rec., §12.5)

- Data currently not collected
- Could not see whole market
- Infrastructure costs
- Debate over transparency benefits

Western Climate Initiative

Offsets Definition and Criteria and Report on Existing Protocols

WCI Partners Meeting
Vancouver, BC
March 3, 2010

Overview

1. For Partner approval: public release of the Offsets Definition and Criteria Draft Recommendations Paper
2. For Partner Approval: Report on existing Protocols

Offset Definition

Section	Draft Recommendation
3.1	A WCI offset certificate is issued by a WCI Partner Jurisdiction and represents a reduction or removal of one metric ton of carbon dioxide equivalent (tCO2e). The reduction or removal must meet the WCI's essential criteria for reductions and removals to be real, additional, permanent, and verifiable. Reductions and removals must also be clearly owned, adhere to an approved protocol, and result from a project located in a qualifying geographic area.

Real

Section	Draft Recommendation
4.1	A WCI offset certificate represents a reduction or removal of one metric ton of CO_2e that results from a clearly identified action or decision. A WCI offset project's reduction or removal is quantified using accurate and conservative methodologies that appropriately account for all relevant greenhouse gas sources and sinks and leakage risks. WCI offset projects result in direct emissions reductions or removals that take place at sources controlled by the project proponent.

Additional

Section	Draft Recommendation
5.1	Offsets may only be issued for the portion of greenhouse gas emissions reductions or removals that occur above the reductions or removals achieved under the baseline scenario. When possible, protocols will use a sectoral performance standard to determine additionality. For project types where a performance standard approach cannot be taken due to insufficient data availability, varying regional conditions, or other difficulties, or where a more appropriate method is justified, the WCI Partner Jurisdictions may alternatively consider recommending protocols with the appropriate additionality tests. The baseline scenario shall be set to reflect a conservative estimate of business-as-usual performance or practices for the relevant type of activity in the absence of an offset program. The baseline scenario must, at a minimum, include any reduced or sequestered GHG emissions that result from activities required by any existing binding agreement, consent order, regulation, or law in the jurisdiction where the project is located. *When reductions or sequestrations are obtained via a government incentive program, the baseline scenario must include the part of the reductions or sequestrations corresponding to the amount of the financial incentive.* Additionality will be applied to create a level playing field for all Partner

Permanent (1 of 2)

Section	Draft Recommendation
6.1	With respect to offset project activities, permanence means either that reductions or removals are not reversible or that, if reductions or removals are reversible, then requirements outlined in the remainder of this recommendation are met. Sequestration projects must ensure the atmospheric effect of their greenhouse gas removal will endure for a period that is comparable to the atmospheric effect achieved by non-sequestration projects. The duration for this period is to be based upon current scientific findings that are widely accepted and followed. The current international standard of 100 years has been established by the UNFCCC and will be followed by the WCI. The WCI will adopt new international standards (likely UNFCCC) if/when they are updated. Offset projects where the reduction or removal is maintained for less than the WCI standard may be pro-rated and/or replaced in order to maintain the environmental integrity of the offsets system. If pro-rating is allowed for a project type it will be included in the appropriate WCI approved protocol)

Permanent (2 of 2)

Section	Draft Recommendation
6.1	Project proponents shall follow or establish effective (i) monitoring systems, (ii) risk mitigation approaches, and (iii) contingency plans which address how, in the event of a reversal that is the result of proponent intention or negligence, any affected offset certificates will be replaced. The contingency plan shall include specific mechanisms that are exercisable at the time a reversal is identified whether or not the proponent is solvent, exists in its original form, and/or has ownership of or responsibility for the project. The WCI partner jurisdictions will establish mechanisms to address reversals that are not the result of proponent intention or negligence and to ensure replacement of credits where proponent's contingency measures prove inadequate.

Verifiable

Section	Draft Recommendation
7.1	With respect to offset project activities, verifiable means that a GHG reduction or removal, or assertion thereof, is well documented and transparent such that it lends itself to an objective review by a qualified verifier. Verifiers for WCI offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner Jurisdiction in which the project is registered.

Transparency

Section	Draft Recommendation
8.1	The WCI offset system will provide transparency such that sufficient and appropriate protocol, project and certificate information is disclosed to allow offset system participants and the general public to make decisions with reasonable confidence.

Report on existing Protocols

Purpose of the Report

- Assist the WCI to identify protocols that could be incorporated into a WCI offsets system

Scope of the Report

- Review of 31 protocols from 11 offset programs particular to ten project types in agriculture, forestry, and waste management

Final DNV Report on existing Protocols

Next steps:

- Cover memo being prepared
- Public release anticipated in March
- Webinar following public release
- Public comment period

Carbon Neutral Event

Pacific Carbon Trust

Pacific Carbon Trust
Growing BC's Green Economy

Western Climate Initiative: Partners' Meeting

March 3, 2010

Pacific Carbon Trust

Objectives

1 **Introduction**

Introduce Pacific Carbon Trust and its mandate within the provincial climate change framework

2 **Perspective**

Share how PCT is driving BC's offset market forward

3 **PCT and WCI**

Highlight how we can work together to grow the low carbon economy in BC and North America

Pacific Carbon Trust was launched with an ambitious dual mandate

Deliver quality BC-based **offsets** to clients and support growth of the **low-carbon economy** in BC

- New commercial BC Crown corporation
- Capitalised at $24 million
- Exclusive supplier of 1,000,000 tonnes annually for carbon neutral public sector
- Aggressively sourcing high-quality BC offsets to meet this demand
- Sourced over 300,000 tonnes from 15 offset projects – and more soon
- Acquiring clients outside of government

BC is pursuing an innovative approach to creating an offset market

Creating **Demand** for Carbon Offsets

- Carbon Neutral Public Sector
- Municipal Charters

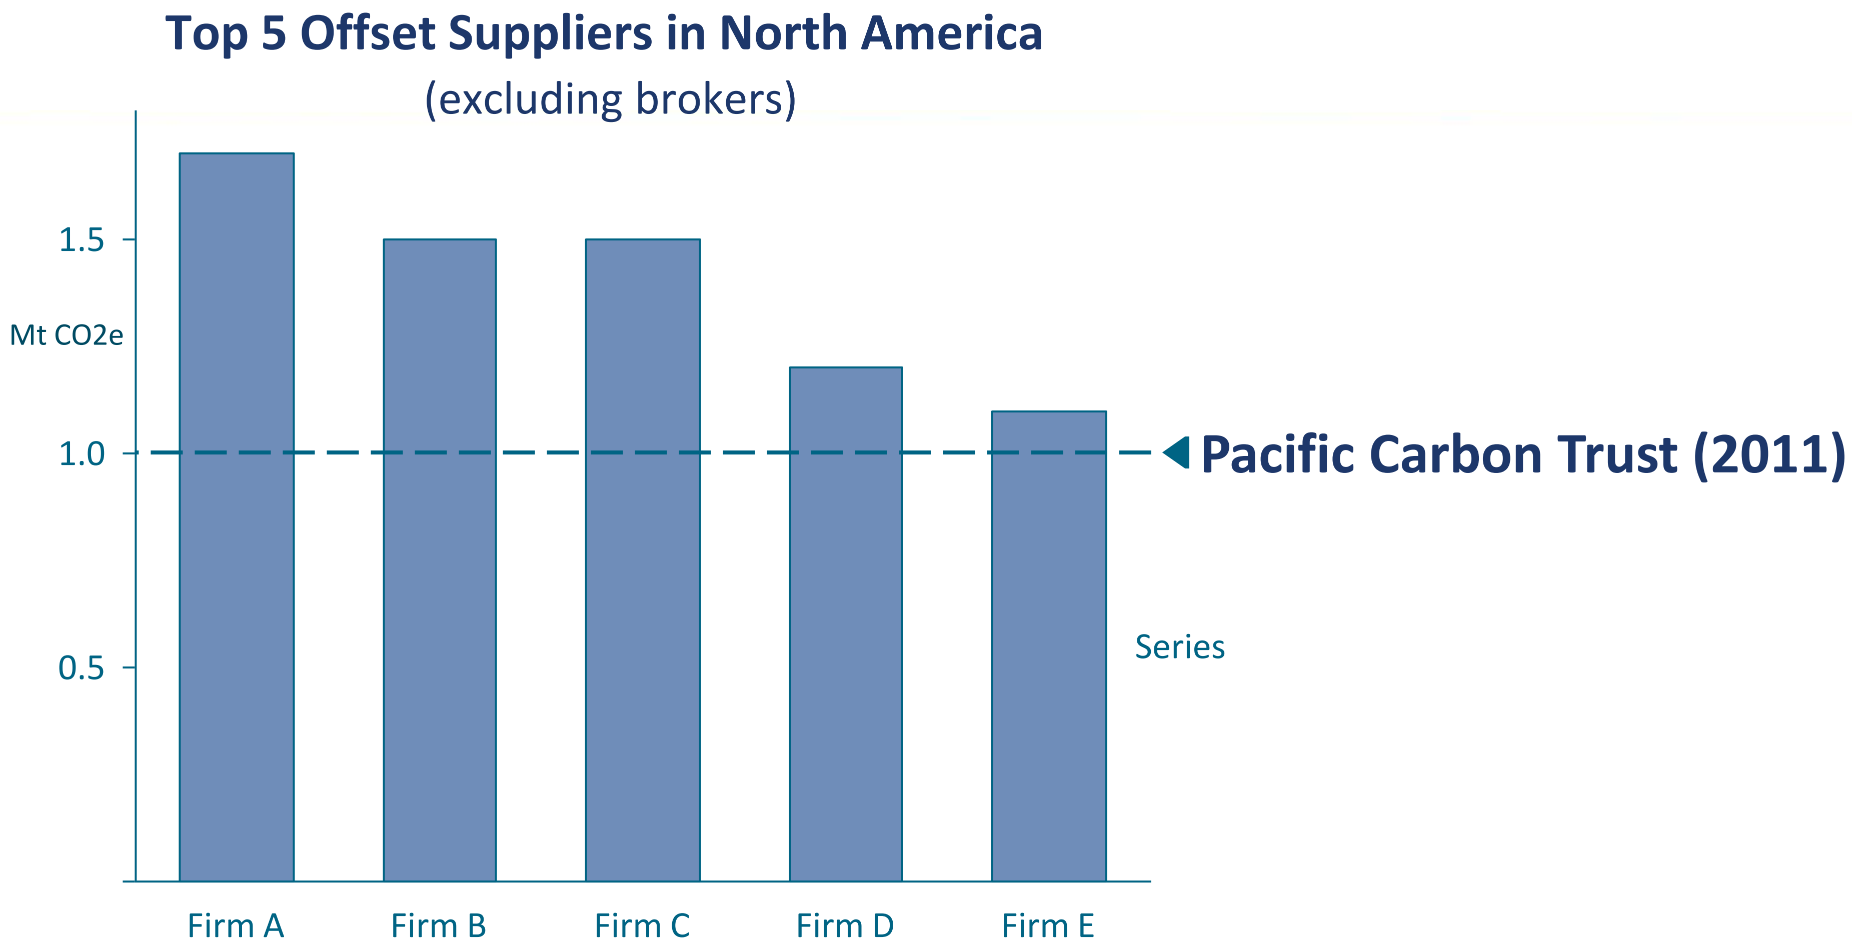
AND

Building the **Supply** of Carbon Offsets

- Strong Price Signal
- BC Offset Regulation

1	Fundamentally changing the **economics** of the investment decision by putting a **price** on carbon
2	Combining **rigorous** offset standards and **financial** incentives to spur innovative clean technology
3	**Identifying** and **removing barriers** at a structural and project level

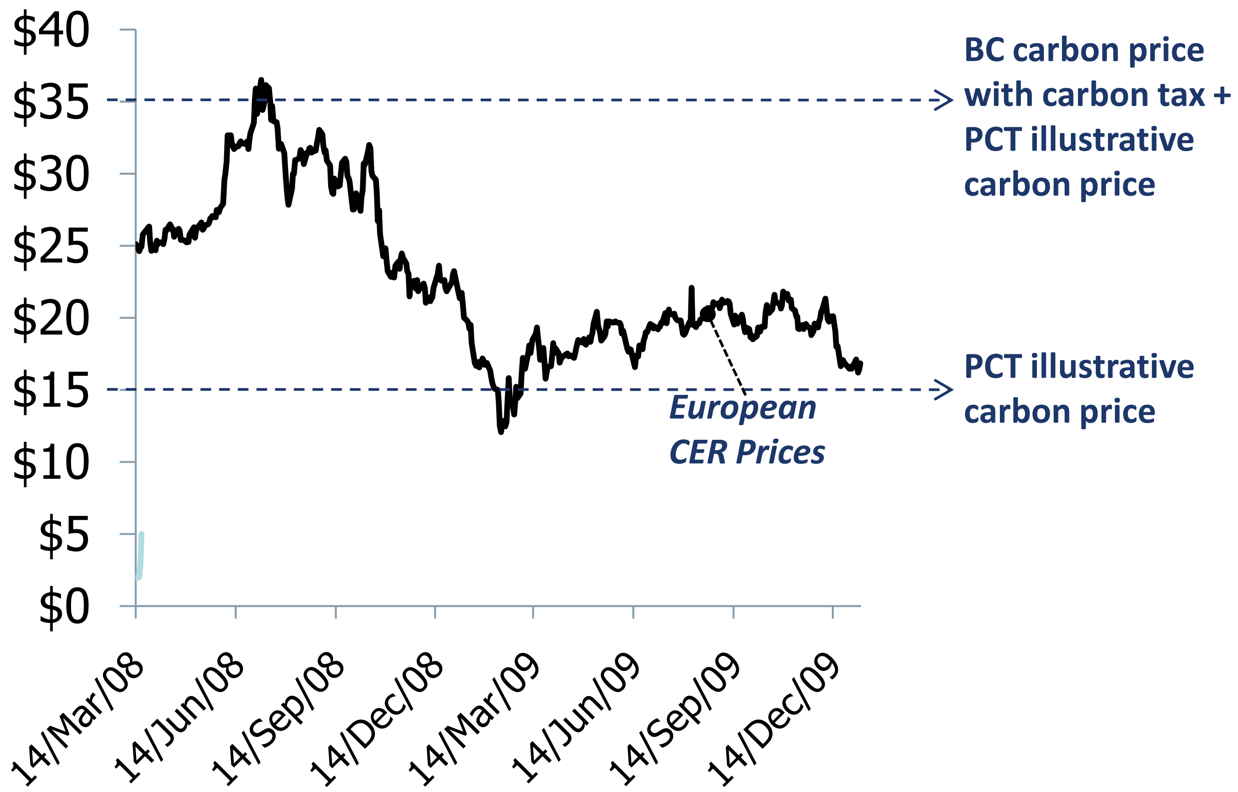
Pacific Carbon Trust will be one of the largest offset suppliers in North America next year



Source: Bloomberg New Energy Finance.
Confidential data from the State of the Voluntary Carbon Markets Report, 2009

BC has a globally significant carbon price from the carbon tax and investments that PCT is making in GHG reductions

Carbon pricing comparison ($CAD / tonne CO2e)



Pacific Carbon Trust pursues 3 core types of offset projects

	Opportunity	Description	Sample projects
1	**Low carbon fuel supply opportunities**	▪ Facilitating switch to a fuel source with lower CO2 emissions (e.g. from coal to natural gas)	▪ Switch from natural gas to biomass
2	**Energy efficiency initiatives**	▪ Reducing amount of energy required to achieve similar output ▪ Minimizing waste energy lost from a process (e.g. methane loss)	▪ Elimination of waste methane from landfills ▪ Coal mine methane destruction ▪ Co-Gen / CHP
3	**Terrestrial carbon sequestration**	▪ Increased storage of CO2 in sinks, such as forests ▪ Capture and sequestration of CO2 from industrial emissions	▪ Forestry projects ▪ Carbon Capture and Storage (CCS)

Revenues from offsets can make the difference in adopting clean technology and energy efficiency equipment

Initial Projects in PCT's Portfolio

1

Industrial Fuel Switching

- Lafarge - Richmond
- 189kT CO_2 over 3 yrs
- Ability to monetize CO2 reductions allowed for fuel switch from coal to biomass

2

Agricultural Sector Fuel Switching

- Greenhouses - Lower Mainland
- 2 projects – 98kT CO_2 reduction over 5 years
- Sale of offsets allowed for switch to biomass based fuels

3

Agricultural Sector Energy Efficiency

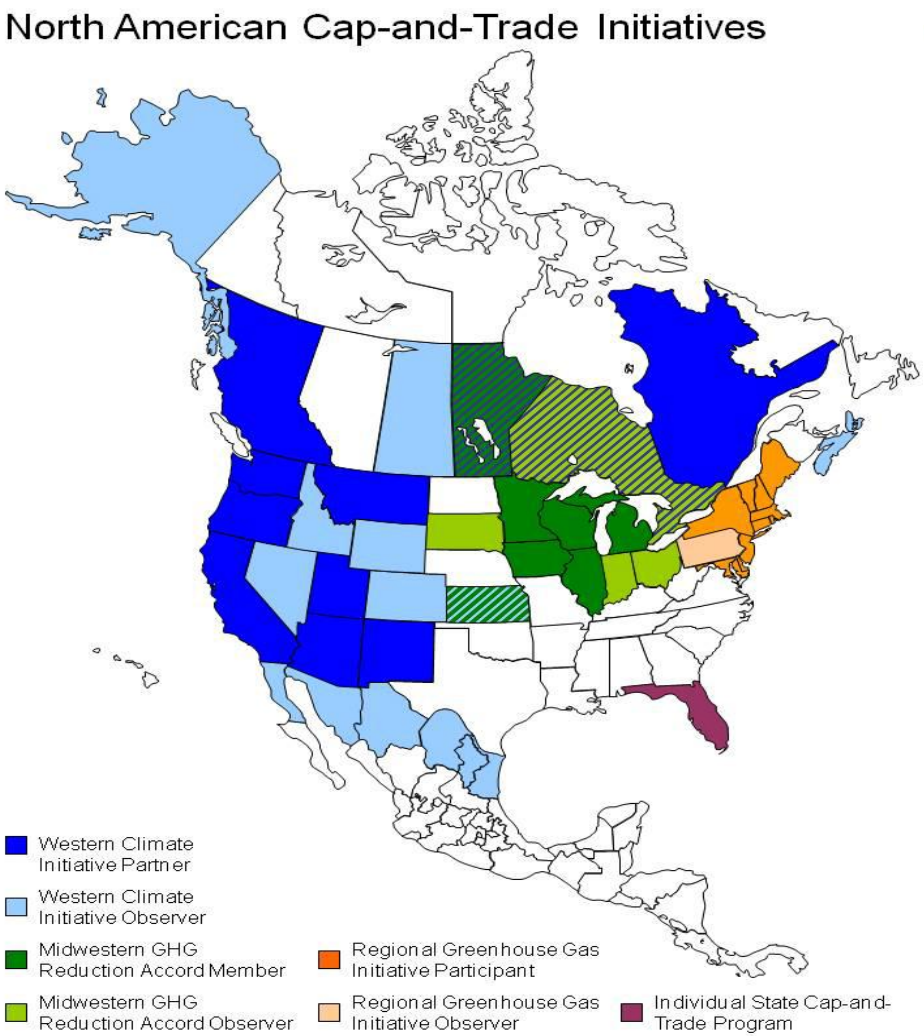
- Energy Curtains – Lower Mainland
- 2 projects – 43kT CO_2 reduction over 5 yrs
- Sale of offsets allowed investments in energy saving technologies

4

Energy Efficiency & Cleantech

- Hotels across BC
- 10 projects – 11 kT CO_2
- Intelligent fuel switching systems

PCT wants to work with you to build the North American carbon market



Where we're heading:

- 1 million tonnes of offsets annually
- Economic incentives for early action and adopting new technologies
- Market infrastructure in place and tested
- Engagement with offset organizations throughout North America

Reporting Committee

- Task 1: Harmonization of WCI Essential Requirements for Mandatory Reporting (ERs) with EPA Mandatory Reporting Rule (EPA Rule)
  - Products and Timing
    - In Process: Committee technical work to review EPA Rule and identify changes needed for
      - WCI Program
      - Conformance to Canadian regulatory norms
    - March-April: First present final recommendations, stakeholder calls and comments
    - April: Final ERs
    - Resources: No additional needed

Reporting Committee, *cont.*

- Task 2: Develop Essential Requirements for Mandatory Reporting of Oil and Gas Exploration and Production and Natural Gas Processing
- Production and timing:
  - In Process: Ongoing calls with subcommittee/stakeholder Technical Working Group
  - April 1: WCI comments to US EPA on re-proposed Subpart W of their mandatory reporting rule
  - December: First present harmonized ERs for Mandatory Reporting for Oil and Gas, stakeholder comment period
  - January 2011: Approve final ERs
  - Resources: Seeking EPA funding

Agenda

Western Climate Initiative and Goods Movement Collaborative

8:30am to 4:00pm, March 4, 2010

Hyatt Regency Vancouver, Vancouver, BC

Meeting Objectives:

1) Inform participants of the North American transportation industry's GHG emission pathways and the differences in managing sectors (marine, rail and truck) across WCI Partners jurisdictions;
2) Identify specific emission reduction opportunities in the transportation sectors;
3) Initiate dialogue on transportation industry treatment within the WCI; and
4) Determine next steps for continued transportation industry engagement in WCI.

		Lead Presenters
8:30 – 8:45	**1. Call to Order: Opening Remarks** • Introductions • Review Purpose and Agenda • Context for today's discussion	Tim Lesiuk (BC)
8:45 – 10:00	**2. North American Transportation Sector and Climate Change** • Introduction and Overview ○ Defining the sector ▪ Differences between goods movement and personal transportation ○ Major sources of emissions across subsectors • Focusing on freight transportation – tools for a unified approach ○ Marine ○ Rail ○ Truck • Treatment and challenges of addressing the Transportation sector under other GHG programs ○ North American ▪ Tailpipe emission standards ▪ Low carbon fuel standard ▪ BC Carbon Tax ▪ Cap and trade ▪ Smartaway	Mike Gerbis, Delphi John Fowlis, Seaspan Normand Pellerin, CN Bob Purdy, Fraser Basin Council Jotham Peters, M.K. Jaccard
10:00 – 10:15	**Break**	
10:15 – 12:00	**3. Facilitated Breakout Groups** • Split into key subsectors to discuss ○ What is the right outcome for this sector in a carbon constrained world (modes, optimizations, fuels, vehicles, infrastructure and logistics)? ○ Key challenges for sector to achieving these outcomes ○ Transition strategies to a low carbon sector ▪ Industry ▪ Government ▪ Consumers ○ Near and mid-term actions (research, competitiveness, infrastructure, policy, incentives) ▪ Industry ▪ Government	Facilitators: Dennis Cunningham, IISD Nick Nigro, PEW Mike Gerbis, Delphi
12:00 – 1:00	**Lunch**	
1:00 – 1:15	**Minister Penner, Ministry of Environment, Government of British Columbia**	Minister Penner
1:15 – 2:30	**Subsector Presentations**(15-20 minutes each)	All
2:30 – 2:45	**Break**	
2:45 – 3:45	**4. Collaborative Discussion** • Group evaluation of presented materials	All
3:45 – 4:00	**5. Wrap up and Next Steps**	Tim Lesiuk (BC) Michael Gibbs (CA)

Western Climate Initiative Goods Movement Collaborative

Objectives for the Day

- **Inform participants** – NA transportation industry's GHG emissions
- **Identify opportunities** – to reduce GHG emissions in the transportation sector
- **Initiate dialogue** - on transportation industry treatment within the WCI
- **Identify next steps** - for continued transportation industry engagement in WCI

Chamber of Shipping of British Columbia

Marine Activities in Western Canada

- International shipping and Trade
- Domestic marine transportation
- Public marine transportation
- Fisheries
- Government vessels
  - Coast Guard
  - Dept of Fisheries
  - Navy
- Recreational

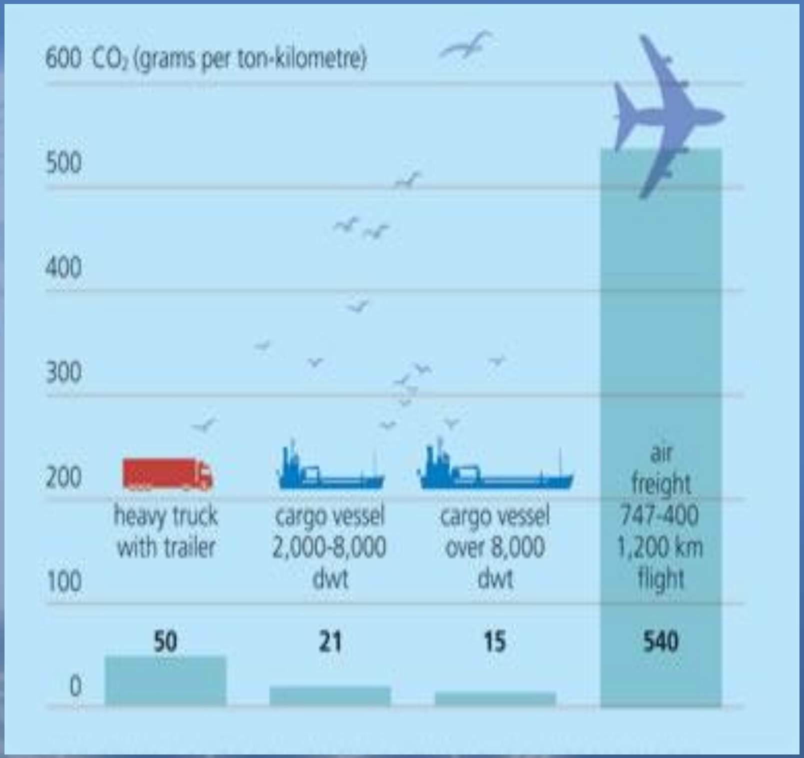
seaspan

International Shipping Initiatives

- Led by IMO
- Deep sea fleet predominantly uses HFO as fuel.
- Attention has been on Sulfur reductions
- GHG reduction initiatives driven by governments and customers.
- use of light fuels in ports or shore power
- Economy of scale and speed effect GHG

ATMOSPHERIC POLLUTION

- The shipping industry is a small contributor to the total volume of atmospheric emissions compared to road vehicles and air transport as well as public utilities such as power stations.
- Atmospheric pollution from ships has reduced in the last decade on account of improvements in engine efficiency, hull design, and the use of larger ships.
- .



CHAMBER of SHIPPING

WHAT MORE CAN BE DONE?

- Owners are extremely proactive in seeking a reduction in emissions and an increase in fuel efficiency.
- At the same time there is acknowledgment of the worldwide concern related to atmospheric pollution and the role of the shipping industry.
- The industry is therefore fully engaged in discussions at IMO on substantial further reduction of ships' emissions.

CASE STUDY “MSC DANIT”
14,000 TEU CAPACITY CONTAINER SHIP

DESIGN CRITERIA

- LOA approx 380 m
- Beam approx 52 m
- Design draft of 14 m
- Guaranteed speed of 24 knots
- Fn approx. 0.207 *
- 90% MCR with 15% sea margin

*Fn = factor of vessel design speed to size)

TO ACHIEVE

- Reduction in wave resistance by more than 50 percent
- Better propulsion
- Generation of stable wave patterns
- Higher vessel robustness
- Optimal trim

Domestic Shipping in BC

Cargos transported on BC Coast

- Forest sector
  - Logs
  - Cut lumber
  - Pulp / paper
  - Wood chips
  - Chemicals
- Bulk products
  - Oil / refined products
  - Gravel / Limestone / silica / coal
  - Salt
- Domestic freight
  - Ferries and passenger ships
  - Trailers
  - Project cargos
  - Specialty cargos / oversized load

Opportunities for Domestic Marine GHG reductions

- Replace older engines in vessels with new clean(er) engines
- Leverage economy of scale
- Voyage planning / speed reductions
- Alternate propulsion,

Opportunities to reduce GHG in other modes and increase Marine GHG for a net gain

- Marine Transportation represents 4% total GHG in transportation
- Marine is 1.4x more efficient than rail and 3.5x more efficient than trucks in fuel burned / ton mile moving bulk cargos.
- Marine requires limited infrastructure construction and maintenance.

- Where possible marine transportation of goods can reduce heavy truck traffic on roads and reduce overall GHG on a tons delivered basis.
  - In BC and Washington state there are several possible opportunities to leverage this advantage.
  - It will not happen without impetus from regulators / local governments

seaspan

Challenges in GHG reductions

- Limited applications of hybrid technology
- Alternative Fuel supply and cost
- Energy efficiency is not a new concept in marine transportation systems.
- Largest gains will come from a cultural shift in the public and the workplace.
- Existing emissions legislation will increase GHG output of new diesels to reduce NOx and SOx emissions.

Gaining "Traction for Action" in On-Road Transportation

March 4, 2010

Fraser Basin Council

Presentation Summary

1. Fraser Basin Council Overview
2. The Challenge: Transportation Sector GHG Emissions
3. The Council's Fleet Greening Initiatives
4. Opportunities Ahead

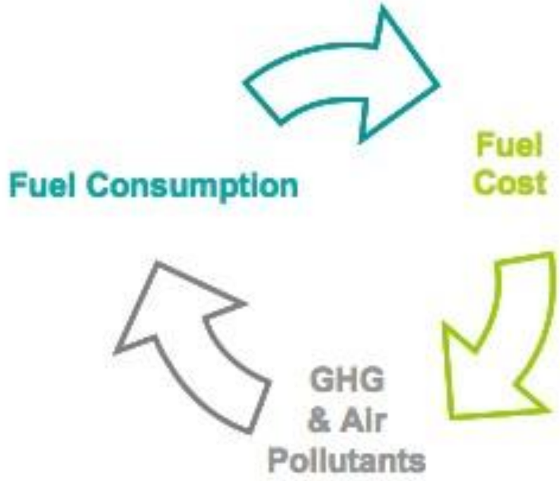
Fraser Basin Council

- Non-government organization formed in 1997
- Key roles: catalyst, facilitator, “bridge builder”, sustainability educator
- Uses inclusive governance approach involving:
    - All Orders of Canadian Government
    - Private Sector
    - Civil Society
- Implementing programs across BC and Canada

Fraser Basin Council

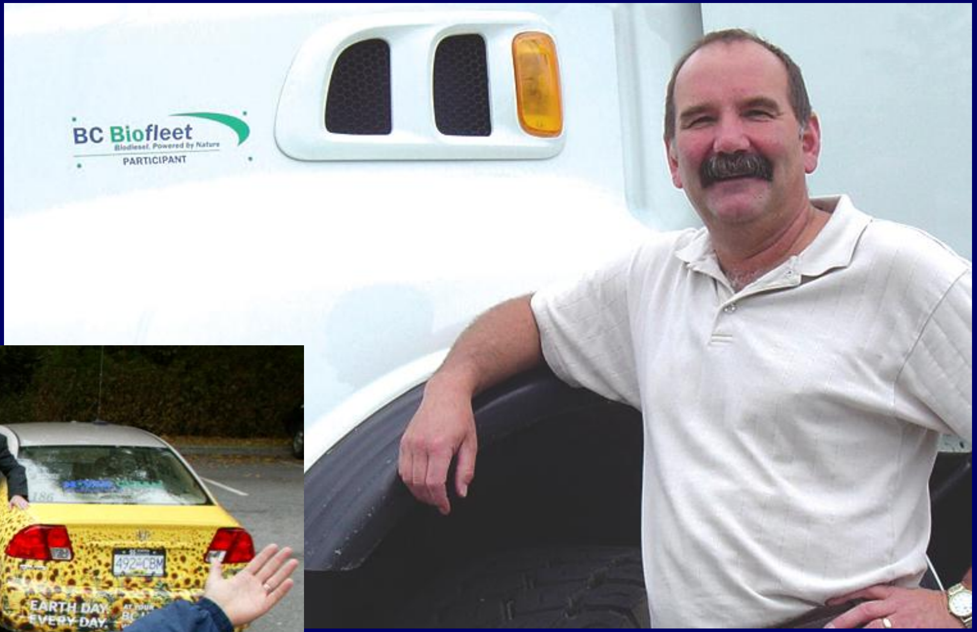
The Challenge: Transportation GHG Emissions

- GHG emissions continuing to grow
- GHG emissions in transportation ~36% of total emissions in BC
- On-road commercial transport about 8%
- *Many opportunities for emission reductions*



E3 fleet
Energy Environment Excellence

North America's First Green Rating System for Fleets



Fraser Basin Council

E3 Fleet: Program Priorities

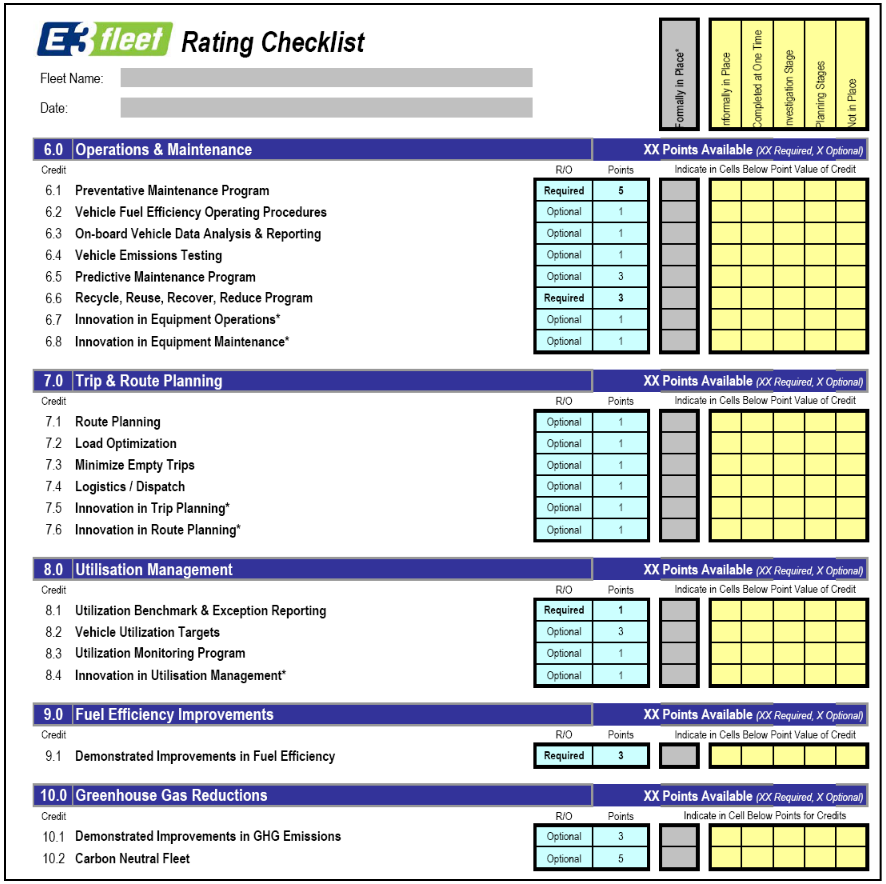
- Integrated analysis and rating program services
- Promote and recognize cost and emissions reduction successes
- Lead / coordinate demonstration programs
- Provide tools to evaluate efficiency alternatives
- Provide practices / technologies knowledge

Fraser Basin Council

E3 Fleet Rating

Points achievable in the following areas:

1. Green Fleet Action Plan
2. Training & Awareness
3. Idling Reduction
4. Vehicle Purchasing
5. Fuel Data Management
6. Operations & Maintenance
7. Trip & Route Planning
8. Utilisation Management
9. Fuel Efficiency
10. Emissions Performance



E3 fleet Rating Checklist

Indicate in Cell Below Points for Credits

Fraser Basin Council

E3 Fleet System Results

City of Vancouver and Corp of Delta

- BC's First Gold Rated Fleets
- Corporate members:
  - Novex courier
  - Bell Canada
  - Canadian Springs
  - Hydro One

Emissions Reduction Impact in BC

- 150 fleet commitments to reduce emissions (40,000 vehicles)
- 15,000 vehicles with better performance
- Estimated emissions reductions since 2007:
  - 23,000 tonnes of greenhouse gases
  - 150 tonnes of NOx
  - 3 tonnes of PM2.5

Fraser Basin Council

Trucking Efficiency Examples

Promising Advancements:

- Hybrid trucks - Savings of 20-40% in urban environment
- Electric trucks- Coming soon to urban fleets
- Driver behavior changes - achieving early reductions

Fraser Basin Council

Opportunities for MORE Traction for Action:

- Join an influential and motivated collaboration
- Enhance support for real world demonstrations
- Increase influence on purchasers of fleet services
- Policy/regulatory support for technologies once viability is confirmed
- Continued support for the Council's knowledge, skills and relationships network

Fraser Basin Council

Thank You!

Fraser Basin Council

Hybrid Trucks

- Savings of 20-40% in urban environment
- Trucks now available from OEMs for class 3-7
- Strong interest from fleets
- Fuel savings don’t yet justify incremental cost (~$50k), but getting close

Electric Trucks

- Coming soon to urban fleets
- Zero tailpipe emissions
- Incremental capital costs much higher (e.g. 2-3X)
- First truck coming to Novex fleet soon…

Driver Training: Port Metro Vancouver

- Driver behaviour can affect performance by 10-20%
- Pilot training program for container trucking fleet (urban), with future work to build on results
- Combining with telematics provides ultimate tracking solution

Fraser Basin Council

Focusing on Rail Freight Transportation Emission Reductions

Normand Pellerin
Assistant Vice President
Environment

CN-WCI Transportation Collaborative
March 4 2010 • Vancouver, BC

OUTLINE

Rail Emission Sources

Regulatory Approach

Rail Emission Reduction Opportunities

Opportunities

Challenges

Key rail emission sources

- Line-haul locomotives
- Switch yard locomotives
- Other fleets: trucks, vehicles, cranes, tractors, gen sets, heaters and reefers
- Facilities: terminals, shops, and other buildings

A fragmented approach to regulation

Government of British Columbia	CARBON TAX
Government of Alberta	ASSISTANCE PROGRAM
Government of Quebec	CAP & TRADE – MODAL SHIFT
U.S. EPA	EMISSION REGULATIONS – LOCOMOTIVES AND ENGINES

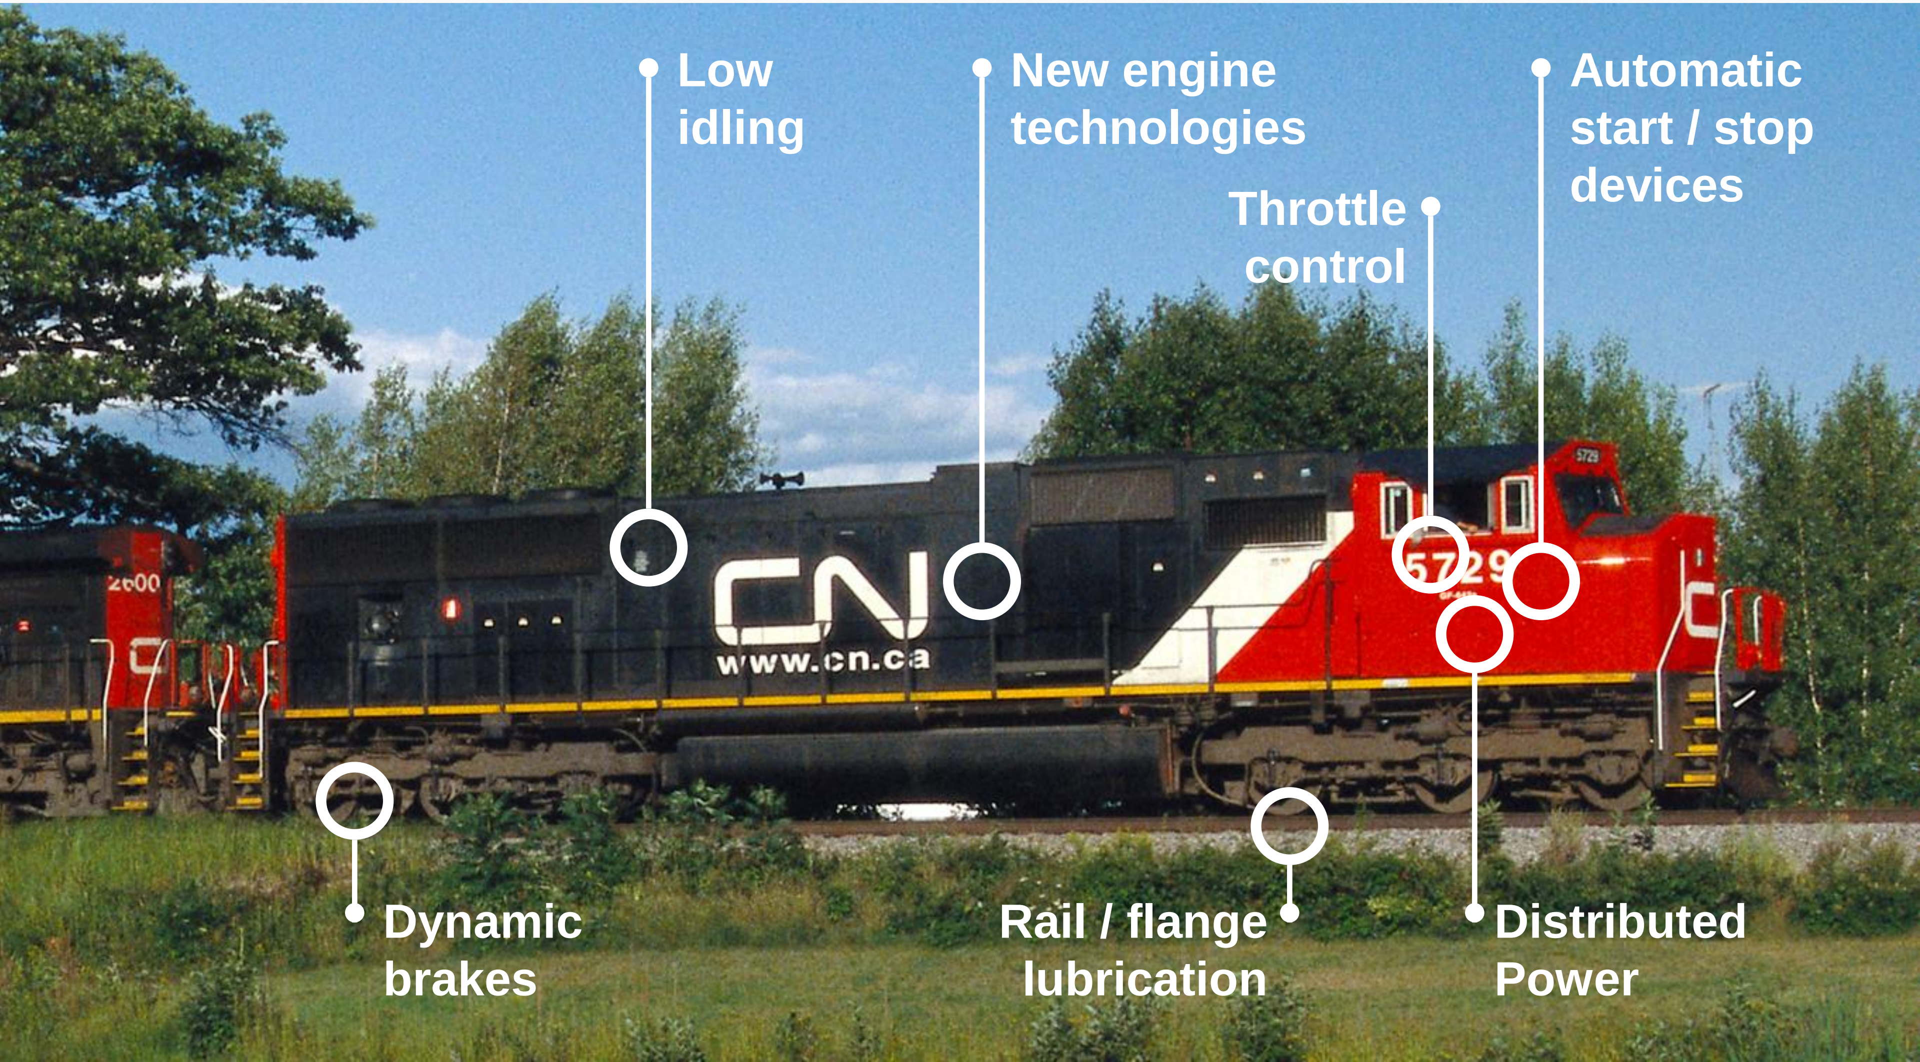
Tenacity is required

Voluntary programs and pending regulation

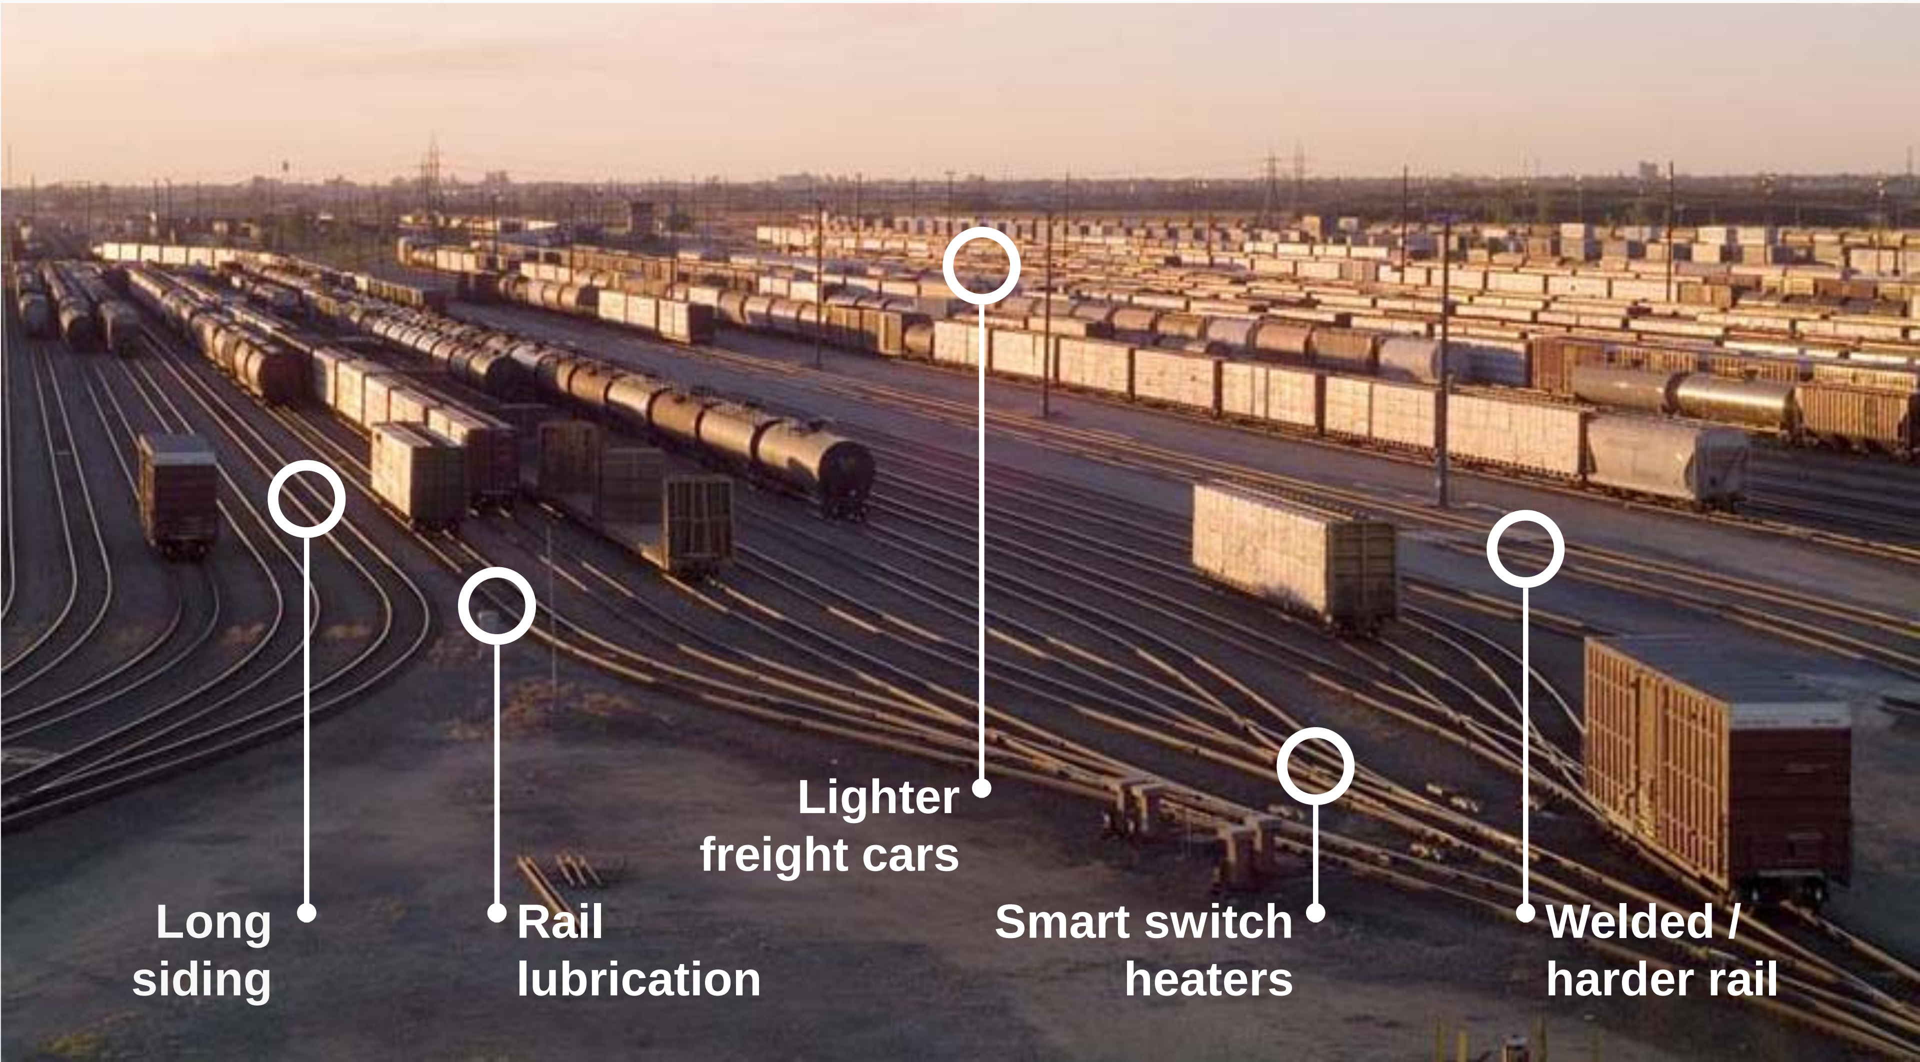
Environment Canada/RAC	Voluntary agreement to reduce emissions intensity over time
U.S. SmartWay Agreement	Increase energy efficiency while reducing air pollution & GHGs
Renewable Fuel Content	Increase % renewable content in diesel
Federal Government	Proposed emission standards following expiration of RAC MOU in 2010

Change = Risk and Opportunity

Rail emission reduction opportunities - new and upgraded locomotives



Rail emission reduction opportunities – on the rails and in yards



Rail emission reduction opportunities – operating and training for efficiency

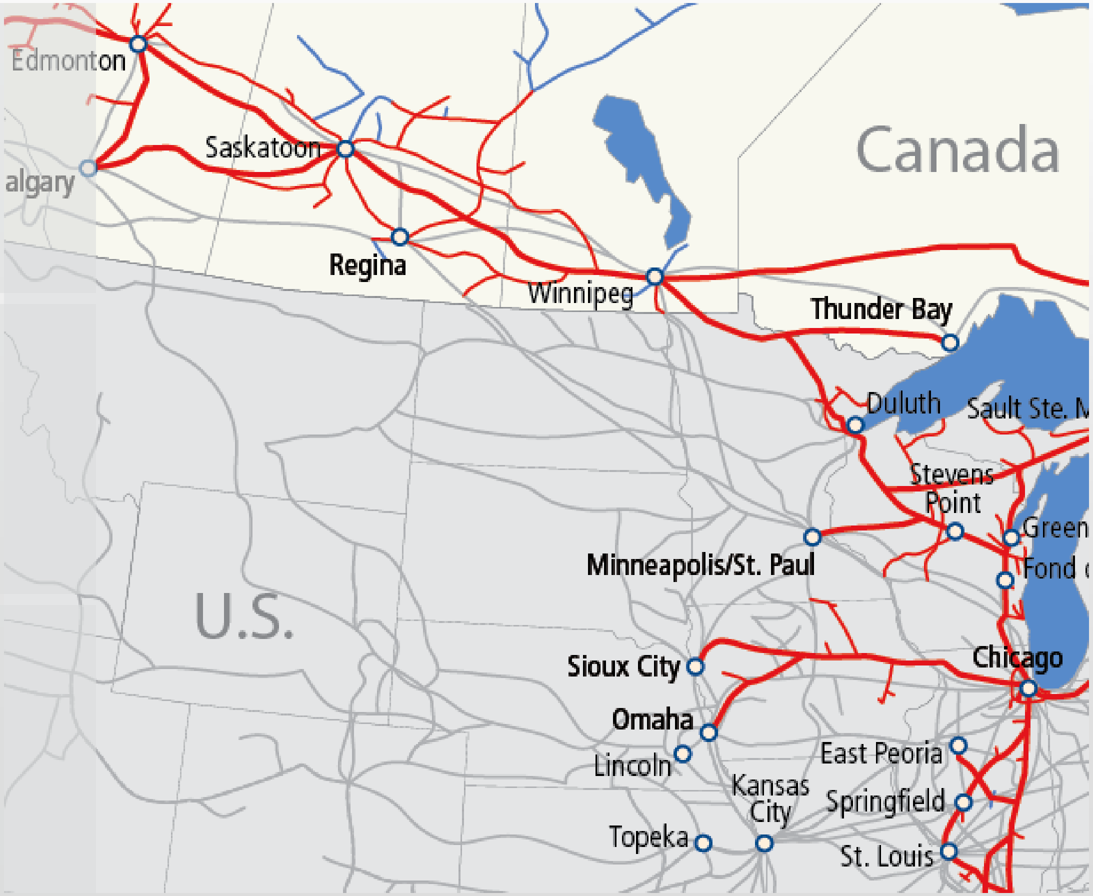
- Crew training focused on fuel conservation
- Locomotive shutdowns
- Streamlined car handling practices to switch only the number of cars needed
- Train pacing, coasting and braking strategies
- Notch limiting

Routing protocols and co-production - partnering to create efficiency

Routing protocols define the shortest, most efficient routes

Co-production leverages existing infrastructure to maximize fluidity and capacity

Results in less fuel used and minimizes the impact on the environment



Opportunities

- Operational efficiencies/costs
- Government R&D support
- Technological innovation
- Enhanced branding & positioning
- New/emerging markets
- Carbon credits

Challenges

- **Evolving regulatory landscape**
- **New technologies can present risks or costs**
- **Training is required to change the way we work/operate**
- **Industry measures and standards are required**

CN

Policies to Achieve Deep Emission Reductions in Transportation

Goods Movement Collaborative
March 4, 2010

Jotham Peters
M.K. Jaccard and Associates, Inc.

MKJA
MK Jaccard and Associates Inc

Outline

- Context
- Summary of key challenges with reducing emissions from transportation
- Policies available to induce emissions reductions

Context

- In British Columbia, greenhouse gas emissions from transportation accounted for 25 Mt CO_2e in 2005, representing over a third of total emissions.
- Under the Climate Action Plan emissions from transportation are expected to stabilize, but not decline.
- Reaching a 33% reduction from 2006 levels of emissions by 2020, and deep long-term targets for emissions in 2050 will require a more significant reduction from transportation.

MKJA
MK Jaccard and Associates Inc

Challenges reducing emissions in transportation

- Energy efficiency actions alone will not achieve deep reductions
- Abatement options to achieve deep reductions are not yet commercially available
  - Battery-electric vehicles
  - Battery exchanges for electric vehicles
  - Biofuels
  - Hydrogen

MKJA
MK Jaccard and Associates Inc

Policy options to reduce emissions in transportation

- Carbon tax:
  - GHG Reductions:
    - Targets all decisions that affect emissions
    - Emissions of vehicle stock is uncertain
  - Compliance Costs:
    - Costs are limited to the price for emissions
- Tailpipe emissions standard:
  - GHG Reductions:
    - Emissions of vehicle stock is more certain
  - Compliance Costs:
    - Costs are less certain

MKJA
MK Jaccard and Associates Inc

Policy options to reduce emissions in transportation, continued

- Mandates for sales zero-emissions vehicles:
  - GHG reductions:
    - Very effective at inducing technological change
  - Costs of compliance:
    - Dependent on the cost of the low- or zero-emissions vehicles and the price for fuel
- Low-carbon fuel standard:
  - GHG Reductions:
    - Encourages the adoption of low- or zero-emissions fuels (i.e., biofuels, electricity)
    - Questionable whether this policy can effect upstream emissions, if these emissions occur outside the jurisdiction

MKJA
MK Jaccard and Associates Inc

Concluding remarks

- There are likely to be trade-offs between the certainty of achieving an emissions reduction and the costs of compliance.
- Regulatory policies (such as the zero emission vehicle standard) are likely to provide greater certainty that zero-emissions vehicles will be commercialized.

Thank-you!
Questions?

MKJA
MK Jaccard and Associates Inc

Policy	*Emissions Reductions*	*Compliance Costs*	*Induce Technological Change*
Carbon Tax	Pros: Targets all decisions that affect vehicle emissions.	Pros: Costs are limited to the price of the carbon tax	Pros: Uniform signal to innovate any process that affects emissions.
	Cons: Reductions are sensitive to other variables (e.g., price for oil).		Cons: Still sensitive to other variables.
Tailpipe emissions standards	Pros: More certain than carbon tax	Cons: Costs of the policy are uncertain.	Pros: Strong incentive to improve emissions intensity of vehicles.
	Cons: Does not influence vehicle use		Cons: No incentive to reduce emissions via other actions (e.g., improved public transit)

MKJA
MK Jaccard and Associates Inc

<table>
<tr><th>Policy</th><th>Emissions Reductions</th><th>Compliance Costs</th><th>Induce Technological Change</th></tr>
<tr><td rowspan="3">Low carbon fuel standard</td><td>Pros: May influence upstream emissions from oil production</td><td rowspan="3"></td><td>Pros: Encourages development of biofuels.</td></tr>
<tr><td>Pros: Encourages biofuel adoption</td><td rowspan="2">Cons: Less likely</td></tr>
<tr><td>Cons: It is difficult to influence decisions outside your jurisdiction in a global economy</td></tr>
<tr><td rowspan="2">Information programs (e.g., Smartway)</td><td>Pros: Improves information.</td><td rowspan="2">Pros: Costs are minimal</td><td rowspan="2">Policy not intended to induce technological change.</td></tr>
<tr><td>Cons: Unlikely to have a significant effect if implemented by itself.</td></tr>
</table>

Western Climate Initiative

WCI Recommendations for Implementing the Offset Limit

March 11, 2010

Background

As part of the design for the WCI Regional Cap-and-Trade Program, the WCI Partner jurisdictions recommended that a rigorous offset system be developed and implemented. The purpose of the offset system is to reduce compliance costs while encouraging emission reductions, innovation, and technology development for sources and sinks not covered by the cap-and-trade program.

The Design Recommendations for the WCI Regional Cap-and-Trade Program specify that a majority of emission reductions required under the program occur at covered entities and facilities. Consequently, for compliance purposes, the WCI Partner jurisdictions set a limit on the use of offset credits issued by WCI Partner jurisdictions, as well as the use of offset credits and allowances from other GHG emission trading systems that are recognized by the WCI Partner jurisdictions, to no more than 49 percent of the total emission reductions from 2012 to 2020. [1] This limit and rationale are established in the WCI's Design Recommendations (September 23, 2008). This document provides the Partners' recommendation on how this limit should be implemented.

To develop this recommendation, the WCI Cap Setting and Allowance Distribution (CSAD) Committee produced two background papers, conducted an in-person stakeholder dialogue, and solicited and carefully considered written comments from over 30 stakeholders. In May 2009, the CSAD issued a white paper (May 2009) describing options to address the following questions related to implementation of the WCI offset limit:

1. What mechanism should be used to impose the limit?
2. How should the offset limit be applied across jurisdictions?
3. How should the limit be applied across compliance periods?

On the basis of input received and further deliberations, the Committee developed a draft recommendation on how to implement the offset limit, which was posted for comment on October 6, 2009. The WCI Partners considered these comments in preparing the final recommendations presented here.

[1] It is important to note that where there is reference to the "offset limit", it should be understood to encompass not only offsets issued by WCI Partner jurisdictions, but also offsets and allowances issued by other GHG emission trading systems approved for use in the system by the WCI Partner jurisdictions.

Recommendations

The WCI Partners make the following recommendations for limiting the use of all offsets, and allowances issued by other GHG emission trading systems recognized by the WCI Partner jurisdictions (all such commodities hereafter referred to simply as "offsets"):

1. **The WCI Partners recommend limiting the use of offsets at the point of regulation[2].** The Partners find that limiting offset use is preferable to limiting offset supply; nearly all stakeholder comments concur with this finding. Compared to a supply limit, a use limit should result in lower overall compliance costs for covered sources.[3] Furthermore, the Partners recommend a use limit be applied as a percentage of compliance obligations (i.e., emissions) at the point at which WCI compliance will rest. This option provides predictability for covered sources, is relatively simple to implement, and minimizes both administrative and compliance costs relative to a supply limit.

2. **The WCI Partners recommend that a common offset use limit be implemented across Partner jurisdictions**. A common limit provides equal opportunity to covered sources across the WCI region, and helps to ensure that the overall limit will not be exceeded. However, as stated in the WCI Design Recommendations, each WCI Partner jurisdiction will have the discretion to set a lower limit. Several stakeholders recommended a differentiation of offset limits among jurisdictions to provide greater flexibility and to provide entities with more access to offsets where tighter emission reduction targets have been adopted. The CSAD Task 3 (competitiveness) group will consider whether the common use limit might pose competitiveness concerns for entities in jurisdictions that have adopted lower emission targets relative to historical levels, and if so, how to address these concerns.

3. **The WCI Partners recommend that the offset limit be set at an equal percentage of compliance obligations across compliance periods.** This option allows for the use of a greater number of offsets in earlier compliance periods (adjusting for the expansion of program scope in 2015), thus easing the transition into the cap and trade program. Some stakeholders favored increasing access to offsets over time either to encourage greater investment in emission reductions in early periods or to allow for greater offset

[2] The precise point of compliance (entity, facility, or other unit) for each type of emissions source is not the subject of this recommendations paper, and will be determined separately. However, for a better understanding of where compliance will rest, see section 2 of the September 23, 2008 Design Recommendation for the WCI Regional Cap-and-Trade Program.

[3] It is important to note that where there is reference to "covered sources", it should be understood to encompass: industrial sources, electricity producers and deliverers, and fuel deliverers, blenders and distributors.

use in later periods, when allowance prices are expected to be higher. The WCI Partners believe the recommended approach accommodates this form of cost control since covered sources may maximize their use of offsets in early periods in order to create and bank excess allowances for use in later periods, in lieu of where an increasing number of offsets would be permitted.

4. **The WCI Partners recommend no carry-over mechanism be added to the offset limit.** Considering that offsets themselves are fully fungible and that offset-to-allowance arbitrage can help to fully utilize offsets, the Partners find that the potential benefits of a carry-over mechanism are not worth the complexity it would introduce in the system design and administration. The Partners prefer to maintain the simplicity and certainty of the offset limit and therefore do not recommend the adoption of an offset carry-over mechanism.

5. **The WCI Partners recommend that changes in membership of the WCI cap-and-trade program not affect the offset limit established at the start of the program unless those changes cumulatively result in an increase to the offset limit equal to or greater than one half of a percentage point.** While changes in membership might affect the calculation of the offset limit (to reflect 49% of emissions reductions), the more important consideration is to establish a clear and predictable offset limit so that covered sources and offset project developers can make plans and investments accordingly. Partners will proceed with increasing the offset limit only when new membership would cumulatively result in an increase to the offset limit equal to or greater than one half of a percentage point.

For a description of the offset limit options considered and the criteria and process used to arrive at these recommendations, see the Offset Limit Draft Recommendations Paper and public comments posted on the WCI website.

Upcoming Events

April 14: Partners Meeting and Stakeholder Dialogue in San Francisco

The next WCI Partner meeting will be April 14 in San Francisco, CA at the Sir Francis Drake Hotel. Click here and register if you plan to attend in person. The meeting will take place from 9:00 am to 12:30 pm. Following the meeting, the WCI Partners will host a stakeholder dialogue at the nearby Marriot Marquis Hotel from 3:30 to 5:00 pm. This time and venue will enable broader stakeholder participation, as well as coordination with pre-conference activities of the annual Navigating the American Carbon World conference. Details on the WCI meetings will be posted to the website and distributed via the WCI list server when available.

May 19: Benchmarking Symposium in Seattle

The symposium, described in the adjacent column of this newsletter, will take place from 8:30 am to 4:30 pm in downtown Seattle, WA. The exact location and other details will be posted to the WCI website and distributed via the WCI list server when available.

WCI Partners Welcome New Canadian Co-Chair

At their March 3 meeting in Vancouver, the WCI Partners thanked Tim Lesiuk (Province of British Columbia) for his leadership serving as the WCI Canadian Co-chair during the 2009 term. The Partners welcomed Robert Noel de Tilly (Province of Québec) as the new WCI Canadian Co-chair for the 2010 term.

WCI Partners Approve Final Recommendations on Limiting the Use of Offsets

To assure a majority of emission reductions required under the cap-and-trade program occur at covered entities and facilities, the WCI Cap Setting & Allowance Distribution Committee released draft recommendations in October 2009 to limit the use of offsets issued by the WCI, as well as offsets and allowances issued by other trading systems that are recognized by the WCI Partner jurisdictions, to no more than 49 percent of the total emission reductions from 2012 to 2020. The WCI Partners considered public comments on the draft recommendations, further discussed the recommendations at their March 3 meeting in Vancouver, and have since approved the recommendations with some modifications. The final recommendations are available here.

WCI Electricity Team Invites Stakeholder Comment on Documents Regarding Electricity

May 20: Partners Meeting in Seattle
The specific location and agenda for this meeting will be posted to the website and distributed via the list server when available.

Imports

On February 18, the WCI Electricity Team posted three documents to the WCI website that were presented at the January 21 Electricity Industry Collaborative and invited stakeholder input on these documents. Interested stakeholders that have not yet submitted their comments should do so as soon as possible. Click here to access and comment on the Draft Open Access Technologies Inc. (OATI) analysis of electricity imports in the Western Electricity Coordinating Council (WECC) region. Click here to access and comment on the 2006 Draft Default Emissions Factor Calculator and the 2007 Draft Default Emissions Factor Calculator.

Material Available from WCI Partners Meeting and Goods Movement Collaborative

Material and presentations from the March 3 Partners Meeting and March 4 Goods Movement Collaborative in Vancouver, BC are available on the WCI website. The Partners meeting was an opportunity for Partners to continue their collective work to develop a detailed design for the WCI cap-and-trade program. The detailed design will represent the cumulative set of decisions Partners have made through the WCI committee work. Partners also discussed regional collaboration on complementary policies and broader action to advance clean energy with other regional and national initiatives. The Goods Movement Collaborative was a chance for Partners to engage with representatives of various transportation industry sectors (marine, rail and truck) and identify specific emissions reduction opportunities and opportunities for continued engagement.

New Mexico Seeks Public Comment on Draft Document Outlining Options for Greenhouse Gas Emissions Trading in New Mexico

On March 16, the New Mexico Environment Department released a draft issues paper, consistent with the Design Recommendations of the WCI, on Greenhouse Gas Emissions Allowance and Trading in New Mexico. "It's important for the [New Mexico] Environmental Improvement Board to adopt a cap-and-trade program that will best suit the needs of our state," said New Mexico Environment Department Secretary Ron Curry. "This paper helps to clarify the options that are available for us." Click here for the paper and to submit comments.

State of Washington and WCI Hosting a Benchmarking Symposium

The Washington State Department of Ecology and the WCI will host a Greenhouse Gas (GHG) Benchmarking Symposium from 8:30 am to 4:30 pm on May 19 in downtown Seattle, WA (location to be announced). A GHG benchmark is a quantity of emissions per unit of industrial output or production, and is meant to enable comparison of facilities according to a common measure. Speakers, panelists, and participants at the symposium will address a number of topics and discuss questions such as:

- What are industry GHG benchmarks?
- What role can benchmarks play under various policy approaches to reducing GHG emissions, such cap-and-trade programs, performance standards, or voluntary actions?
- What are the benefits and challenges of developing and applying benchmarks?

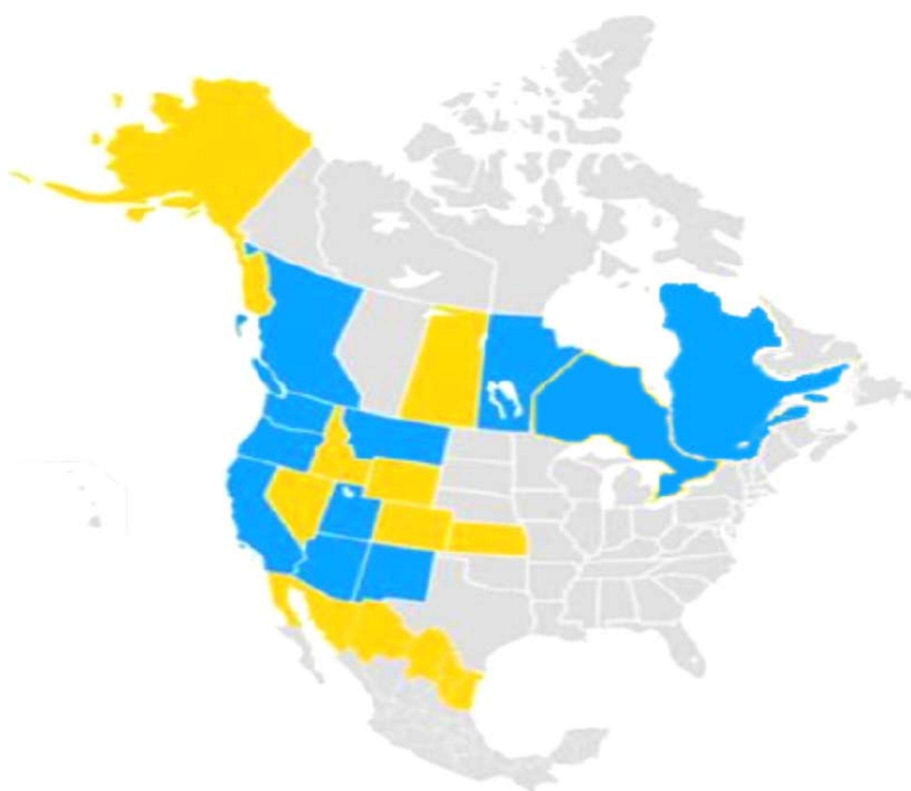
1 Introduction

The Western Climate Initiative (WCI) is a collaboration between seven U.S. Governors and four Canadian Premiers. Its purpose is to facilitate a way for WCI Partners to reduce total greenhouse gas (GHG) emissions in the region to 15 percent below 2005 levels by 2020.[1] The regulatory structure and rules governing the WCI are still under development by Partner states and provinces; however it is clear that the WCI will focus on a market-based cap and trade program as one means of achieving this collective emissions reduction goal. Figure 1 below shows the WCI Partner states and provinces in blue and the WCI Observer states and provinces in yellow.

Figure 1. WCI Partner and Observer States and Provinces

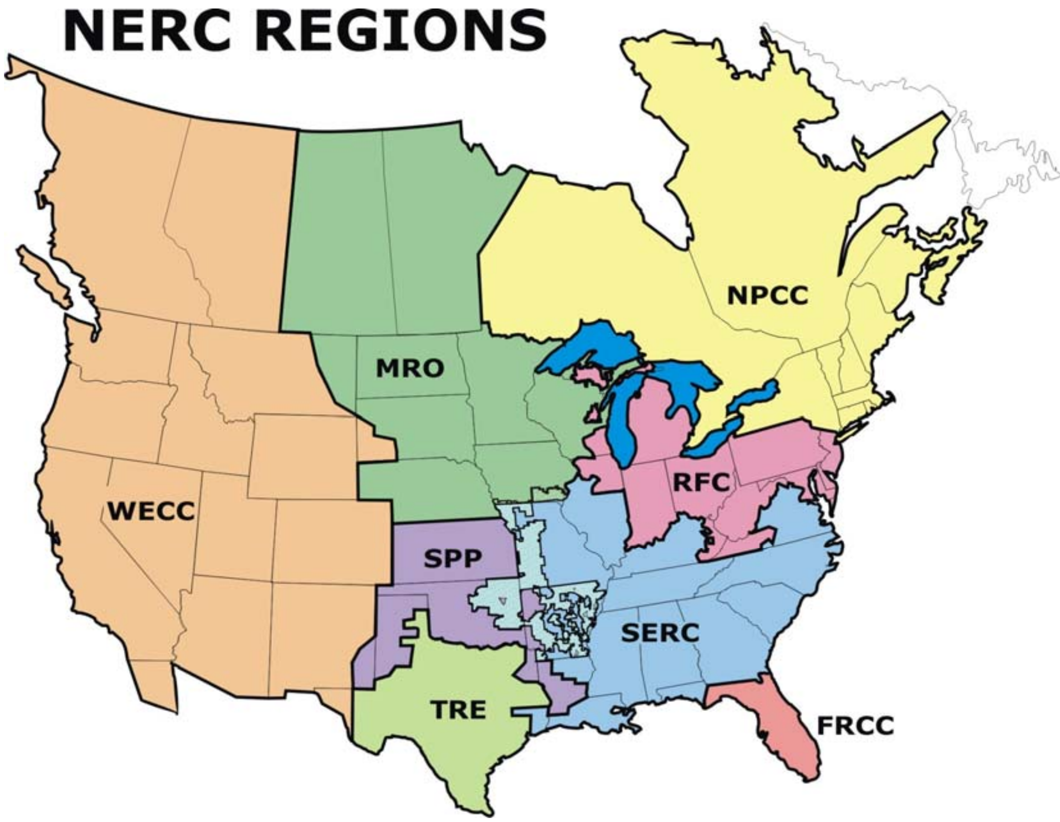


[1] Thirteen Western states and provinces are observers to the WCI but are not currently committed to a greenhouse gas reduction target. More information about the WCI is available at www.westernclimateinitiative.org

In September 2008, the Western Governor's Association engaged Energy and Environmental Economics, Inc. (E3) to investigate the potential for 'leakage' of greenhouse gas emissions from the electricity sector under the WCI. In greenhouse gas regulation terminology, 'leakage' in the electricity sector refers to the potential for a shift in electricity generation from sources in GHG regulated jurisdictions to jurisdictions without such regulation. Leakage from the regulated regions can undermine the cap and trade market by distorting actual emissions levels and providing incentives to shift, rather than reduce, GHG emissions.

The potential for leakage exists because not all of the states and provinces that WCI jurisdictions can trade electricity with have adopted GHG caps that are equivalent to the WCI GHG cap. In the North American Electric Reliability Corporation (NERC) Regions, such as the Western Electricity Coordinating Council (WECC) (where the majority of the WCI states and provinces are located), or the Northeast Power Coordinating Council (NPCC) (where Ontario and Quebec are located), electricity moves relatively freely across the system. Figure 2 shows that many of the states and provinces in the WECC and NPCC regions are not Partners in the WCI (WCI Partners are shown in blue in Figure 1). Therefore, to assess leakage potential, we evaluate how well the proposed WCI regulations would track GHG obligations associated with electricity flows between WCI and non-WCI states and provinces.

Figure 2. North American Electric Reliability Corporation Regions[2]



To perform the WCI leakage analysis, we make use of the detailed 2020 WECC system dispatch simulation completed in early 2008 for the California Public Utilities Commission (CPUC), the California Energy Commission (CEC), and the California Air Resources Board (CARB). This earlier modeling effort sought to analyze California's greenhouse gas policy options in the electricity sector. Using the generator dispatch and CO_2 emissions data from that modeling work, we were able generate estimates of the potential for leakage among the Western WCI members.[3] E3 did not have similar data available for Manitoba, Ontario, or Quebec, so these Partner provinces are not included in the analysis. This summary report provides an overview of the analysis performed for the WCI and presented to the WCI Electricity Subcommittee Technical Working Session in Salt Lake City, Utah on October 16th, 2008.

[2] Image source: http://www.nerc.com/page.php?cid=1|9|119

[3] E3 performed the original modeling work, on which this WCI analysis is based, for the CPUC and CARB under the CEC and CPUC's Joint-Agency Rulemaking on Greenhouse Gas Regulatory Strategies in California (CPUC R.06-04-009/CEC #07-OIIP-1). Documentation of this work is available on the E3 website at: http://www.ethree.com/CPUC_GHG_Model.html

1.1 WCI Electricity Sector Design Recommendations

Since its launch in February 2007, the WCI Partners have been working to design a comprehensive greenhouse gas emissions reduction plan. On September 23rd, 2008, the WCI released proposed reporting standards for emissions and design recommendations for a cap and trade emissions reduction scheme. The Design Recommendations suggest that electricity sector emissions generated within WCI Jurisdictions, and emissions from electricity generated outside of the WCI that is delivered to a WCI Partner Jurisdiction for consumption in the WCI, should be included in the WCI regulatory approach.

The Design Recommendations also state that for the electricity sector, the point of regulation is the First Jurisdictional Deliverer (FJD). The FJD is defined in the following way: "For sources within WCI jurisdictions the FJD is the generator. For power that is generated outside the WCI jurisdictions (or generated by a federal entity or on tribal lands) for consumption within a WCI Partner jurisdiction, the FJD is the first entity that delivers that electricity over which the consuming WCI partner jurisdiction has regulatory authority."[4]

To understand how FJD might become operational in the WCI it is useful to define several key terms.[5] These are 1) specified imports, 2) unspecified imports, and 3) a deemed emissions rate.

- *Specified imports:* Electricity imports into WCI jurisdictions whose CO_2 content is known and claimed by the FJD. These imports are called 'specified' because they are designated by the deliverer as originating from a specific generator.
- *Unspecified imports:* Electricity imports whose source is not known, such as purchases from a non-WCI trading hub, and thus whose CO_2 obligation is not

[4] Western Climate Initiative, September 23rd 2008, "Design Recommendations for the WCI Regional Cap-and-Trade Program," Section 2.2, pg. 3. Available at: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F20432.PDF

[5] For additional background, see the November 10th 2008, "Straw Proposal on Reporting GHG Emissions Associated with Electricity Imported from non-WCI Jurisdictions." Available at: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F20477.pdf

known. These imports may also be referred to as market purchases or power pool purchases.

- *Deemed emissions rate:* The CO_2 emissions rate (CO_2 per MWh) applied to unspecified imports into the WCI. The WCI Partners have not yet decided how a deemed emissions rate might be selected and implemented in the WCI.

This report takes the WCI Design Recommendations as a starting point, and seeks to quantify the leakage potential under different regulatory scenarios. The regulatory scenarios analyzed in this report are used as a means of analyzing some of the important considerations regarding the implementation of FJD to reduce leakage. The report also highlights some of the important design choices for an FJD point of regulation which are still under development by the WCI partners, such as considerations in setting the deemed emissions rate for unspecified electricity imports into WCI Jurisdictions and the importance of tracking coal generation located outside of the WCI which delivers power into WCI jurisdictions.

2 Research Questions

To understand the potential challenges to implementing and enforcing an environmentally rigorous cap and trade program in the WCI electricity sector, we identify three key, related issues: 'coverage', 'shuffling' and 'leakage'. Together, these concepts address important electricity sector considerations for developing a cap and trade program.

'Coverage' is measured as the share of emissions attributable to WCI consumption that is captured by the market design. Thus, the key question we investigate related to coverage is:

- How well does the WCI system cover the actual CO_2 emitted by the electricity sector associated with electricity consumption in WCI Jurisdictions?

Higher coverage is reflective of a more comprehensive GHG regulatory strategy. The key determinant of coverage in the electricity sector is the treatment of emissions generated outside the WCI but delivered into a WCI jurisdiction. After assessing the coverage of different regulatory strategies, we then consider the potential for contract 'shuffling.'

Shuffling is defined as an action that reduces regulated CO_2 obligations without any actual change in power plant operations or reduction in actual emissions. Contract shuffling is basically an accounting problem. Because generators in the WCI will be regulated at the source, contract shuffling is limited to changes in the attribution of the sources of power imported from non-WCI locations. An example of contract shuffling would be if the obligation for CO_2 emissions from a non-WCI coal plant could be shifted from a WCI jurisdiction to a non-WCI jurisdiction, without actually reducing the emissions from the coal plant. For example, the Deliverer of the energy from a non-WCI coal plant to a WCI Partner state may sell the energy from the coal plant to a non-WCI load serving entity (LSE) and then buy energy from a non-WCI hydro facility to deliver to the WCI. The key question regarding contract shuffling is:

- What is the potential to reduce the amount of CO_2 accounted for in the WCI by changing power contracts and power sales, without actually changing total CO_2 emissions?

The third potential source of problems with electricity sector GHG regulation is 'leakage.' Leakage is defined as a shift in power plant operations or investment from WCI to non-WCI jurisdictions, which reduces WCI CO_2 emissions while increasing non-WCI CO_2 emissions. An example of this would be if a coal-fired generator were built outside of the WCI jurisdictions in order to serve WCI electricity demand, and then delivered electricity to the WCI without incurring the full CO_2 obligation associated with the coal generation. We identify two related questions to investigate with regard to leakage:

- What is the potential to change *generator operations* to shift CO_2 emissions from the WCI to non-WCI jurisdictions?
- What is the potential to change *new generation investment* choices to shift CO_2 emissions from the WCI to non-WCI jurisdictions?

3 Analysis Approach

There are many possible analytic approaches which could address the four research questions described above. In this project, we sought to build on prior analysis which E3 performed for the CPUC and the CARB in 2007 and 2008 to analyze California's greenhouse gas policy options in the electricity sector. For the CPUC and CARB project, we developed a 2020 forecast of generation, CO_2 emissions and transmission flows based on the results of a production simulation dispatch model, called PLEXOS.[6] The PLEXOS model uses a least-cost, constrained dispatch algorithm to simulate how generators in the WECC would likely operate in 2020. PLEXOS contains a full model of generators in the WECC and the WECC high voltage transmission system, and provides hourly energy flows across each major transmission line in the WECC.

Using the PLEXOS results, we were able to estimate the generator dispatch, emissions levels, and the imports and exports between major WECC 'zones' based on estimates of 2020 generation, loads, forecasted fuel costs and variable costs. This strategy to leverage existing modeling work allowed this WCI leakage analysis to be completed within a one-month time frame. However, this strategy also means that the analysis was limited by the availability of pre-existing modeling data. The data used in this analysis is based on a single snapshot of forecast generation and transmission in 2020 in the WECC and Manitoba, Ontario and Quebec are not included in the analysis. In addition, we were not able to apply differential CO_2 prices in WCI versus non-WCI jurisdictions to estimate how different CO_2 prices or fuel prices would affect the generator dispatch.[7] However, we believe that our findings are robust across reasonable ranges of natural gas and CO_2 prices, and that the PLEXOS data is useful to apply for the purposes of this analysis.

The results of the PLEXOS generator dispatch simulation allow us to estimate the energy production for each generator in the WECC. Figure 3 below shows the percentage of energy generated by fuel-type for generators located in WCI and non-WCI jurisdictions. As the figure shows, 16% of the energy produced by generators located in the WCI use coal, and over 50% of the non-WCI's generation is expected to come from coal. This is significant for GHG regulation, because coal-fired generation produces approximately twice the CO_2 emissions per MWh as natural gas-fired generation.

[6] More information on the PLEXOS software and analysis team is available at http://www.plexossolutions.com/

[7] In the model, natural gas and coal prices are based on forecasts from March 2008 NYMEX forward price data. 2020 California natural gas prices are forecast at $7.85/MMBtu and 2020 coal prices are forecast at $1.01/MMBtu in real 2008 dollars.

Figure 3. 2020 Generation by Fuel Type in WCI and Non-WCI Jurisdictions (including tribal land located in WCI states) within the Western Electricity Coordinating Council

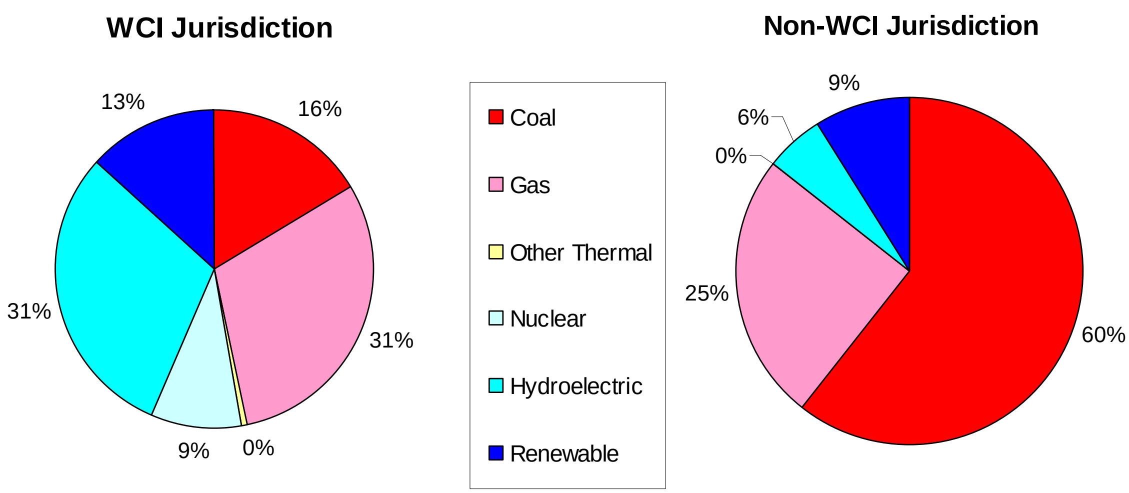


Table 1 below shows the same data as Figure 3 above, but shows actual generation in terms of 2020 forecasted energy (GWh). The coal generators located on tribal lands include Navajo, Four Corners and the proposed Desert Rock coal plant, which is projected to be operational by 2020. Although these generators are physically located within Arizona and New Mexico, which are both WCI Partner states, regulation of the emissions from these generators would not fall within the purview the WCI because they are located within Native American reservations.

Table 1. 2020 Generation by Fuel Type in WCI and Non-WCI Jurisdictions within the Western Electricity Coordinating Council

Regulation at the Source
Generation (GWh)

	WCI	Non-WCI	Tribal Lands	TOTAL
Coal	126,675	146,510	42,556	*315,741*

4 Coverage Results

Before evaluating the potential for contract shuffling or leakage, it is important to first understand how much of the WCI's electricity sector emissions would be covered under different regulatory regimes. As discussed above, 'coverage' is measured as the share of CO_2 emissions attributable to WCI consumption that is captured by the market design.

4.1 Approach

In this section we address the question: "How well does the WCI regulatory system cover the actual CO_2 emitted by the electricity sector associated with electricity consumption in WCI states?" Since the details of the FJD point of regulation are still under development, it is not possible to answer this question will full certainty. Therefore, we bound the problem by estimating two book-ends, representing the amount of emissions which would be covered under two different regulatory approaches. We then discuss how coverage under the WCI-proposed FJD regulatory approach could vary, depending on the ultimate FJD rules. The 'book-ends' of emissions coverage evaluated here represent two regulatory scenarios:

- *The 'source-based' point of regulation*. A source-based point of regulation is defined as a regulatory approach that only covers emissions from generators which are physically located within the WCI. The source-based approach would not regulate any emissions associated with imported electricity. Because the source-based point of regulation does not regulate imported electricity, it is the low 'book-end' in the analysis.

- *The 'consumption-based' point of regulation*. We define a consumption-based point of regulation as an approach which would account for the emissions from all generators producing electricity for consumption within the WCI. Thus, in this approach, the physical location of the power plant is not important. Since it is impossible to actually track electrons from a power point to the load source, the consumption-based regulatory approach is a theoretical construct rather than an actual regulatory strategy. In this analysis we approximate a consumption-based approach by using known utility contract and ownership data to assign emissions to loads. This approach is imperfect, because we do not have complete

> information about all contracts and generator ownership – many of these contracts are confidential, and many contractual relationships will change by 2020. Thus, the consumption-based emissions estimate represents our best estimate of the actual emissions associated with electricity consumption in WCI Partner jurisdictions. The consumption-based analysis results in a higher estimate of WCI electricity sector emissions because it includes the estimated carbon content of imported electricity.

Developing an estimate of the source-based emissions is a fairly straightforward accounting task which simply requires assigning generators to WCI and non-WCI jurisdictions based on their physical location. In contrast, developing the consumption-based emissions estimate requires some research into the individual contracts and ownership of generators by LSEs.[8] The main focus of this research on generator contracts and ownership was to correctly assign the coal generators to WCI and non-WCI jurisdictions for the purpose of assessing regulatory coverage, contract shuffling and leakage potential. This research revealed that currently, nearly every coal generator in the WECC is owned or directly contracted by a utility. In other words, there is currently very little unspecified coal generation in the WECC power pool. This finding is significant because if WCI FJD regulations could successfully track these coal contracts, the integrity of the WCI GHG cap could be improved. The implications of this finding will be discussed in more detail in the sections 5 and 6 of this report.

A secondary focus was to assign hydroelectric, renewable, and nuclear generation to WCI and non-WCI jurisdictions. E3 did not attempt to assign specific natural gas generators directly to jurisdictions in this analysis; instead, natural gas CO_2 emissions were treated as a 'residual' and the average natural gas mix was assigned to the remaining load in each region after the coal, hydro, nuclear, and renewable generation was assigned.

For example, in the consumption-based approach, if an LSE which operates in California owns a percentage of the output of a coal plant located in Utah, that share of the coal plant's CO_2 emissions would be assigned to the California load serving entity. As another

[8] A spreadsheet containing E3's assumptions about the assignment of generators to load serving entities and states is available on the E3 website at: http://www.ethree.com/E3_Public_Docs.html

example, if a load serving entity's service territory spans both WCI and non-WCI states, the emissions from the LSE's generators would be assigned to the WCI and non-WCI states proportionally to their load in both jurisdictions under a consumption-based regulatory approach. Under a source-based approach, only the physical location of the generators would matter, not the utility service territory.

The ratio of the source-based emissions to the consumption-based emissions provides an estimate of the percentage of the total WCI electricity sector emissions which would be covered by a source-based regulatory approach.

4.2 Findings

Our analysis suggests that if the CO_2 associated with the imports of electricity were not regulated, as would be the case under a source-based point of regulation, approximately 74 percent of the electricity sector's emissions would be covered by the WCI in 2020. This estimate is based on the ratio of the emissions which would be covered under a source-based point-of-regulation (216 million metric tons (MMT) of CO_2), to the emissions which would be covered by a consumption-based point-of-regulation (293 MMT of CO_2).[9]

Table 2 and Table 3 below represent the 2020 estimated CO_2 emissions of WCI and non-WCI jurisdictions based on the source-based emissions accounting approach and the consumption-based emissions accounting approach.

Table 2. 2020 Greenhouse Gas Emissions by Jurisdiction Based on Accounting for Emissions at the Source

Regulation at the Source
MMT CO2

	WCI	Non-WCI	Tribal Lands	TOTAL
Coal	122	145	41	*309*

Other	4	0	*4*
TOTAL	*293*	*139*	*432*

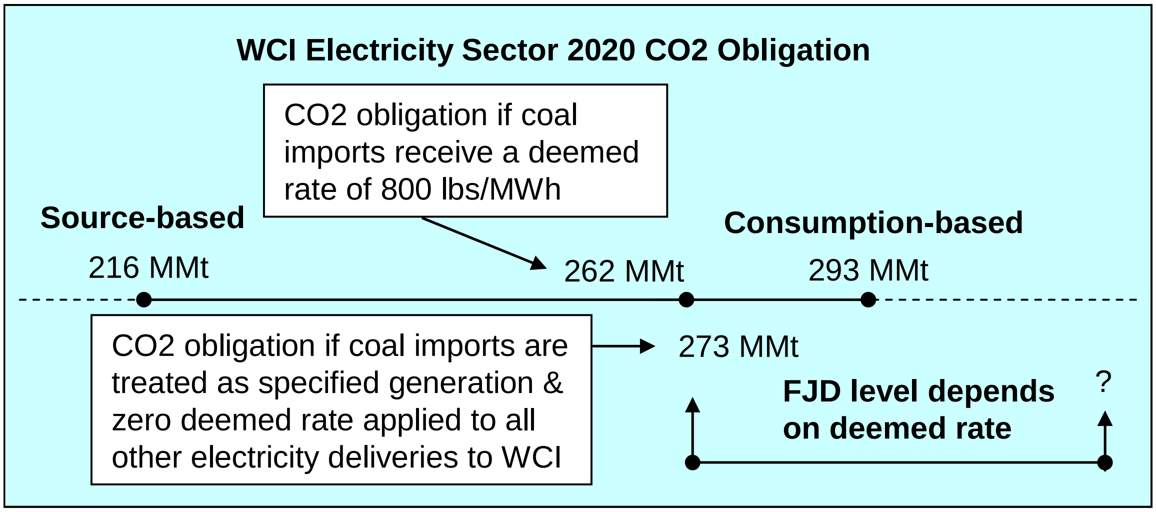
The WCI-recommended approach of applying the FJD point-of-regulation could result in a coverage level which is close to the consumption-based emissions estimate. How close the FJD coverage level ultimately is to a consumption-based emissions level will depend on the rules for FJD which are ultimately adopted, including the deemed emissions rate applied to unspecified imports and the treatment of non-WCI coal generation which is delivered into the WCI.

Figure 4, below, compares the CO_2 obligation under a purely source-based approach versus a consumption-based approach, and highlights the importance of the deemed emissions rate for unspecified power in determining the level of coverage achieved by the WCI. If the deemed rate is set to zero, and all coal imports are regulated as specified generation, then the coverage improves from 216 MMT CO_2 to 273 MMT $CO_{2.}$

If the deemed rate is set close to the ‘actual’ average emissions intensity of unspecified generation, which currently is mostly natural gas-fired generation, the FJD approach could approach the theoretical consumption-based emissions coverage level. It is important to note that the emissions intensity of unspecified generation will vary by hour and by region. Therefore, it is not possible to select a single, fixed deemed emissions intensity rate which will always result in the same emissions obligations to all Deliverers as the consumption-based approach.

Also, recall that currently nearly all coal-fired generation represents specified power. Whether this remains true going forward will depend, in part, on how FJD regulations are constructed to track existing coal ownership and coal contracts. However, even under the best regulatory strategy, it may not be possible to guarantee that currently specified coal generation will remain specified power in the future. If specified coal generation switches to unspecified power by operating in a merchant generation mode, for example, this could reduce the electricity-sector coverage of the WCI system, and increase the challenges surrounding the deterrence of GHG leakage and shuffling.

Figure 4. Estimate of the Emissions of the WCI Electricity Sector in 2020 Based on Different Regulatory Approaches



To demonstrate how the deemed emissions intensity of the FJD approach could result in different levels of emissions coverage, consider two possible cases.

1) In case 1, all coal contracts and coal ownership contracts with utilities serving WCI load are known. If it were possible to track all of the emissions from these specified coal power plants, their power deliveries to the WCI could be tagged with their actual emissions intensity. The remaining, unspecified electricity deliveries into the WCI would face a deemed emissions rate. If the deemed rate is zero, the resulting WCI electricity sector CO_2 obligation would be 273 MMT CO_2. This is 20 MMT lower than the more accurate consumption-based approach, but still significantly improved over the source-based regulatory approach. Here, 93% of the GHG emissions from the electricity sector are covered under the WCI, compared to the consumption-based theoretical maximum. At a deemed emissions rate closer to 800 or 900 lbs/MWh for unspecified system power coverage will approach 100% of the consumption based theoretical maximum, assuming coal contracts can be separately tracked and tagged with their actual emissions rate.

2) In case 2, specified coal ownership and contracts of out-of-state coal generators ***cannot*** be tracked. In this case, all coal power delivered to WCI jurisdictions would receive a

deemed emissions rate instead of their actual emissions rate. For purposes of this example, if a deemed rate of 800 lbs/MWh were applied to all coal-fired power delivered to the WCI, coverage would decrease by 31 MMT CO_2. Thus, the total coverage of the WCI system would be reduced to 262 MMT CO_2. In this scenario, coverage would be approximately 89% of the theoretical ideal of the consumption-based approach. Another possibility, if specified coal contracts cannot be tracked, is to set the deemed CO_2 emissions rate closer to that of a conventional coal plant (eg. 2,200 lbs CO_2/MWh). In this case, deliveries of power into the WCI from natural gas generation with lower emissions intensities would most likely switch to specified generation to avoid being assessed at the higher deemed emissions rate. In addition, market purchases with unknown origin would receive the emissions rate of coal, most likely driving power out of the market pool and into specified power contracts. This could decrease market liquidity. With a deemed emissions rate of 2,200 lbs CO_2/MWh coverage of the WCI system would be high, although the extent of coverage under this system would depend on power marketers behavior in response the high deemed rate.

These scenarios demonstrate that coverage can be greatly improved by tracking, to the extent possible, emissions from specified generation, especially of existing non-WCI coal generation that is delivered into the WCI. The deemed emissions rate could then be used simply to improve coverage of the remaining, unspecified power pool electricity deliveries, which should be mostly natural gas generation once the coal contracts are tracked separately. Conversely, if emissions from specified coal generation is not explicitly accounted for, it becomes problematic to set a single appropriate deemed rate, because both coal and gas would receive the same emissions rate despite their very different emissions profile. Setting a deemed emissions rate also reduces the incentive for contract shuffling and leakage which can affect the effectiveness of the regulatory system, as discussed in sections 5 and 6.

Figure 4, above, also shows that if the deemed rate is set too high (low), the WCI may end up with a higher (lower) CO_2 obligation than it should. On the high end, the CO_2 obligation could increase indefinitely, depending on the deemed rate, until the point at which energy deliverers find it more attractive to either 1) curtail energy deliveries, or 2) specify the source and emissions content of all electricity imported into the WCI. This outcome would have a deleterious effect on the liquidity of energy markets.

This analysis of coverage highlights the importance of accounting for the carbon content of electricity imports into the WCI to the extent it is practical to do so. The FJD recommendation seems to be an appropriate method of ensuring that the coverage of the WCI electricity sector emissions exceeds 74 percent. The coverage analysis discussed here also helps to provide some insights regarding the upper bound on the potential for contract shuffling, as discussed in the next section.

5 Contract Shuffling Results

Contract shuffling is an action that reduces regulated CO_2 obligations without any change in operations or total emissions. Since all generators located in WCI partner jurisdictions will be regulated under FJD, the potential for shuffling only exists for generators located outside the WCI. We identify two principle types of contract shuffling:

1) ***Specified power → lower-carbon, specified power:*** Emissions could be 'shuffled' from specified generation with a high CO_2 content to specified generation with a lower CO_2 content. In this case, imported power is shifted from a relatively dirty source to a relatively clean generation source. Total emissions, however, would remain unchanged. If, for example, it was possible for a WCI jurisdiction to swap some of its specified, imported power from coal to hydro or natural gas, without resulting in a change in either the coal plant or the hydro or natural gas facility's operational patterns, the emissions of the coal plant would be 'shuffled' to zero (in the case of shuffling to hydro) or effectively cut in half (in the case of shuffling to natural gas).

2) ***Specified power → lower-carbon, unspecified power:*** Emissions could be shuffled from their actual, specified generation level to the deemed emissions intensity. This would occur if previously specified generation were able to shift to unspecified generation and claim a lower, deemed emissions rate. For example, assume that a WCI jurisdiction imports power from a specified coal plant. Also, assume that the WCI jurisdiction is thus tagged with the coal plant's emissions. After CO_2 regulations are put in place, assume the WCI entity is able to eliminate this coal contract, and import unspecified power instead. This would mean that the coal plant emissions were shuffled to unspecified power at the deemed emissions intensity, assuming that the coal plant still operates as it did before the shuffling transaction.

We evaluate the potential for contract shuffling under both of these circumstances.

5.1 Approach

If there were no limits on contract shuffling, all electricity imports from a non-WCI jurisdiction to a WCI-jurisdiction could theoretically be shuffled to zero emissions. This situation would result in emissions coverage equivalent to the source-based point-of-regulation, where electricity imports are not regulated. In this case, up to 77 MMT of CO_2 could be shuffled, or 26 percent of the WCI electricity sector CO_2 obligation, as seen in Table 4 below.

Table 4. Unconstrained Contract Shuffling Potential

MMT CO2

	WCI States	Non-WCI States	Change in CO2
Coal	57	-57	*0*
Gas	20	-20	*0*
Other	0	0	*0*
TOTAL	*77*	*-77*	*0*

5.1.1 Shuffling to 'Specified' Zero-Carbon Emissions

However, appropriate regulatory structures could limit contract shuffling, making the unconstrained shuffling case unrealistic. For contract shuffling to occur, two criteria must be met:

1) A CO_2-emitting generator which is not physically located in the WCI, but which directly serves WCI load (through ownership or contractual obligation), must be able to avoid CO_2 regulation; and

2) A cleaner generator, which is not physically located in the WCI and which does not directly serve WCI load (through ownership or contractual obligations) must be able to claim it is exporting specified power into the WCI.

If both of these criteria are met, it is possible for contract shuffling to occur. A WCI Partner jurisdiction could claim that, over time, more of its imported power comes from specified, low-carbon sources, while more of the non-WCI load is served by high-carbon generation. This is despite the fact that no actual reduction in emissions has occurred.

One of the most significant sources of low-carbon generation, which could be a candidate for shuffling, is hydroelectric power. Nearly 20,000 GWh of hydroelectric power is located within the non-WCI Western States and Provinces. However, the vast majority of this power is not available to be used for contract shuffling because of existing contractual obligations and restrictions on the resale of federal hydro allocations.[10] Table 5 below shows the amount of hydroelectric energy which is located within or currently contractually-obligated to non-WCI jurisdictions.

Table 5. Hydroelectric generation in the non-WCI states in the WECC (GWh/year)

Hydroelectric Generation (GWh)

	AB	CO	ID	WY	TOTAL
Federal Hydro	0	1984	3667	1279	6929
Non-Federal Hydro	2051	1380	9386	577	13394
Total	*2051*	*3364*	*13053*	*1855*	20324

In the worst-case contract shuffling scenario, specified coal power which is currently imported into the WCI would be shuffled to a zero-carbon source, such as hydroelectric power. If this scenario were to occur, 20 MMT of CO_2 could be shuffled and could effectively avoid regulation under the WCI. However, if it were not possible to use Federal hydroelectric power for contract shuffling purposes, the potential for shuffling

[10] This report does not provide a legal interpretation of the regulations surrounding the re-sale of federal hydropower. However, we do note that, in general, re-sale of federal hydropower is discouraged. The Western Area Power Administration (WAPA), which oversees a large share of the federal hydropower in the West, requires as part of its General Power Contract Provisions (Section 4, para. 17) that, “The Contractor shall not sell any firm electric power or energy supplied under the contract to any electric utility customer of the Contractor for resale by that utility customer.” Similar provisions apply to the Bonneville Power Authority (BPA) administered federal power. The Bonneville Power Act of 1937 amended the U.S. code, §16USC832d(a), to read, “Contracts for the sale of electric energy to any private person or agency other than a privately owned public utility engaged in selling electric energy to the general public, shall contain a provision forbidding such private purchaser to resell any of such electric energy so purchased to any private utility or agency engaged in the sale of electric energy to the general public, and requiring the immediate canceling of such contract of sale in the event of violation of such provision.” BPA is authorized to sell “unused excess power” under certain conditions as described in U.S. code, §16USC832m(b).

from coal to hydro power would fall to only 13 MMT of CO_2. If it were not possible to use other non-Federal hydroelectric power for shuffling, due to careful tracking of ownership and contractual obligations, contract shuffling potential would fall even further. Table 6 below shows the worst-case scenario for contract shuffling, in terms of CO_2 shuffled from coal power to hydro power, in each of the non-WCI states and provinces in the WECC. As the table shows, even in this unlikely circumstance, the contract shuffling potential using hydroelectric power is fairly limited.

Table 6. Maximum Shuffling Opportunity for non-WCI Hydro in the WECC (MMT CO_2/year)

MMT CO2

	AB	CO	ID	WY	TOTAL
Federal Hydro	0	2	4	1	7
Non-Federal Hydro	2	1	9	1	13
Total	2	3	13	2	20

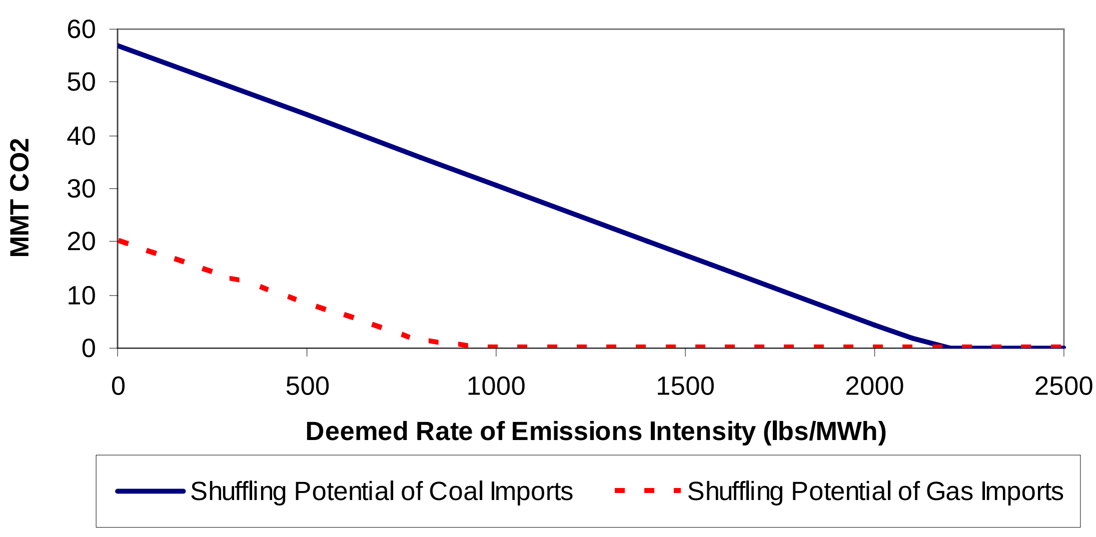
The only other sources of zero-carbon generation which could be used for contract shuffling to specified sources are nuclear or renewable energy generators. However, all nuclear generators in the WECC are located in WCI (see Table 1), thus limiting the potential for using nuclear energy for contract shuffling. Unspecified, non-WCI renewable energy could also be used for shuffling. However, we expect that most of this generation is specified for compliance with state renewable portfolio standards (RPS), thus limiting the potential for using renewable energy for contract shuffling as well. While we don't have data regarding what percentage of renewable generation is currently specified, or will be specified in 2020, the fact that nearly every state in the WECC has an RPS target which has not yet been met implies that renewable generation should remain a valuable source of specified power.

5.1.2 Shuffling to 'Unspecified' Emissions

The other type of shuffling potential which we evaluate is the possibility of shuffling emissions from specified power to 'unspecified' power. As discussed in Section 1.1, under the FJD regulatory approach, specified imports would likely be tagged with their actual emissions. In contrast, unspecified power, would be tagged with a deemed emissions intensity. The deemed emissions rate therefore plays a central role in the incentives to shuffle from specified to unspecified power.

Figure 5 below shows how the choice of the deemed emissions rate affects the incentive to shuffle both coal and natural gas-fired generation to unspecified power. If the deemed emissions rate were set at zero, up to 57 MMT of CO_2 from coal plants could be shuffled, while 20 MMT of CO_2 from natural gas-fired generation could be shuffled. As the deemed emissions rate increases, the incentive to shuffle to unspecified power decreases for both coal and natural-gas fired generation. Once the deemed emissions rate is equal to the emissions intensity of a natural gas fired generator (approximately 800 or 900 lbs CO_2/MWh), it is no longer possible to shuffle CO_2 from natural-gas fired generation. However, at this deemed rate, over 30 MMT CO_2 of emissions from specified coal-fired generation could still be shuffled to the GHG equivalent of natural gas generation. In the absence of other regulations on coal, to eliminate the incentive to shuffle specified coal to the "deemed rate", the rate would need to be closer to 2,200 lbs CO_2/MWh. However, a deemed rate which was set this high would basically force all natural-gas fired generation into specified contracts, reducing liquidity in short-term electricity markets. Therefore, to reduce the incentive for shuffling from specified to unspecified power, the deemed emissions rate should probably be set somewhere near the emissions intensity of a typical natural gas-fired generator.

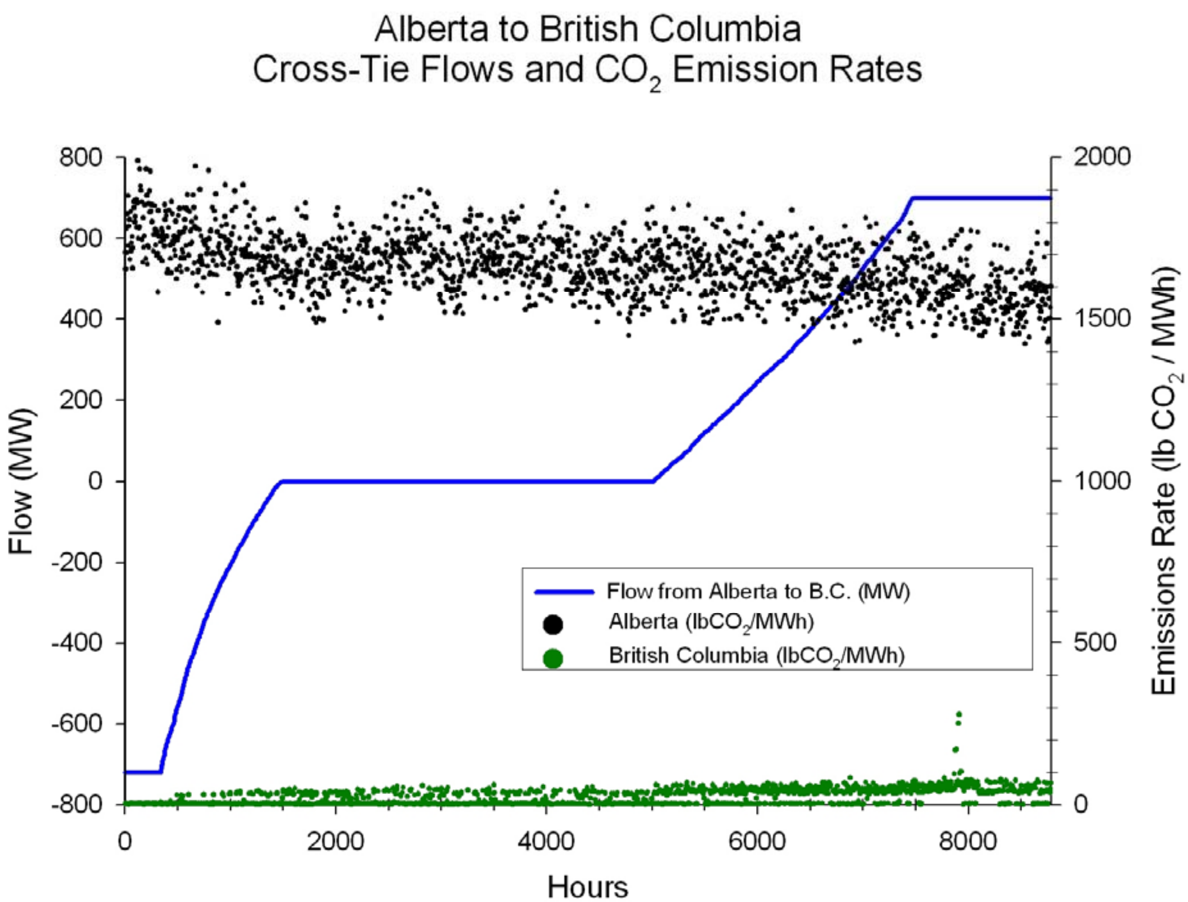
Figure 5. Shuffling Potential from Specified to Unspecified Power for Coal and Natural Gas-fired Generation as a Function of the Deemed Emissions Intensity



5.1.3 Regionally-Specific Deemed Emissions Rates

It is beyond the scope of this analysis to make recommendations regarding an optimal level for a deemed emissions rate. However, we do point out that the average emissions intensity of unspecified power is not the same in all regions of the WECC. This reality suggests that it may be worthwhile to consider establishing different deemed rates for specific non-WCI regions. Figure 6 below, for example, illustrates the simulated average hourly emissions intensity of British Columbia and Alberta over a one-year period in 2020.

Figure 6. Hourly Average Emissions Intensity of Alberta and British Columbia and the Hourly Power Flows across the Alberta-British Columbia Transmission Line



The black dots represent the average hourly emissions intensity of all generators in Alberta. As can be seen on the right-side axis, the average emissions intensity of Alberta generation varies by hour between 2,200 lbs CO_2/MWh to 1,400 lbs CO_2/MWh. In contrast, the average emissions intensity of generators in British Columbia (B.C.) is much lower, less than 200 lbs CO_2/MWh in nearly every hour of the year. The blue line represents the hourly flow of power over an Alberta-B.C. transmission line in the PLEXOS simulation. In the figure, the hourly flows are sorted from lowest to highest. Positive flows represent power moving from Alberta to B.C. The transmission line is operating at full capacity with power flows from Alberta to B.C. during approximately 1500 hours (approximately 2 months) of the year. Negative flows represent power moving from B.C. to Alberta. The transmission line is operating at full capacity with power flows from B.C. to Alberta during approximately 500 hours (less than 1 month) of the year. The rest of the year, the transmission line is not operating at full capacity, and could carry additional power transfers from one region to the other.

Figure 6 demonstrates two important points. First, since the Alberta-B.C. transmission line is not currently utilized at full capacity for most hours of the year, it would be possible to import additional power to B.C. from Alberta. Secondly, the average emissions intensity of Alberta is much closer to that of a coal-fired generator than a natural-gas fired generator. This implies that it may be appropriate to consider setting the deemed emissions rate for imports from Alberta power to B.C. well above the level of a natural-gas fired generator. There may be other transmission links connecting high carbon intensity, non-WCI jurisdictions to WCI jurisdictions to consider when establishing deemed emissions rates. As a starting point, a CPUC straw proposal suggests creating deemed emissions factors that are disaggregated by the following major geographic zones: Alberta, Western U.S. (NV, ID, WY, and CO), Mexico, central U.S./Canada (MN, ND, SK), and northeastern U.S.[11] More research into the issue of regional deemed factors may be warranted.

5.2 Findings

The potential for contract shuffling among the Western members of the WCI is relatively limited if an FJD point of regulation is pursued and specified power contracts are tracked

[11] See the November 10th 2008, "Straw Proposal on Reporting GHG Emissions Associated with Electricity Imported from non-WCI Jurisdictions." Available at: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F20477.pdf

and reported. Tracking specified generation imports seems to be an important component of creating a solid WCI regulatory regime. This implies that reporting rules should probably be developed which focus on tracking and accounting for specified coal-fired generation.

In addition, applying a deemed emissions rate to unspecified electricity delivered to WCI Partner jurisdictions (for consumption in the WCI) eliminates the incentive to shuffle emissions from all generation that has an emissions rate less than or equal to the deemed rate. Contract shuffling is further limited if hydroelectric generation under Federal control is not available for contract shuffling due to the rules governing the use of Federal hydroelectric power which restrict resale of delivered energy (see footnote 10 for an elaboration on this point). Finally, special consideration of how to regulate electricity delivery on some WCI-to-non-WCI transmission paths may be warranted, including the development of separate regionally-specific, or transmission path-dependent, deemed emissions rates.

6 Leakage Results

Leakage from the electricity sector is defined as a shift in generation which reduces WCI CO_2 emissions while increasing non-WCI CO_2 emissions. We identify two principal types of electricity sector leakage:

1) A change in power plant operations, such that generation in non-WCI jurisdictions increases and generation in WCI jurisdictions decreases.
2) A shift of new power plant investment into non-WCI jurisdictions as a means of generating more power for import into the WCI without incurring all of the CO_2 obligations.

Unlike contract shuffling, which results in a reduction in CO_2 emissions in the regulated jurisdiction on paper only, leakage could potentially increase total WECC-wide emissions even as reported WCI emissions drop.

6.1 Approach

In order for leakage to occur <u>due to a change in the operations</u> of existing power plants, two criteria must be met:

1) Non-WCI generators must have the capacity to increase their output.
2) The transmission ties from WCI to non-WCI jurisdictions must have available capacity to import additional power.

In order for leakage to occur <u>due to a change in investment</u> in new power plants two criteria must be met as well:

1) The transmission ties from WCI to non-WCI jurisdictions must have available capacity to import additional power.
2) The new generation (resulting from new investment) must be sold into the WCI either as:
    a. unspecified power at a deemed emissions rate which is lower than the generator’s actual emissions rate, or

b. specified generation at a deemed emissions rate which is lower than the generator's actual emissions rate. The barriers to shuffling, discussed above, would also apply in this case.

Fortunately, there are natural limits to leakage, which combined with appropriate regulatory design of the FJD rules, could reduce the potential for leakage.

6.1.1 Leakage Resulting from a Change in Existing Power Plant Operations

We first consider leakage resulting from a change in power plant operations. The next two figures provide some indication of the potential for this type of leakage. Figure 7 shows the coal-fired generators located in the WECC; non-WCI coal plants are indicated with blue triangles. As might be expected, all of these coal-fired generators are operating at a capacity factor above 80 percent, which is near the technical limit of a coal plant. This means that there is little possibility for leakage to occur due to an increase in existing coal-fired power plant generation.

Figure 7. Available Capacity among Coal-Fired Generators in the WECC

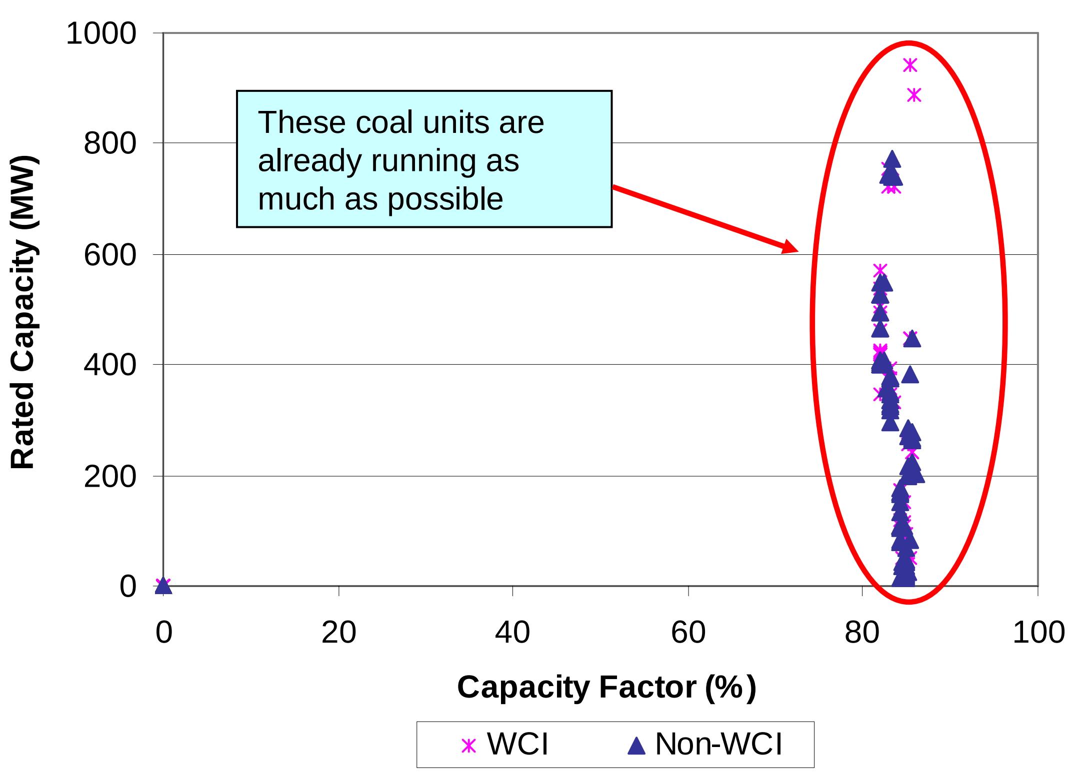


Figure 8 shows the combined-cycle natural gas units located in the WECC; the units located outside the WCI are indicated with blue triangles.[12]

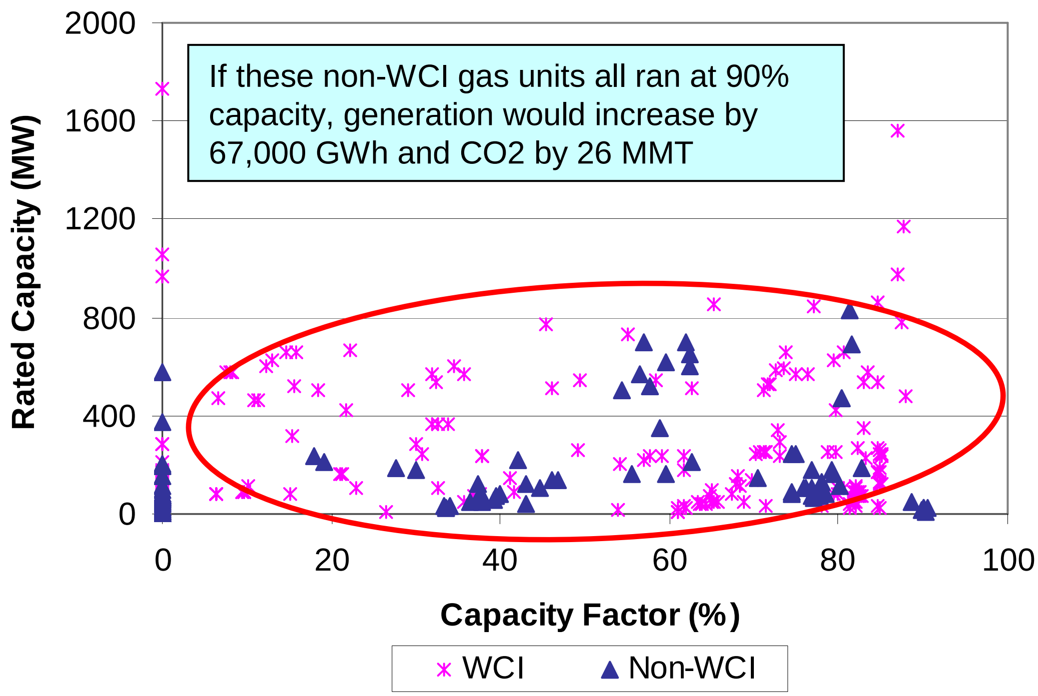
Figure 8. Available Capacity among Combined-Cycle Natural Gas Generators in the WECC



Many of these combined cycle gas turbines (CCGT) are not operating at their full technical potential, which for most units is probably close to a capacity factor of 90 percent. Therefore, leakage could occur by increasing the hours of operation of existing non-WCI combined cycle gas units and backing down natural gas generation in WCI jurisdictions. In the extreme case, if all of the non-WCI CCGT units increased their hours of operation to a 90 percent capacity factor, replacing zero-carbon generation, emissions could increase by 26 MMT of CO_2. However, in order for these emissions to 'leak', there would need to be a way to import this natural-gas power into the WCI without counting all of the associated emissions towards the WCI's emission obligation. If the deemed emissions rate for unspecified power were set near the emissions intensity of a combined-

[12] The figure does not include combustion turbines which would be used for peaking power.

cycle natural gas unit, the potential for leaking these 26 MMT of CO_2 could be nearly eliminated.[13]

6.1.2 Leakage Resulting from a Change in Power Plant Investment

This section investigates the question of whether GHG regulation in the WCI could increase the economic incentive to build new fossil generation in non-WCI jurisdictions as a means of avoiding CO_2 regulation. We consider the economics of building a coal plant in the WCI compared with the economics of building a coal plant in non-WCI jurisdictions as a means of illustrating the worst-case scenario for this form of leakage. We do not consider the case of leakage due to new investment in natural gas fired generation in non-WCI jurisdictions. The example presented here would look similar for the new natural gas generator case. In addition, if the deemed emissions rate were set near to the emissions intensity of natural gas fired generation this would basically eliminate the incentive for leakage through new natural gas fired generation.

There are three cases of new, non-WCI coal generation investment which are worth considering in this analysis:

1) The coal developer could sign a long-term contract with a load-serving entity in the WCI. In this case, there would be no potential for leakage if the FJD emissions reporting rules tracked this contract as specified generation.

2) The coal developer could sell the new generation into the WCI as unspecified (system) power. In this case, the FJD deemed emissions rate would apply.

3) The coal developer could sell its power to a non-WCI entity, and thus free-up other low-carbon generation for sale into the WCI. This case would reflect a combination of leakage and shuffling.

Cases 2 and 3 above represent a leakage potential. There are three key variables which drive the new-generation investment economics in these two cases: 1) the price of

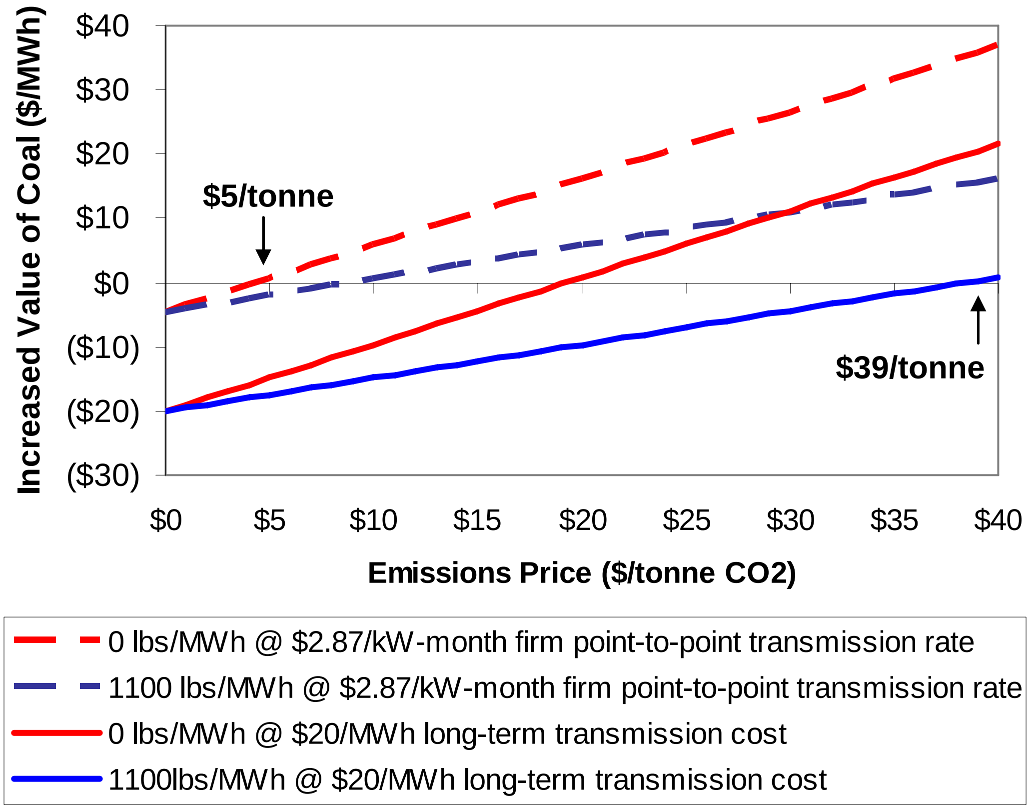
[13] The emissions intensity of combined cycle natural gas turbines varies slightly among units, and can also vary by temperature, so there is not a single emissions rate which would be applicable to all natural gas units in the WECC. Also, note that we have excluded combustion turbines (CTs) from this leakage analysis, under the assumption that CTs are used for load following and local capacity and not for energy needs.

transmission from a non-WCI to a WCI jurisdiction, 2) the deemed emissions rate for unspecified power, and 3) the price of CO_2 emissions in the WCI.

Figure 9 below demonstrates how changes in these three variables impact the economic incentive for leakage through new investment in a coal-fired generator in a non-WCI jurisdiction. The vertical axis represents the incremental, or additional economic incentive, in terms of dollars per MWh, to build a non-WCI coal plant for the purposes of importing the power into the WCI. When the incremental value of coal ($/MWh) is positive, this indicates that there would be an economic *incentive* to build the power plant. When the incremental value of coal ($/MWh) is negative, there is an economic *disincentive* to build the new power plant. The dotted lines represent scenarios where transmission costs are assumed to be lower compared to the scenarios represented by the solid lines.[14] Here, we have selected two typical, indicative transmission costs for illustrative purposes. Actual transmission costs will vary by region and by the specific circumstances of the new generator.

[14] In this example, we assume that the cost of construction for a new coal plant is identical in WCI and non-WCI jurisdictions.

Figure 9. Incremental Economic Incentive to Build New Coal-Fired Generation Outside the WCI, as a Function of Transmission Price, CO_2 Price and the Deemed Emissions Intensity (0 lbs CO_2/MWh or 1,100 lbs CO_2/MWh)



As can be seen, higher transmission costs reduce the incentive for leakage through new generation investment. Likewise, a higher deemed rate for unspecified power reduces the economic incentive for building new generation in non-WCI jurisdictions. This is because power deliverer of the new coal generation, if selling unspecified power, will face a higher emissions burden as the deemed rate increases. In contrast, as the price of CO_2 emissions in the WCI increases, the economic incentive to build new generation in non-WCI jurisdictions increases. This is because under this leakage scenario, the power generated in a non-WCI jurisdiction but delivered to the WCI would not face the full CO_2 price associated with its emissions.

Figure 9 shows that if there is no deemed emissions rate (0 lbs CO_2/MWh), and if the firm point-to-point transmission rate is $2.87/kW-month, then the CO_2 price in the WCI must be greater than $5/tonne CO_2 before there is an increased economic incentive for a developer to build new coal-fired generation in a non-WCI jurisdiction to serve WCI load. Under these conditions, and at a CO_2 price less than $5/tonne, the developer would be indifferent between constructing the coal plant in the WCI or outside the WCI. In contrast, if the deemed emissions rate were higher (in this example, 1,100 lbs CO_2/MWh), and if long-term transmission prices were higher (in this example, $20/MWh), then the CO_2 price would have to be much higher, above $39/tonne CO_2 in this example, before developers would face an increased economic incentive to build new coal fired generation in a non-WCI jurisdiction to serve WCI load.

If a new coal plant's emissions cannot be tracked by FJD reporting rules, we conclude that the potential for leakage due to new generation investment is limited by three key factors: 1) the price of CO_2 in the WCI (lower CO_2 prices reduce the incentive for leakage), 2) the cost of building new transmission (higher transmission costs reduce the incentive for leakage), and 3) the deemed emissions rate (higher deemed emissions rates reduce the incentive for leakage).

6.2 Findings

This section has discussed two types of leakage potential in the electricity sector: leakage due to a change in operation of existing generation and leakage due to a change in investment in new generation. The leakage potential from each is relatively limited, and may be further deterred through appropriate FJD policies regarding the treatment of electricity delivered into the WCI. However, this report does not speculate on the expected effectiveness of the FJD approach – this will ultimately depend on how the regulations are implemented and enforced.

There is very little leakage potential from existing non-WCI coal plants, since these currently operate near their maximum technical capacity. The potential for leakage due to a change in operation of natural gas fired generation could be problematic if there were no regulation of unspecified energy delivered into the WCI through a deemed rate. If the deemed emissions rate for unspecified energy were set somewhere between the emissions intensity of a coal-fired generator and a gas-fired generator, the economic incentive for leakage due to increased generation from natural gas would be drastically curtailed.

The economic incentive for leakage through new investment is limited by several factors, including the cost of transmission, the deemed emissions intensity of unspecified electricity and the CO_2 price in WCI jurisdictions. In addition, leakage from new coal-fired generation investment could be further deterred if reporting standards required tracking specified deliveries of coal-generation into the WCI, and if the standards required that specified generation receive its actual emissions rate rather than a deemed emissions rate.

The deemed rate also serves to reduce the economic incentive to build new coal generation in non-WCI jurisdictions to serve WCI load. For example, if the deemed emissions intensity for unspecified delivered energy were set at 1,100 lbs CO_2/MWh, then the CO_2 price in the WCI would need to be above $10 to $30/tonne CO_2, depending on the price of transmission access. If new transmission needed to be built to deliver new coal-fired generation into the WCI, the economic barrier to this type of leakage would be even higher. In addition, the numerous other barriers to new coal-fired generation investments further reduce the possibility of this form of leakage. Environmental opposition and limitations on water availability in the West are two examples of non-economic barriers to new coal generation.

7 Conclusions

This report has considered the coverage of the WCI's electricity sector emissions under different regulatory approaches, and concluded that the FJD approach is an appropriate way to increase coverage of electricity sector emissions. Without any regulation of emissions from electricity generated outside the WCI and delivered into WCI Partner jurisdictions, only about 74 percent of the WCI's total electricity sector emissions would be covered. Electricity sector emissions in the WCI can be increased above 74 percent depending on the choice of the deemed emissions rate and other FJD reporting rules.

The potential for contract shuffling and leakage can also be limited by effective regulatory design. FJD has the potential to greatly reduce the potential for both shuffling and leakage, especially if the deemed emissions rate for unspecified electricity deliveries into the WCI is set at an appropriate level. This report does not analyze regional emissions intensities of electricity in depth, but we suggest that WCI consider regionally-specific deemed emissions rates that reflect regional differences in generation resources.

Contract shuffling in the WCI is limited by the availability of unspecified low-carbon generation, and by the deemed emissions rate. Assuming that Federal hydroelectric generation and all renewable energy can be tracked as specified power, the potential for contract shuffling in the WCI is only approximately 13 MMT CO_2, and may be lower if other hydroelectric generation is unavailable for shuffling due to long-term contracts and ownership rights to the hydroelectric power.

The leakage potential is limited as well. There is basically no possibility of leakage through increased operation of existing coal generation, because these units already operate at full capacity. There is some potential for leakage through increased operation of existing natural gas generation, but this potential could be severely curtailed by a deemed emissions rate set near or just above the emissions intensity of a typical natural gas-fired generator. The leakage potential due to changes in investment patterns is harder to quantify, but it is limited by transmission availability, FJD rules and other non-economic factors limiting new investment in coal-generation.

In sum, the WCI-proposed approach for regulation of GHG emissions from the electricity sector has the potential to maximize emissions coverage and to limit contract shuffling and leakage. Moving forward, we recommend that the WCI Partners consider establishing a deemed emissions rate which is near or just above the emissions rate of natural gas-fired generation. As this summary report has demonstrated, this will improve coverage of the regulatory system, will reduce the economic gains of shuffling emissions to unspecified, or system power, and could eliminate the incentive for leakage to non-WCI natural gas generation, among other benefits.

We also recommend that the WCI Partners consider tracking and regulating specified imports of coal power into the WCI. Tracking specified imports of coal power both increases coverage and reduces the ability to shuffle coal-fired generation to system power or to low-carbon generation. Tracking and regulating specified coal generation could also eliminate the potential for leakage from new non-WCI coal.

Western Climate Initiative

Market Oversight
Draft Recommendations

April 1, 2010

Executive Summary

The Western Climate Initiative is a collaboration of seven US states and four Canadian provinces to reduce greenhouse gas emissions, including the design and implementation of a cap-and-trade program. The WCI is working through five committees, including the Markets Committee, to complete tasks and deliverables for implementation. Recommendations on oversight of markets for greenhouse gas allowances and offset certificates (“compliance instruments”) is among the Markets Committee’s tasks. This document provides draft recommendations on market oversight. Following public comment and continued work by the Markets Committee, the Committee will issue Final Recommendations.

The Markets Committee has used a variety of sources of information in developing its recommendations, including published reports, presentations, stakeholder comment, contact with market participants and regulators, and contracting with outside advisers. It adopted principles to guide its work and recommendations.

The Markets Committee has identified twelve items as the tools or decisions WCI Partner jurisdictions can use or make to establish effective oversight of compliance instruments. The Draft Recommendations are:

1. Treat Compliance Instruments as Commodities for Market Oversight Purposes
2. Information on Derivatives Positions
3. Treat Allowances and Offset Certificates Identically for Market Oversight Purposes
4. Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System
5. Do Not Limit Market Participation to Compliance Entities
6. Require Registration of Intermediaries as Market Professionals
7. Holdings Limits

8. Require Use of a Central Limit Order Book for Secondary Market Transactions
9. Require Reporting of Beneficial Ownership
10. Information Required for Compliance Instrument Transfer
11. Secondary Market Holdings and Transfer Information Disclosed to Public
12. Market Monitoring

In many cases, the Draft Recommendations are interrelated, and changing one could change another. Importantly, the first Draft Recommendation implies the adoption of an existing framework for regulating compliance instrument derivatives. Consequently, Draft Recommendations 3 – 12 are primarily focused on secondary markets.

In considering Draft Recommendations, the Markets Committee recognized and attempted to weigh a number of factors that were often difficult to predict and sometimes were in competition. These included transparency, market liquidity, allowing markets to evolve, adopting best practices and lessons from more mature markets, leadership, resource demands on jurisdictions and participants, unique characteristics of markets for compliance instruments, and enforceability. The Committee believes that the resulting Draft Recommendations describe policies that will enhance the ability of the cap-and-trade program to contribute to greenhouse gas emissions reductions at relatively low cost, provide regulatory oversight, and promote market participant confidence. The Committee welcomes comment on the Draft Recommendations individually and collectively, and in particular on:

A. Whether the tools available to WCI Partner jurisdictions for market oversight have been completely and correctly identified;
B. Whether the Draft Recommendations would correctly maximize the environmental and economic benefit to the public and support WCI's Principles of Market Oversight;
C. Whether the Committee should recommend collection of derivatives position information from market participants, including on over-the-counter derivatives; and if so, what of that information to disclose to the public; and
D. The Draft Recommendation to require secondary market trades to use a central limit order book.

4.4 Market Monitoring 48

4.4.1 Draft Recommendation 12: Market Monitoring 48

5 Roles of Provincial, State, and Federal Regulatory Agencies **49**

6 Conclusion **49**

1 Purpose and Background

The Western Climate Initiative (WCI) is a cooperative effort of seven U.S. states and four Canadian provinces that are collaborating to identify, evaluate, and implement policies to reduce greenhouse gas (GHG) emissions, including the design and implementation of a regional cap-and-trade program. The WCI began in February 2007 with the governors of Arizona, California, New Mexico, Oregon, and Washington, who have since been joined by the premiers of British Columbia, Manitoba, Ontario, and Quebec, and the governors of Montana and Utah. Participation in the WCI reflects each Partner jurisdiction's strong commitment to identifying, evaluating, and implementing collective and cooperative actions to address climate change.

In September 2008, the Partner jurisdictions released the final "Design Recommendations for the WCI Regional Cap-and-Trade Program."[1] The first compliance period for the cap-and-trade program will begin January 1, 2012, covering GHG emissions from electricity generation (including emissions associated with imported electricity), combustion at large industrial and commercial facilities, and industrial process emissions for which adequate measurement methods exist. Starting in 2015, the program's coverage expands to include transportation fuels in addition to residential, commercial, and small industrial combustion. Thus, by 2015 the cap-and-trade program will cover almost 90% of GHG emissions in the Partner jurisdictions.

In February 2009, the Partner jurisdictions released the WCI 2009 – 2010 Work Plan, describing the approach to implementing the Design Recommendations.[2] The WCI is working through five committees: Offsets, Reporting, Complementary Policies, Cap Setting and Allowance Distribution, and Markets. The Work Plan describes the tasks and deliverables for each committee. The purpose of one of the Markets Committee's tasks, "market oversight," is to recommend measures to ensure that the allowance and offset certificate trading market is organized properly to operate reliably and prevent or minimize manipulation. This task was included in the work plan based on the consensus among WCI Partner jurisdictions on the need to provide effective oversight to assure an efficient and transparent carbon market.

These Draft Recommendations are based on the information collected and reviewed by the Markets Committee on market oversight approaches and issues. The information was obtained through several means, including the following:

---

[1] The Design Recommendations and accompanying Background Report can be found at http://westernclimateinitiative.org/the-wci-cap-and-trade-program/design-recommendations.
[2] The 2009 – 2010 Work Plan can be found at http://westernclimateinitiative.org/component/remository/general/workplans/2009-2010-WCI-Work-Plan/.

- The Markets Committee held a stakeholder workshop on market oversight in Seattle, Washington in April 2009. The Committee presented a draft set of principles of market oversight, and a list of questions for discussion with those who attended in person or online.[3] Stakeholders were invited to submit written comments.[4] Stakeholders' responses guided the Committee's consideration of issues and the Committee revised the principles of market oversight as set forth below. The principles guided the Committee's research, analysis, and deliberation, and will continue to do so as the Committee progresses towards final recommendations.

- The Markets Committee made a presentation to the WCI Partners on September 16, 2009, at a public meeting in Toronto, Canada, and invited stakeholder comment at the meeting.

- The Markets Committee made a presentation to the WCI Partners on November 18, 2009, at a public meeting in Santa Fe, New Mexico, and invited stakeholder comment at the meeting.

- The Markets Committee issued a white paper on market oversight[5] on November 19, 2009, and invited written public comment by December 18, 2009. Eleven parties submitted comments.[6]

- The Markets Committee held a stakeholder call December 2, 2009, to present and discuss the market oversight white paper.[7]

- The Markets Committee made a presentation to the WCI Partners on March 3, 2010, at a public meeting in Vancouver, British Columbia, and invited stakeholder comment at the meeting.

- The Markets Committee held a webinar with the market monitor used by the Regional Greenhouse Gas Initiative (RGGI).[8]

---

[3] The principles and questions can be found at http://westernclimateinitiative.org/component/remository/func-startdown/25/. Market oversight was one of three tasks for which the Committee developed draft principles for comment; the others were auction design and compliance verification and enforcement.
[4] Stakeholder comments were submitted to the WCI website, and can be found at http://westernclimateinitiative.org/documents/public-comments/document/2.
[5] The white paper can be found at the WCI website, at http://westernclimateinitiative.org/component/remository/func-startdown/174/.
[6] Comments can be found at the WCI website, at http://westernclimateinitiative.org/public-comments/document/13.
[7] The presentation from the stakeholder call is available on the WCI website, at http://westernclimateinitiative.org/component/remository/Markets-Committee-Documents/Market-Oversight-White-Paper-Presentation/.

- The Markets Committee consulted with U.S., Canadian, state, and provincial regulatory authorities, and received input from European market regulators, potential market participants, trade associations, market infrastructure providers, and other stakeholders.

- The Markets Committee conducted a literature review with the assistance of our task advisor at the Nicholas Institute for Environmental Policy Solutions at Duke University.

Through this process, the Committee acquired substantial knowledge about the types of regulation in place in existing financial markets, the roles of regulators and exchanges, and the scope of existing carbon-related financial products.

In this document, "compliance instrument" refers to either an allowance or an offset certificate, unless otherwise noted. This document builds on the definitions and discussion in the market oversight White Paper without restating them, in most cases.

2 Principles

These principles were adopted with the publication of the white paper on November 18, 2009, and have been modified only to change "allowance" to "compliance instrument" and "offset credit" to "offset certificate" to standardize nomenclature. They serve as guidelines for developing oversight of the compliance instrument and associated derivatives trading markets to assure maximum environmental and economic benefit to the public.

- **Fairness:** All market participants, especially covered entities, have fair and equal access to the market.

- **Efficiency:** The market is designed to operate efficiently so that greenhouse gas (GHG) emission reductions can be achieved at the least cost. An efficient market means that allowance and offset certificate prices reflect supply and demand, and accurately reveal the value of allowances and offset certificates.

- **Effective Oversight:** The design and oversight of the market is effective in preventing or minimizing fraud, manipulation, and speculative excess.

---

[8] The presentation from the webinar is available at http://westernclimateinitiative.org/component/remository/Markets-Committee-Documents/Monitoring-Emissions-Allowance-Markets/.

- **Transparency and the Reporting and Disclosure of Relevant Information:** Transparency in the design and the operation of the allowance and offset credit market builds and retains public confidence.

    - Reporting of relevant information to regulatory authorities and public disclosure of information has important benefits. It enables regulatory authorities to conduct effective oversight and ensure compliance. It also helps to ensure market efficiency, effective oversight, and compliance and enforcement. The release of information can change the decisions of market participants, which impacts the prices of allowances and offset credits. Timely, accurate, coordinated and consistent release of market-relevant information allows all market participants to have equal access to public information.
    - The reporting and disclosure requirements for compliance, verification and enforcement balance these benefits against the need for entities to protect certain sensitive information. The potential to disclose certain information that could be used to manipulate the market is also considered. This balancing is consistent with applicable law relating to the disclosure of information.

- **Administrative Simplicity and Cost:** Proposed rules are designed to be understood and enable entities to have a clear compliance path. Administrative costs and transaction costs are minimized for all parties, consistent with the need to provide effective oversight.

- **Accountability:** All entities involved in the allowance and offset credit market, as either regulators or market participants, are accountable for their actions. The responsibility, authority, and capacity to conduct the necessary oversight and take appropriate action are fully defined for all agencies charged with compliance, verification and enforcement.

- **Conflicts of Interest:** Conflicts of interest between market participants, monitors, and regulators are prevented.

3 Stakeholder Comments on White Paper

The Markets Committee received 11 written comments to the white paper. The Committee identified and asked for comment on three key issues, as well as general comment on the content of the white paper.

The first key issue was, "Whether current U.S. and Canadian regulation of commodity markets is appropriate." Five commenters responded to this issue. In general, the comments favored treating allowances as commodities, rather than construct a new definition or new framework for their regulation. One commenter, however, said that though allowances would fit the framework for regulation as commodities, oversight of over-the-counter (OTC) derivatives beyond current commodity oversight was needed.

The second key issue was, "Whether to place restrictions on OTC instruments." Seven commenters responded to this issue. Six commenters recommended not restricting the use of OTC instruments, citing their flexibility and the costs of clearing in exchange transactions. Of those six, three recommended requiring more information on such transactions than is currently reported to regulators. One commenter recommended restricting transactions to exchanges, to reduce complexity and the risk of market manipulation.

The third key issue was, "The appropriate transparency and disclosure requirements." Five commenters responded to this issue. They said that an appropriate balance of transparency and confidentiality, as well as the costs and benefits of collecting particular data, exists. Three commenters recommended that more information be revealed to regulators than would be made public, and specifically recommended aggregation of data prior to public disclosure. On the December 2, 2009 stakeholder call, some stakeholders requested a specific proposal to respond to. One commenter made specific recommendations on information requirements to restrict the use of inside information.

Commenters made further recommendations to the WCI Partner jurisdictions. Two described recommended roles for a central market monitor. Two requested clarification of the legal authority jurisdictions had over allowance markets, as prerequisites for determining the specific recommendations for oversight. A short discussion of the roles of provincial, state, and federal regulatory authorities is in section 5 of this paper. The Final Recommendations paper will include a more detailed discussion.

Some comments addressed issues outside the scope of the market oversight task, and some commenters took issue with phrasing in the white paper. Two commenters requested a fuller acknowledgement than in the white paper of the possibility and consequences of market manipulation. One commenter requested more information on the risks of low market liquidity, including the risk that liquidity would be harmfully low.

4 Draft Recommendations

The Draft Recommendations presented here incorporate the information the Markets Committee has received and developed on market oversight. Among the general conclusions the Committee reached is that many aspects of oversight are interrelated. In many cases, a Draft Recommendation below depends on the implementation of another Draft Recommendation. For each Draft Recommendation, the Committee has noted these relationships; if one were to change, others likely would as well. For this reason, the Committee has considered the Draft Recommendations as a package.

Of particular note is Draft Recommendation 1 (Treat Compliance Instruments as Commodities for Market Oversight Purposes). It does not recommend that the Partner jurisdictions implement new restrictions on the trading of derivatives. This influences the discussion of the further Draft Recommendations, especially by narrowing the focus of several to secondary markets.

Second, some of the Draft Recommendations imply or require particular technical capabilities in a cap-and-trade compliance instrument tracking system. Where this is the case, the requirements are discussed with the Draft Recommendation. An electronic tracking system provides complete accounting of compliance units, recording the real-time status of issuance, holdings and transfer of compliance units between accounts, and providing the function to reconcile reported emissions for each compliance period with the compliance entity's holdings.

4.1 Allowances, Offset Certificates, and Derivatives

4.1.1 Draft Recommendation 1: Treat Compliance Instruments as Commodities for Market Oversight Purposes

4.1.1.1 Background

Commodity cash and derivatives markets are closely linked, and activity in one will affect behavior in the other. Nevertheless, they are different in definition and in legal framework and warrant separate treatment. The market oversight white paper described commodity derivatives and the regulatory framework for them, and the discussion here builds on that.

4.1.1.2 Options

The first of the "key issues" the Markets Committee asked for comment on in the white paper was:

A) Whether cap-and-trade compliance instruments should be treated as commodities, which would place them in the context of a body of existing law and regulation, or
B) Whether to attempt to define compliance instruments in such a way that they would not be commodities, and develop a new body of law and regulation.

4.1.1.3 Evaluation of Options

As described in the market oversight white paper, "Commodities are goods that are interchangeable with other goods of the same type." Cap-and-trade compliance instruments in the US Acid Rain Program, RGGI, and the European Union Emissions Trading Scheme (EU ETS) have been treated in many ways as commodities by market participants and regulators. Though they are instruments that will ultimately be used to satisfy legal requirements, as finite resources they have market prices.

Whether to treat compliance instruments as commodities for market oversight purposes is a fundamental question in the US especially, because federal law preempts the states from certain regulation of commodity derivatives. By “derivatives” we mean both exchange-traded instruments, such as futures and options contracts, as well as instruments traded over-the-counter. Therefore, determining that compliance instruments are commodities places the responsibility for regulation of their derivatives in the US primarily with the US Commodity Futures Trading Commission (CFTC). The advantages to this include the long history of futures and options regulation, and staff and infrastructure resources at the CFTC. The disadvantages include potentially less control of the non-cash markets by the Partner jurisdictions.

Like energy commodities, compliance instruments could be considered an input to many kinds of economic activity, including production of electricity and use of transportation fuels. In addition to concern that financial manipulation might benefit a few persons at the expense of many, high volatility and higher-than-expected prices in compliance instrument markets have the potential to undermine public support for a cap-and-trade program, which could make achievement of environmental goals more difficult. Partners, therefore, might weigh tradeoffs between transparency, market efficiency, prices, and volatility differently from the legislators and regulators who have established the framework for commodity derivatives regulation.

Participants trading compliance instruments in existing carbon markets have generally treated them as commodities. Many firms that are covered in existing cap-and-trade programs require energy commodities as inputs. As with commodities, compliance instrument prices should reflect market fundamentals, such as economic conditions and industrial production more than the decision of a single firm. (In contrast, the price of a firm’s securities can be linked closely to the business decisions of that firm.)

In its consideration of alternatives to treating compliance instruments as commodities, the Markets Committee found three additional strong arguments not to create an alternative framework. First, the definition of “commodity” in the Commodity Exchange Act[9] is sufficiently broad that it would be difficult to devise a definition of compliance instruments that would not place their derivatives under CFTC regulation in the US. Second, no alternative framework rose up as superior. Third, though the Canadian provinces each have a securities commission that regulate derivatives, in general, because of federal preemption, the US state governments

---

[9] 7 U.S.C. 1a (4)

retain less authority to regulate national financial markets and, as a result, creating the regulatory capacity for oversight of compliance instrument derivatives traded on national markets could require a significant investment of time and funds.

4.1.1.4 Experience in Existing Environmental Cap-and-Trade Programs

In the US, Acid Rain Program and RGGI compliance instrument derivatives are regulated by the CFTC as commodity derivatives. In the EU ETS, regulation of derivatives is performed by individual countries. That said, most of the exchange-based derivatives activity takes place on the European Climate Exchange, based in London, which is regulated as a commodity derivatives exchange by the UK Financial Services Authority.

4.1.1.5 Draft Recommendation

The Markets Committee recommends that compliance instruments be treated in the same framework and by the same regulators as commodities for the purpose of derivatives regulation. This implies the primacy of the provincial securities commissions and the CFTC in oversight of that aspect of the market. The Committee recommends a close coordination of oversight efforts between agencies of the Partner jurisdictions and US federal regulators.

4.1.1.6 Relationship to Other Draft Recommendations

A discussion on the collection and dissemination of data on derivative positions is included in Draft Recommendation 2 (Information on Derivatives Positions). Some of the data that could be collected is not currently collected by the CFTC or provincial securities commissions, and would then be an exception to the general recommendation that compliance instruments be treated like other commodities.

The remainder of the Draft Recommendations would then apply only to secondary markets in compliance instruments.

4.1.1.7 Requirements of Tracking System

This Draft Recommendation does not imply technical requirements of the tracking system.

4.1.2 Draft Recommendation 2: Information on Derivatives Positions

4.1.2.1 Background

The WCI cap-and-trade program will likely lead to the development of a market for compliance instrument derivatives, as covered entities seek to hedge the cost and availability of compliance instruments in order to meet their compliance obligations. In the United States, regulation of commodity derivative markets occurs at the federal level. In Canada, these markets are regulated at the provincial level. Currently, derivative trading in energy commodity markets occurs in a variety of venues including regulated exchanges and through private “over-the-counter” (OTC) contracts. Market regulators in Canada and the United States do not track OTC trading of energy-related derivatives as closely as exchange-traded contracts. As a result, it is difficult to track trading activity across the energy derivative markets. Efforts are underway in both countries to reform market regulation, in part because of concerns that OTC opacity allows for undetectable manipulative behavior or drives speculative bubbles. These efforts may increase surveillance of OTC trading but the likely outcome is unclear.

4.1.2.2 Options

The Markets Committee identified the following options regarding collection of information on derivative positions:

A. Collect on an ongoing basis information on derivative positions from those with accounts in the cap-and-trade tracking system or ownership interest in a compliance instrument that is additional to the information currently collected by commodities regulators;
B. Collect on an ongoing basis information on derivative positions from some entities, e.g., registered intermediaries;
C. Do not collect derivative position information on an ongoing basis, but ensure that regulatory authorities are authorized to collect and fully disclose derivative position-related information in a timely fashion on an as-needed basis, including information that would be material to an investor’s decision to acquire or dispose of a derivative;
D. Do not collect additional information on derivative positions.

Depending upon which of the options above the Markets Committee recommends, the WCI cap-and-trade program may or may not have information on derivative positions to retain internally or disclose publicly. If information on derivative positions is collected on an ongoing basis, the Markets Committee has identified the following options for disclosure of derivatives market information:

A. Disclose all derivative positions reported (i.e., those of participants with tracking system accounts or ownership interest in a compliance instrument);
B. Disclose the largest derivative positions (e.g., exceeding a certain percentage of the total market);
C. Disclose derivative positions aggregated to a level similar to the Commodity Futures Trading Commission Commitments of Traders reports; or
D. Do not disclose information on derivative positions.

The Markets Committee has considered the following options in terms of how derivatives market information could be disclosed:

A. Directly through a central derivatives information repository, and through search functions;
B. Through exchanges where transactions occur;

C. Through periodic WCI market reports published on a website; and/or,
D. Situationally by commodities derivatives regulators, as they deem appropriate.

Frequency of data collection will also have important consequences for each of the above options. The Markets Committee has considered daily, weekly, monthly, and quarterly disclosures.

4.1.2.3 Evaluation of Options: Data Collection

Rationale for Data Collection

Three main benefits may accrue from collecting data on account holders' derivative positions. First, though data on exchange transactions is relatively transparent to regulators, the Partner jurisdictions appear to be in a position to collect information on OTC transactions that is not currently routinely accessible to market monitors. Data collection as part of the cap-and-trade program could supplement the regular efforts to monitor compliance instrument derivatives markets; the data could be transmitted to provincial and US federal monitors. A consolidated repository of information on the compliance instrument derivatives markets across jurisdictions and trading venues could enhance transparency of the cap-and-trade market.

Second, in the event of unexpected or suspicious activity, the derivatives position data collected could serve a forensic purpose as regulators examined market activity and traced causes.

Third, as stated in the Design Recommendations for the WCI Regional Cap-and-Trade Program, "the WCI Partner jurisdictions are committed to providing appropriate technical and other compliance assistance to the program participants."[10] If it is using derivatives contracts as part of its strategy, an entity may be better able to demonstrate that it is on track and managing its risk in the accumulation of compliance instruments during a compliance period if derivative positions are reported. (In the EU ETS, the majority of the market is in derivatives, not the spot market. Derivatives would not be reflected in the tracking system until settlement.)

Timing

To identify trading irregularities as they occur and initiate immediate enforcement actions, regulators need to receive and evaluate market data on an ongoing basis. Product innovation and market structure changes challenge regulators, in their policymaking role, to constantly consider whether the current regulatory framework continues to provide investor protection and market integrity given new products and structures. Collecting, aggregating, maintaining,

---

[10] "Design Recommendations for the WCI Regional Cap-and-Trade Program," Western Climate Initiative, September 23, 2008, http://www.westernclimateinitiative.org/component/remository/general/design-recommendations/Design-Recommendations-for-the-WCI-Regional-Cap-and-Trade-Program/ (Accessed February 12, 2010), p. 13.

and analyzing large amounts of data requires informational technology and staff resources. The cost of collecting data more frequently should also be weighed against its benefits.

If the goal is more limited, e.g. to identify trends and maintain data for use during longer-term enforcement actions, daily reporting by market participants becomes less important. In that instance, weekly or monthly reports may be sufficient to monitor general trends in trading behavior and have on record in the event enforcement actions become necessary.

Proposed Derivative Reforms

Systematic ongoing collection of OTC derivatives data would go beyond the approach currently used by commodities regulators in North America, which may be seen to be an advantage or disadvantage. The Partner jurisdictions may feel that a nascent market created by government action has intrinsic differences from other commodities, including necessary public support, to say that the standards and tools of effective oversight are also different. The Partners jurisdictions may wish to anticipate or influence the financial reform efforts in favor of reporting OTC derivatives. Requiring such reporting in advance of the uncertain outcome of such reform efforts would make a strong statement about its importance in effective market oversight, and could influence the reforms.

US federal legislative proposals on financial market reform generally would require increased reporting and disclosure of OTC derivatives. In May 2009, the US Treasury Department released a proposal to reform OTC derivative markets.[11] A key component of the proposal is mandatory clearing of standardized contracts and giving the regulators authority to determine whether a contract is standardized or not.

The US House of Representatives passed a financial reform bill in December 2009 that addresses mandatory clearing and transparency.[12] Title III of the bill applies to derivative markets and creates a presumption that standardized swap transactions will be cleared. The clearing requirement does not apply if one of the counterparties (a) is not a swap dealer or major swap participant, (b) is using swaps to hedge a commercial risk, or (c) notifies the CFTC how it meets financial obligations when entering into non-cleared swaps. If one of these exemptions applies and a swap transaction is not cleared through a registered clearing facility, the transaction must be reported to a registered swap repository. If no repository will accept the transaction, the transaction must be reported directly to the CFTC.

[11] "Regulatory Reform Over-the-Counter Derivatives," US Department of the Treasury press release, May 13, 2009, http://www.ustreas.gov/press/releases/tg129.htm (Accessed March 14, 2010).

[12] "House Approves Historic New Rules to Govern America's Financial System," House Committee on Financial Services press release, December 11, 2009, http://house.gov/frank/pressreleases/2009/12-11-09-fsc-press-release-final-bill.html (Accessed March 14, 2010).

Senate Banking Committee Chairman Christopher Dodd released a financial reform bill on March 16, 2010. As in the bill that passed the House of Representatives, Senator Dodd's bill would require central clearing of standardized OTC contracts. The bill includes exemptions for certain swap transactions, but would require the CFTC to consult a Financial Stability Oversight Council before issuing an exemption. The Dodd bill would expand the CFTC's jurisdiction over OTC instruments and grant federal regulators and clearing houses a role in determining whether clearing is required; regulators would have to pre-approve contracts before clearing houses could clear them. The bill would require federal regulators to determine margin requirements for un-cleared transactions and also require data collection through clearing houses or swap repositories. The Senate has not acted on the Dodd bill, and the Senate Banking Committee may amend the OTC provisions during the committee process.

Collecting information about derivatives contracts from registered intermediaries (e.g., brokers, merchants, traders, advisors, and pool operators) could provide regulators with a more complete picture of market activity, thereby helping regulators identify and prevent fraudulent activity. The WCI Partner jurisdictions could collect information from these entities about the products offered and sold during the reporting period, including volume, prices, contracting parties, types of contracts, and locations of the trades.

Arguments

There may be a number of drawbacks to collecting data on account holders' derivative positions. First, assuming the implementation of Draft Recommendation 4 (Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System), the WCI Partner jurisdictions may not be able to collect derivatives information from some entities who have neither tracking system accounts nor ownership interest in compliance instruments. Such participants represent a potentially large portion of the derivatives market. For example, entities who only participated in cash-settled derivatives markets would not need to hold accounts. Entities trading physically-delivered derivatives could still avoid holding accounts if they closed their positions before the delivery date. In addition, violations of the reporting requirement might not be visible to regulators; whether or not a report was complete in its listing of OTC derivatives would be difficult to determine.

Second, the potential benefit of collecting information on derivatives positions must be weighed against the potential increase administrative burden and cost for regulators and for the compliance entities that use derivatives to manage their risk. It may be challenging to anticipate new financial innovations that lead to market manipulation by analyzing the information on derivatives positions, so regulators may be limited to primarily using the information for forensic purposes.

Third, due to the nature of OTC derivatives, it may be difficult to collect derivatives positions information in a sufficiently consistent manner through the tracking system to allow broad analysis.

It is important to note that mandatory reporting of OTC derivative positions would require development of a new information technology platform. There exist companies that provide repository services and associated automated processing services for OTC derivatives. WCI Partner jurisdictions may therefore consider that there are models for collection of derivatives information that would not require an investment of funds from the jurisdictions. However, the process to select a provider would demand time and resources.

The International Swaps and Derivatives Association (ISDA) has recently concluded the selection of independent systems as global repositories for interest rate and equity derivatives, and is rumored to be considering a selection process for a commodity derivatives repository. If ISDA designates a repository, it could be a strong candidate for selection by the WCI jurisdictions as well, depending in part on the access regulators would have to collected data.

4.1.2.4 Evaluation of Options: Public Disclosure

In the view of at least one trade association of professional derivatives market participants (ISDA), policy makers tend to view transaction transparency—meaning in this circumstance "public disclosure"—as a desirable end in itself.[13] In contrast, ISDA asserts, the academic literature tends to view transparency as a means to an end, for example, improved market efficiency, which implies the existence of tradeoffs. On the one hand, ISDA states, transparent markets might be more efficient from the standpoint of the information content of prices; but on the other hand, transparent markets might be less efficient when considering spreads and other transaction costs. For example, ISDA asserts that one would expect mandated transparency to lead to increased explicit costs (e.g., for accounting) because of the necessity to maintain both systems and staff to comply with the requirements; in addition, central reporting structures, if used, might charge fees to reporting firms.

ISDA argues that this trade-off suggests that market transparency should be evaluated in the context of specific market circumstances and public policy should push for higher transparency only in those cases where it can demonstrably make markets more efficient and more beneficial to users. To the extent that market participants demand more transparency as markets mature, ISDA believes that financial markets are likely to evolve ways to address market participants' desire for more information relevant to their trading and risk transfer

---

[13] "Transparency and over-the-counter derivatives: The role of transaction transparency," International Swaps and Derivatives Association, Research Note, No. 1, 2009, http://www.isda.org/researchnotes/pdf/ISDA-Research-Notes1.pdf (Accessed March 10, 2010).

decisions. Mandated transparency, in contrast, specifies a particular solution across the board. ISDA cautions that such a "one-size-fits-all policy" runs the danger of disregarding the inherent nature of specific markets and could short-circuit the evolution of market-based transparency provision that would otherwise arise in response to real market demands.

The current Chairman of the CFTC, Gary Gensler, has a different view. In his words, "[t]he financial regulatory system failed the American public."[14] He has testified that "as a critical component of reform… we have to bring comprehensive regulation to the over-the-counter (OTC) derivatives markets. We must lower risk, promote greater market integrity and improve market transparency." He proposes to "eliminate exclusions and exemptions from regulation for OTC derivatives," such that the law "covers the entire marketplace, without exception." The reforms he proposes have many components, only one of which is public disclosure. On that subject, he calls for "mandatory public disclosure of aggregate data on swap trading volumes and positions." Rather than arguing for transparency as a desirable end in itself, Chairman Gensler argues for transparency and other steps "to protect the American Public."

Canada's financial regulatory system has fared well through the economic recession, illuminating an alternate perspective. Prime Minister Stephen Harper delivered a message at the World Economic Forum in Davos, Switzerland that "Canada believes that financial sector regulation… must not be excessive." Canada's model is based on a simpler regulatory approach that focuses more on the outcomes the regulated community must achieve than how they are achieved, to ensure innovation is not stifled.

In comments to the WCI Markets Committee on the market oversight white paper issued November 19, 2009, several commenters recommended greater transparency in and oversight of the OTC derivatives markets.

In this issue as in many that the Markets Committee is considering, there may be a tradeoff between a desire to allow a secondary market to evolve and a desire to adopt lessons and best practices from experience in other markets.

4.1.2.5 Comparison to Other Markets

In the United States, the Commodity Exchange Act (CEA) and its implementing regulations require that regulated exchanges provide information regarding derivative trades to the CFTC.

---

[14] "Testimony of Chairman Gary Gensler, Commodities Futures Trading Commission Before the House Committee on Agriculture," September 22, 2009, http://www.cftc.gov/ucm/groups/public/@newsroom/documents/speechandtestimony/opagensler-10.pdf (Accessed March 10, 2010).

This information is collected on a daily basis and includes aggregated position limits and trading activity for all of their members. The aggregated data for each member includes:

> open long and short positions, purchases and sales, exchanges of futures for cash, and futures delivery notices for the previous trading day. This data is reported separately by proprietary and customer accounts by futures month, and for options by puts and calls, expiration date and strike price.[15]

The CEA also requires regulated exchanges to make data available to the public regarding trading volume, open contracts, futures delivery notices, exchanges for cash, and prices.[16]

Futures commission merchants, members of regulated exchanges, and foreign brokers must provide a daily report to the CFTC regarding "special accounts," those with futures and options positions above the reporting level specified by the CFTC. The requirement to provide this specific data is referred to as the CFTC's Large Trader Reporting Program.[17] The reports must include data regarding "each futures position, separately for each reporting market and for each future, and each put and call options position separately for each reporting market...."[18] Reporting entities must aggregate their interest in or control of multiple accounts for the purpose of determining whether their positions trigger reporting requirements.[19]

In Canadian provinces, the obligation to report positions or trades is determined by exchange rules. For example, in Quebec all members of the Montréal Exchange,[20] a derivatives exchange, must disclose to the exchange their net positions when they exceed a certain threshold that triggers the reporting requirement. There are no obligations to disclose, on a daily basis, information to the regulator, the Autorité des marchés financiers (AMF).

The US Acid Rain Program, RGGI, and the EU ETS do not require special reporting of OTC derivatives in compliance instrument markets.

4.1.2.6 No Draft Recommendation

The Markets Committee has not yet decided upon a Draft Recommendation on the collection and public disclosure of derivative positions. The Committee requests public comment on this issue.

4.1.2.7 Requirements of Tracking System

Collecting information on derivative positions would require the establishment of a repository for that information. Such a repository could, but is not required to be, a part of the compliance instrument tracking system. If the repository and tracking system are different, protocols for information exchange between them may be necessary.

4.1.3 Draft Recommendation 3: Treat Allowances and Offset Certificates Identically for Market Oversight Purposes

4.1.3.1 Background

The WCI cap-and-trade design involves two types of compliance instruments: allowances and offset certificates. There are differences between the creation and use of these two types of compliance instruments. First, Partner jurisdictions will issue offset certificates for projects that can demonstrate that removed or avoided emissions are real, additional, verifiable, and permanent. That process will have requirements for information transparency and disclosure, project approval, monitoring, and treatment of the risk of reversal that are separately being considered by the Offsets Committee. The process by which allowances are created and issued, in a predetermined quantity, will be different. Second, the WCI Partners have approved final recommendations for limiting the use of offset certificates to meet compliance.[21] Third, offset projects and allowances have differing risks; offset certificates may carry some risk of reversal, depending on jurisdictions' policy choices. Partly for these reasons, the market prices for allowances and offset certificates are different in the EU ETS, and likely to be different in a WCI market. Further, the number of offset certificates will be much smaller than the number of allowances.

4.1.3.2 Options

The Markets Committee has identified the following options for treatment of different types of compliance units:

A. Treat allowances and offset certificates identically for market oversight purposes; or,
B. Establish distinct requirements for offset certificates.

---

[21] "WCI Recommendations for Implementing the Offset Limit," Western Climate Initiative, March 11, 2010. http://westernclimateinitiative.org/component/remository/func-startdown/224/ (Accessed March 18, 2010).

4.1.3.3 Evaluation of Options

For the purposes of this section, the Markets Committee considered the Market Oversight Draft Recommendations to define the scope of the policy decisions. In the case of each of the eleven other Draft Recommendations, the Committee evaluated the different nature of allowances and offset certificates and the additional complexity that would likely follow if the types of compliance instruments were treated differently.

In two cases, Draft Recommendation 7 (Holdings Limits) and Draft Recommendation 12 (Market Monitoring), the much smaller number of offset certificates could lead to differences in the implementation of a recommendation. In each, for example, the definition of market power would be different. However, these are likely to be quantitative differences rather than qualitative differences.

4.1.3.4 Experience in Existing Environmental Cap-and-Trade Programs

No offset certificates are issued in the Acid Rain Program, and none have yet been issued in RGGI. To the best of our knowledge, offset certificates usable for compliance in the EU ETS are treated, like allowances, as commodities.

4.1.3.5 Draft Recommendation

The Markets Committee recommends that the WCI cap-and-trade system treat allowances and offset certificates identically for market oversight purposes.

4.1.3.6 Relationship to Other Draft Recommendations

All other Draft Recommendations assume the adoption of this one, and are written for compliance instruments without distinction.

4.1.3.7 Requirements of Tracking System

This Draft Recommendation implies no additional requirements of a tracking system.

4.2 Market Participants

4.2.1 Draft Recommendation 4: Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System

4.2.1.1 Background

The WCI Partner jurisdictions intend to create a system to track compliance instruments. The instruments would exist as electronic records rather than physical certificates. The Partner jurisdictions are designing the requirements for this tracking system, and considering options for implementation.

This paper describes Draft Recommendations on market oversight. For each, the Markets Committee evaluated enforceability of the Draft Recommendation. A consideration for enforceability is the existence and nature of the relationship between the regulator and the market participant. The nature of the relationship will differ, for example, depending on whether or not a person has a legal obligation to surrender compliance instruments (is a “compliance entity”).

The nature of the relationship will also hold some combination of a “regulatory” relationship, and a “contractual” relationship. Here, a regulatory relationship is considered to be mandatory for designated persons, with the authority of a regulator established by statute and written into the regulations of a jurisdiction. A “contractual” relationship would be one voluntarily entered into by a person, with a counterparty of one or more jurisdictions or the tracking system, that provides the person the ability to take certain actions, under certain conditions. These types of relationships also imply differences in enforcement actions.

The Partner jurisdictions will have established relationships with the entities that will have compliance obligations under the cap-and-trade program. These relationships include reporting requirements and surrender obligations, though they are not the subject of these Draft Recommendations, which are focused on the activities around the holding and trading of compliance instruments.

The Markets Committee is particularly interested in defining the relationship between regulators and entities that do not have a compliance obligation under the cap-and-trade program.

4.2.1.2 Draft Recommendation

The Markets Committee recommends that either or both of having ownership interest in a compliance instrument and having an account in the tracking system would establish a legal relationship between one or more regulators and the account holder. These relationships would entail certain obligations of the entity.

4.2.1.3 Relationship to Other Draft Recommendations

Among the obligations entailed by holding an account in the tracking system would be Draft Recommendations 6 (Require Registration of Intermediaries as Market Professionals) and 9 (Require Disclosure of Beneficial Ownership). In addition, this Draft Recommendation assumes the implementation of Draft Recommendation 5 (Do Not Limit Market Participation to Compliance Entities), that compliance entities not be the only market participants. If participation is limited to compliance entities, the need to create a regulatory relationship to implement trading rules would probably be largely satisfied.

4.2.1.4 Requirements of Tracking System

This Draft Recommendation suggests a conceptual role for the tracking system. Technical requirements may include the ability to perform enforcement actions, such as revocation or suspension of trading for an entity or for all accounts.

4.2.2 Draft Recommendation 5: Do Not Limit Market Participation to Compliance Entities

4.2.2.1 Background

A WCI carbon market could involve diverse participants who may trade to satisfy a compliance obligation, purchase for resale to emitters, speculate on the price of compliance instruments, or diversify an investment portfolio. Entities that could participate in the carbon market may include compliance entities, investors, brokers and other intermediaries. Each entity would play a different role in the market.

Even if compliance entities receive allowances without charge from a government, the number may not be equal to their obligation, perhaps due to growth or contraction in their emissions or policy decisions on the quantity or formula for distribution. These entities may then choose to purchase additional compliance instruments from the primary or secondary market, or sell compliance instruments they will not require for compliance or for other reasons. In early 2009, industrial facilities in the EU ETS sold allowances, many freely allocated, to raise cash when other avenues of raising funds became more difficult.[22]

Though they would not be required to hold compliance instruments for compliance, other categories of participants could play market roles. Brokers and other intermediaries may, for a fee, arrange trades of compliance instruments between parties, or provide advice or other services. Investors may desire to be market participants to profit from trading.

4.2.2.2 Options

With regard to the secondary market, the WCI cap-and-trade program could either:

A) Limit market participation to compliance entities; or,
B) Open market participation to non-compliance entities.

---

[22] E.g., "Carbon Markets 2009," IFSL Research, July 2009, http://www.ifsl.org.uk/upload/Carbon_Markets_2009.pdf (accessed October 1, 2009).

The Market Committee is separately developing Draft Recommendations on participants in the auctioning of allowances (primary market).

4.2.2.3 Evaluation of Options

The WCI Partner jurisdictions have received oral and written comments from stakeholders suggesting that market participation be limited to compliance entities. Many of these comments referred specifically to auctions, which are the subject of a separate WCI white paper, but may also be addressed in the context of secondary markets. The concerns expressed can be summarized as:

1) That participation by non-compliance entities will increase the price of allowances.
2) That participation by non-compliance entities increases the chances of market manipulation.
3) That participation by non-compliance entities will limit access to allowances.

The first concern may be related to questions regarding the role of speculation in markets. Investors can play important roles in competitive markets by increasing liquidity. A healthy market is “liquid,” meaning there is a sufficient number of buyers and sellers in the marketplace to allow trading to take place. Larger numbers of market participants make it more likely that there will be counterparty (i.e., another party willing to participate in a trade). A market with less liquidity may be subject to more price volatility and it may be more difficult for entities needing to buy compliance instruments to locate willing sellers. Unlike a traditional commodity market, a compliance instrument market will not have natural sellers outside of the primary market. Consequently, concerns about potential “excess” speculation by investors must be weighed against these benefits of allowing investors access to the carbon market.

The second concern implies either that more market participants increases the ease or risk of manipulation, or that non-compliance entities might attempt market manipulation while compliance entities would not. However, a larger number of market participants would most likely make manipulation more difficult, not less, by increasing liquidity and making control of a significant proportion of compliance instruments by one or a few persons harder.

The Markets Committee assumes for this discussion that the fraction of potential market participants who would attempt a manipulation is small. However, the potential for damage from a successful manipulation is large, and has precedent in recent experience in energy markets in WCI Partner jurisdictions, notably the energy crisis of 2000 – 2001. The Committee believes that participants who would consider an attempt to manipulate the market exist both among compliance and non-compliance entities. Limiting market participation to compliance entities would exclude some number of beneficial participants without measurable benefit in changing the fraction of participants who would consider market manipulation.

The third concern is that non-compliance entities may hold compliance instruments for some period of time, making them unavailable to compliance entities that may need them for compliance. There are many possible non-compliance reasons to hold compliance instruments; the auction design recommendation report commissioned by RGGI identifies five:[23] speculation; allowance market manipulation; electricity market interference; competitive advantage; and external compliance. In none of these cases would market risks be reduced by restricting the market to compliance entities, save potentially external compliance.[24] When restricting a market reduces liquidity, in fact, the risks are increased. Though this risk might be enhanced by allowing non-compliance entities to participate, it is nevertheless very small, as it has not been proposed by the existing GHG cap-and-trade programs, RGGI and the EU ETS.

In addition to considering whether participation limits are desirable, the Committee has considered whether they are practical. Fairly and reliably determining who has a compliance obligation in advance of the reporting deadline for a given year's emissions is not possible. The identities of compliance entities will also change as some enter or leave the program due to changes in their emissions or change in program scope, such as the inclusion of transportation fuels and residential and commercial fuel combustion in the second compliance period.

Limiting participation to compliance entities would also be difficult to enforce. For example, a person who would like to attempt a market manipulation but was otherwise excluded by participation rules might purchase some fractional interest in a facility that was a compliance entity, with an agreement that the person could trade as a representative of the entity. Under Draft Recommendation 1 (Treat Compliance Instruments as Commodities for Market Oversight Purposes), US states in the WCI would not have primary jurisdiction over derivatives markets and would therefore have constrained ability to enforce a participation limit in markets considered broadly.

4.2.2.4 Experience in Existing Environmental Cap-and-Trade Programs

The Acid Rain Program, RGGI, and EU ETS do not limit participation to compliance entities.

---

[23] "Auction Design for Selling CO2 Emission Allowances Under the Regional Greenhouse Gas Initiative," Charles Holt, William Shobe, Dallas Burtraw, Karen Palmer, Jacob Goeree, October, 2007, section 9, "Hoarding of Allowances," http://www.rggi.org/docs/rggi_auction_final.pdf (Accessed October 6, 2009).

[24] "External compliance" is the possibility of another cap-and-trade program accepting WCI compliance instruments in lieu of its own, without any reciprocal acceptance of the program's compliance instruments by WCI jurisdictions.

4.2.2.5 Draft Recommendation

The Markets Committee recommends that both compliance and non-compliance entities be allowed to participate in the secondary compliance instrument market. Broad participation would be beneficial, and narrow participation harmful, to an compliance instrument market, especially in its early stages. Limiting participation to compliance entities would not be an effective policy to reduce the potential for market manipulation.

4.2.2.6 Relationship to Other Draft Recommendations

Draft Recommendation 6 (Require Registration of Intermediaries as Market Professionals) describes a requirement for a type of participant, assuming that intermediaries who are not compliance entities could be participants.

4.2.2.7 Requirements of Tracking System

The adoption of this Draft Recommendation would require that the tracking system be able to accommodate more accounts, and potentially more trades, than one for a program with limited participation.

4.2.3 Draft Recommendation 6: Require Registration of Intermediaries as Market Professionals

4.2.3.1 Background

There will likely be numerous types of market participants in the WCI cap-and-trade program. Each account holder would be required to provide some information (e.g., identifying information) to regulators in order to establish an account, a process that could be called "registration."

One category of market participants could be "intermediaries," which would include traders, dealers, advisers and investment managers in the market. There exist precedents of registration requirements for intermediaries operating in the majority of commodities derivatives markets and in limited commodities markets. In both the US and Canada, some commodities derivatives traders are required to register with regulators and/or self-regulatory organizations. This process is also widely referred to as "registration." According to the National Futures Association (NFA), "The primary purposes of registration are to screen an applicant's fitness to engage in business as a futures professional and to identify those individuals and organizations whose activities are subject to federal regulation." [25] The screening can improve consumer and market protection. In this discussion, the question is whether to require that persons be subject

[25] "Registration," National Futures Association, http://www.nfa.futures.org/NFA-registration/index.HTML (Accessed February 11, 2010).

to the requirements of knowledge of trading law, capital requirements, etc. that are needed to trade or offer professional advice on derivatives in the US and Canada, as described below. This type of registration is referred to in this paper as "market professional registration."

In the US, the CFTC oversees market professional registration of entities engaged in trading of commodities and derivatives. The CFTC authorizes the NFA, a private organization, to perform registration processing functions on behalf of the Commission. Regulation of similar activities in Canada is performed by a combination of provincial regulatory authorities, a national database, and the Investment Industry Regulatory Organization of Canada (IIROC). Like the NFA, the IIROC is a private organization.

Under both countries' regulatory systems, entities must determine whether the business being conducted qualifies as trading or advising under the applicable law. If the activity does fall within the applicable law, the next step is to determine whether there is an exemption from the requirement to be registered set out in the law. If there is no exemption, the person or firm will be required to obtain market professional registration in order to conduct trading activities.

US Registration Requirements[26]

The US Commodity Exchange Act sets forth registration requirements for entities engaged in trading commodities and regulated derivative transactions. The CFTC identifies the following categories of market participants that must register with the NFA unless they qualify for an exemption:

- **Merchants**
  - Futures Commission Merchant (FCM) – A FCM is an individual or organization which does both of the following:
    - Solicits or accepts orders to buy or sell futures contracts or options on futures and
    - Accepts money or other assets from customers to support such orders.
  - Agricultural Trade Option Merchant (ATOM) – Any person that is in the business of soliciting or entering option transactions involving an agricultural commodity listed in the CEA that are not conducted or executed on or subject to the rules of an exchange.
- **Brokers**
  - Introducing Broker (IB) – A person who is engaged in soliciting or in accepting orders for the purchase or sale of any commodity for future delivery on an

[26] "Intermediaries," Commodity Futures Trading Commission, http://www.cftc.gov/industryoversight/intermediaries/index.htm (Accessed February 11, 2010)

    exchange who does not accept any money, securities, or property to margin, guarantee, or secure any trades or contracts that result therefrom.
    - Floor Broker (FB) – A person with exchange trading privileges who executes trades for others by being personally present in the pit or ring for futures trading.
- **Floor Trader** (FT) – A person with exchange trading privileges who executes his or her own trades by being personally present in the pit or ring for futures trading.
- **Commodity Trading Advisor** (CTA) – A person who, for pay, regularly engages in the business of advising others as to the value of commodity futures or options or the advisability of trading in commodity futures or options, or issues analyses or reports concerning commodity futures or options.
- **Commodity Pool Operators** (CPOs) – A person engaged in a business similar to an investment trust or a syndicate and who solicits or accepts funds, securities, or property for the purpose of trading commodity futures contracts or commodity options. The commodity pool operator either itself makes trading decisions on behalf of the pool or engages a commodity trading advisor to do so.
- **Associated Person** (AP) – An individual who solicits or accepts (other than in a clerical capacity) orders, discretionary accounts, or participation in a commodity pool, or supervises any individual so engaged, on behalf of a FCM, IB, CTA, CPO, or an ATOM.

The NFA develops registration requirements for each category of intermediary listed above. In general, the registration requirements include a completed registration form with information about the activities of the intermediary, an application fee, NFA membership dues, and fingerprint cards for principals and associated persons, as well as proficiency requirements.

FCMs and IBs must also include a financial statement (if the firm does not meet minimum capital requirements, it may face additional reporting requirements), and a description of procedures regarding the following:

- money laundering;
- business continuity and disaster recovery;
- electronic order routing;
- promotional materials;
- supervision of associated persons;
- customer complaints; and
- margins/segregation (if applicable).

Canadian Registration Requirements

i. Provincial legislation

Depending on their type of market activity, intermediaries may be required to register with provinces and with the Investment Industry Regulatory Organization of Canada. The statute that establishes jurisdiction in a province and territory varies. In most provinces and territories

The Securities Act establishes the requirement to register to trade or advise in the trading of securities or derivatives.

In Ontario and Manitoba, The Commodity Futures Act requires that entities register with the provincial regulator before trading or providing advice regarding the trading of exchange-traded derivatives. The Act also provides jurisdiction to define what will be included under the term “commodity.”

In Quebec, registration to trade or provide advice in exchange traded or over the counter derivatives is mandated in The Derivatives Act.

The legislation in each province permits enactment of regulations or rules that provide the detailed requirements to obtain or maintain registration. In many cases these requirements are consistent among the provinces and territories and are referred to as National Instruments (when all jurisdictions have adopted the requirements) or Multilateral Instruments (when one or more jurisdictions have not adopted the requirements).

Canadian Securities Administrators interpret and apply the “National Instrument 31-103,” enacted in September 2009, and Companion Policy 31-103CP “Registration Requirements and Exemption,” which contain categories and requirements for registration of individuals and firms for trading or advising in exchange contracts.

ii. National Registration Database

In Canada, the National Registration Database[27] (NRD) is an internet-based system which provides firms and individuals with the ability to file most registration information electronically with any number of the provinces and territories. The use of NRD is mandated by all provinces and territories for securities and derivatives registrations.

The forms that are required to be used and submitted on NRD are standardized.

iii. Investment Industry Regulatory Organization of Canada (IIROC)

In all provinces and territories in Canada, in most cases a business or individual in the business of trading or advising in the trading of derivatives contracts is required to be a member of the IIROC. IIROC has been recognized as a self regulatory organization responsible for setting standards and regulating the conduct of its members.

[27] “National Registration Database Information | Site d’information de la BDNI,” National Registration Database, http://www.nrd-info.ca/ (Accessed February 11, 2010)

The inclusion of the IIROC membership requirement by the provincial and territorial regulators means the same standards apply to all Investment Dealers in the business of carrying out derivatives transactions in Canada.

Applicability of the provincial and territorial laws, as well as the requirements of IIROC establishes a comprehensive set of proficiency, capital, solvency, and client relationship requirements. In addition there is authority to conduct compliance audits of members, investigate and take action to suspend or cancel registration, and take action to stop activities that pose a risk to markets and market participants.

4.2.3.2 Options

The Markets Committee has identified the following options:

A. Requiring every account holder to register as a commodities market professional .
B. Requiring every account holder in the business of advising or trading on behalf of other entities to register as a commodities market professional.
C. Not requiring any market participants to register as a commodities market professionals.

In addition, the Committee considered with whom an entity would register: with the state and provincial governments, or with a third party.

4.2.3.3 Evaluation of Options

As stated by the NFA, the two primary advantages of requiring registration are to screen the fitness of potential traders, and an identification of those traders to regulators. The disadvantages are that market professional registration requirements impose burdens on the entities that are required to register, as well as on the governments enforcing the requirements and the entity (government or third-party) that establishes criteria and evaluates applicants against them. In addition, assuming the implementation of Draft Recommendation 4 (Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System), WCI Partner jurisdictions would be able to require registration of account and compliance instrument holders, but may not have the ability to require registration of entities without tracking system accounts or ownership interest in compliance instruments.

Requiring market professional registration would also create an enforcement obligation for government regulators to maintain and monitor registration data.

The specialized expertise to register as a market professional is not typically found in the firms that will be compliance entities, and so would have to be acquired if all participants were required to register. The NFA's two arguments for registration are also weaker when considering compliance entities: First, they have been identified to regulators through their compliance obligation. Second, it could be argued that they have been "pre-screened" by their very inclusion in the cap-and-trade program—that is, regulators have already determined them to be fit to trade.

Intermediaries with tracking system accounts could similarly be said to be identified to Partner jurisdiction regulators. However, they would not necessarily be identified to US federal regulators in the way that derivatives traders are. In addition, it may aid confidence in the market to have intermediaries "screened" as described above. Especially in a new market, participant confidence in intermediaries is important. Many prospective intermediaries are already registered to trade commodity derivatives, and standards for, e.g., record keeping and accounting for customer funds are reasonable protections for clients.

Intermediaries without tracking system accounts or ownership interest in compliance instruments, who are active only in the secondary market, may fall outside this requirement, which could weaken its effect.

The Partner jurisdictions could require market professional registration with an agency of the jurisdiction. This would allow for determination of the specific market professional registration requirements appropriate for the regional cap-and-trade system, and could expand upon existing registration requirements in Canada. It could also mean that requirements would not necessarily be subject to changes in US law. It could further provide for consistency across jurisdictions. Partner jurisdictions would also have full access to registration documents and any required reports.

Alternatively, Partners jurisdictions could require market professional registration with a third party. Doing so could reduce administrative costs for governments by shifting the burden to define requirements, evaluating applications, and receiving reports. The WCI Partners could contract with an independent market monitor to facilitate market professional registration, or attempt to establish relationships with the NFA and/or the IIROC. As noted above, many potential intermediaries are already registered with those organizations.

4.2.3.4 Experience in Existing Environmental Cap-and-Trade Programs

Neither RGGI nor the US Acid Rain Program requires market professional registration to participate in the secondary market. Derivatives trading in both markets, including registration requirements, is overseen by the CFTC.

4.2.3.5 Draft Recommendation

The Markets Committee recommends that brokers, merchants, and advisors who hold accounts in the tracking system and are in the business of trading or offering financial advice regarding

WCI compliance instruments be required to register as market professionals with an SRO to do so. Compliance entities and entities trading on their own behalf should not be required to register. The Committee recommends that Partner jurisdictions use or establish relationships with the NFA and IIROC to authorize them to register intermediaries on the jurisdictions' behalf.

4.2.3.6 Relationship to Other Draft Recommendations

This recommendation assumes the implementation of Draft Recommendation 4 (Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System), Draft Recommendation 1 (Treat Compliance Instruments as Commodities for Market Oversight Purposes), and Draft Recommendation 5 (Do Not Limit Market Participation to Compliance Entities).

4.2.3.7 Requirements of Tracking System

Adoption of this Draft Recommendation would necessitate a way to associate a registration number with a tracking system account.

4.3 Holdings and Transfers

4.3.1 Draft Recommendation 7: Holdings Limits

"Market power" is the ability of an entity to move prices through its behavior. Market power can be derived from the control of a large fraction of the instruments in question. Though not all exercises of market power are malign, some are intended to manipulate the market. The Markets Committee is interested in the possibility of reducing the risk of market manipulation by limiting the accumulation of market power. One mechanism it has identified is the use of "holdings limits," or limits on the number of compliance instruments any one entity could control in the tracking system. The Committee has commissioned a consultant's report on holdings limits, and will consider that report among other information as it works towards final recommendations.

4.3.2 Draft Recommendation 8: Require Use of a Central Limit Order Book for Secondary Market Transactions

4.3.2.1 Background

In secondary market trading, counterparties exchange cash or its equivalent for prompt delivery of compliance instruments. Any other type of transaction or contract—one, for example, in which counterparties agree to exchange cash for compliance instruments at some future date—is not a secondary-market trade but a derivative contract, and is subject to derivatives market regulations. For the purpose of discussion in this section, adoption of Draft Recommendation 1 (Treat Compliance Instruments as Commodities for Market Oversight Purposes), is assumed, implying no new restrictions on derivatives trades. The discussion here will then be of secondary markets.

Secondary market trades may be executed in a variety of venues, with different characteristics, including how market participants determine prices, transparency, and clearing. The Markets Committee has focused on three types of venues: exchanges, central limit order books (CLOBs), and "over the counter" (OTC) transactions.

Exchange Transactions:
Exchanges are trading venues that have agreed rules for membership, trade reporting, order matching, and many other facets of transactions. One set of rules determines how buyers and sellers agree on prices. In general, exchanges maintain "order books." An order is the instruction to buy (a "bid") or sell (an "offer" or "ask") under certain conditions. A "limit order" is the instruction to buy or sell a certain quantity at a certain price (the bid or ask price). A "market order" is the instruction to buy or sell a certain quantity at the best price available. The order book lists the bids and offers, arranged by price and then by the time the order was placed. If there are a bid and offer at the same price, an order matching system will pair them and the transaction will be completed, for the volume of the smaller order. The remainder of the larger order remains on the order book for a subsequent match. In very liquid markets, the time between the posting of an order and its fulfillment is very short.

Members of an exchange can see the entire order book, and the available orders—both price and volume—contain information that will influence orders they place. For example, the "bid-ask spread" is the difference between bid prices and offer prices. A trader would typically place an order within the spread. Visibility of the order book may tend to keep the spread smaller, as a central price is clear to market participants. However, exchange order books and transactions are typically anonymous.

Exchanges typically make the price and volume of transactions publicly available after they have been executed.

Exchange transactions also imply other services to participants, including settlement (the exchange of money and goods or instruments) and clearing (in which a central organization is the counterparty for both the buyer and the seller). Clearing is discussed in more detail in the next section.

Central Limit Order Book Transactions:
A central limit order book (CLOB) is separable from the other services of an exchange. A CLOB would be an order book visible to market participants. A "hard" CLOB would, like the order-matching system on an exchange, execute matching orders automatically. A hard CLOB would

allow orders either anonymously or with an identification of the participant. A “soft” CLOB would be a central location to post and find bids and offers, but would not automatically match them; traders would have to separately contact each other to complete the transaction. A soft CLOB could not be anonymous. Bids and offers would be as transparent as on an exchange. Post-transaction data could also be reported by a CLOB; this could be largely automatic on a hard CLOB, where orders were automatically and bindingly matched, but on a soft CLOB participants would have to report final prices and volume for public disclosure. Final prices and volume might well be different than the posted order as a result of the counterparties’ negotiation.

Clearing, if it were used, and settlement would be through venues other than the CLOB, selected by the counterparties.

Over-the-Counter Transactions:
For purposes of this discussion, “OTC” refers to cash market trades of compliance instruments that bypass centralized quotation and execution systems, and which may trade outside the bid-ask spread listed on those systems. There is no central order book; prices are determined by bilateral negotiation between parties, who may refer to data on transactions in other venues, if they are available, to determine a fair price. In most OTC markets, there is no prompt and automatic reporting and disclosure of price and volume, making activity relatively opaque. Whether this opacity is damaging is subject to debate, and depends among other things on the liquidity of trades in more transparent venues. Clearing, if it is used, and settlement are through venues chosen by the counterparties.

4.3.2.2 Options

The Markets Committee has identified two categories of options in trading venues.
The first category is whether or not to require transparency in orders:

A. Require all secondary market transactions to occur on one or more exchanges.
B. Require orders for all secondary market transactions to be posted on a hard CLOB.
C. Require orders for all secondary market transactions to be posted on a soft CLOB.
D. Allow OTC transactions without use of a central order book.

The second category is whether or not to require clearing of all transactions, independent of order book transparency.

4.3.2.3 Evaluation of Options

Choice of Venue
The Markets Committee seeks a recommendation that would maximize both market transparency and market liquidity. It believes that both are needed for price discovery for compliance instruments, which is necessary for entities to make efficient decisions on

investments and compliance strategies. However, there may be tradeoffs between transparency and liquidity.

Transparency is important for several reasons. First, transparency is crucial to market participants' evaluation of the trades they are considering. Participants without knowledge of the current buying and selling interest in the form of firm bid and ask quotations and transaction reports are at a distinct disadvantage in assessing the value of traded assets. Thus, transparency is crucial to pricing efficiency, the market's ability to accurately reveal the value of traded assets. In addition, transparency permits investors to evaluate whether the market is treating them fairly by identifying the best available price. Without access to the prices other market participants are paying for the same asset, they cannot effectively determine whether they have paid a fair price.

Second, access to accurate market information enhances the ability of regulatory examiners and independent auditors to carry out their respective responsibilities to ensure that transactions and positions are priced appropriately.

Pre-trade market transparency is supported by exchange-based and central limit order book trading. Pre-trade transparency makes the price and quantity of actionable buying and selling interest accessible to all market participants.

Post-trade transparency makes the price and size of the most recently executed trades accessible to all market participants. An exchange or a hard CLOB could make immediate post-trade transparency automatic. If a transaction price is required to transfer allowances from one account to another, post-trade transparency from all venues, including OTC, could also be supported by publication of data submitted to the tracking system (see section 4.3.4). However, timing is crucial. If the market is changing rapidly, delays in reporting by participants could obscure important information. The Markets Committee is concerned about the enforceability of requirements to report transactions promptly.

In a wholly OTC secondary market, buyers or sellers would solicit prices by telephone or email from whatever subset of intermediaries or potential counterparties they have the time and resources to contact, and hope that they have gotten a fair price. If traded prices are not promptly reported, traders cannot confirm whether or not they have obtained a fair price. In the absence of centralized collection and reporting of quotations and traded prices, intermediaries such as brokers and broker-dealers may emerge as market makers, offering pockets of liquidity to counterparties who might not otherwise find each other. The less transparent the market is, the more reliant compliance entities and others would be on intermediaries that would charge fees for transactions and could have significant information advantages.

At the same time, intermediaries can increase liquidity. First, a broker may have a broader understanding of a market than compliance entities or other participants, and may be able to facilitate negotiation of trades. Second, dealers may act as “market makers,” willing to either buy or sell compliance instruments at any time. Market makers make money on the spread, always attempting to sell allowances for a price higher than they paid. The narrower the spread is, the less incentive there is for an intermediary to be a market maker. Narrower spreads could then decrease liquidity.

Selecting one or a small number of trading venues may “drive liquidity” to that venue and ensure that buyers and sellers can find each other. However, exchanges and CLOBs fund themselves in part through fees which, though small, may discourage some transactions. Liquidity is not only affected by policy decisions, but can affect them as well. The importance of driving transactions to one or more regulated platforms depends in part on the liquidity of other pieces of the market. If a sufficient number of transactions occur that the current fair market price for a compliance instrument is discernable from widely available data, e.g., from exchanges, then bid and ask spreads should be small and transactions should seldom deviate far from that price. However, if secondary market transactions are rare, the reported price could be quite volatile, and current orders opaque.

The derivatives markets also play roles in price discovery and liquidity that may affect the tradeoffs in a policy decision to select one or more venues. The various inputs to consider appear to be impossible to predict.

In principle, multiple venues could be linked to a single quotation system. As an example of such a system, in the secondary market for US equity securities, all exchanges and Alternative Trading Systems (ATSs) are required to contribute their quotations in real time to a central quotation system called a securities information processor. The collection, processing, and distribution of quotations is a central function of a collection of rules, practices, and infrastructure known as the national market system (NMS). The purpose of the NMS is to ensure transparency, effective oversight, fairness and pricing efficiency. Nearly all secondary-market transactions of U.S. securities listed on exchanges and ATSs are executed at prices within the NMS’s published bid-ask spread for listed shares, and last-trade price and quantity are available in real time to all market participants.

Customization in OTC transactions and duration of OTC contracts compared to illiquid long-term markets are often cited as reasons to allow OTC derivative contracts. However, in secondary markets, neither of these is a strong argument: there is very little to customize, and the timescale is short by definition. An exception is repurchase or “repo” agreements, in which compliance instruments are sold by one entity to another, with an agreement that the first entity will buy them back in the future. This is effectively creating a loan with the compliance instruments as collateral. Technically derivatives, repos still require an OTC transfer of ownership.

Partner jurisdictions could enforce use of a particular venue by requiring an identifying number for an order or executed transaction to accompany transfers of allowances from one account to another. The venue could be required to provide information on transactions to the jurisdictions, as well as quotations and last-trade prices. Compliance entities might be offered low- or no-cost access to order-matching services at the designated venue (though see section 4.2.2 for a discussion of identifying compliance entities).

However, there is a blurry line between the secondary and derivatives markets. The European Climate Exchange offers a standard contract for European Union Emission Allowance Daily Futures, which are settled by physical delivery in at most two business days. If the Draft Recommendation 1 (Treat Compliance Instruments as Commodities for Market Oversight Purposes) is adopted and the Partner jurisdictions make no collective recommendations to restrict derivatives trades, then restrictions on secondary market transactions might be easily dodged by firms creating forward contracts with very short expirations. Treatment of allowance transfers that are the fulfillment of derivatives contracts and not secondary market transactions would be another implementation consideration. Also, compliance entities might desire to transfer compliance instruments between facilities owned by a single company, or between entities owned by the same holding company. From 1994 – 2003, only about half of the allowance transfers in the U.S. Acid Rain Program were between "economically distinct organizations."[28] The implications for creating and enforcing exceptions to a venue requirement should be considered.

Clearing

In a recent case of a systemic problem due to counterparty risk, the September 15, 2008 bankruptcy filing of Lehman Brothers was part of, and greatly accelerated, a financial panic, in part because Lehman Brothers was counterparty to many other large financial institutions in a variety of transactions. Its collapse left counterparties uncertain about their losses, and uncertain about the exposure of others. This uncertainty helped to freeze financial activity.

The clearing organizations associated with exchanges require from all members security deposits that can be used if a member defaults on its contracts. In this way, the risk of default

---

[28] WCI staff analysis of data at "Trading Activity Breakdown | Market Analyses | Assessments and Tools | Clean Air Markets | Air &", Environmental Protection Agency, http://www.epa.gov/airmarkt/progress/transtable.html (Accessed January 4, 2010).

from one company is shared by clearing members. The members then have a strong incentive to set the rules for membership and for transactions to balance default risk and the cost of doing businesses.

Clearing through a central counterparty can reduce the risk of systemic problems by setting requirements for collateral, limiting the exposure of any single member, and collecting information for regulators and the public. On the other hand, clearing organizations may not be willing to guarantee all trades that would be economically efficient, and will charge for their services. The clearing function is typically integrated with trade confirmation, netting, registry (or "depository") and settlement services. Without clearing organizations, traders would need to individually evaluate the credit risk of every trade and counterparty, and establish separate payment and delivery arrangements with each counterparty. Central counterparty clearing reduces transaction processing costs for participating traders, and enables higher trading volumes by streamlining post-trade processing. However, clearing is effectively the extension of credit by the central counterparty, which comes at some cost. Many end users of commodities can obtain similar credit for at smaller expense, and so prefer not to clear transactions.

Though there are differing opinions about the advantages of clearing, in general it is believed to reduce the risk of systemic problems by reducing or redistributing counterparty risk. This risk is larger in derivatives markets, where positions may be built up over some period of time, and during which time the price may change, than in secondary market transactions, which are settled in the matter of a day or two at an agreed-upon price.

In a typical secondary-market exchange, only firms that sustain a high volume of trades are clearing members. Lower-volume or occasional traders trade through intermediaries (brokers or asset managers, e.g.) that are also clearing member firms. It is not necessary to operate as a clearing member firm in order to benefit from the transaction-processing efficiencies of a cleared market. However, requiring an intermediary that is a clearing member is potentially a cost to compliance entities and others.

4.3.2.4 Experience in Existing Environmental Cap-and-Trade Programs

Neither the Acid Rain Program nor RGGI requires secondary market transactions to go through a single venue, quotations to be reported to a central service, or clearing for secondary market transactions.

4.3.2.5 Draft Recommendation

The Markets Committee recommends that orders for secondary market transactions be required to be reported to a "hard" central limit order book to centralize liquidity and enhance transparency. The CLOB could be the order-matching system of a designated exchange or another system designated by the WCI Partner jurisdictions. Considering all the tradeoffs identified above, the Committee believes that the public is best served by clear and immediate price signals. However, we recognize that this is a particularly complex issue and we invite stakeholder comment on this Draft Recommendation.

In the event that the CLOB is not part of an exchange, the Committee does not recommend requiring clearing of non-exchange transactions. The risks identified are small in secondary markets.

4.3.2.6 Relationship to Other Draft Recommendations

This Draft Recommendation relies on the adoption of Draft Recommendation 4 (Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System). It assumes the adoption of Draft Recommendations 1 (Treat Compliance Instruments as Commodities for Market Oversight Purposes); 5 (Do Not Limit Market Participation to Compliance Entities), and 10 (Information Required for Compliance Instrument Transfer).

4.3.2.7 Requirements of Tracking System

The tracking system would be required at least to accept and verify a transaction number from the central limit order book before compliance instruments were transferred between accounts. The tracking system could potentially provide the function of the central limit order book.

4.3.3 Draft Recommendation 9: Require Reporting of Beneficial Ownership

4.3.3.1 Background

When one person holds property (or some other interest) for the benefit of another person, the person holding the property is referred to as the “record” or “legal” owner and the person for whom the property is being held is referred to as the “beneficial,” “equitable,” or "indirect" owner. For example, where title to land is registered in the name of a trustee who holds the property for the benefit of the owners of the trust, the trustee is the record owner and the beneficiaries of the trust are the beneficial owners. Similarly, when a brokerage firm holds securities (e.g., stock certificates) in their own firm’s name (their “street name”) for their customers’ accounts with the firm, the firm is the legal owner and the customers are the beneficial owners.

4.3.3.2 Options

WCI Partner jurisdictions have several options regarding reporting of beneficial ownership, including, but not limited to the following:

A. Requiring that account holders publicly disclose beneficial ownership;

B. Requiring that account holders report beneficial ownership to regulators on a confidential basis;
C. Require that account holders maintain records of beneficial ownership and produce such records upon written request of regulators; or
D. Not require that account holders maintain records of or disclose information regarding beneficial ownership.

Should the WCI jurisdictions elect to require reporting of beneficial ownership to regulators and/or disclosure to the public, decisions must also be made regarding the timing of such disclosures. For example, disclosure of the beneficial ownership could be required

A. When an account is opened on the registry;
B. Contemporaneously with any transaction transferring ownership
C. On a periodic basis, or
D. With some other fixed or variable requirement regarding the timing of the disclosure.

4.3.3.3 Evaluation of Options

The different options outlined above in 4.3.3.2 have significant implications for the regulators charged with the administration, monitoring and enforcement of the compliance instrument markets and the overall cap and trade program. In addition, the different options have impacts on the level of transparency in the market. Below we discuss the major implications identified to date.

The regulators responsible for prevention of manipulation and speculative activity that leads to price distortion in the compliance instrument markets will benefit from access to information regarding the beneficial ownership of compliance instruments. Absent this information, regulators may not be able to perform their duties, which may include: (a) monitoring the market for manipulative trading schemes such as “wash” sales, which are trades that appear to be between two parties but are really between different accounts controlled by the same person; (b) detecting the accumulation of substantial positions in compliance instruments that could allow the beneficial owner to exercise of market power; (c) enforcing a holdings limit or other rule designed to avoid speculative activity that leads to price distortion; or (d) providing accurate and timely information on the compliance instrument and derivatives market to other regulators (e.g., US federal regulators of derivatives markets).

In addition, the regulators responsible for environmental compliance could also benefit from access to information regarding beneficial ownership. Those regulators may want the ability to track the actual compliance instrument holdings of reporting sources (at least at a business entity level) over time, rather than simply at the end of a three-year compliance period. Such information would allow early detection of sources that have (a) taken insufficient steps to procure the compliance instruments they will need at the end of the compliance period, or (b) appear to be taking on excessive risk through the accumulation of a large excess of compliance instruments. Such assessments would be difficult, if not impossible, without accurate information as to the beneficial ownership of compliance instruments.

The public disclosure of beneficial ownership has several potential implications we have identified to date. Public disclosure of beneficial ownership would enhance the transparency of the cap and trade program. This may help maintain pubic confidence in the program. Transparency in ownership also would allow local interests to track the market position of local sources. Transparency in ownership would enhance the flow of information in the market, which could lead to improved efficiency. Transparency in ownership also puts more "eyes" on the market, increasing the likelihood that market violations will be detected and reported. Transparency in ownership could also reveal corporate trading strategies; however, such information may already be public for a large number of sources (e.g., because the account holder and owner are one and the same, or because disclosure is required by another regulator such as the SEC or a Utilities Commission).

4.3.3.4 Experience in Existing Environmental Cap-and-Trade Programs

In existing emissions markets in the United States, the EPA and RGGI have set up at least two classifications of accounts on their registries: compliance accounts and general accounts. Each facility with a compliance obligation must have a compliance account registered in its own name. In creating the compliance account, EPA and RGGI regulations require that the facility disclose the names of the legal and equitable owners and operators of all emitting units at the facility, identify those units in detail and assign an individual as the authorized account representative. Since the compliance account is tied to a single facility, it is relatively easy to track beneficial ownership.

Under the EPA's and RGGI's regulations, general accounts may be opened by a facility, a person owning one or more facilities, or a person with no compliance obligation (e.g., brokers, dealers, banks, individuals, non-governmental organizations, etc.). General accounts are opened in the name of the representative and her company or organization, as opposed to the name of a single facility. Registration of a general account requires identification of "all parties with an ownership interest in the allowances held in this account."[29] If the parties to an account change, the form must be amended and resubmitted within 30 days.[30] In this way, the EPA and RGGI appear to capture some beneficial ownership information both up front and on an ongoing basis through the registration process.

---

[29] "Instructions for General Account Form," Environmental Protection Agency Form 7610-5 (Revised 12-2009), http://www.epa.gov/airmarkets/business/docs/forms/gen_acct2010.pdf (Accessed February 22, 2010).
[30] US Code of Federal Regulations, Title 40, section 73.31 (c)(iv).

In addition, all persons or groups participating in a RGGI auction must disclose their beneficial relationships to other persons and groups participating in the auction. Information on beneficial ownership is gathered via a thorough an online application system for participants in the regional auctions and is used, in part, to ensure that participants comply with the 25% purchase limit.

Not currently gathered by RGGI and the EU ETS, however, is each beneficial owner's fractional interest in compliance instruments in an account. This information would be necessary if the WCI Partner jurisdictions were to decide to fully evaluate an entity's holdings (see section 4.3.1).

4.3.3.5 Draft Recommendation

The Markets Committee recommends that account holders be required to report beneficial ownership of all compliance instrument holdings to regulators on a confidential basis, including each owner's share in an account. This means each participant in compliance instrument markets where WCI compliance instruments are sold will be obligated to report any party who sponsors or benefits from an agent's activities.

The Committee further recommends that account holders be required to report changes in the fractional ownership of compliance instruments in an account immediately upon the transaction, even if the transaction does not involve a transfer of allowances between accounts.

When some portion of the ownership information is proprietary, it should be kept confidential.

4.3.3.6 Relationship to Other Draft Recommendations

This Draft Recommendation assumes the adoption of Draft Recommendations 4 (Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System), 5 (Do Not Limit Market Participation to Compliance Entities), 6 (Require Registration of Intermediaries as Market Professionals), and interacts with Draft Recommendations 10 (Information Required for Compliance Instrument Transfer), and 11 (Secondary Market Holdings and Transfer Information Disclosed to Public). Implementing a holdings limit, discussed in Draft Recommendation 7 (Holdings Limits), would require disclosure of beneficial ownership to regulators.

4.3.3.7 Requirements of Tracking System

If disclosure of beneficial ownership is required, the tracking system would need to accommodate multiple owners for accounts, their fractional ownership, and mechanisms to update this information quickly as it changes.

4.3.4 Draft Recommendation 10: Information Required for Compliance Instrument Transfer

4.3.4.1 Background

Assuming the adoption of Draft Recommendation 4 (Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System), the tracking system would hold the record of ownership of compliance instruments. Collection of basic information would be required upon transfer of ownership to make the tracking system a reliable repository and to collect market information that is important for transparency. (Draft Recommendation 11 considers which of this collected information would be disclosed to the public).

4.3.4.2 Options

At a minimum, the tracking system, to be a complete record of ownership, would need to record for each transfer:

A. The account of origin, and name of the authorized person for that account;
B. The receiving account;
C. The serial numbers of the compliance instruments being transferred (and by implication the quantity being transferred); and,
D. The date and time of the transfer.

Any number of additional data could be collected; the Markets Committee has identified the following to be of particular interest:

E. Changes to beneficial ownership;
F. The name of an authorized person for the account that will receive compliance instruments;
G. The compliance instrument price and currency (US or Canadian dollars);
H. Date of the contract, if different from date of transfer (e.g., for derivatives contracts);
I. Other information related to derivatives transactions.

4.3.4.3 Evaluation of Options

A minimum amount of information must be kept by the tracking system in order for it to be a reliable record of ownership. Additional information may assist regulators in oversight of the market, and disclosure to the public would increase market transparency. These benefits can be weighed against the additional burden to participants of reporting more information, and to regulators in collecting and analyzing it.

Draft Recommendation 9 (Require Disclosure of Beneficial Ownership) includes a discussion of beneficial ownership. Draft Recommendation 8 (Require Use of a Centralized Order-Matching

System for Transactions) includes a discussion of a centralized quotation service. Draft Recommendation 11 (Secondary Market Holdings and Transfer Information Disclosed to Public) includes a discussion of public disclosure of both account holder information and secondary market information.

In general, it is only a small amount of additional reporting burden to request the name of the authorized person for the receiving account. In the case of exchange trading where transactions are netted and anonymous, the jurisdictions may choose to require a net report of accounts from which or to which allowances were transferred. The compliance instrument price for the transaction could be challenging if, for example, compliance instruments were bundled with another product (electricity or natural gas) with a single price. However, the Partner jurisdictions could insist on a price report.

The price and date of contract could also be challenging for some derivatives. For example, an exchange-traded futures contract is settled at an agreed-on date, with the product transferred for a settlement price that is likely to be different than the price at which the contract was purchased. The gain or loss is computed at some interval, say, daily, and added to or subtracted from the margin accounts of market participants. The "date of contract" and price would then have to be carefully defined in order to avoid confusion.

4.3.4.4 Experience in Existing Environmental Cap-and-Trade Programs

The Acid Rain Program does not require price information or any information about the date of a contract to deliver compliance instruments. RGGI requires price information for any transfer between non-affiliated entities, as well as date of contract; the date of contract is defined to be the settlement date.

4.3.4.5 Draft Recommendation

The Markets Committee recommends requiring identification of: the name of the authorized person for the account of origin; the number of the account of origin; the name of the authorized person for the account that receives compliance instruments; the account receiving compliance instruments; the serial numbers of the compliance instruments being transferred, and the compliance instrument price. It further recommends requiring a net report from an exchange or any organization that nets transactions. It recommends that the tracking system supply the time and date stamp. If the Partner jurisdictions require collection of derivative positions (Section 4.1.2) it would be duplicative to require information on date of contract.

4.3.4.6 Relationship to Other Draft Recommendations

This Draft Recommendation assumes the adoption of Draft Recommendations 4 (Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System), 5 (Do Not Limit Market Participation to Compliance Entities), 8 (Require Use of a Centralized Order-Matching System for Transactions), 9 (Require Disclosure of Beneficial Ownership), and 11 (Secondary Market Holdings and Transfer Information Disclosed to Public).

4.3.4.7 Requirements of Tracking System

This Draft Recommendation would require the tracking system to allow and require that the fields for all the above named data, as well as net reports, and supply a time and date stamp with the submission of information.

4.3.5 Draft Recommendation 11: Secondary Market Holdings and Transfer Information Disclosed to Public

4.3.5.1 Background

As stated in the Market Oversight white paper released in November 2009, the central purpose of a market mechanism is to aggregate and transmit price information. With full, true and plain disclosure, both regular and timely, market participants can use the information to determine a fair market price. In the secondary market, it is important for participants to have reliable, good quality and timely information about outstanding bids and offers, and recent trades, so they can discover the right price and act accordingly.

The WCI Markets Committee has proposed the principle of "Transparency and the Reporting and Disclosure of Relevant Information," to acknowledge that the release of information on the operation of the compliance instrument market builds and retains public confidence, and can change the decisions of market participants.

> "A transparent marketplace could provide carbon market participants, regulators, and potentially the general public with information to determine where carbon instruments are trading, the entities involved in the transactions, the trading volume, and the prices at which they are trading. This, in turn, could allow government officials and market watchdogs to quickly determine the cause(s) of unusual price volatility. In addition, information about prices, volume, and bid/ask spreads could also help market participants make informed investment decisions, thereby reducing some of the causes of price volatility in the first place."[31]

[31] Source: "U.S. Carbon Market Design: Regulating Emission Allowances as Financial Instruments", Jonas Monast, Jon Anda, Tim Profeta, Duke University, February 2009, CCPP 09-01, working paper, Climate Change Policy Partnership http://www.nicholas.duke.edu/ccpp/ccpp_pdfs/carbon_market_primer.pdf (Accessed March 30, 2010).

As noted in section 4.3.3.4, RGGI and the Acid Rain Program have created two types of accounts: general accounts, which any person may have and can be used for trading; and compliance accounts, which are established for entities that must surrender compliance instruments matching their emissions to satisfy a regulatory obligation. The Partners are developing requirements for a tracking system; the Markets Committee considered the possibility of two types of accounts in developing this Draft Recommendation.

4.3.5.2 Options

Account Information Disclosure

The Markets Committee has considered the following options for public disclosure of account holder information:

A. Account representative for compliance and trading accounts;
B. Owner/operator associated with compliance accounts;
C. Beneficial owners of compliance units held within account;
D. State/province in which account representative is located.

Secondary Market Information Disclosure

The Markets Committee has considered the following options in for public disclosure of compliance instrument transfers:

A. Trade volume, quantity and settlement prices of compliance units traded;
B. Names of counterparties to each transaction;
C. Names of beneficial owners;
D. Compliance account holdings;
E. Trading account holdings.

The Markets Committee has considered the following options for means of disclosure of secondary market information:

A. Directly through the online tracking system, and through search functions;
B. Through exchanges where transactions occur; and/or,
C. Through periodic WCI market reports published on the WCI website.

The Markets Committee has considered the following options for the frequency and timing of the secondary market information disclosure:

A. In real time for volumes and prices;
B. Daily for volumes and prices; and/or,
C. Quarterly or post-regional auctions for summaries.

4.3.5.3 Evaluation of Options

The WCI Markets Committee recognizes that a balance must be struck between the benefits of transparency and the need for entities to protect certain sensitive information, consistent with applicable law relating to the disclosure of information. Some information may reveal competitive positions that would do more to assist market manipulation than prevent it. Thus, certain information collected through the tracking system or other aspects of the WCI cap and trade system should not be disclosed publicly in its original reported form. In some cases information can be aggregated in order to maintain the anonymity of the actors while still relaying important market information.

The WCI Partner jurisdictions will have access to the raw information reported to the tracking system, as it is required for regulatory authorities to conduct effective oversight and monitor compliance. In its Final Recommendations, the Markets Committee may recommend restrictions on staff of those regulatory authorities who have access to confidential market information collected through the tracking system from operating in the market, to prohibit insider trading based on undisclosed material information and tipping.

The key characteristics that the WCI Markets Committee seeks in terms of disclosed information are that it is:

- Full;
- Straightforward;
- Good quality;
- Reliable;
- Regular; and,
- Timely.

The holdings in a compliance account are useful to reveal to support compliance, as an indication of whether a regulated entity is on track to retiring as many compliance instruments as are required to cover its covered emissions for a compliance period. However, holdings in trading account are not required for the same purpose, and may reveal sensitive information. The total number of compliance instruments within the cap and trade will be publicly established by the Partner jurisdictions as they create their allowance budgets.

The increased transparency resulting from a high frequency of market information disclosure must be balanced against the administrative cost to market participants and regulatory authorities to report, collect and process that information within the given timeframe.

4.3.5.4 Experience in Existing Environmental Cap-and-Trade Programs

Existing environmental cap and trade programs handle public disclosure in the following ways:

DISCLOSURE	EU ETS: Community Independent Transaction Log	RGGI: RGGI COATS[32]
Delivery	Information on all transactions (transfer, issuance, etc. of allowances) recorded by the Community Independent Transaction Log, including originating and destination account number, holder and type. This information will be made available online and at EU level but not until five years after the year in which the transaction took place. Price is not recorded in ETS registries or in the CITL.	RGGI CO_2 Allowance Tracking System (COATS) allows public to view, customize and download reports of allowance market activity
Account information	Varies by country. In the UK, reports listing operator holding accounts and person holding accounts are published on UK registry website. Reports are updated regularly.	Account number, account name, facility owner/operator (for compliance accounts), parties with an ownership interest in the allowances in the account (for general accounts), account type, authorized account representative, and state are all public.
Transaction information	Counterparties not disclosed.	Transaction type, financial transaction date, RGGI COATS allowance transfer recordation date, price and number of allowances for each transaction, and weighted average price of all transactions during the range of dates specified by the query are public. Counterparties not disclosed.
Trading/active account holdings	Number of instruments in each account is not disclosed.	Number of instruments in each account is not disclosed.
Compliance/ retirement account holdings	Not applicable.	Number of instruments in each account is not disclosed.
Derivatives positions	Not disclosed.	Not disclosed.
Market reports	Exchanges and news services produce daily and real-time market reports.	Exchanges and news services produce market reports; the third-party market monitor prepares a public report on each auction.

4.3.5.5 Draft Recommendation

The WCI Markets Committee recommends the following:

Tracking system account information publicly disclosed on an ongoing basis:

[32] RGGI > CO2 Allowance Tracking System > Data in RGGI COATS > Public Reports (http://www.rggi.org/tracking/data/public_reporting)

A. Account representative for compliance and trading accounts;
B. Owner/operator associated with compliance accounts;
C. Names of beneficial owners of compliance units held within account;
D. State or province in which account representative is located.

Market information publicly disclosed daily through the tracking system:

E. Compliance account holdings.

Market information not publicly disclosed:

F. Names of counterparties and beneficial owners to each transaction;
G. Fraction of each beneficial owner's interest in an account;
H. Trading account holdings.

4.3.5.6 Relationship to Other Draft Recommendations

Assuming the adoption of Draft Recommendation 8 (Require Use of a Central Limit Order Book for Secondary Market Transactions), price information will be publicly disclosed through that mechanism, and need not be duplicated through the tracking system. This Draft Recommendation also relies on the implementation of Draft Recommendations 9 (Require Disclosure of Beneficial Ownership) and 10 (Information Required for Compliance Instrument Transfer). Draft Recommendation 2 (Information on Derivatives Positions) includes a related discussion on disclosure of derivatives position information.

4.3.5.7 Requirements of Tracking System

This Draft Recommendation implies that the tracking system must:

- Be online;
- Have some services of the tracking system accessible to the public;
- Have some services of the tracking system restricted to account holders, to authorized staff of regulatory authorities, or to system maintenance service providers;
- Have filters such that, for example: compliance account holdings are shown but general trading account holders are not;
- Have the ability to generate customized reports for regulatory authorities.

4.4 Market Monitoring

4.4.1 Draft Recommendation 12: Market Monitoring

The Markets Committee believes that a third-party contractor may improve oversight by complementing and supplementing the monitoring of the Partner jurisdictions. For its Final Recommendations, the Committee will evaluate options more fully and may describe the recommended role of a contractor.

5 Roles of Provincial, State, and Federal Regulatory Agencies

The Markets Committee is analyzing market oversight jurisdiction at the US federal and state and Canadian federal and provincial levels, for both secondary and derivatives markets. Specifically, the committee is examining whether WCI jurisdictions currently have the authority to implement the recommendations made for oversight of the secondary market, and what agencies have this authority. In its Final Recommendations, the Committee intends to include a discussion of jurisdiction for the oversight authorities recommended, as well as coordination between the relevant regulatory bodies.

6 Conclusion

The Markets Committee believes that these Draft Recommendations, collectively, are in accord with the principles adopted for market oversight, and that they provide good risk management in balancing the potential for market manipulation against the potential to stifle legitimate market activity. It has also identified some areas where additional work is required to make a recommendation. The Committee welcomes comment on the Draft Recommendations individually and collectively, and in particular on:

A. Whether the tools available to WCI Partner jurisdictions for market oversight have been completely and correctly identified;
B. Whether the Draft Recommendations would correctly maximize the environmental and economic benefit to the public and support WCI's Principles of Market Oversight;
C. Whether the Committee should recommend collection of derivatives position information from market participants, including on over-the-counter derivatives; and if so, what of that information to disclose to the public;
D. The Draft Recommendation to require secondary market trades to use a central limit order book.

Incorporating stakeholder comment on the Draft Recommendations among other sources of information, the Committee plans to release Final Recommendations before June 30, 2010.

Draft Recommendations

Four categories:

- Allowances, Offset Certificates, and Derivatives
- Market Participants
- Holdings and Transfers
- Market Monitoring

Allowances, Offset Certificates, and Derivatives

- #1: Treat Compliance Instruments as Commodities for Market Oversight Purposes
  - Implies primary regulation of derivatives by provincial securities commissions and US federal regulators
- #2: Information on Derivatives Positions
- #3: Treat Allowances and Offset Certificates Identically for Market Oversight Purposes

Market Participants

- #4: Establish Legal Relationship with Market Participants Through Compliance Instrument Ownership Interest and Tracking System
- #5: Do Not Limit Market Participation to Compliance Entities
- #6: Require Registration of Intermediaries as Market Professionals

Holdings and Transfers

- #7: Holdings Limits
- #8: Require Use of a Central Limit Order Book for Secondary Market Transactions
- #9: Require Reporting of Beneficial Ownership
- #10: Information Required for Compliance Instrument Transfer
- #11: Secondary Market Holdings and Transfer Information Disclosed to Public

Market Monitoring

- #12: Market Monitoring

Request for Stakeholder Comments

A. Whether the tools available to WCI Partner jurisdictions for market oversight have been completely and correctly identified;

B. Whether the Draft Recommendations would correctly maximize the environmental and economic benefit to the public and support WCI's Principles of Market Oversight;

C. Whether the Committee should recommend collection of derivatives position information from market participants, including on over-the-counter derivatives; and if so, what of that information to disclose to the public; and

D. The Draft Recommendation to require secondary market trades to use a single central limit order book.

1 Executive Summary

This paper is the second paper issued by the WCI Offsets Committee as part of its efforts to design the WCI Offset System. The first paper, entitled *Offset Definition (Task 1.1) and Eligibility Criteria (Task 1.2) White Paper*[1] ("the Criteria White Paper") was released in July and presented options for defining a WCI offset and the essential criteria. The release of the first paper was followed by a period of gathering stakeholder input through webinars and written comments.[2] This recommendations paper was prepared by members of the WCI Offsets Committee based on the first options paper, stakeholder feedback, and input from WCI Partners. This recommendations paper presents draft recommendations for the offset definition and essential criteria. Following the release of this paper, stakeholders will have an opportunity to provide feedback prior to issuing the final WCI recommendations. A final recommendations paper is expected to be released in early spring 2010.

For ease of reference, all of the draft recommendations in this paper are copied in Table 1.0 below.

Table 1.0 Draft Recommendations

Section	Criteria	Draft Recommendation
3.1	Offset Definition	A WCI offset certificate is issued by a WCI Partner Jurisdiction and represents a reduction or removal of one metric ton of carbon dioxide equivalent (tCO_2e). The reduction or removal must meet the recommended essential criteria for reductions and removals to be real, additional, permanent, and verifiable. Reductions and removals must also be clearly owned, adhere to recommended protocols, and result from a project located in a qualifying geographic area.
3.2.1	Offset Ownership	An offset project proponent must have legal ownership of the greenhouse gas emission reduction or removal resulting from the offset project. The offset project proponent will be responsible for all statements and information provided to the

[1] Available at: http://www.westernclimateinitiative.org/components/com_publiccomments/documents/WCI-Offset_Definition_and_Criteria_072409.pdf
[2] The stakeholder comments are archived here: http://www.westernclimateinitiative.org/public-comments/document/7

		WCI Partner Jurisdiction issuing the offset certificate during the creation of the offset certificate and verification of the reduction or removal. The WCI Partners should establish a registry of offset certificates issued and make the registry publicly available.
3.2.2	Use of Recommended Protocols	A WCI Partner jurisdiction will issue WCI offset certificates for compliance with the WCI cap-and-trade program only from projects which employ protocols that have been recommended through the WCI protocol review process ("WCI offset protocols").
3.2.3	Geographic Limits	A WCI Partner jurisdiction may issue offset certificates for projects located within its own jurisdiction as well as jurisdictions outside the WCI cap-and-trade region within North America. A WCI Partner jurisdiction will accept offset certificates issued by other WCI Partner jurisdictions. As described in section 9.8 of WCI's design document, WCI Partner jurisdictions may also accept offset certificates from outside North America.
4.1	Real	A WCI offset certificate represents a reduction or removal of one metric ton of CO_2e that results from a clearly identified action or decision. A WCI offset project's reduction or removal is quantified using accurate and conservative methodologies that appropriately account for all relevant greenhouse gas sources and sinks and leakage risks. WCI offset projects result in emissions reductions or removals that take place at sources controlled by the project proponent.
4.2.1	Quantification, Uncertainty, and Accuracy	Quantification: WCI Partner Jurisdictions shall ensure that net emission reductions or removals are capable of being measured or modeled in a reliable and repeatable manner that includes all relevant sources and sinks. Quantification methodologies for GHG emissions or emission reductions shall: • Be appropriate to the GHG source or sink • Be current at the time of quantification • Consider local conditions, whenever applicable • Account for uncertainty – be calculated in a manner that yields accurate and reproducible results • When uncertainty is above the defined threshold, apply the principle of conservativeness to GHG accounting. During quantification procedures, project proponents shall

		convert each type of GHG to metric tons of CO2e. In addition, WCI offset protocols shall use uniform quantification methods whenever feasible. Uncertainty and accuracy: Quantification methodologies and measurement techniques shall set standards for acceptable statistical precision and be based on the best available science. They shall also reduce bias, except for promoting conservative estimates. When uncertainty remains high in quantifying the amount of a greenhouse gas emission reduction or removal, the principle of conservativeness shall be applied. Principle of conservativeness: Where uncertainties are above the defined threshold, offset quantification methods should use more conservative quantification parameters, assumptions, and measurement techniques that minimize the risk of overestimating emission reductions and removals credited for a given project. The principle should be employed when significant uncertainties arise to ensure a higher level of confidence that all calculated reductions are real.
4.2.2	Leakage	To address activity-shifting and market leakage, WCI Partner Jurisdictions will require assessments of whether functional equivalence has been maintained within projects and require that protocols include methods for leakage assessments. WCI offset protocols will evaluate functional equivalence for each project. WCI offset protocols will also require an assessment of potential leakage associated with each project type. In general, WCI jurisdictions prefer the following methods to review leakage risk: • A quantitative assessment of leakage will be performed whenever possible. • When a quantitative assessment is not feasible, a qualitative risk assessment will determine whether the risk of systematic leakage is significant or not. • WCI offset protocols will include a threshold to identify significant leakage. If leakage is found to be above the threshold, the protocol quantification methodology will include a factor to account for leakage.

5.1	Additional	The WCI Partner jurisdictions intend for additionality to be established in a manner that will require offset projects to be evaluated against a baseline that reflects conservative assumptions that are consistent across all WCI jurisdictions. These assumptions will be described in the procedures for setting a baseline in WCI offset protocols. Modeling or other methods of developing the baseline shall use assumptions, methodologies, and values that provide the WCI Partner jurisdictions with assurance that GHG reductions or removals from a project are not over-estimated (consistent with the principle of conservativeness in 4.2.1). When possible, the baseline shall be set using a sector-specific or activity -specific performance standard; otherwise a project-specific baseline may be used. Performance standards used to establish a baseline will be set so as to reflect the most stringent regulatory requirements and legal requirements of any WCI Partner jurisdiction (those requirements leading to the most conservative calculation of emission reductions). When a project specific baseline is used, the baseline will be set so as to reflect all binding agreements, regulatory requirements and legal requirements in the jurisdiction where the project is located.
5.2.1	Eligibility Date	Offsets may only be awarded for projects that are initially commenced on or after September 23, 2008; the date of the WCI Design Recommendations that identified the priority project types for WCI offsets. Offsets may be awarded for all GHG reductions or removals occurring after September 23, 2008. An offset project proponent must apply to register its project with a WCI Partner Jurisdiction within one year of project commencement. Projects that commenced prior to finalization of the applicable protocol must apply within one year of the protocol's finalization.
5.2.2	Crediting Period	The crediting period for non-sequestration WCI offset projects will be 10 years, which may be once renewed for an additional 10 years. The crediting period for sequestration projects will be specified by the applicable protocol. However, any individual crediting period may not exceed 25 years before a renewal, and the total crediting period including all renewals may not exceed

		100 years. Renewal of a project at the end of a crediting period will include a reevaluation of a project's additionality and reevaluation of how the reductions are quantified and verified. Thus, the baseline scenario will be reevaluated at each renewal.
6.1	Permanent	With respect to offset project activities, permanence means either that reductions or removals are not reversible or that, if reductions or removals are reversible, then the text outlined in the remainder of this recommendation are met. Sequestration projects must ensure the atmospheric effect of their greenhouse gas removal will endure for a period that is comparable to the atmospheric effect achieved by non-sequestration projects. The duration for this period is to be based upon current scientific findings that are widely accepted and followed. The current international standard of 100 years has been established by the UNFCCC and will be followed by WCI Partner jurisdictions. WCI Partner jurisdictions will adopt new international standards (likely UNFCCC) if/when they are updated. Offset projects where the reduction or removal is maintained for less than the WCI standard may be pro-rated and/or replaced in order to maintain the environmental integrity of the offsets system. If pro-rating is allowed for a project type it will be included in the appropriate WCI offset protocol) Project proponents shall follow or establish effective (i) monitoring systems, (ii) risk mitigation approaches, and (iii) contingency plans which address how, in the event of a reversal that is the result of proponent intention or negligence, any affected offset certificates will be replaced. The contingency plan shall include specific mechanisms that are exercisable at the time a reversal is identified whether or not the proponent is solvent, exists in its original form, and/or has ownership of or responsibility for the project. WCI Partner Jurisdictions will establish mechanisms to address reversals that are not the result of proponent intention or

		negligence and to ensure replacement of credits where proponent's contingency measures prove inadequate.
7.1	Verifiable	With respect to offset project activities, verifiable means that a GHG reduction or removal, or assertion thereof, is well documented and transparent such that it lends itself to an objective review by a qualified verifier. Verifiers for WCI offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner Jurisdiction in which the project is registered.
7.2.1	Validation	With regards to WCI offsets, validation is a review by an independent third party to assess the likely result of reductions or sequestration from a proposed project that would use a WCI offset protocol. The WCI Partner Jurisdictions may not require third party validation in all cases but may approve protocols that require a validation step.
7.2.2	Enforceable	Each Partner Jurisdiction will, to the extent permissible by law, put in place sufficient compliance/enforcement mechanisms and detail for the jurisdiction to compel compliance with its requirements and with WCI offset protocols.
7.2.3	Material	Material misstatement means that errors, omissions or an aggregation of both in the reported GHG reductions or assertion exceeds a ±5% threshold. For a WCI offset, the verifier must be able to state with reasonable assurance the total reported reductions or removals are free of material misstatement.
8.1	Transparency	The WCI offset system will provide transparency such that sufficient and appropriate protocol, project and certificate information is disclosed in a timely manner to allow offset system participants and the general public to make decisions with reasonable confidence.
8.2	Co-Benefits	WCI Partners recognize the environmental, social, economic and health benefits that may arise from an offset project and the offset system will focus on those benefits directly related to mitigating climate change. A WCI offset project is required only to result in a greenhouse gas emission reduction or removal.
8.3	Assessment of Environmental or Social Impacts	WCI offset projects must meet all applicable local environmental regulations and be in compliance with all applicable laws in the jurisdiction where the project is located. If environmental or socioeconomic assessments of the

		proposed project have been done, the project's registration application should reference this work and include a summary of the findings. Protocols for specific offset project types may require analysis of environmental and socioeconomic impacts beyond what the local jurisdiction would otherwise require and may require additional mitigation of potential negative impacts.

2 Purpose and Background

The purpose of the WCI Offset Committee is to make recommendations to the WCI Partner Jurisdictions on the design and operation of the offset system as part of the WCI cap-and-trade program. In particular, this paper includes the Offsets Committee's recommendations for criteria that reductions must meet in order to demonstrate that reductions from offset projects are rigorous enough to meet compliance obligations within the regional cap-and-trade program. The WCI's September 2008 Design Recommendations included that the criteria ensure offsets result in a GHG reduction or removal that is real, additional, permanent, and verifiable.[3] The design of the offsets system must also ensure that the quantification of the GHG reduction or removal is accurate and not double-counted. According to the WCI's design principles, reductions from offsets must also be enforceable by the WCI Partner jurisdictions.

This Draft Recommendations White Paper is the second stage in developing a clear definition of a WCI greenhouse gas (GHG) offset and the detailed eligibility criteria for GHG offset projects used for compliance purposes as identified in the WCI 2009/10 Work plan released February 2009. On July 24, 2009 the WCI Offsets Committee released the *Offset Definition (Task 1.1) and Eligibility Criteria (Task 1.2) White Paper* ("the Criteria White Paper") describing options for defining a WCI GHG offset and the WCI essential offset criteria (real, additional, verifiable, and permanent), as well as other principles and technical considerations that are important in establishing criteria for the WCI offset system. On July 30, 2009 and August 27, 2009, the WCI Offset Committee held stakeholder webinars to discuss the released white paper. Stakeholders also submitted written comments via the WCI website by the August 21, 2009 deadline.

[3] WCI Design Recommendations for the WCI Regional Cap-and-Trade Program: September 23, 2008; revised March 13, 2009. p. 10 Available at: http://www.westernclimateinitiative.org/ewebeditpro/items/O104F21252.pdf.

Specifically this draft recommendations white paper provides the following:

- a draft recommendation for the criteria, reflecting the criteria's essential requirements
- a summary of stakeholder comments received, and
- a discussion of the criteria recommendation.

Each of the additional principles and technical considerations are nested under the related essential criteria or included in Section 8's "Other considerations." These principles and technical considerations include ownership, use of recommended protocols, and geographic limits (Section 3); quantification, uncertainty and accuracy, conservativeness, and leakage (Section 4); additionality tests, baseline determination, eligibility date, and crediting period (Section 5); validation, enforcement, and materiality (Section 7); and transparency, co-benefits, and assessment of environmental and social impacts (Section 8).

The purpose of this draft recommendation paper is to seek stakeholders' input prior to a final decision by the WCI Partner jurisdictions.

These recommendations will provide the basis for further work of the WCI Offsets Committee. The next paper to be released by Task 1, referred to as the "*Process White Paper"* will present options for detailed requirements for the registration, validation, monitoring, quantification, reporting, verification, certification, and issuance of offsets; aspects of regulation and enforcement related to offsets that should be included in the cap-and-trade essential elements; and functions of the regional administrative body and tracking system related to the offset system. Task 3, the review and development of WCI offset protocols; will use the draft recommendations as the basis for the offset protocol evaluation. It will also provide a basis for Task 2's review of offsets and allowances from outside the WCI jurisdictions. The recommendations from Task 1 may not universally apply to Task 2. Rather Task 2 will have to determine the extent to which the criteria and supporting criteria are appropriate to offsets from other systems. For example, this paper includes a recommendation for the appropriate length of crediting periods used by WCI Partner Jurisdictions. That does not imply that the offsets any other system which uses crediting periods of a different length would be ineligible to meet compliance obligations established by WCI Partners Jurisdictions.

This paper frequently employs the terms such as "WCI offset", "WCI offset projects" and "WCI Offset System". This paper uses the terms to succinctly describe an offset certificate issued by a WCI Partner Jurisdiction, the projects from which these offsets are generated and resulting system created by WCI Partner Jurisdictions.

3 Definition of an Offset

The offset definition should establish the tradability of offsets and provide guidance about their fungibility within the WCI cap-and-trade program. The definition should also address how offsets are created and recognized.

3.1 Offset

A major consideration for defining an offset is how broad the definition should be. For example, the definition could require that offsets meet all WCI recommendations; alternatively, the system recommendations could be specified in the offset definition itself or referred to in other parts of the regulation or program design. The Criteria White Paper discussed three options:

- Option A: Specific parameters or requirements included in the definition;
- Option B: General parameters or requirements covered in the definition with specific requirements referred to elsewhere in the document; and
- Option C: Specific parameters or requirements with the condition that additional requirements specified in the WCI offset system must be met.

The draft recommendation below most closely resembles Option B.

3.1.1 Draft recommendation

A WCI offset certificate is issued by a WCI Partner Jurisdiction and represents a reduction or removal of one metric ton of carbon dioxide equivalent (tCO_2e). The reduction or removal must meet the recommended essential criteria for reductions and removals to be real, additional, permanent, and verifiable. Reductions and removals must also be clearly owned, adhere to recommended protocols, and result from a project located in a qualifying geographic area

3.1.2 Summary of stakeholder input

Stakeholders offered various comments regarding the offset definition. The comments generally support a simpler offset definition and/or a definition that is open and flexible to cover any projects that have direct or indirect potential to reduce emissions. Stakeholders wanted to ensure fungibility across WCI Partner Jurisdictions to increase market fluidity.

3.1.3 Explanation of draft recommendation

The WCI Offsets Committee is recommending a definition using Option B because it is simple, flexible, and should support a robust offset market. The proposed offset definition requires that WCI offsets meet the essential criteria of the WCI offsets system (i.e., real, additional, permanent, and verifiable) but does not specify parameters or requirements for those criteria.

Carbon dioxide equivalent is an internationally accepted standard of measurement of the radiative forcing of greenhouse gases. Establishing that a WCI offset represents one metric ton carbon dioxide equivalent (tCO_2e) allows it to be employed interchangeably with a WCI emission allowance which also represent one tCO_2e. It also facilitates linkage internationally, which is a design principle of the WCI program,[4] with other programs using this accepted measurement standard.

One issue which the WCI Offsets Committee internally debated for its draft recommendation was whether to define the offset as the reduction or removal itself or as the compliance unit. The recommendation above equating an offset with the compliance unit is based on the understanding that a reduction or removal is just a reduction or removal until a WCI Partner Jurisdiction has recognized it as an offset through the issuance of a compliance unit. The committee also discussed whether the definition should include a positive statement that offsets are tradable and bankable. Since these features seemed to more appropriately belong to the domain of the overall cap-and-trade program than to the offsets system, such a statement was not included.

3.2 Other considerations

This section further discusses three key considerations referenced in the final sentence of the offsets definition draft recommendation. These considerations are offset ownership, use of recommended protocols, and geographic limitations of recognized offsets.

3.2.1 Ownership issues

Establishing clear ownership of the emissions reductions generated by an offset project is important prior to registration, acceptance, and issuance of offsets in the WCI program. In regards to ownership, it is useful to distinguish between ownership claims to a reduction or removal prior to the issuance of compliance and the ownership of those compliance units after their issuance. The draft recommendation below focuses on the former, while the latter is an issue for a subsequent paper.

3.2.1.1 Draft recommendation

An offset project proponent must have legal ownership of the greenhouse gas emission reduction or removal resulting from the offset project. The offset project proponent will be responsible for all statements and information provided to the WCI Partner Jurisdiction issuing the offset certificate during the creation of the offset certificate and verification of the

---

[4] See the final bullet point in the WCI Design Principles section on pages 52-53 of the WCI Design Recommendations Document.

reduction or removal. The WCI Partners should establish a registry of offset certificates issued and make the registry publicly available.

3.2.1.2 Summary of stakeholder input

Nearly all respondents supported a clear delineation of offset ownership. Many of the respondents supported the creation of a centralized registry, and/or legal contracts that specify and establish ownership claims.

3.2.1.3 Explanation of draft recommendation

Clear rules around ownership are necessary in a trading system. The draft recommendation attempts to reduce the likelihood of disagreement over ownership by clarifying the expectations for the project proponent. The proponent may or may not have an ownership interest in the project itself or in the emissions source(s) or sink(s) that lie within the project's boundaries. The proponent may be a person(s) or entity(ies) acting on behalf of the project owner(s). The identity of the project owner (who receives the issued compliance units) and the project proponent (who makes the offset application), as well as their relationship to each other, must be clear.

After issuance, the WCI offsets system will require tracking offsets, perhaps through a registry. Registry rules would govern ownership of the issued compliance units. Possible provisions and recommendations for an offset registry or other tracking methodologies are a topic for the WCI Offsets Committee's upcoming Process White Paper.

3.2.2 Use of recommended protocols

The WCI Partners will recommend protocols that will detail specific instructions for project developers, describe standard approaches, equipment, procedures and requirements for projects. The protocols will apply to all aspects of the project life cycle including: planning, operation, monitoring, calculation, reporting, and verification. Recommended protocols must meet the WCI's essential criteria.

3.2.2.1 Draft recommendation

A WCI Partner jurisdiction will issue WCI offset certificates for compliance with the WCI cap-and-trade program only from projects which employ protocols that have been recommended through the WCI protocol review process ("WCI offset protocols").

3.2.2.2 Summary of stakeholder input

Stakeholders supported the use of existing protocols from other programs. None suggested that the WCI Partners should not consider using or adapting protocols that have already been developed.

3.2.2.3 Explanation of draft recommendation

Establishing WCI offset protocols help ensure the integrity of the offsets issued and accepted by the WCI Partner Jurisdictions. The WCI Offsets Committee Task 3 (Offset Protocols) group is evaluating which existing protocols in the priority project type areas meet the WCI Partners' recommended criteria and are consistent with ISO standards. Protocols will be recommended for WCI Partner Jurisdiction review and will include adequate stakeholder engagement prior to final WCI Partner Jurisdiction adoption.

3.2.3 Geographic limits

Geographic limits can take different forms and may restrict offsets from certain geographic areas. One form would restrict from where WCI Partners might accept offsets; another would restrict where the WCI Partners might issue offsets. The WCI Partners have previously indicated a restriction of this latter type. More specifically, the WCI Design Document (September 23, 2008) recommended that the WCI Partner Jurisdictions would issue offsets for reductions or removals only in the three North America countries Canada, Mexico, and the United States. The recommendation in this paper reaffirms that earlier policy decision.

3.2.3.1 Draft recommendation

A WCI Partner jurisdiction may issue offset certificates for projects located within its own jurisdiction as well as jurisdictions outside the WCI cap-and-trade region within North America. A WCI Partner jurisdiction will accept offset certificates issued by other WCI Partner jurisdictions. As described in section 9.8 of WCI's design document, WCI Partner jurisdictions may also accept offset certificates from outside North America.

3.2.3.2 Summary of stakeholder input

Many stakeholders' responses to the *Criteria White Paper* included comments regarding geographic limits. Some stakeholders opposed setting geographic limits because doing so would limit potential compliance cost savings. Multi-national organizations would be restricted from pursuing their lowest cost offset projects regardless of location and organizations with offset projects located outside of Canada, Mexico, and the United States would be excluded. Other stakeholders expressed a preference for limiting offset projects to States and Provinces.

3.2.3.3 Explanation of draft recommendation

As the Design Recommendations document stated, "The WCI Partner jurisdictions encourage the development of offset projects located inside WCI Partner jurisdictions for compliance purposes in the WCI cap-and-trade regulatory program in order to capture collateral benefits associated with some offsets projects, such as health, social, and environmental benefits."[5] In addition, there are practical concerns about implementing and overseeing an offset system beyond North America. Even within North America, MOUs or other agreements between WCI Partner jurisdictions and non-WCI jurisdictions may be needed to help oversee projects located outside of the WCI jurisdictions.

The WCI Partner Jurisdictions are concerned that offset reductions or removals are not counted in multiple registries. They will have to develop a mechanism to ensure reductions are not counted in both the WCI offset system and any other offset system.[6]

The WCI Partner Jurisdictions may still accept offsets generated from reductions or removals outside these three countries, but another program authority will have to issue those offsets. As part of its work under Task 2, the WCI Offsets Committee will recommend standards for evaluating and (if appropriate) accepting compliance units (offsets and allowances) from other programs.

4 Defining the criterion Real

4.1 Real

The WCI offset criteria must ensure that all offset projects generate real GHG reductions or removals. WCI offset protocols must ensure that the quantification of a reduction or removal is accurate and not double counted.[7] For this reason, robust accounting methods are essential to any offsets system. Inaccurate or incomplete accounting could lead to crediting offset reductions that did not actually occur. Offsets can be used in place of emissions reductions at capped sources, and thus offsets become fungible compliance units. It is therefore critical that offset reductions or removals are real in order to ensure the integrity of the cap-and-trade system.

4.1.1 Draft recommendation

A WCI offset certificate represents a reduction or removal of one metric ton of CO_2e that results from a clearly identified action or decision. A WCI offset project's reduction or removal is quantified using accurate and conservative methodologies that appropriately account for all

[5] *Ibid*. p. 40.
[6] This may be a topic in part for the upcoming *Process White Paper*, specifically relating to the offset tracking system as part of Task 1.5.
[7] WCI Design – Section 9.2 (September 2008)

relevant greenhouse gas sources and sinks and leakage risks. WCI offset projects result in emissions reductions or removals that take place at sources controlled by the project proponent.

4.1.2 Summary of stakeholder input

Several stakeholders believe that a definition of real is necessary. Some stakeholders contended that a specific definition of real is not needed and suggested that issues around real and double counting be addressed in verification or certification. Some stakeholders included in their comments that the WCI Partners should issue offsets for indirect emission reductions achieved through electricity efficiency.

4.1.3 Explanation of draft recommendation

Assuring that offsets are real is closely related to other criteria such as permanent, verifiable, and quantifiable. Permanence is discussed in Section 6, verifiable in Section 7, and quantification, uncertainty, conservativeness, accuracy, and leakage are discussed later in this section.

It is vital that reductions or removals in the WCI program are not double counted and not claimed in other voluntary or mandatory GHG trading programs. The *Process White Paper* will detail administrative options and mechanisms to register, track, and retire offsets in order to prevent double counting. The registration and tracking systems play a key role in ensuring rigorous accounting – the transfer of ownership of an offset credit must be clearly defined and documented.

WCI offsets must be generated from reductions or removals within the project boundary of a registered project. Only reductions which occur at controlled sources may be included in the project boundary. For example, renewable energy and energy efficiency projects (typically) result in indirect emission reductions. These would not be recognized under the WCI offset criteria.

In addition, WCI Design recommendations describes offsets as "… emission reduction project[s] undertaken to address emissions *not included* in a cap-and-trade program" (emphasis added).[8] The electricity sector will be subject to the cap. This recommendation was designed to prohibit double counting by the offsets system.

---

[8] WCI Design (September 23, 2008) footnote 13.

At least one stakeholder responding to the Criteria White Paper advocated for allowing offsets from industrial source emitters which fall below the threshold for inclusion in the cap and trade program. Projects which occur outside of capped sectors or generate reductions at facilities that fall below the threshold for compliance could be eligible for offsets.

Real is generally understood to mean that all credited emission reductions or removals genuinely took place. Thus, real offsets have the following requirements:

- Account for uncertainty and accuracy in calculating reductions or removals (Section 4.2.1)
- Require sound quantification methodologies (Section 4.2.1)
- Prohibit double counting (Section 4.1.3)
- Account for emissions leakage (Section 4.2.2)
- Ensure reductions or removals are permanent (Section 6)
- Verify reductions or removals (Section 7)

4.2 Supporting criteria

This section examines supporting criteria for real: quantification, uncertainty, and accuracy are considered, followed by a section addressing leakage.

4.2.1 Quantification, uncertainty, and accuracy

Accurate quantification ensures that offsets represent real reductions that can be converted into a common currency that accurately reflects the GHG reductions or removals generated by of an offset project.

Sound methods to measure and quantify GHG reductions are a prerequisite for eligible offset project types. Quantification methods will be subject to periodic review to make sure they reflect current science and accurate GHG accounting practices. In addition, it is worthwhile to encourage consistency in quantification and monitoring procedures across project types.

Higher levels of uncertainty in calculating emission reductions from project activities lead to lower levels of confidence that all offsets generated by a project are real. It is vital for an offsets system to consider how to address uncertainty within project protocols.

A number of offset programs employ a principle of conservativeness to address uncertainty and ensure that emissions reductions are real. The concept is that where uncertainty exists, it is best to credit reductions where there is high confidence that reductions actually occurred. This option is distinct from using a discount factor to address uncertainty. A principle of conservativeness would mean using uncertainty values at the lower end of the range whenever possible to ensure that there is a high level of confidence that all calculated reductions are real.

4.2.1.1 Draft recommendation

Quantification: WCI Partner Jurisdictions shall ensure that net emission reductions or removals are capable of being measured or modeled in a reliable and repeatable manner that includes all relevant sources and sinks. Quantification methodologies for GHG emissions or emission reductions shall:

- Be appropriate to the GHG source or sink
- Be current at the time of quantification
- Consider local conditions, whenever applicable
- Account for uncertainty – be calculated in a manner that yields accurate and reproducible results
- When uncertainty is above the defined threshold, apply the principle of conservativeness to GHG accounting.

During quantification procedures, project proponents shall convert each type of GHG to metric tons of CO_2e. In addition, WCI offset protocols shall use uniform quantification methods whenever feasible.

Uncertainty and accuracy: Quantification methodologies and measurement techniques shall set standards for acceptable statistical precision and be based on the best available science. They shall also reduce bias, except for promoting conservative estimates. When uncertainty remains high in quantifying the amount of a greenhouse gas emission reduction or removal, the principle of conservativeness shall be applied.

Principle of conservativeness: Where uncertainties are above the defined threshold, offset quantification methods should use more conservative quantification parameters, assumptions, and measurement techniques that minimize the risk of overestimating emission reductions and removals credited for a given project. The principle should be employed when significant uncertainties arise to ensure a higher level of confidence that all calculated reductions are real.

4.2.1.2 Summary of stakeholder input

Quantification: Several stakeholders commented on quantification. Support was expressed for conservative quantification methods or approaches in general. There was support for the use of existing quantification methods where possible and a call to customize quantification methods for local environmental conditions. In addition, the stakeholders generally supported the use of methods and models for quantification that are peer reviewed, based on science, and rigorous.

Uncertainty and accuracy: Public comments generally supported an assessment of uncertainty, although proposed methods varied. Stakeholders generally commented that assessments of uncertainty may vary by scale. Some suggested that uncertainty be considered in the quantification methods not as stand-alone assessments, while others suggested that uncertainty discounts should be applied or that project types with high uncertainty should be excluded.

Conservativeness: Stakeholders who provided public comments on this topic generally (but not uniformly) supported the use of "conservative" methods for quantifying offsets.

4.2.1.3 Explanation of draft recommendation

Quantification generally means that reductions must be accurately quantified and includes these components:

- Using calculation methods that are measurable, credible, and reproducible.
- Undergoing periodic review of quantification methods to ensure appropriateness and consideration of local conditions.

Uncertainty assessments should be carried out, whenever possible, during protocol review and development phases. The assessment should determine if uncertainty is or is not significant.

Where appropriate, project protocols should strive to set standards for precision and allowable error defined by acceptable standards for statistical sampling at the project level. Statistical accuracy and precision (reduced error) standards will increase confidence in quantification methods and thus the overall quantity of offsets credited for a given project. Protocols should provide straightforward guidelines on how to assess uncertainty and how to appropriately adjust the quantification based on risk assessments or analysis of sampling confidence.

Periodic review of protocols is recommended to ensure that quantification methods reflect current science and adequately address uncertainty, accuracy, and conservativeness.

An initial step in scoping and developing an offset project is to reduce uncertainty and error to the extent possible during protocol development and review stages. In dealing with uncertainties in protocol quantification the protocol should apply principles of conservativeness should be used to ensure that any resulting offsets are real and not over-estimated.

A principle of conservativeness should be applied when relatively uncertain parameters or data sources are used to determine baselines and the quantification of project GHG reductions and removals. Employing this principle when high levels of uncertainty are encountered during protocol development would make reductions and removals more likely to be under-estimated instead of over-estimated.

Protocols should call for project documentation that details how chosen assumptions and parameters are conservative (more details and guidance in *Process White Paper*). Use of this principle does not dictate the use of the "most conservative" set of assumptions and methodologies. Implementing a principle of conservativeness means erring on the side of caution, and it requires balancing standards for accuracy with the need for cost-effective offset projects. When less accurate methods are selected, more conservative assumptions and methodologies should be applied at the protocol level.

4.2.2 Leakage

Leakage is an increase in GHG emissions outside of a project's boundary as a result of the offset project's activity. Reviewed offset systems often define two types of leakage:

- **Activity-shifting leakage:** greenhouse gas emissions that result from the displacement of activities from inside the project's boundary to locations outside of the project's boundary as a result of the project activity.
- **Market leakage: greenhous**e gas emissions that occur outside a project's boundaries resulting from substitution or replacement due to the project activity impacting an established market for goods

As discussed in the Criteria White Paper, there are several options available to address leakage. One is to require that each WCI offset protocol include a method to account for leakage in emission reductions or removal calculations specific to a project type. A second option is to have a project validation step that requires an opinion or assessment of leakage risk associated with a project. This step would require further elaboration and guidance to determine the outcome and significance of the validator's opinion or assessment. A final option to assess leakage is to use standard algorithms and methods for leakage quantification – as CDM does for some of their methodologies. .

4.2.2.1 Draft recommendation

To address activity-shifting and market leakage, WCI Partner Jurisdictions will require assessments of whether functional equivalence has been maintained within projects and require that protocols include methods for leakage assessments. WCI offset protocols will evaluate functional equivalence for each project. WCI offset protocols will also require an assessment of potential leakage associated with each project type. In general, WCI jurisdictions prefer the following methods to review leakage risk:

- A quantitative assessment of leakage will be performed whenever possible.
- When a quantitative assessment is not feasible, a qualitative risk assessment will determine whether the risk of systematic leakage is significant or not.

- WCI offset protocols will include a threshold to identify significant leakage.

If leakage is found to be above the threshold, the protocol quantification methodology will include a factor to account for leakage.

4.2.2.2 Summary of stakeholder input

Stakeholder comments generally supported the consideration of leakage, although proposed methods varied. Several suggested that leakage should be addressed in protocol development, and some suggested that it be addressed through discount rates.

4.2.2.3 Explanation of draft recommendation

Emissions leakage is an important concern for any offsets system. Market leakage is difficult to address on a regional level because commercial markets are often national or multi-national in scale. Ensuring functional equivalence means that project proponents must demonstrate that emissions are not shifted within an organization or entity (from within the project boundary to sources or sinks outside the project boundary). Practical leakage quantification methods do exist. For this reason, WCI jurisdictions prefer that project protocols:

- Quantify leakage risks whenever possible,
- Conduct a qualitative assessment of leakage risk when quantification of leakage proves to be unfeasible, and
- Employ factors to address leakage when risk is determined to be significant within the project type protocol.

If leakage risk is found to be medium or high, then the protocol quantification methodology should include a factor to account for leakage to ensure that offsets generated in the system are real.

5 Defining the criterion Additional

The concept of additionality addresses the need for offsets to represent reductions or removals of GHG emissions that would not have otherwise occurred but for the incentive provided by the offset program. Additionality is essential to maintaining the integrity of the emissions cap. To be considered additional, emissions reductions or sequestrations are those that occur beyond the business-as-usual baseline of emission activity that would occur without the offset project.

5.1 Additionality and Baseline

In defining additionality it is important to identify the type of tests that will be used to ensure the offset activity would not have occurred on its own in the absence of the WCI offset opportunity. The *Criteria White Paper* identified these options for analyzing additionality:

Option A: Project Specific – The additionality of each individual project activity is scrutinized through application of specific additionality tests.

Option B: Performance Standard – For each sector or project type, a performance standard is established where projects meeting or exceeding the standard are considered to be additional.

Option C: Protocol Specific Approach – Approach to additionality assessment may vary by protocol, seeking to adopt the best approach for each sector or class of activities.

Option D: Hybrid Approach – A combination of Options A, B, and C would set a performance standard, but still include some aspects of a project-specific additionality, and may vary by protocol.

In order to determine if a project is additional the baseline emissions for that project must be modeled. The options to estimate the baseline scenario revolve around how to estimate the emission activity that would occur in the absence of the offset project. One option is to use a regulatory floor of required compliance activity as the baseline scenario. Another option is to use sector specific performance standards as the measure of baseline emission activity. The WCI Partner Jurisdictions could also require that baselines be estimated for individual offset projects such one based on historical practices on an individual piece of land. Alternatively, baselines can be calculated at a sector-specific scale where an aggregate of project activity is estimated as the baseline.

5.1.1 Draft recommendation

The WCI Partner jurisdictions intend for additionality to be established in a manner that will require offset projects to be evaluated against a baseline that reflects conservative assumptions that are consistent across all WCI jurisdictions. These assumptions will be described in the procedures for setting a baseline in WCI offset protocols. Modeling or other methods of developing the baseline shall use assumptions, methodologies, and values that provide the WCI Partner jurisdictions with assurance that GHG reductions or removals from a project are not over-estimated (consistent with the principle of conservativeness in 4.2.1).

When possible, the baseline shall be set using a sector-specific or activity -specific performance standard; otherwise a project-specific baseline may be used. Performance standards used to establish a baseline will be set so as to reflect the most stringent regulatory requirements and legal requirements of any WCI Partner jurisdiction (those requirements leading to the most conservative calculation of emission reductions). When a project specific baseline is used, the baseline will be set so as to reflect all binding agreements, regulatory requirements and legal requirements in the jurisdiction where the project is located.

5.1.2 Summary of stakeholder input

There was fairly little stakeholder input about how the WCI Partner Jurisdictions should specifically define additionality. However, the WCI Partners received comments that supported all four of the additionality options highlighted above. Of those that commented directly on the options, many preferred Option D, with significant support for Option B as well. This indicates widespread preference to a performance standard approach to additionality and baseline, but at the same time some flexibility to incorporate alternative tests should a performance standard approach proves infeasible.

Stakeholders generally favored that specific methods to estimate baseline be laid out in protocols. There was also some support for modeling the baseline using historical practices in either one or multiple years prior to the start date of the project and for using performance standards that exceed common practice. For stakeholders that commented on project-specific additionality tests, there was some support for common practice tests but at the same time, near unanimous dislike for financial, funding, or investment tests.

5.1.3 Explanation of draft recommendation

The recommended definition of additionality and baseline is consistent with the International Standards Organization's (ISO) 14064-2 standard by defining what is additional as reduced or sequestered emissions beyond any reductions or sequestration achieved under a baseline scenario. At a minimum, the baseline scenario must incorporate reductions or sequestration of emissions required through regulation or other legal requirements. Offset projects can generate offsets for early adoption of activities that will be required in the future by a current or expected regulation until the requirement takes effect. However, new regulations or requirements that were not implemented or expected during project registration or renewal will not affect project additionality until the end of the current crediting period.

Each WCI offset protocol must lay out the methodologies that a project proponent shall use to determine additionality and model the baseline scenario. The WCI Partners prefer protocols that take a performance standard approach to determining additionality. In this method, the baseline is set as the performance standard or the minimum actions required by law, whichever is higher. When a performance standard approach is not the best alternative for a certain project type or it will take a number of years to develop a reasonable performance standard, the WCI Partners may recommend including protocols that use alternative methods as long as they meet the criteria for determining additionality and baseline.

Regulatory baselines are viewed by the WCI Partners as a minimum. The WCI Partners intend to use baselines that exceed this minimum by favoring performance standards since performance standards generally set higher baselines and are thus more conservative. Performance standards are designed to capture common practice or business-as-usual investment activity such that there is high confidence that the reductions or removals of greenhouse gas emissions by offset projects exceed those already occurring – especially when what is already occurring exceeds regulatory requirements.

The WCI Partners are retaining the option of using proportional additionality as the means to develop performance standards for sequestration projects in agriculture and forestry. Proportional additionality models sector activity in aggregate – the level of project activity that would occur absent the WCI offset program (i.e., baseline activity) and the level of aggregate project activity that is induced in response to the WCI offset program. The portion of a projects emissions reductions or sequestration over the sectoral baseline is considered additional.

The WCI Partners' draft recommendation for additionality and baseline sets an overall standard but at the same time provides flexibility by deferring to the offset protocols the specific methods used to achieve the standard. For example, protocols may include additionality tests for project types that do not lend themselves to a performance standard approach. In this way, protocols for project types that otherwise would be excluded can still be included in the WCI offset program. The WCI Offset Committee generally concurs with the prevailing view of commenting stakeholders concerned about using investment, funding or financial barriers tests in determining additionality. Thus, the WCI offsets system will not require them on a system-wide level, although they could be required by a protocol where they are deemed appropriate for a given project type.

5.2 Supporting criteria

Two other considerations related to additionality—eligibility date and crediting period—related to additionality are discussed in this section.

5.2.1 Eligibility date

The issues regarding eligibility date can be divided into two areas: the earliest start date that offset projects may be undertaken to be eligible for inclusion in the WCI offset system and the earliest year in which offsets arising from a project can be eligible for verification and use in the WCI Partner jurisdictions. The first seeks to identify a cut-off date, where projects initiated before that date would not be eligible. If the date identified in the first is before the start of the first WCI compliance period (i.e., 2012), the second gets at what vintages of offsets arising from these projects may be used in the WCI jurisdictions. The consideration is whether reductions need to occur over the same time period as the emissions that they are offsetting or whether earlier offsets can be banked and used against later emissions. For projects undertaken before 2012, one approach would be to consider the reductions occurring before 2012 to be early actions, while reductions after 2012 would generate offsets (subject to crediting period limits).

The *Criteria White Paper* outlined three primary options for eligibility dates for project initiation and qualifying reductions:

- both dates coincide with the launch of WCI cap-and-trade program in 2012
- project initiation may precede 2012, but WCI Partners may issue offsets only for reductions in 2012 or later
- project initiation may precede 2012, and the WCI Partners may issue offsets for all reductions resulting from project activity (at least through the initial crediting period).

5.2.1.1 Draft recommendation

Offsets may only be awarded for projects that are initially commenced on or after September 23, 2008; the date of the WCI Design Recommendations that identified the priority project types for WCI offsets. Offsets may be awarded for all GHG reductions or removals occurring after September 23, 2008.
An offset project proponent must apply to register its project with a WCI Partner Jurisdiction within one year of project commencement. Projects that commenced prior to finalization of the applicable protocol must apply within one year of the protocol's finalization.

5.2.1.2 Summary of stakeholder input

There was support from stakeholders who would be either offset purchasers or developers for both a start-date and eligibility date pre-2012. The suggested dates ranged from 2000 to the year the jurisdiction sourcing the project joined the WCI.

5.2.1.3 Explanation for draft recommendation

The WCI Partners recommend a project start and eligibility date of the date the WCI Design Framework was released. This supports the discussions about establishing a WCI offset system and the need to establish a rigorous offset system to support WCI Partner Jurisdictions. By choosing one date for all jurisdictions we provide consistency in eligibility across all jurisdictions. We also believe that the chosen date provides a good compromise. It hopefully works to bring offsets into the WCI system in the early years, while ensuring the quality of offsets allowed into the system. Projects will be able to seek verification for offsets based on the WCI Jurisdictions' recommended protocol for the offset project type. Verified offsets for the reduction or sequestration of emissions occurring before 2012 will still need to meet the strict monitoring and verification standards laid out in each protocol. For any offsets that have previously been issued in any voluntary or compliance offset system, those offsets must be retired or removed from the other system before a WCI Partner Jurisdiction may issue a compliance unit in recognition of that reduction.

5.2.2 Crediting period

A crediting period determines how long an offset project is eligible to generate offsets once it has been approved by a WCI Partner Jurisdiction. Different project types may have different crediting periods. For example, sequestration projects tend to have longer crediting periods because their gradual greenhouse gas removals occur over longer timescales. In general, the length of crediting period should give project developers some certainty in their investment. Another option is to adopt shorter crediting periods but at the same time allow for their renewal based on a periodic review of conditions for eligibility. All or some of the following could be re-evaluated at the time of renewal and only those projects passing would be renewed:

Eligibility– Is the project type still eligible as a WCI offset project?

Applicable Protocol – Besides questions of additionality and baseline, has the WCI Partner Jurisdiction adopted a revised or new protocol for the project type that is now applicable?

Additionality and Baseline – Are their new regulatory or other legal requirements that need to be incorporated into the project baseline? Similarly, have performance standards evolved since the original baseline determination? For project types that originally needed to pass project-specific additionality tests, are there now available performance standards that could be used as an alternative?

Quantification – Is there opportunity to incorporate new quantification methods that reduce the uncertainty in the measurement of offsets or modeling of baselines?

5.2.2.1 Draft recommendation

The crediting period for non-sequestration WCI offset projects will be 10 years, which may be once renewed for an additional 10 years. The crediting period for sequestration projects will be specified by the applicable protocol. However, any individual crediting period may not exceed 25 years before a renewal, and the total crediting period including all renewals may not exceed 100 years.

Renewal of a project at the end of a crediting period will include a reevaluation of a project's additionality and reevaluation of how the reductions are quantified and verified. Thus, the baseline scenario will be reevaluated at each renewal.

5.2.2.2 Summary of stakeholder input

Stakeholder comments on the length of crediting periods varied. Many comments stated it was necessary to credit offsets for a minimum period of time in order to provide some investment certainty for project developers. Many stakeholders supported longer crediting periods with more opportunity for renewals, including some who favored unlimited renewal of crediting periods. By contrast, others generally supported shorter initial crediting periods with fewer opportunities to renew.

5.2.2.3 Explanation of draft recommendation

The recommendation above tries to balance investment certainty with the need to develop a rigorous offset system. Project types eligible for offsets will likely be subject to advances in common practice, technological revolutions, increasing regulatory standards, and other factors that make periodic reevaluation of additionality prudent.

Presently the WCI Offsets Committee is recommending a fixed 10-year crediting period for all non-sequestration projects. Alternatively, the Committee considered recommending that crediting periods be determined by the applicable protocol but no longer than 10 years. Since there was not a non-sequestration project type currently under consideration for which the Committee thought a period shorter than 10 years would be clearly preferred, the Committee is recommending this uniform period, although it acknowledges that this recommendation may need future reevaluation.

The recommendation also recognizes that sequestration require long-term investment and commitment by project developers and provides the option of longer crediting periods for them. Within a crediting period, protocols for projects with longer crediting periods may require updates to changes in quantification methodologies to reflect current science. For sequestration projects, there is not a cap on the number of renewals, just a cap on the total length of the crediting period including all renewals.

Renewal of a project at the end of a crediting period will include a reevaluation of a project's additionality and reevaluation of how the reductions are quantified and verified. Thus, the baseline scenario will be reevaluated at each renewal. For projects whose crediting period has expired and not been renewed, previously verified offsets will still need to meet protocol requirements for permanence, and any reversal of previously verified reductions remain subject to the WCI Partner Jurisdictions' enforcement provisions.

6 Defining the criterion Permanent

The *Criteria White Paper* outlined a range of options for the definition and implementation of permanence. This section reviews stakeholder comments to that paper and offers the WCI Partners' draft recommendation for ensuring permanence.

6.1 Permanent

As an offset element, permanence refers to the duration of an emission reduction. Permanence needs to be addressed in projects which involve a risk or reversal, most notably geologic and terrestrial (i.e., carbon that is stored in biomass and soil) sequestration of carbon. The draft recommendation below outlines the mechanisms required to ensure equivalency of offset emissions reductions across different project types.

Implementation mechanisms discussed in the *Criteria White Paper* fell into two broad categories: *ex ante* and *ex post facto*. *Ex ante* mechanisms do not guarantee against a reversal but do make a legally binding commitment which, in the case of land-based projects, "run with the land" and can serve to reduce the risk on non-permanence. *Ex post facto* obligations provide assurance in the case of failure of permanence and are achieved through replacement of lost tons.

6.1.1 Draft recommendation

With respect to offset project activities, permanence means either that reductions or removals are not reversible or that, if reductions or removals are reversible, then the text outlined in the remainder of this recommendation is met.

Sequestration projects must ensure the atmospheric effect of their greenhouse gas removal will endure for a period that is comparable to the atmospheric effect achieved by non-sequestration projects. The duration for this period is to be based upon current scientific findings that are widely accepted and followed. The current international standard of 100 years has been established by the UNFCCC and will be followed by WCI Partner jurisdictions. WCI Partner jurisdictions will adopt new international standards (likely UNFCCC) if/when they are updated.

Offset projects where the reduction or removal is maintained for less than the WCI recommended standard may be pro-rated and/or replaced in order to maintain the environmental integrity of the offsets system. If pro-rating is allowed for a project type it will be included in the appropriate WCI offset protocol)

Project proponents shall follow or establish effective (i) monitoring systems, (ii) risk mitigation approaches, and (iii) contingency plans which address how, in the event of a reversal that is the result of proponent intention or negligence, any affected offset certificates will be replaced. The contingency plan shall include specific mechanisms that are exercisable at the time a reversal is identified whether or not the proponent is solvent, exists in its original form, and/or has ownership of or responsibility for the project. WCI Partner Jurisdictions will establish mechanisms to address reversals that are not the result of proponent intention or negligence and to ensure replacement of credits where proponent's contingency measures prove inadequate.

6.1.2 Summary of stakeholder input

Stakeholder groups offered valuable feedback on the permanent criterion. There was consensus that the environmental integrity of the offsets system needs to be ensured. There was also broad agreement that the benchmark of permanent should be a 100 year standard. Methods for ensuring the environmental effect of this standard varied, but the objective of ensuring that sequestration offsets may be employed with equal confidence as emission allowances or non-sequestration offsets was universal.

Stakeholder comments included these suggestions which vary from the draft recommendation:

- creating temporary or short-term credits
- having the purchaser of sequestration offsets assume the liability of replacement in the event of a reversal
- avoiding long-term monitoring as much as possible
- allowing a *force majeure* safe harbor (i.e., in the event of an unintentional reversal, project proponents would not be immediately liable for offset replacement, although they would be required to accrue additional removals to build carbon stocks up to the level that had been depleted)

6.1.3 Explanation of draft recommendation

Strictly speaking the true time frame for permanence is forever. However, practicality and GHG accounting conventions suggest a more finite time be utilized. The second IPCC report effectively established a 100-year standard for permanence. This was adopted by the UNFCCC. The WCI Partners intend to remain consistent with international GHG accounting conventions. Thus, as UNFCCC conventions are updated the WCI Partner recommendations will also be updated. Still, the WCI Offsets Committee envisions that the standard for permanence in effect at the start of a project's crediting period would remain the standard for reductions achieved in that crediting period and would not be changed retroactively. This certainty should facilitate investor confidence.

The draft recommendation establishes strict liability for intentional or avoidable reversals. It also establishes the broad recommendation of monitoring and risk mitigation for all sequestration projects, but specific requirements may vary by project type. Thus, guidelines will be established through a combination of universally applied WCI offset program essential elements and WCI offset protocols which may allow for flexibility by project.

Protocols for sequestration projects should require the projects in general, and their monitoring and risk mitigation plans in particular, be developed and carried out in a manner which considers project specific risks from climate change. These risks might include susceptibility to fire, drought, flooding, windstorms, or insects. Risk mitigation plans could include *ex ante* permanence mechanisms such as conservation easements.

Contingency plan measures to be established or followed by the proponent to ensure the replacement of offsets in the event of an intentional reversal or a reversal which occurs as the result of proponent negligence might include:

- Contractual or other arrangements for securities, contingency funds, discounts or set-asides
- Insurance or other guarantees

Ultimately the WCI Partner Jurisdictions will adopt measures and mechanisms that provide a degree of confidence that the environmental credibility of the offset system is assured. Potential WCI Partner contingency plan measures might include:

- A buffer pool (established through contributions which would be determined through a project risk assessment)
- Contractual or other arrangements for securities, contingency funds, discounts or set-asides
- Insurance or other guarantees established to replace offsets in the event of a reversal

7 Defining the criterion Verifiable

This section provides the WCI Partners' draft recommendation for defining the verifiable offset criterion. This section also includes recommendations for three other supporting criteria.

7.1 Verifiable

For something to be verifiable, it must be transparent and documented well enough that a person can objectively review the GHG assertion or reduction and make a finding that the GHG assertion or reduction is accurate. However, the biggest question related to the term verifiable is who will be that person objectively reviewing the GHG assertion or reduction.

As outlined in the *Criteria White Paper*, there are three options for whom that person should be. The first is to follow international convention and only allow third-party independent verifiers to verify GHG assertions or reductions. An alternative is for jurisdictions to play that role, and the last option is to allow the project developers to self-certify that they are providing accurate and truthful information about reductions.

7.1.1 Draft recommendation

With respect to offset project activities, verifiable means that a GHG reduction or removal, or assertion thereof, is well documented and transparent such that it lends itself to an objective review by a qualified verifier. Verifiers for WCI offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner Jurisdiction in which the project is registered.

7.1.2 Summary of stakeholder input

Most stakeholder comments supported third-party verification.

7.1.3 Explanation of draft recommendation

In order for a stated GHG reduction to be verifiable it must be developed using transparent methods and be well documented. Only reductions that meet these conditions lend themselves to careful review by a third-party. Review should be conducted by an accredited verifier that is recognized by WCI Partner Jurisdictions. The WCI's Reporting Committee is building accreditation mechanisms and criteria for third-party verification of reported emissions. The WCI's offset system could build on that work and help foster a consistent approach to verification within the overall program. Most importantly, independent third-party verification of offsets is an international practice in existing voluntary programs and in the CDM.

7.2 Supporting Criteria

7.2.1 Validation

Validation is the process of reviewing the documentation and other information related to an offset project before it is actually implemented. The process provides assurance to the project developer that they are meeting the full requirements of the project protocol and the project is expected to produce GHG reductions if implemented as documented. WCI Partners could choose to recommend validation or make it optional. In either case, a project developer may be able to use a third-party validator or a jurisdiction could play that role.

7.2.1.1 Draft recommendation

With regards to WCI offsets, validation is a review by an independent third party to assess the likely result of reductions or sequestration from a proposed project that would use a WCI offset protocol. The WCI Partner Jurisdictions may not require third party validation in all cases but may approve protocols that require a validation step.

7.2.1.2 Summary of stakeholder input

Several respondents suggested that validation be optional or at the discretion of the project developer. Others supported mandatory validation including requiring third-party audit of application materials, or including validation as part of the verification process.

7.2.1.3 Explanation for draft recommendation

In a program where standardized protocols for specific project types must be approved, validation may not be necessary. Programs, like CDM, require validation because each reduction project is considered unique and project protocols allow some flexibility in how they are applied. Since the draft recommendations in this document also include following a standardized project protocol approach, validation would be an extra unnecessary step.

If the WCI Partners recommend that validation be optional at the discretion of the project developer and is thereby an option that has no legal weight within the WCI program, it is not necessary to develop a definition or include the concept in WCI Partner rule-making language. Implementing this option could be as simple as making project developers aware that they may engage a consultant to review their documentation and proposed project before it is implemented.

7.2.2 Enforceable

Enforceability is key to maintaining the WCI offset system's integrity. Enforcement ensures that the parties involved with the WCI offset system comply with the protocols and system recommendations.

7.2.2.1 Draft recommendation

Each Partner Jurisdiction will, to the extent permissible by law, put in place sufficient compliance/enforcement mechanisms and detail for the jurisdiction to compel compliance with its requirements and with WCI offset protocols.

7.2.2.2 Summary of stakeholder input

Stakeholders offered few comments for defining enforceable. Stakeholder comments generally supported offsets being enforceable. One comment supported strict enforcement for the WCI offset program. Another comment suggested supporting local enforcement and suggested enforcement should be similar to those in other environmental programs. Another comment suggested that capped entities that purchase offsets must be held responsible for surrendering valid credits for their emissions.

7.2.2.3 Explanation of draft recommendation

Since a definition for "enforceable" was not found in any existing offset system, the Black Law Dictionary was referenced to draft the recommended definition above. Although it does not define "enforceable," it does define "enforce" and "enforcement."[9]

Experience shows that compliance is ensured only by assurance that enforcement can be taken. Compliance assurance mechanisms in the enforcement process must be sufficiently effective to ensure enforceability within the WCI offset system. Compliance mechanisms are not directly referenced in the definition of enforceable above, but the Process White Paper will expand upon them and how their role in the enforcement process relates to enforceability. The following is a non-exhaustive list of enforcement mechanisms for further consideration:

- MOUs or contracts;
- Legal authority;
- Transparency;
- Penalty structures and mechanisms for collecting fines;
- Enforcement staff, infrastructure and capacity necessary to enforce;
- Registration and tracking system to establish and track ownership;
- Attestation of Title;
- Prohibitions for "double counting";
- Monitoring, reporting and third-party verification;
- Mechanism for project reversals, and
- Recourse for early project termination.

Another issue which the draft recommendation above does not address is the relationship between the enforcing regulatory authority and project proponents, as well as with any other persons or entities participating in the offsets system. The WCI's Design Recommendations document stated that "each WCI Partner jurisdiction will retain and/or enhance its regulatory and enforcement authority and responsibilities to enforce compliance with the cap-and-trade program within its own jurisdiction,"[10] and similarly that, "offset projects must also be enforceable by the individual WCI partner jurisdiction that is issuing the credit, and the credit must be verifiable by the individual WCI Partner jurisdiction that is accepting it."[11] The recommendations and provisions of the WCI offset system must be enforced to ensure that

---

[9] *"…Enforce. To put into execution, to cause to take effective; as, to enforce a particular law, a writ, a judgment, or the collection of a debt or fine; to compel obedience to...". Also: "Enforcement. The act of putting something such as a law into effect; the execution of a law; the carrying out of a mandate or command".* (Taken from Black's Law Dictionary, Sixth Edition, Centennial Edition (1891-1991) page 528. No definition was available for "enforceable".)

[10] WCI Design Recommendations, p. 12.

[11] Ibid. p. 10.

offset system participants follow the rules and do not harm the integrity of the offsets system. The Process White Paper will lay out additional options for the relationship between the WCI's regulatory authorities and offset system participants.

7.2.3 Material

A term of art specific to verification is 'materiality.' This term relates to a threshold where differences above that number in reported emissions/reductions are deemed unacceptable. The WCI Essential Reporting Requirements document has a materiality threshold of ±5%, consistent with EU ETS and The Climate Registry. As briefly discussed in the Criteria White Paper, the WCI offset system could have a lower materiality threshold to be conservative. In regards to materiality, the WCI offset system could also apply an asymmetric materiality threshold that would entail not allowing any errors that overestimate the total emission reductions but accepting errors that underestimate reductions within a prescribed materiality threshold.

The term "material misstatement" refers to any error or aggregation of errors found by a verifier that would cause a verifier to believe with reasonable assurance that the GHG assertion does not meet the materiality threshold.

7.2.3.1 Draft recommendation

Material misstatement means that errors, omissions or an aggregation of both in the reported GHG reductions or assertion exceeds a ±5% threshold. For a WCI offset, the verifier must be able to state with reasonable assurance the total reported reductions or removals are free of material misstatement.

7.2.3.2 Summary of stakeholder input

WCI Partners received limited stakeholder input regarding materiality criteria. Comments received supported the ±5% threshold.

7.2.3.3 Explanation of draft recommendation

The recommended threshold of ±5% for the WCI offsets system is consistent with the materiality threshold for emitters with mandatory reporting obligations in the WCI Jurisdictions (as described in the Essential Reporting Requirements document). Neither the WCI Offsets Committee nor its stakeholders have identified a sufficient reason to alter the materiality threshold for offsets from what has previously been suggested for mandatory reporting.

8 Other considerations

In addition to the main criteria of real, additional, permanent, and verifiable, the WCI Offsets Committee also identified other factors to consider. Those factors were discussed previously in the Criteria White Paper. Following the format of the previous sections in this paper, this section includes for each of those factors a recap of that discussion, a draft recommendation, a summary of stakeholder comment, and an explanation for the draft recommendation.

8.1 Transparency

Transparency means that assumptions and methodologies for offset projects and protocols should be clearly explained and available for the public and system users. Transparency standards should allow users and stakeholders to assess and replicate projects and protocols in the offsets system.

Options to enhance transparency focus on increasing stakeholder input and public comment on project and protocol development, as well as public access to offset project information, except where important confidentiality issues exist.

8.1.1 Draft recommendation

The WCI offset system will provide transparency such that sufficient and appropriate protocol, project and certificate information is disclosed in a timely manner to allow offset system participants and the general public to make decisions with reasonable confidence.

8.1.2 Summary of stakeholder input

Overall stakeholders expressed their support for transparency within the WCI offset system. Specifically stakeholders supported a transparent protocol development process with public access to information on offset projects, tracking numbers, ownership, selling price, audit/enforcement activities, use for compliance and protocol quantification methodologies that are well documented for all algorithms and models. Some stakeholders qualified their support that information should be made available with consideration of confidentiality concerns. Some stakeholders supported public comment of offset protocols, project documents, credit issuance and enforcement, while other stakeholders supported limited public consultation, suggesting exclusion public consultation for project registration.

8.1.3 Explanation of draft recommendation

As identified in the WCI Offsets Task 1, the forthcoming Process White Paper will evaluate information needs for system users and the public, including details on how the review and approval of offset projects and protocols will take place, as well as standards for information releases. This paper confirms the importance of transparency and the Process White Paper and subsequent draft recommendations will identify options when the paper is released.

8.2 Co-benefits

Offset projects provide benefits in the form of greenhouse gas reductions or removals. An offset project may also lead to a number of other benefits ("co-benefits") beyond the emission reductions or removals. These co-benefits may include categories such as air quality improvements and economic development activity. Whether to require offset projects to generate co-benefits is an important question in establishing an offset system. Most offset systems do not require projects to generate co-benefits with some exceptions, most notably the Clean Development Mechanism. Note that this question is focused on the generation of co-benefits above and beyond what may exist prior to implementation of the offset project, and not on maintaining or mitigating the loss of co-benefits in existence prior to the project.

8.2.1 Draft recommendation

WCI Partners recognize the environmental, social, economic and health benefits that may arise from an offset project and the offset system will focus on those benefits directly related to mitigating climate change. A WCI offset project is required only to result in a greenhouse gas emission reduction or removal.

8.2.2 Summary of stakeholder input

Most stakeholder comments did not support requiring project co-benefits to be generated in order for a project to receive credit as a WCI offset. Some stakeholders generally supported making the presence of co-benefits either a necessary criterion to receive credit, or a weighting factor when evaluating offset projects against each other. Others supported requiring documenting, but not requiring, co-benefits in the process to apply for and credited with compliance units.

8.2.3 Explanation of draft recommendation

The draft recommendation on co-benefits keeps the WCI offset program focused on greenhouse gas reductions and removals—the reason behind establishing the WCI regional cap-and-trade program. A WCI offset makes no claim to any benefits or properties associated with the offset project other than the greenhouse gas emission reduction or removal resulting from implementation of the project. Any benefits attributable to an offset project beyond the greenhouse gas reduction or removal properties of the project are incidental to the offset. Under this recommendation, the WCI Partners remain neutral on how co-benefits associated with an offset project may be treated or claimed by policies or programs other than the greenhouse gas cap-and-trade program. By remaining "policy neutral" regarding co-benefit attributes associated with an offset project, jurisdictions are free to take different approaches towards using these attributes in emerging attribute valuation schemes, such as ecosystem service markets (e.g., markets in habitat protection or wetland mitigation).

8.3 Assessment of Environmental or Social Impacts

Offset projects reduce or remove greenhouse gas emissions. However, offset project activity may impact its environment or social environment. Transparency can be enhanced by informing stakeholders about the impacts of an offset project. Examples of options for assessing the impacts of offset projects include requiring documentation of impacts in the project plan, a policy of "offsets should do no net harm," requirements to meet all local environmental regulations, or having no specific requirement.

8.3.1 Draft recommendation

WCI offset projects must meet all applicable local environmental regulations and be in compliance with all applicable laws in the jurisdiction where the project is located. If environmental or socioeconomic assessments of the proposed project have been done, the project's registration application should reference this work and include a summary of the findings. Protocols for specific offset project types may require analysis of environmental and socioeconomic impacts beyond what the local jurisdiction would otherwise require and may require additional mitigation of potential negative impacts.

8.3.2 Summary of stakeholder input

Stakeholders were divided about whether the WCI Partner Jurisdictions should require projects to provide an assessment of environmental or social impacts. Some stakeholders stated that they do not support any recommendations for impact assessments. Other stakeholders suggested that WCI Partner Jurisdictions should ensure that offset projects do no net environmental or social harm through consultation in the protocol development process. Others suggested that projects provide proof, through an EIA assessment or other form, which the project does not result in net negative impacts.

8.3.3 Explanation of draft recommendation

WCI Design Recommendations state that the WCI cap-and-trade system will aim to "[maximize] total benefits in jurisdictions throughout the region, including reducing air pollutants, diversifying energy sources, and advancing economic, environmental, and public health objectives, while also avoiding localized or disproportionate environmental or economic impacts" (p. 52). The draft recommendation is consistent with this earlier policy direction. WCI Partners will consider recommending additional assessments on a case by case basis as part of their protocol recommendation process.

9 Conclusion

This paper provides the WCI Partner Jurisdictions' draft recommendations for defining a WCI offset and defining the WCI Partners' main offset criteria of real, additional, permanent and verifiable. It has also offers recommended definitions for other criteria in support of the offset definition and main offset criteria, as well as recommendations for a few other considerations. This paper summarizes stakeholder response to the Criteria White Paper and attempts to explain the reasoning for the Committee's recommendations.

The WCI Offsets Committee will receive stakeholder comment on this paper and its recommendations before issuing its final recommendations. Written comments may be received via the WCI website through May 12, 2010. As with the Criteria White Paper, the WCI Offsets Committee will also hold two stakeholders calls. The first call on Thursday April 22, 2010 from 10:30 a.m. to 12:00 p.m. Pacific Time will provide an initial presentation and discussion of this paper. The second call on Wednesday May 5, 2010 from 9:00to 10:30 a.m. Pacific Time will be focused on hearing from stakeholders and responding to stakeholder questions.

The WCI Offsets Committee poses these questions to stakeholders:

- What is your impression of the draft recommendations overall and individually?
- What has been your experience with offset systems utilizing these or similar recommended definitions for an offset and its essential criteria? Have the advantages of these definitions outweighed the disadvantages?

This is the second paper from the WCI Offsets Committee Task 1 work. A forthcoming white paper will cover the process of registration, validation, monitoring, quantification, reporting, verification, certification, and issuance of offsets.

This draft recommendations paper supports the WCI Offsets Committee's work to reach final definitions for a WCI GHG offset and the detailed eligibility criteria for GHG offset projects for compliance purposes.

Offset Protocol Review Report

Offset Committee, Task Group 3

April 2010

The *WCI Design Recommendations* establishes a rigorous offset system to support the WCI cap-and-trade program.[1] The WCI design goes on to prioritize project types in agriculture, forestry and waste management for investigation and development to participate in the offset system. Other project types outside the capped sectors in the cap-and-trade program may also participate in the offset system.

The WCI's Offsets Committee was tasked with developing recommendations for offset criteria and carrying out the joint review, adaptation, and development of protocols by the Partner jurisdictions. WCI Partners have publicly released draft recommendations on criteria for offsets in an offsets system.[2] The draft offset criteria are being designed to ensure that all offsets credits issued or accepted by WCI Partner jurisdictions are real, additional, permanent, verifiable, and enforceable. The attached report is part of the Offset Committee's effort to coordinate the review and adaptation of existing protocols in the priority project types outlined above against the WCI draft offset criteria. The WCI Partners' intent is to build off the existing work done on offset protocols. The result of this work identify how well existing protocols satisfy the WCI criteria. The Offsets Committee will then concentrate on modifications to existing protocols for priority project types or developing new protocols where suitable ones do not exist. Stakeholder input will be sought in modifying or developing protocols.

Following a competitive and open RFP process, WCI Partners contracted Det Norske Veritas (DNV) to evaluate existing offset protocols. The goal of the evaluation was to help the WCI Partners identify opportunities to incorporate existing protocols into an offset system. The evaluation included 31 protocols from 11 offset systems particular to ten project types in agriculture, forestry, and waste management.

[1] As described in Section 9 of the *Design Recommendations for the WCI Regional Cap-and-Trade Program, September 23, 2008* (http://www.westernclimateinitiative.org/ewebeditpro/items/O104F21252.pdf).
[2] Available at www.westernclimateinitiative.org/component/remository/Offsets-Committee-Documents/Offset-Criteria-Draft-Recommendations/.

The WCI Partners asked DNV to evaluate protocols from existing offset systems to determine whether each protocol:

- Corresponds to the offset criteria as outlined in the WCI's *Offset System Essential Elements Draft Recommendations Paper*;
- Meets the relevant requirements described in the ISO framework, and
- Is applicable to the geographies of the Partner jurisdictions.

WCI Partners invite stakeholder comments on the report's evaluation. These comments will assist the Offsets Committee as they make a recommendation to WCI Partners on adapting existing offset protocols. In recommending adapted protocols for WCI Partner jurisdictions' adoption, the WCI Partners will work to:

- Review existing materials for the protocol project type, including DNV's evaluation, the changes from previous versions of the protocol and the existing public comments on the protocol.
- Draft proposed amendments to the protocol.
- Release the draft protocol for public review, requesting stakeholders for specific feedback on those portions of protocols that have been amended.
- Analyze and incorporate public input.

Each WCI Partner jurisdiction may then choose to put the protocol into force in its own jurisdiction either directly and/or by reference, as its rules allow.

1 EXECUTIVE SUMMARY

The purpose of this report is to provide the results of the evaluation of protocols identified by the Partners in the Western Climate Initiative (WCI). The goal of the evaluation was to help the WCI identify opportunities to incorporate existing protocols into a new offset system created by the WCI. The evaluation included 31 protocols[1] from 11 offset systems[2] particular to ten project types in agriculture, forestry, and waste management.

The WCI Partners asked DNV to evaluate protocols from existing offset systems to determine whether each protocol:

- Corresponds to the offset criteria as outlined in the WCI's *Offset System Essential Elements Draft Recommendations Paper*
- Meets the relevant requirements described in the ISO framework, and
- Is applicable to the geographies of the Partner jurisdictions.

In practice, DNV could not identify instances where a protocol satisfies the WCI guidelines without also satisfying ISO guidelines. As a result, DNV's evaluation focused on whether the protocol's provisions correspond to WCI guidance with respect to the following WCI criteria:

- Real (which is based on the following WCI supporting criteria)
    - Quantification
    - Uncertainty & Accuracy
    - Conservativeness
    - Leakage
- Additional
- Permanent
- Verifiable
- Applicable to the regions within the WCI's jurisdiction

For each of these criteria, DNV worked with WCI Offsets Committee members to establish evaluation guidelines to be used to determine if the protocol:

- Appears to correspond to WCI and ISO definitions for this criterion.
- Is likely to correspond to, with modification, WCI and ISO definitions for this criterion.
- Could correspond to, with significant modification, WCI and ISO definitions for this criterion.

For the protocols that did not appear to match the WCI's draft criteria, DNV identified potential modifications to the protocols that would enable the WCI to consider them in accordance with the WCI draft criteria. DNV also sought to identify the degree of difference between the protocol and the WCI's criteria, and whether revisions to the protocols would require editorial revisions or research-based modifications. While DNV estimated the degree of change required, it did not estimate the amount of time or effort necessary to make the identified changes--an editorial change is not necessarily an easy one.

DNV was not asked to evaluate the WCI draft offset definitions, criteria, and guidelines outlined in *Offset System Essential Elements Draft Recommendations* or to provide DNV's own interpretation of any of these guidelines while carrying out this evaluation. The protocols are evaluated solely on the basis of their apparent conformance with WCI recommendations as written.

Summary of Evaluations for each Protocol and Criterion

[1] For the purposes of this report, the term protocol refers to the guidance, procedures, and methodologies that detail procedures for creating offsets under an offset system.

[2] For the purposes of this report, the term offset system refers to an organization or entity that has sought to provide guidance to implementing greenhouse gas reductions and/or to creating offsets through projects.

Table 1 summarizes DNV's findings, with each color corresponding to an assessment of the degree of change that would be necessary for the protocol to correspond to WCI's guidelines. In addition to the color coding, black dots represent modifications appearing to require conceptual or research-based changes, while clear dots represent modifications that appear to be editorial in nature.

The paragraphs below summarize commonalities and differences found in the protocols, by project type. It is not a complete description of findings and is instead intended to highlight the most notable aspects of the review.

Soil sequestration:
Neither the Alberta Offset System nor the Chicago Climate □xchange corresponds to the criteria for quantification, leakage, additionality, and permanence□the reasons for this are similar across the two protocols:

- □eographic applicability is an issue, and the protocols need new parameters and emission factors to make their quantification methods applicable to all three countries, i.e., the United States, Canada, and Mexico. The same is true for additionality, as both protocols use a performance test that is country/region specific.
- Neither protocol justifies why leakage is not a concern.
- Neither protocol meets the WCI criterion for permanence because they do not adequately ensure that carbon is stored at least 1□□ years.

Manure management:

- The CDM methodology corresponds to all the WCI criteria, except for the criterion additional, and so is the closest to meeting the WCI criteria as-is. That said, the CDM methodology is the only protocol that takes a project-by-project approach to additionality, rather than the WCI's preferred performance-based approach.
- □eographic applicability is an issue, and the protocols need new parameters and emission factors to make their quantification methods applicable to all three countries, i.e., the United States, Canada, and Mexico. The same is true for additionality, as both protocols use a performance test that relies on market penetration rates that are country/region specific.
- In cases where □□ncertainty and accuracy□is not met, it is because protocols do not require managing uncertainties by, for example, requiring discounting.
- Most of the manure management protocols do not explicitly address leakage, except for the CDM and Climate Leaders, which do.
- All the protocols require third-party certification except for the Climate Leaders.

Rangeland Management:
Only the CC□ protocol was reviewed in this project type.

- □eographic applicability is an issue, and the protocol needs new parameters and emission factors to make its quantification method applicable to all three countries. The same is true for additionality.
- It does not meet the WCI criterion for permanence because it does not adequately ensure that carbon is stored at least 1□□ years.

Afforestation & Reforestation:

- With respect to baseline and project quantification, CC□, CAR and Climate Leaders rely upon models and look-up tables that are specific to regions and types of trees. For that reason, these protocols need modification to ensure that the look-up tables are appropriate to all WCI regions, but the CDM and R□□I protocols seem to be applicable to projects in any countries/regions because they rely upon sampling.
- CC□ and R□□I do not consider leakage emissions. While Climate Leaders and CDM require quantifying leakage emissions, the CAR protocol requires determining leakage risks percentage from the decision tree provided in the protocol.

- The CC□, CAR, and Climate Leaders protocols all use a performance standard approach to ensure additionality, and so need modifications to the thresholds to make them applicable to all three countries.
- Among all the reviewed afforestation and reforestation protocols, the CDM and R□□I protocols are the only ones to take a project-by-project approach to additionality.
- The CDM is the only system that issues temporary credits to ensure permanence. The other protocols require withholding proportion of offsets to compensate for reversals. The CAR protocol is the only one that tries to ensure carbon is stored at least for 1□□ years by requiring signing a 1□□-year-commitment.
- All the protocols except for the Climate Leaders require a third-party verification.

Forest Management:
Only the CC□ and CAR protocols were reviewed for this project type, and there were key differences in how each deals with leakage and with permanence.

- While the CC□ assumes leakage emissions are zero without justification and therefore provides no measures for addressing any potential leakage, the CAR protocol requires determining the leakage risk percentages
- The CC□ requires that all project proponents reserve a certain percentage of offsets to ensure permanence, while CAR requires withholding certain percentages depending upon risks of reversals

Forest Preservation & Conservation:
The CAR protocol is the only one reviewed in this project type.

- It did not meet the WCI criteria for quantification and additional because the models, parameters, and performance tests are applicable only to the California region.

Urban Forestry:
CC□ and CAR protocols were reviewed.

- While the CC□ protocol assumes leakage emissions are zero without justification and therefore provide no measures for addressing any potential leakage, the CAR protocol addresses any leakage by denying registration of offsets in that year that activity-shifting leakage is confirmed from a tree maintenance plan.
- The CC□ requires that all project proponents reserve a certain percentage of offsets to ensure permanence, but CAR does not make a similar requirement.

Landfill Gas:
Protocols from the Alberta Offset System, CAR, □□-A□S, and Climate Leaders all need parameters that are applicable to projects in all three countries. CC□, CDM and R□□I protocols do not need such modifications.

- □xcept for the Climate Leaders protocol, leakage emissions are considered to be insignificant and are not accounted for. The Climate Leaders protocol provides a quantification methodology that needs to be applied in case where leakage is a concern. The CC□, CDM and R□□I protocols do not justify why leakage emissions are not a concern.
- The CC□, CAR and Climate Leaders protocols takes a performance standard based approach to additionality. These protocols need modifications to the additionality thresholds as they are not applicable to al three countries.
- Climate Leaders is the only protocol that does not require third-party verification.

Waste and Wastewater Treatment:
The CDM methodologies in the waste and wastewater category are rated as closer to WCI criteria because they use global parameters or refer to region specific parameters found in the IPCC guideline for quantification, which are applicable to all three WCI regions. Other protocols in this project type use

parameters that are regional-specific (but not specific to all three regions), which means that they do not meet the WCI's sub-criterion for quantification and additionality.

- The CDM compost protocol corresponds to the WCI criteria (with the exception of crediting period and early starting date, an issue shared by all protocols).
- The CDM wastewater protocol has an additional issue with leakage because though it asserts that the risk of leakage is not present, it does not justify its assertion.
- The Alberta Waste Water protocol corresponds to the WCI criteria with the exceptions of the criteria additional and quantification, both due to issues of geographical applicability. (Again, this is with the exception of crediting period and early starting date, an issue shared by all protocols).
- The Alberta Compost protocol shares the issues of the Alberta Waste Water protocol but additionally does not address leakage risk.
- The □□-A□S protocol shares the issues of geographical applicability and, additionally, fails to justify why leakage is not a concern.

2 INTRODUCTION

The purpose of this report is to provide the results of DNV's evaluation of protocols[3] identified by the Partners in the Western Climate Initiative (WCI). The goal of the evaluation was to assess how easily the existing protocols could be incorporated into an offset system for the Western Climate Initiative (WCI), should the WCI choose to do so. The initial list for consideration included □□ protocols from 11 offset systems□ particular to ten project types in the agriculture, forestry, and waste management sectors.

Note: in some cases, a dot in this table represents more than one protocol. In other cases, a protocol addresses more than one project type or dot.

The WCI's offset criteria are outlined in its *Offset System Essential Elements Draft Recommendations Paper*[6], in which a WCI offset is defined as:

> a quantified, independently verified reduction or removal of a greenhouse gas (□□□). It is expressed as one metric ton, or one tonne, of carbon dioxide equivalent. Offsets credits must meet the WCI essential criteria requirements for the WCI Offset System. A WCI offset is tradable, and bankable for future use, and may be used by a capped emitter to meet compliance obligations.

and defines the WCI's requirements that the offset be:

[3] For the purposes of this report, the term protocol refers to the guidance, procedures, and methodologies that detail procedures for creating offsets under an offset system.

[4] For the purposes of this report, the term offset system refers to an organization or entity that has sought to provide guidance to implementing greenhouse gas reductions and/or to creating offsets through projects.

□ *Request for Proposals: Review of Existing Offset Protocols for Consistency with Western Climate Initiative Offset Draft Criteria.* Western □overnor's Association. □uly 31, 2□□□ Available online at http://www.westernclimateinitiative.org/component/remository/Offsets-Committee-Documents/

□Offset System □ssential □lements Draft Recommendations Paper. *Western Governor's Association.* Forthcoming.

- Real (which is based on the following supporting WCI criteria)
  - Quantification
  - Uncertainty & Accuracy
  - Conservativeness
  - Leakage
- Additional
- Permanent
- Verifiable

The WCI Partners asked DNV to evaluate protocols from the existing offset systems listed above to determine whether each protocol appears to:

- Meet the WCI offset criteria,
- Meet ISO 1□□□□-2[□], 1□□□□-3[□], and 1□□□□[□] requirements, and
- Is applicable to the geographies of the Partner jurisdictions.

DNV was not asked to evaluate the WCI draft offset definitions, criteria, and guidelines outlined in *Offset System Essential Elements Draft Recommendations* or to provide DNV's own interpretation of any of these guidelines while carrying out this evaluation, and did not do so. The protocols are evaluated solely on the basis of their apparent conformance with WCI guidelines as written.

In cases where an offset system provides system-level guideline documents (e.g., Alberta), DNV reviewed these additional documents because specific information such as project starting dates are only specified in the system guidance documents and not at each protocol level. DNV, however, did not review any previous versions of the protocols or background information about how the protocols were developed. DNV's assessment is based on a □strict reading□of the protocols, which means that DNV did not carryout a technical review of the protocol or use our professional judgment to make inferences where information was not explicitly provided in the protocol.

For the protocols that did not fully correspond to the WCI guidelines, DNV identified potential modifications to the protocol. DNV's evaluation was framed within the context of how much modification would be necessary to meet the WCI's guidelines. DNV's evaluation refers to the conceptual degree of change required for a protocol to conform to WCI guidelines, not to the amount of work, time, or effort necessary to make that change. That said, DNV further identified whether the necessary changes appear to be editorial in nature or are instead research-based.

It can be noted that no protocol perfectly met all of the WCI conditions, if only because none of the specified protocols provide region-specific factors or rules for all potential projects in the United States, Canada, and Mexico. For all project types, crediting periods and project start dates fail to match up with the WCI. It also cannot be concluded that any given protocol could never be made to fully correspond to the WCI guidelines, with sufficient modification.

DNV excluded from the analysis the following protocols that the WCI had initially suggested in the *Request For Proposals*, for the specified reasons:

- U.S. DO□ 1□□□(b), as they do not refer to specific stand-alone project activities, and so cannot be fairly evaluated against project-specific protocols□

[□] *ISO 14064-2:2006: Specification with guidance at the project level for quantification, monitoring and reporting of greenhouse gas emission reductions or removal enhancements.* (2□□□). Available at http://www.iso.org

[□] *ISO 14064-3:2006: Specification with guidance for the validation and verification of greenhouse gas assertions.* (2□□□). Available at http://www.iso.org

[□] *ISO 14065:2007: Requirements for greenhouse gas validation and verification bodies for use in accreditation or other forms of recognition.* (2□□□). Available at http://www.iso.org

- All protocols listed in the VCS, as they do not provide quantification methodologies for soil sequestration, rangeland management, or forestry projects, and so cannot be fairly evaluated against offset qualification/quantification protocols. These documents are rather guidelines for quantification/qualification of offsets[1□]□
- CC□ Forest Preservation/Conservation, as it no longer exists under the revised CC□ guidelines□
- New South Wales, as they do not provide quantification methodologies, and so cannot be fairly evaluated against offset qualification/quantification protocols□
- American Carbon Registry forestry protocol, as it does not provide its own quantification methodology□and
- All Forest Products protocols, as they do not refer to specific stand-alone project activities, and so cannot be fairly evaluated against project-specific protocols.

After this initial review, 31 protocols were considered for further analysis, including some protocols that DNV substituted for protocols that the Partners had identified:

- CC□ 2□□□ protocols for the protocols described in the 2□□□ Rulebook Chapter □, as these have displaced the 2□□□ rules.
- CDM ACM □□1□ for AMS-3.D (covering manure management), and AM □□1□ for AMS-III.□ (covering wastewater treatment) as these are applicable to large-scale projects whereas those identified by the WCI are not.

For each of the WCI criteria (real, additional, permanent, and verifiable), DNV evaluated each protocol to determine if it:

- Appears to correspond to WCI and ISO definitions for this criterion.
- Is likely to correspond to, with modification, WCI and ISO definitions for this criterion.
- Could correspond to, with significant modification, WCI and ISO definitions for this criterion.

For each of the WCI criteria, DNV applied a general evaluation approach as described in Table 3, as well as criterion-specific evaluation metrics as specified in Table □

To draft the guidelines, DNV reviewed each of the WCI's draft criteria and determined that they were consistent with the ISO framework□in the evaluation, there was no instance in which a protocol met the WCI criteria and failed to meet the ISO criteria.

[10] At the time of this writing there were several Agriculture, Forestry and Other Land Use (AFOLU) protocols being proposed and going through the VCS approval process, but none that had been approved.

General Evaluative Approach Used

Table 3: Evaluations Possible for Each Criterion

Appears to correspond to WCI and ISO definitions for this criterion.
Likely to correspond to, with modification, WCI and ISO definitions for this criterion.
Could correspond to, with significant modification, WCI and ISO definitions for this criterion.

where "modification" and "significant modification" refer to the conceptual degree of change required, rather than to the amount of work, time, or effort necessary to make that change.

The criterion "real" consists of sub-criteria "quantification", "uncertainty & accuracy", "conservativeness" and "leakage." Evaluation for "real" is a summary result of the four sub-criteria and in cases where a sub-criterion was assessed to "could correspond to with significant modification", and then the overall evaluation for "real" corresponds to that result.

DNV's choice of the above evaluation was based on the corresponding guidelines summarized below (matched by color):

Table 4: Evaluation Guidelines for Determining if a Protocol Meets Each Criterion

	Evaluation
REAL	
Quantification	Protocol clearly states project boundaries, quantification methodology based on recognizable scientific sources and emission factors are appropriate to all the WCI jurisdictions.
	Uses default values that are not appropriate to all the WCI regions. Alternatively, Project boundary is not clearly stated.
	No quantification methods are provided.
Uncertainty & Accuracy	Protocol provides guidelines to reduce uncertainty/bias and quantification methodologies are based on recognizable scientific sources. The protocol discounts to adjust for high uncertainty. Additionally, the protocol requires that the proponent institute quality assurance measures in data management.
	Protocol does not appear to be based on recognizable scientific sources or does not institute quality assurance measures for data measurement. Alternatively, protocol does not manage uncertainty, for example, by requiring discounting emission reductions to adjust for high uncertainty.
	Protocol does not identify uncertainty or provide guidelines to reduce uncertainty.
Conservativeness	The protocol provides a principle of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions.
	The conservativeness of the parameters is not justified.

Leakage	Protocol identifies sources of leakage. If leakage is a concern, quantification/qualification and management of leakage are required. If leakage is qualified as opposed to quantified, the protocol justifies why quantification is not possible.
	The protocol finds that leakage is a concern but does not establish guidelines to mitigate the risk
	There is no evidence that the protocol examines leakage. Alternatively, the protocol states that leakage is not a concern but does not justify the assertion.

ADDITIONAL	Additionality is assessed via a performance test that is appropriate for all WCI jurisdictions. Further, the protocol meets criteria for start date and crediting period. Alternatively, the protocol uses a project-specific approach that ensures that at a minimum the project is not required by law. Further, the protocol meets criteria for start date and crediting period.
	The protocol employs a performance test or project specific additionality test (that at a minimum ensures the project is not required by law) but does not meet the criteria for crediting period or start date. Alternatively, the analysis used to justify the performance test is not appropriate for the entire WCI region.
	The protocol applies no additionality test, either performance or project-based, and do not ensure that the project was not required by law.

PERMANENT	The protocol assesses the risk for reversal. If present, it establishes or requires that the project proponent establish: a monitoring system, a risk mitigation approach, and a contingency plan for the case of reversal. Further, the protocol has the legal means to enforce the contingency plan and the plan is adequate for the risk of reversal over a 1□□ year time span. Reversals could be balanced, for example, by the set-aside of a certain number of offsets or the issuance of temporary credits. Alternatively, non-sequestration projects automatically meet the WCI criteria for permanence.
	The protocol assesses the risk for reversal. If present, it establishes or requires that the project proponent establish: a monitoring system, a risk mitigation approach, and a contingency plan for the case of reversal. □owever, the protocol□s plan is inadequate for the risk of reversal over a 1□□ year time span.
	The protocol describes a sequestration project but does not provide any requirements for preventing, managing, or compensating for reversals.

VERIFIABLE	Protocol requires documents, evidence and data be available for 3rd party verification.
	The protocol does not require verification.

Work Process Flowchart

The flowchart below illustrates the process by which DNV conducted this assessment. □rey boxes refer to documents or work product□ tangible objects that can be referenced. White boxes refer to actions that were taken to modify the preceding document or to make an assessment.

ISO Documents
WCI Draft Recommendations Paper
Step 1: Reviewed ISO and WCI documents and pulled out text relevant to the WCI's criteria (Real, Additional, Permanent, Verifiable, and Applicable to the regions within the WCI's jurisdiction)
Relevant text from ISO and WCI documents (see Appendix 2)
Step 2: Drafted for approval by WCI Offsets Committee Members □valuation □uidelines to determine what □appears to correspond to□ □is likely to correspond to, with modification□ and □could correspond to, with significant modification□the relevant text from ISO and WCI documents.
□valuation □uidelines for Determining if a Protocol Meets □ach Criterion (Table □ in this document, page 11)
Step 3: Developed evaluative questions for DNV team to use when determining what the protocol text would need to state in order to meet WCI's □valuation □uidelines.
□valuative Questions (see Appendix 2)
Step □ Reviewed Protocol Text and Offset System □uidance Documents and pulled out text relevant to the WCI's criteria
Relevant Protocol Text (see Appendix 2)
□xcel-based tracking sheet relevant text from ISO and WCI documents, relevant text from Protocols, and DNV's □valuative Questions (see Appendix 2)
Step □ Asked question: According to □valuative Questions, what category does the relevant protocol text apply to□Assigned each criterion to green, yellow, or blue category as appropriate.
Step □(when appropriate): Where not green, determine what must be done to qualify as green. Make judgment of whether the necessary changes are editorial or research-based in nature.
DNV Assessments (Sections □-12 of this document)

3 STAKEHOLDER PROCESS OF EACH OFFSET SYSTEM

As part of its review, DNV summarized the stakeholder process of each offset system.

Offset System	Stakeholder Process
Alberta Offset System	The Alberta government first provides feedback to protocol developers. The protocol then goes through three rounds of review. The first is by an expert technical review committee, and the second is by a broader stakeholder group. If there are no objections, the protocol is posted for the final public review for 3□days.
Chicago Climate Exchange	A technical subcommittee drafts protocols, and protocols are posted on the website for public review and comment.
Clean Development Mechanism	All proposed new CDM baseline and monitoring methodologies go through a public comment process. The CDM Executive Board approves methodologies.
Climate Action Reserve	The Climate Action Reserve develops offset protocols in an open, transparent and consensus-based process. It takes a multi-stakeholder approach to developing protocols.
GE Energy Financial Services & AES	Proposed methodologies are assigned a point of contact within Greenhouse Gas Services, LLC and this person is responsible for drafting the methodology and securing stakeholder input. Greenhouse Gas Services, LLC is ultimately responsible for the adoption of new methodologies.
Regional Greenhouse Gas Initiative	The Model Rule was developed by the RGGI Staff Working Group, comprised of staff members from the environmental and energy regulatory agencies in each participating state. This effort was supported by a regional stakeholder process that engaged the regulated community, environmental groups, and other organizations with technical expertise in the design of cap-and-trade programs.
U.S. EPA Climate Leaders	The U.S. EPA developed the protocols. It is possible to propose a new protocol. When a new protocol is proposed, the EPA reviews it. The protocol review process is not well defined or transparent, and appears to have no public stakeholder consultation process.
American Carbon Registry	Excluded from the review
DOE 1605 (b)	Excluded from the review
VCS	Excluded from the review
New South Wales	Excluded from the review

4 SOIL SEQUESTRATION PROTOCOLS[11]

4.1 Alberta Offset System Quantification Protocol for Tillage System Management, Version 1.3

	Evaluation
REAL	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Uncertainty & Accuracy and Conservativeness. (See below) *Modifications that are necessary to fully meet:* The protocol would need to modify Quantification and Leakage (See below)
Quantification	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states project boundaries and quantification methodology are based on recognizable scientific sources. *Modifications that are necessary to fully meet:* The protocol would need to develop emission factors that are appropriate to all the WCI jurisdictions.
Uncertainty & Accuracy	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* Protocol provides guidelines to reduce uncertainty bias and quantification methodologies are based on recognizable scientific sources. The protocol discounts to adjust for high uncertainty. Additionally, the protocol requires that the proponent institute quality assurance measures in data management. *Modifications that are necessary to fully meet:* NA
Conservativeness	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principle of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* NA
Leakage	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* NA

[11] This project type includes improved tillage management (both the Alberta Offset System and Chicago Climate Exchange) and permanent grassland cover (Chicago Climate Exchange only).

	Modifications that are necessary to fully meet: The protocol would need to examine concerns over leakage and, if leakage is a concern, to quantify or qualify the leakage and manage it. Leakage is unlikely to be an issue for this project type, as leakage would require that tillage activities be transferred to areas where tillage is currently not practiced. That said, the protocol would at least need to justify its analysis of why leakage is not a concern.
ADDITIONAL	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol uses a performance test and ensures that reductions are not required by law. Further, the protocol meets the WCI criterion for crediting period. *Modifications that are necessary to fully meet:* The protocol would need to establish a performance test that analyzes market penetration for the implementation of no-till farming in Mexico and the US, not just to Canada.
PERMANENT	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol assesses the risk for reversal, which is found present. It establishes a monitoring system, a risk mitigation approach, and a contingency plan for the case of reversal in the form of an assurance factor that discounts the total crediting value over each year of the □□-year crediting period to account for expected reversals during those □□ years. *Modifications that are necessary to fully meet:* The protocol's contingency plan would need to be adequate over a □□□-year time span. The current crediting period of the protocol is □□ years, with renewal of □□ years.
VERIFIABLE	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* Protocol requires □rd party verification and sufficient enforcement mechanisms exist. *Modifications that are necessary to fully meet:* □A

4.2 Chicago Climate Exchange Rules for Exchange Soil Offsets Continuous Conservation Tillage and Conversion to Grassland: Soil Carbon Sequestration Offset Project Protocol, Updated as of 9/30/2009

	Evaluation
Real	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Uncertainty □ Accuracy and Conservativeness. □See below□ *Modifications that are necessary to fully meet:* The protocol would need to modify □uantification and Leakage □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states pro□ect boundaries and □uantification methodology are based on recognizable scientific sources. *Modifications that are necessary to fully meet:* The protocol would need to develop emission factors that are appropriate to all the WCI □urisdictions. It currently uses a US database to describe soil type, and would need to develop e□uivalent emission factors for Canada and Mexico.
Uncertainty & Accuracy	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty bias by providing default factors for proponents to use. It cites □uantification methodologies that are based on recognizable scientific sources in the form of peer-reviewed □ournals. The protocol discounts by □□□ to ad□ust for high uncertainty. Additionally, the protocol re□uires that the proponent institute □uality assurance measures in data management. *Modifications that are necessary to fully meet:* □A
Conservativeness	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principle of conservatism and provides assertions that it selected its parameters so as to underestimate rather than overestimate the calculation of emission reductions. Default emission factors were selected by taking the average of se□uestration rates for specific regions published in peer-reviewed academic literature and discounting that number by □□□. The literature *Modifications that are necessary to fully meet:* □A

Leakage	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* □A *Modifications that are necessary to fully meet:* The protocol would need to examine concerns over leakage and, if leakage is a concern, to □uantify or □ualify the leakage and manage it. If leakage is stated to not be a concern, the protocol would need to □ustify its analysis.
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol uses a performance test to ensure that the pro□ect activity is not common practice by citing that professional soil scientists in the USDA and academia estimate between □-□□□ of US farmland is currently managed under continuous conservation tillage and asserting that the implementation of continuous conservation tillage therefore does not meet CC□'s threshold for common practice. It also ensures that reductions are not re□uired by law. □urther, the protocol meets the WCI criterion for crediting period. *Modifications that are necessary to fully meet:* The protocol would need to ensure that its performance test analyzes market penetration for the implementation of no-till farming in Mexico and the Canada, not □ust to the United States. □urther, the start date would need to be modified from □anuary □, □□□□.
Permanent	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol assesses the risk for reversal, which is found present. It establishes a monitoring system, a risk mitigation approach, and a contingency plan that discounts average se□uestration rates by □□□ to account for the loss of carbon should pro□ect participants return to conventional tillage. The □□□ of credits that are withheld from the pro□ect participant are kept in a Soil Carbon Reserve Pool that is released to the Pro□ect □wner at the end of the crediting period. *Modifications that are necessary to fully meet:* The protocol's contingency plan would need to be ade□uate over a □□□-year time span.
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* Protocol re□uires □rd party verification, and sufficient enforcement mechanisms exist. *Modifications that are necessary to fully meet:* □A

5 MANURE MANAGEMENT PROTOCOLS

5.1 Alberta Offset System Quantification Protocol for the Anaerobic Decomposition of Agricultural Materials

	Evaluation
Real	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Quantification, and Conservativeness (See below) *Modifications that are necessary to fully meet:* The protocol would need to modify Uncertainty and Accuracy, and Leakage (See below)
Quantification	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states project boundaries, quantification methodology based on recognizable scientific sources and emission factors are appropriate to all the WCI jurisdictions. *Modifications that are necessary to fully meet:* *NA*
Uncertainty & Accuracy	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty/bias and quantification methodologies are based on recognizable scientific sources. Additionally, the protocol requires that the proponent institute quality assurance measures in data management. *Modifications that are necessary to fully meet:* The protocol would need to be modified to manage uncertainty, for example, by requiring discounting emission reductions to adjust for high uncertainty.
Conservativeness	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* NA

Leakage	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* □A *Modifications that are necessary to fully meet:* There is no evidence that the protocol examines leakage. The protocol would need to be modified to address the leakage issues. If it is not a concern, the protocol would need to □ustify the assertion.
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires that the pro□ect is not re□uired by law. *Modifications that are necessary to fully meet:* The technology threshold would need to be modified to be applicable to the entire WCI region.
Permanent	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* This is a non-se□uestration pro□ect protocol. *Modifications that are necessary to fully meet:* □A
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification. *Modifications that are necessary to fully meet:* □A

5.2 Chicago Climate Exchange Agricultural Methane Collection and Combustion Offset Project Protocol

	Evaluation
Real	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Conservativeness (See below) *Modifications that are necessary to fully meet:* The protocol would need to modify Quantification, Uncertainty and Accuracy, and Leakage (See below)
Quantification	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states project boundaries, quantification methodology based on recognizable scientific sources *Modifications that are necessary to fully meet:* The protocol would need to be modified to include appropriate factors for the other eligible regions (i.e., Canada and Mexico)
Uncertainty & Accuracy	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty/bias and quantification methodologies are based on recognizable scientific sources. Additionally, the protocol requires that the proponent institute quality assurance measures in data management. *Modifications that are necessary to fully meet:* The protocol would need to be modified to manage uncertainty, for example, by requiring discounting emission reductions to adjust for high uncertainty.
Conservativeness	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* NA

Leakage	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* □A *Modifications that are necessary to fully meet:* The protocol would need to □stify why leakage is not a concern. The protocol states that it does not expect agricultural methane pro□cts to result in leakage emissions, but does not explicitly state why.
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol employs a performance test. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a technology threshold applicable to Canada and Mexico-based pro□ect. The pro□ect starting date as well as the crediting period would need to be ad□usted.
Permanent	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* This is a non-se□uestration pro□ect protocol. *Modifications that are necessary to fully meet:* □A
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification. *Modifications that are necessary to fully meet:* □A

5.3 Clean Development Mechanism, ACM0010 "Consolidated baseline methodology for GHG emissions reductions from manure management systems"

	Evaluation
Real	Appears to correspond to WCI and ISO definitions for this criterion. Aspects of criterion definition that are met: The protocol meets Quantification, Uncertainty and Accuracy, Conservativeness, and leakage. (See below) *Modifications that are necessary to fully meet:* NA
Quantification	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states project boundaries. Quantification methodology based on recognizable scientific sources and emission factors are appropriate to all the WCI jurisdictions. *Modifications that are necessary to fully meet:* NA
Uncertainty & Accuracy	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty bias and quantification methodologies are based on recognizable scientific sources. The protocol discounts to adjust for high uncertainty. Additionally, the protocol requires that the proponent institute quality assurance measures in data management. *Modifications that are necessary to fully meet:* NA
Conservativeness	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* NA
Leakage	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol identifies sources of leakage. The protocol provides quantification methods for leakage emissions. *Modifications that are necessary to fully meet:* NA

Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol uses a pro□ect-specific approach that ensures that at a minimum the pro□ect is not re□uired by law. *Modifications that are necessary to fully meet:* The pro□ect starting date and the crediting period would need to be ad□usted.
Permanent	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* This is a non-se□uestration project protocol *Modifications that are necessary to fully meet:* □A
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification. *Modifications that are necessary to fully meet:* □A

5.4 Climate Action Reserve Livestock Project Reporting Protocol Capturing and destroying methane from manure management systems

	Evaluation
Real	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Uncertainty □ Accuracy and Conservativeness □See below□ *Modifications that are necessary to fully meet:* The protocol would need to modify □uantification and Leakage □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states pro□ect boundaries, □uantification methodology based on recognizable scientific sources *Modifications that are necessary to fully meet:* The protocol would need to be modified to include factors that are applicable to pro□ects in Canada. The defaults are specific to the U.S. In addition to this protocol, the Climate Action Reserve has another livestock protocol that is applicable to Mexico.

Uncertainty & Accuracy	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol identifies potential uncertainties, provides guidelines to reduce uncertainty/bias, and references recognizable scientific sources. The protocol discounts to adjust for high uncertainty. Additionally, the protocol requires that the proponent institute quality assurance measures in data management. *Modifications that are necessary to fully meet:* NA
Conservativeness	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* NA
Leakage	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* NA *Modifications that are necessary to fully meet:* There is no evidence that the protocol examines leakage. The protocol would need to be modified to address the leakage issues. If it is not a concern, the protocol would need to justify the assertion[illegible].
Additional	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol employs a performance test. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a technology threshold applicable to Canada-based project. In addition to this protocol, the Climate Action Reserve has another livestock protocol that is applicable to Mexico. The project starting date as well as the crediting period need to be adjusted.

[illegible] When examining leakage, DNV performed a strict reading of protocol document language to determine whether leakage was addressed and, if so, how. A protocol that does not address leakage explicitly (perhaps because it indirectly addresses it by defining the project boundary so that any affected emissions sources are included in the project activity) would need to justify in the protocol why leakage is not a concern. DNV did not examine whether a project boundary was defined so as to avoid leakage concerns due to project activities.

Permanent	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* This is a non-se□uestration pro□ect protocol. *Modifications that are necessary to fully meet:* □A
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification. *Modifications that are necessary to fully meet:* □A

5.5 Regional Greenhouse Gas Initiative Model Rule

	Evaluation
Real	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. Aspects of criterion definition that are met□ □A Modifications that are necessary to fully meet□ The protocol would need to modify □uantification, Uncertainty and Accuracy, Conservativeness, and Leakage □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states □uantification methodology based on recognizable scientific sources *Modifications that are necessary to fully meet:* Some of the factors provided are applicable to the U.S. region□states. □ew factors that are applicable to pro□ects in Canada and Mexico are needed. The protocol would need to be modified to clearly define the pro□ect boundary.
Uncertainty & Accuracy	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty□bias and □uantification methodologies are based on recognizable scientific sources. Additionally, the protocol re□uires that the proponent institute □uality assurance measures in data management. *Modifications that are necessary to fully meet:* The protocol would need to be modified to manage uncertainty, for example, by re□uiring discounting emission reductions to ad□ust for high uncertainty.

Conservativeness	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. Aspects of criterion definition that are met□ □A Modifications that are necessary to fully meet□ The conservativeness of the parameters is not □ustified. The protocol would need to provide parameter values that are selected so as to be biased toward underestimation rather than overestimation of emission reductions.
Leakage	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* □A *Modifications that are necessary to fully meet:* There is no evidence that the protocol examines leakage. The protocol would need to be modified to address the leakage issues. If it is not a concern, the protocol would need to □ustify the assertion.
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol employs a performance test. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a technology threshold applicable to Canada and Mexico-based pro□ect. The pro□ect starting date as well as the crediting period need to be ad□usted.
Permanent	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* This is a non-se□uestration pro□ect protocol. *Modifications that are necessary to fully meet:* □A
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd-party verification. *Modifications that are necessary to fully meet:* □A

5.6 US EPA Climate Leaders GHG Inventory Protocol- Offset Project Methodology for Managing Manure with Biogas Recovery Systems

	Evaluation
Real	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Conservativeness, and Leakage □See below□ *Modifications that are necessary to fully meet:* The protocol would need to modify □uantification, and Uncertainty and Accuracy □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states pro□ect boundaries, □uantification methodology based on recognizable scientific sources *Modifications that are necessary to fully meet:* The protocol would need to be modified to include appropriate factors for the other eligible regions □i.e., Canada and Mexico□ Some parameters are U.S.-based pro□ect specific.
Uncertainty & Accuracy	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty□bias and □uantification methodologies are based on recognizable scientific sources. Additionally, the protocol re□uires that the proponent institute □uality assurance measures in data management. *Modifications that are necessary to fully meet:* The protocol would need to be modified to manage uncertainty, for example, by re□uiring discounting emission reductions to ad□ust for high uncertainty.
Conservativeness	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* □A

Leakage	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol identifies sources of leakage. While it states that leakages are not a concern, it re□uires □uantifying such emissions if it is determined that leakage emissions are significant. *Modifications that are necessary to fully meet:* □A
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol employs a performance test. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a technology threshold applicable to Canada and Mexico-based pro□ects. The pro□ect starting date as well as the crediting period needs to be ad□usted.
Permanent	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* This is a non-se□uestration project protocol. *Modifications that are necessary to fully meet:* □A
Verifiable	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* □A *Modifications that are necessary to fully meet:* The protocol would need to be modified to re□uire a third party verification.

6 RANGELAND MANAGEMENT PROTOCOLS

6.1 Chicago Climate Exchange Sustainably Managed Rangeland Soil Carbon Sequestration Offset Project Protocol

	Evaluation
Real	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Uncertainty □ Accuracy, Conservativeness, and Leakage. □See below□ *Modifications that are necessary to fully meet:* The protocol would need to modify □uantification □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states project boundaries and □uantification methodology are based on recognizable scientific sources. *Modifications that are necessary to fully meet:* The protocol would need to develop emission factors that are appropriate to all the WCI □urisdictions. It currently uses a US database to describe soil type, and would need to develop e□uivalent emission factors for Canada and Mexico.
Uncertainty & Accuracy	Appears to correspond to WCI and IS□ definitions for this criterion *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty bias by providing default factors for proponents to use. It cites □uantification methodologies that are based on recognizable scientific sources in the form of peer-reviewed □ournals. The protocol discounts by □□□ to ad□ust for high uncertainty. Additionally, the protocol re□uires that the proponent institute □uality assurance measures in data management. *Modifications that are necessary to fully meet:* □A
Conservativeness	Appears to correspond to WCI and IS□ definitions for this criterion *Aspects of criterion definition that are met:* The protocol provides a principle of conservatism and provides assertions that it selected its parameters so as to underestimate rather than overestimate the calculation of emission reductions. Default emission factors were selected by discounting by □□□ the average of se□uestration rates published in peer-reviewed academic literature for specific regions. *Modifications that are necessary to fully meet:* □A

Leakage	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol identifies sources of leakage, and activity-shifting leakage is found to be a concern. It then re□uires that project proponents □□enroll all owned or controlled rangeland that is eligible for offsets to be enrolled in the CC□ and that □□stocking rates on land outside the eligible rangeland have not increased as a result of the project activity. *Modifications that are necessary to fully meet:* □A
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol uses a performance test to ensure that the project activity is not common practice by citing USDA findings that there is the opportunity to make □distinct categorical Rangeland conditions improvements on approximately □□□ of privately managed acres□□p.□□□and asserting that the protocol□s re□uirements for □best in class□Rangeland management practices ensure that project activities have not been practiced on □□□ of eligible acres. It also ensures that reductions are not re□uired by law. □urther, the protocol meets the WCI criterion for crediting period. *Modifications that are necessary to fully meet:* The protocol would need to ensure that its performance test analyzes market penetration for the implementation of no-till farming in Mexico and the Canada, not □ust to the United States. □urther, the start date would need to be modified from □anuary □, □□□□.
Permanent	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol assesses the risk for reversal, which is found present. It establishes a monitoring system, a risk mitigation approach that discounts the credits issued each year to account for reversals due to drought years, and a contingency plan that discounts average se□uestration rates by □□□ to account for the loss of carbon should project participants return to conventional tillage. The □□□ of credits that are withheld from the project participant are kept in a Soil Carbon Reserve Pool that is released to the Project □wner at the end of the crediting period. The protocol also provides an additional contingency approach for periods of prolonged drought. *Modifications that are necessary to fully meet:* The protocol□s contingency plan would need to be ade□uate over a □□□-year time span.
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification, and sufficient enforcement mechanisms exist. *Modifications that are necessary to fully meet:* □A

7 AFFORESTATION & REFORESTATION PROTOCOLS

7.1 Chicago Climate Exchange Forestry Carbon Sequestration Project Protocol

	Evaluation
Real	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Conservativeness □See below□ *Modifications that are necessary to fully meet:* The protocol would need to modify □uantification, Uncertainty and Accuracy, and Leakage □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states pro□ect boundaries, □uantification methodology based on recognizable scientific sources *Modifications that are necessary to fully meet:* The protocol would need to be modified to include appropriate factors for the other eligible regions □i.e., Canada and Mexico□ Some parameters are U.S.-based pro□ect specific.
Uncertainty & Accuracy	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty□bias and □uantification methodologies are based on recognizable scientific sources. Additionally, the protocol re□uires that the proponent institute □uality assurance measures in data management. *Modifications that are necessary to fully meet:* The protocol would need to be modified to manage uncertainty, for example, by re□uiring discounting emission reductions to ad□ust for high uncertainty.
Conservativeness	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* □A

Leakage	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* □A *Modifications that are necessary to fully meet:* The protocol would need to □ustify why leakage is not a concern. The protocol asserts that it does not expect forestry pro□ects to result in leakage emissions, but does not defend its assertion.
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol employs a performance test. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a technology threshold applicable to Canada and Mexico-based pro□ect. The pro□ect starting date as well as the crediting period need to be ad□usted.
Permanent	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol assesses the risk for reversal. If present, it establishes or re□uires that the pro□ect proponent establish□a monitoring system, a risk mitigation approach, and a contingency plan for the case of reversal. All pro□ects are re□uired to reserve □□□ of offsets. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a re□uirement for assessing risks of reversal. The protocol would need to be modified to ensure that carbon is se□uestered over □□□ years. Currently, the participants are re□uired to sign a contract to commit for □□ years.
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification. *Modifications that are necessary to fully meet:* □A

7.2 Clean Development Mechanism AR-ACM0001 "Afforestation and Reforestation of Degraded Land"

	Evaluation
Real	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Quantification, Conservativeness and Leakage (See below). *Modifications that are necessary to fully meet:* NA (See below)
Quantification	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states project boundaries, quantification methodology based on recognizable scientific sources and emission factors are appropriate to all the WCI jurisdictions. *Modifications that are necessary to fully meet:* NA
Uncertainty & Accuracy	Appears to correspond to WCI and ISO definitions for this criterion *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty bias and quantification methodologies are based on recognizable scientific sources. The protocol manages uncertainty. Additionally, the protocol requires that the proponent institute quality assurance measures in data management. *Modifications that are necessary to fully meet:* NA
Conservativeness	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* NA
Leakage	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol identifies sources of leakage. The protocol provides quantification methods for leakage emissions. *Modifications that are necessary to fully meet:* NA

Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol uses a pro□ect-specific approach that ensures that at a minimum the pro□ect is not re□uired by law. *Modifications that are necessary to fully meet:* The pro□ect starting date and the crediting period would need to be ad□usted.
Permanent	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. Aspects of criterion definition that are met□ The CDM deals with permanence issues by issuing temporary credits. Modifications that are necessary to fully meet□ The protocol would need to be modified to include legal means to enforce the contingency plan and the plan is ade□uate for the risk of reversal over a □□□ year time span.
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification. *Modifications that are necessary to fully meet:* □A

7.3 Climate Action Reserve Forest Project Protocol, Version 3.1 October 22, 2009

	Evaluation
Real	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Uncertainty and Accuracy, and Conservativeness □See below□ Modifications that are necessary to fully meet□ □uantification, and Leakage □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states pro□ect boundaries, □uantification methodology based on recognizable scientific sources *Modifications that are necessary to fully meet:* The protocol would need to be modified to include factors that are applicable to pro□ects in outside of California. Currently, the growth pro□ection models approved are only applicable to the pro□ects in California. In addition, Appendix □ is specific to California.[□□]
Uncertainty & Accuracy	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol identifies potential uncertainties, provides guidelines to reduce uncertainty/bias, and references recognizable scientific sources. The protocol discounts to adjust for high uncertainty. Additionally, the protocol re□uires that the proponent institute □uality assurance measures in data management. *Modifications that are necessary to fully meet:* □A
Conservativeness	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides a principal of conservatism or assertion that parameter values are selected so as to underestimate rather than overestimate the calculation of emission reductions. *Modifications that are necessary to fully meet:* □A

[□□] At the time of this writing CAR had only provided factors applicable to California□future release of factors applicable to the entire United States were forthcoming.

Leakage	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol identifies sources of leakage. Leakage is □ualified as opposed to □uantified. Based upon determined leakage risk percentage, discount factors are applied to account for potential leakage. *Modifications that are necessary to fully meet:* Protocol would need to □ustify why leakages are not □uantified as opposed to □ualified.
Additional	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol employs a performance test. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a technology threshold applicable to pro□ects outside of California. Currently, the performance threshold provided in the protocol is applicable to pro□ects within California. The pro□ect starting date as well as the crediting period need to be ad□usted.
Permanent	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol assesses the risk for reversal. If present, pro□ect proponents are re□uired to establish a monitoring system and a risk mitigation approach, and the protocol provides a contingency plan for the case of reversal. Additionally, the protocol the legal means to enforce the contingency plan and the plan is ade□uate for the risk of reversal over a □□□ year time span. Based upon the risk rating, it re□uires setting aside a portion of credits. *Modifications that are necessary to fully meet:* □A
Verifiable	Appears to correspond to WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol re□uires □rd party verification. *Modifications that are necessary to fully meet:* □A

7.4 Regional Greenhouse Gas Initiative Model Rule

	Evaluation
Real	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. Aspects of criterion definition that are met: Quantification Modifications that are necessary to fully meet: The protocol would need to modify Uncertainty and Accuracy, Conservativeness, and Leakage (See below)
Quantification	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states project boundaries, quantification methodology based on recognizable scientific sources and emission factors are appropriate to all the WCI jurisdictions. *Modifications that are necessary to fully meet:* NA
Uncertainty & Accuracy	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty/bias and quantification methodologies are based on recognizable scientific sources. In addition, the protocol manages uncertainty, for example, by requiring discounting emission reductions to adjust for high uncertainty. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include requirements for quality assurance measures for data measurement.
Conservativeness	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. Aspects of criterion definition that are met: NA Modifications that are necessary to fully meet: The conservativeness of the parameters is not justified. The protocol would need to provide parameter values that are selected so as to be biased toward underestimation rather than over estimation of emission reductions.
Leakage	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* NA *Modifications that are necessary to fully meet:* There is no evidence that the protocol examines leakage. The protocol would need to be modified to address the leakage issues. If it is not a concern, the protocol would need to justify the assertion.

Additional	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol ensure that the project is not required by law. *Modifications that are necessary to fully meet:* The project starting date as well as the crediting period would need to be adjusted.
Permanent	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol assesses the risk for reversal. If present, it establishes or requires that the project proponents establish a monitoring system, a risk mitigation approach, and a contingency plan for the case of reversal. All projects are required to reserve [illegible] of offsets. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a requirement for assessing risks of reversal. The protocol would need to be modified to ensure that carbon is sequestered over [illegible] years. The protocol does not specify the length of the legal commitment.
Verifiable	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol requires 3rd party verification. *Modifications that are necessary to fully meet:* NA

7.5 US EPA Climate Leaders GHG Inventory Protocol- Offset Project Methodology for Reforestation/Afforestation

	Evaluation
Real	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol meets Leakage □See below□ *Modifications that are necessary to fully meet:* The protocol would need to modify □uantification, and Uncertainty and Accuracy, and Leakage □See below□
Quantification	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol clearly states pro□ect boundaries, □uantification methodology based on recognizable scientific sources *Modifications that are necessary to fully meet:* The protocol would need to be modified to include appropriate factors for the other eligible regions □i.e., Canada and Mexico□ Some parameters are U.S.-based pro□ect specific.
Uncertainty & Accuracy	Likely to correspond to, with modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* The protocol provides guidelines to reduce uncertainty□bias and □uantification methodologies are based on recognizable scientific sources. *Modifications that are necessary to fully meet:* The protocol would need to be modified to manage uncertainty, for example, by re□uiring discounting emission reductions to ad□ust for high uncertainty. In addition, the protocol would need to be modified to include re□uirements for □uality assurance measures for data measurement.
Conservativeness	Could correspond to, with significant modification, WCI and IS□ definitions for this criterion. *Aspects of criterion definition that are met:* □A *Modifications that are necessary to fully meet:* The conservativeness of the parameters is not □ustified. The protocol would need to provide parameter values that are selected so as to be biased toward underestimation rather than over estimation of emission reductions.

Leakage	Appears to correspond to WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol requires that sources of leakage be identified and quantified if they are determined significant. *Modifications that are necessary to fully meet:* NA
Additional	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol employs a performance test. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a technology threshold applicable to Canada and Mexico-based projects. The project starting date as well as the crediting period need to be adjusted.
Permanent	Likely to correspond to, with modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* The protocol assesses the risk for reversal. If present, it establishes or requires that the project proponents establish a monitoring system, a risk mitigation approach, and a contingency plan for the case of reversal. *Modifications that are necessary to fully meet:* The protocol would need to be modified to include a requirement for assessing risks of reversal. The protocol would need to be modified to ensure that carbon is sequestered over 100 years. Currently, the protocol only specifies that "carbon accumulated from reforestation/afforestation must be monitored over an extended period of time to properly accounted for variable growth rates and reversal risk."
Verifiable	Could correspond to, with significant modification, WCI and ISO definitions for this criterion. *Aspects of criterion definition that are met:* NA *Modifications that are necessary to fully meet:* The protocol would need to be modified to require a third party verification.

8 FOREST MANAGEMENT PROTOCOLS

8.1 Chicago Climate Exchange Forestry Carbon Sequestration Project Protocol

	Evaluation

1. Introduction

The Western Climate Initiative (WCI) is a cooperative effort of seven U.S. states and four Canadian provinces that are collaborating to identify, evaluate, and implement policies to reduce greenhouse gas (GHG) emissions, including the design and implementation of a regional cap-and-trade program. Auctioning will strengthen the aim of the cap-and-trade program by establishing a price for carbon that will inform industry's investment decisions and promote abatement. The WCI Partner jurisdictions released *Design Recommendations for the WCI Regional Cap-and-Trade Program* in September 2008.[1] The program design recommends auctioning a portion of the emission allowances created under the program and coordinating a regional auction.

This white paper is the first step in developing recommendations for the design of the regionally coordinated auction, as called for in the WCI 2009 – 2010 work plan released February, 2009. It will inform decisions on auction design, including identifying design decisions to be made and assessing their inherent tradeoffs.

The remainder of this paper is organized as follows:

- Section 2 presents the draft auction Design Principles released by WCI in April 2009.
- Section 3 presents the parameters being examined to define the auction design.
- Section 4 summarizes the auction designs used in other programs.

2. Auction Design Principles

The auction design principles are guidelines that help inform decisions regarding the auction design to ensure that the auction maximizes environmental and economic benefits. They reflect a set of common principles developed to guide the overall WCI market design effort, including the auction. The principles were developed with input from WCI Partner jurisdictions and stakeholders at a meeting held on April 9th, 2009, in Seattle, Washington.

- *Fairness:* All market participants, including compliance entities, should have fair and equal access to allowance auctions.

- *Efficiency:* The market is designed to operate efficiently so that greenhouse gas emission reductions can be achieved at the least cost. An efficient market means that allowance and offset prices reflect supply and demand, and accurately reflect the value of allowances and offset credits to entities having compliance obligations. The auction design chosen should contribute to market efficiency.

- *Effective Oversight:* The design and oversight of the allowance auctions do not contribute to fraud, manipulation, and speculative excess.

- *Transparency and Openness:* Transparency in the design and the operation of the allowance auction builds and retains public confidence.

[1] The program design recommendations document *Design Recommendations for the WCI Regional Cap-and-Trade Program* is available at: http://www.westernclimateinitiative.org/the-wci-cap-and-trade-program/design-recommendations

- Reporting of relevant information to regulatory authorities and public disclosure of information has important benefits. It enables regulatory authorities to ensure effective oversight, compliance, and enforcement, all of which are necessary for market efficiency.
- The release of information to the public can change the decisions of market participants, which in turn determine the prices of allowances and offset credits. Timely, accurate, coordinated and consistent release of market-relevant information allows all market participants to have equal access to public information.
- The reporting and disclosure requirements for compliance verification and enforcement balance these benefits against the need for entities to protect certain sensitive information. The potential to disclose certain information that could be used to manipulate the market is also considered. This balancing is consistent with applicable law relating to the disclosure of information.

- *Administrative Simplicity and Cost:* The auction is designed to be as simple as possible for participants and administrators. Administrative costs and transaction costs are minimized for all parties, consistent with the need to provide effective oversight.

- *Accountability:* All entities involved in the allowance and offset credit market, as regulators of the market or as participants, are accountable for their actions. The responsibility, authority, and capacity to conduct the necessary oversight and take appropriate action are fully defined for all agencies charged with compliance verification and enforcement.

- *Conflicts of Interest:* Conflicts of interest between auction participants, monitors, and regulators are prevented.

- *Compatibility with Other Markets:* Entities that participate in allowance auctions may also be participants in other markets, such as the secondary market where allowances are traded, or electricity wholesale markets. The auction design considers potential consequences of interactions between the operation of the auction and the operation of other markets and mitigates potential impacts.

3. Parameters

A large number of auction procedures are currently in use in various public sector auctions around the world. Auction operators generally select procedures based on the assessment of the characteristics of the expected participants, the nature and number of the items being sold, whether the auction will be repeated or whether the items will be actively sold on a secondary market, as well as other objectives the operator may have. The implication is that no procedure is optimal for all auctions.

Each auction procedure is defined by a set of design features or parameters. The WCI partners have identified ten parameters that must be set while accommodating the auction design principles set forth in Section 2 (Auction Design Principles) as well as the decisions contained in the WCI Design Document.

a. Auction Format

There are three main auction format elements to be considered: the number of rounds, the bid format and the pricing mechanism.

The auction operator will consider whether the expected auction participants have uniform access to market information, to evaluate possibilities for manipulation. Each bidder's private valuation of the item being auctioned would be the marginal cost to the bidder of one tonne of direct emission reduction from its operations.

If market information is available, either from previous auction results, trades on secondary markets, or studies evaluating the cost of direct abatement strategies for industry, then auction participants will be able to form good estimates of competitors' valuation of the allowances. Bidders will then worry less about the winner's curse (over bidding) and can increase their bids to be closer to their actual private value of an allowance.

Number of Rounds

Auctions may consist of one round of bidding or multiple rounds. Single round formats can be highly efficient even though bidders are known to shade their bids away from their actual private value and toward the expected auction closing price. Multiple round formats are used when the operator expects that bidders may not initially bid their private marginal values. Auction operators expect competition from multiple bidding rounds to result in a final bid equal to the highest private value among the bidders. The auction operator could specify the number of bidding rounds or alternatively, the auction could use a clock mechanism, where the initial auction price is chosen by the operator and price is then adjusted either upwards or downwards at fixed increments each round until the cumulative bid equals the number available.

Bid Format: Open or Sealed bid

The auction operator chooses between open and sealed bids by deciding whether there is benefit to having competitors see all the bids. The main benefit to open bids is that bidders can observe whether their bids are higher or lower than their competitors' bids. This tells them whether their private valuation of the item is shared by their competitors. This knowledge could prevent participants from reducing their bids to avoid the winner's curse. Of course, bid information is only of value if there are multiple rounds of bidding or if the auction is repeated.

The potential downside to open bidding is that bidders may collude to manipulate the auction price. To collude, bidders may signal their intentions and their identities through their bids. Bids can also be used in multi-unit auctions to retaliate against uncooperative bidders. Operators of multi-round auctions with open bidding could avoid some of these potential issues by specifying bid rules to limit signalling or by using a clock mechanism. Auction operators can avoid both problems by using a single round sealed bid format.

Pricing mechanism: Uniform price or pay as bid format

The operator of a multi-unit auction has two main options in the manner the clearing price will be set. First, the operator may specify a single winning price paid by all winners, known as a uniform price format. Alternatively, the operator may choose to have all winners pay their exact bid price, which is known as a pay as bid format.

In a uniform price format, there are two main design choices: first price and second price. Typically, in a multi-unit auction the auction price is set by awarding a unit to the highest bidder and working down the list of bids until the number of winners equals the number of units auctioned. At that point, the operator can set the auction price using the lowest winning bid (first price format), or by the highest losing bid (second price format.) One reason for choosing the second price format is to avoid having bidders worry about the winner's curse. This is less of an issue in multi-unit repeated auctions. The main risk in using the second-price format is that there may be a large difference between the first and second prices. Auction operators might be reluctant to sell items at a much lower price than the winners actually bid. This is unlikely to be a problem in emission allowance auctions where there are likely to be many bids clustered around the auction closing price. In this case, there will generally be either no difference or, at most, a very small difference between the last accepted bid and the first rejected bid.

Table 2 describes the objectives and highlights some tradeoffs for each of the design options.

Table 2: Basic options for auction type[2]

Design Element	Objectives	Tradeoffs
Number of Rounds		
Multiple Rounds Open Bidding and Clock Formats	• Bidders may adjust private valuation based on other bids	• Provides information on demand schedules during auction • Small bidders can obtain market valuations from larger players and vice versa • Manipulation is possible by signaling during bidding in open bid format, not in clock format • Tests have shown clock auctions more prone to collusive outcomes
Single Round	• Efficiently auction large number of items	• Bidders without good information on competitors' valuations may bid less than their private value to avoid winner's curse • Presence of repeated auctions or active secondary market reduces the winner's curse phenomenon
Bidding Format		
Sealed Bid Bidders do not see other participants' bids before the auction closes	• Limits manipulation by minimizing opportunities to signal • Format simpler and more common to emission markets	• Reveals less information about bidders' demand schedules to other participants than open bids • Less information is not a problem if there is an active secondary market (as is expected).
Open Bid Bidders see other participants' bids before the auction closes	• Bidders learn and adjust to competitors' valuations of the item • Smaller bidders are able to piggy-back off larger players when it comes to price discovery	• Potential for manipulation by signaling in multi-round auctions • Potential for retaliation among bidders in repeated or multi-round auctions
Price Mechanism		
Pay-as-bid	• Winning bidders pay their bid for item	• Bidders may learn that others paid much less for allowances • Bidders will avoid overpaying by setting bids by the price they expect the auction to yield, rather than their own valuation of the item
Uniform Price	• All allowances are sold at the lowest successful bid price (or the first rejected bid)	• Bidders may try to drive down marginal price to reduce their cost in a multiunit auction • Conversely, bidders might bid high to ensure receipt of allowances with the knowledge they will pay lowest winning price • Sellers may learn that buyers were willing to pay much more if successful bid amounts are released

[2] Refer to Section 4.0 – Other Jurisdictions for examples on how these basic options for auction type can be used in conjunction.

b. Reserve Price

It is the WCI jurisdictions' intent that the allowance auction design process will determine: the percentage of allowance budgets to be auctioned, the reserve price, the fraction of unsold allowances retired, and the fraction of unsold allowances retained by the individual WCI Partner jurisdictions.[3]

The WCI design calls for a minimum auction level of ten percent of the allowance budget in the first compliance period (2012-2014), increasing to twenty-five percent in 2020.[4]

There is also existing WCI policy on the use of reserve prices and unsold allowances. To manage the risk of setting the program cap too high, resulting in over allocation, the WCI design recommendations paper suggests the use of a reserve price. The WCI recommendations paper also suggests the application of a reserve price for at least five percent of allowances auctioned, but WCI jurisdictions are also considering maintaining a reserve price for all auctions.

If allowances remain unsold at the reserve price, the WCI design recommendations specify that a fraction of the unsold allowances will be retired. The remaining un-retired/unsold allowances may be auctioned at a later date or returned to the jurisdictions for other uses. Further, "[a]ny WCI Partner jurisdiction that does not participate fully in the auction with the reserve or minimum price will retire the same proportion of its allowance budget as those retired by the WCI Partner jurisdictions that participated in the auction."

The reserve price feature could be used in the WCI auction system to advance several objectives.

First, the reserve price could ensure allowances are not sold below the seller's opportunity cost. In private auctions the opportunity cost is typically the expected price at which a seller could sell the item in an alternative venue. The WCI Design Document does not consider direct sales of allowances, so no alternate sales venue exists. The opportunity cost could also be viewed as the value of the item in an alternative use, such as retiring them to benefit the environment.

Second, the reserve price could reduce the incentive for market manipulation by reducing the expected profits from colluding to lower the closing price.

Third, the reserve price would guard against low prices resulting from the cap being set too high. The failure to maintain a minimum price in the presence of low prices could discourage efforts by businesses to reduce their own emissions or create offset projects.

The WCI Design Recommendations indicate that at least five percent of each Partner's annual allowance budget should be auctioned with a reserve price feature. The stated purpose of the reserve price was to guard against over allocation. The Design Recommendations do not include a specific destination for the unsold allowances, only that the Partners should decide what fraction to retire and what fraction to return to the Partner jurisdictions for use in approved programs.

[4] *Design Recommendations for the WCI Regional Cap-and-Trade Program*, September 2008

To apply a reserve price, the auction operator must decide which objective forms the basis in setting the reserve price, and which determines the method of calculating a reserve price. The operator must also determine when the reserve price will be released to bidders.

Setting the Reserve Price to Limit Price Decreases

Whether the objective is to limit the price depressing effects of over allocation or market manipulation, the auction operator would need an estimate of the expected auction clearing price. The expected clearing price could be estimated from secondary market activity or economic modeling. For example, RGGI applied economic modeling to forecast market prices prior to the first auction and the development of a secondary market for allowances. Generally, the auction operator uses the estimated variability to set the reserve price sufficiently below the expected price so that it does not interfere with normal variability.

Setting the Reserve Price Percentage

Currently RGGI has a fixed reserve price of $1.86. However, RGGI rules specify that this be replaced with a reserve price based on market prices once sufficient data is available. Once this criterion is satisfied, RGGI has indicated it will set its reserve price at 80% of the expected auction closing price (See Table 3).

WCI could also consider setting a reserve price percentage to reflect the secondary market. The reserve price in the first WCI compliance period would be based on forecast and modeling data as WCI may not have sufficiently reliable price information from the secondary market. WCI could modify the reserve price after receiving secondary market data.

Setting the Reserve Price to Support Direct Reductions

The value of allowances allocated to set-aside programs also provides a method of setting a reserve price. Consider a set-aside used to support investment in new technologies. The reserve price could be set using an estimate of the cost of reductions provided by the new technologies supported by the set-aside, with the intent being to prevent over allocation from delaying investment in direct emission reductions. This approach could result in setting a reserve price high enough to interfere with the price discovery objective of the auction by setting a price higher than many potential bidders' private valuation.

Determining when to reveal the reserve price

If WCI commits to setting a reserve price, a decision must also be made on when to reveal the reserve price to participants: prior to the auction, during the auction, or after the auction.

The advantage of revealing the reserve price after the auction is to reduce market manipulation. If bidders intend to bid below their private values, they would run the risk of losing an allowance award if they drive the apparent market-clearing bid price below the (unknown) reserve price.

Revealing the reserve price prior to the auction reduces the bidders' need to balance the goal of purchasing an allowance below their private value with the risk of losing an allowance award by bidding below the reserve price. In a repeated auction sophisticated bidders will likely derive a good estimate of the method WCI might use to set a reserve price so the unknown reserve price feature would lose its effectiveness over time.

One advantage of revealing the reserve price prior to the auction is transparency. Those with a private valuation for the item below the reserve price would not participate in the auction. Another advantage is fairness; all bidders would know the reserve price reducing possible advantage of those bidders who are able to accurately estimate the reserve price.

The risk of revealing the reserve price prior to the auction is that it may influence bid schedules, reduce clearing prices for the allowances, and reveal to bidders the potential scope of for manipulation. This may occur if the reserve price is viewed by participants as providing a target for manipulation. This concern is more important if a high reserve price reduces the number of bidders. As long as there many participants in the auction, then it is unlikely that the reserve price would serve as a focal point for bidding because there would be big profits to be made from bidding closer to the expected market value of the allowances. The presence of a secondary market is a much more compelling focal point for competitive traders.

In the long term, the question of releasing the reserve price prior to auction may be moot in the case of a repeated, multi-unit auction (such as WCI is considering). Revealing the reserve price after each auction would inform participants of the method used to set the reserve price. This allows the participants to accurately forecast the reserve price for the next auctions.

Table 3 provides a summary of the reserve price rules in the UK ETS, RGGI, and the planned Australian Carbon Pollution Reduction Scheme. All three trading schemes apply a reserve price, but differ in their decision to make the reserve price known to participants prior to the auction.

Table 3: Reserve price rules applied or planned in other trading programs

Trading Program	Reserve Price Rule
UK – EU ETS	Reserve price is based on the secondary market price in the most liquid EUA market and not made available to participants.
RGGI	Reserve price will be set at 80% of the expected auction closing price, and made available to participants before the auction.
Australia – Carbon Pollution Reduction Scheme	Reserve price will be set at some level below the expected market price and made available to participants prior to the auction.

c. Unsold Allowances

If the WCI does not receive bids above the reserve price for the number of allowances offered at each auction then WCI must have a procedure for reallocating the unsold allowances. The Design Recommendations direct that partners will retire a fraction (effectively tightening the cap) of the unsold allowances which would help prevent chronic oversupply of allowances. The remaining fraction of unsold allowances would be retained by the partner jurisdiction for distribution in future compliance periods consistent with WCI Partner direction. The uses may include auctioning, set-asides or allocations. This section reviews two potential options for unsold allowances, and compares each option to immediate retirement.

Carry Forward to Next Auction

Carrying unsold allowances forward to a future auction is administratively simple and maintains a greater potential supply of allowances than immediate retirement. The risk, however, is that a significant amount of allowances could be carried forward over multiple auctions. If the initial oversupply was large enough, and WCI decided not to retire unsold allowances, several auctions may result in unsold allowances before the surplus is cleared. This may exaggerate the effect of an initial over allocation, compared to a policy of immediate retirement. This result could give the impression that the cap was set too high, not just initially, but over the entire period during which the reserve price resulted in unsold allowances.

Contingent Set-Aside Release Option

Unsold allowances could be used in a set-aside reserve to be released for auction at a predetermined release price. This approach lowers the risk of a glut of allowances building up as is possible under the carry-forward model, and provides some relief from temporary price spikes. The number of allowances in the contingency set-aside account would be known to all parties through the transparency of the allowance tracking system. The availability of a set-aside reserve, to be released during periods of high prices would have the benefit of moderating reactive bidding behavior of those speculating on future shortages.

To implement the measure, partner jurisdictions would have to agree on a release price mechanism as well as the proportion of unsold allowances to be used for the contingent set-aside reserve.

d. Vintages

Vintage refers to the year during or after which the allowance in question may be used for compliance purposes. Typically, in an emissions trading scheme, the regulator can issue allowances for compliance in the current or any future compliance period, although it is possible that allowances can be made available without temporal restrictions. That is, the regulator may sell or issue any vintage. Alternatively, an emissions trading scheme can forego the concept of vintages altogether. Selling allowances without vintages has the distinct advantage of significantly lowering administrative and the transaction costs associated with compliance.

There are several reasons to consider issuing future vintages. First, if current-year allowances could be used for compliance in future years then they would likely be valued more highly (effectively increasing the price). Issuing future vintages could increase the liquidity of the market and so ease the price pressure on current compliance vintages. In so doing the regulator decreases the chance of a spike in price in the early years that could trigger calls for the abandonment of the program. Second, future vintages are useful to businesses as a hedge against future compliance liabilities. However, a well functioning carbon market should see the development of instruments that allow them to do this.

Third, issuing future vintages contributes to the long-term viability of the program by creating an interest in program continuation. (If the program is superseded by U.S. and/or Canadian federal programs, the existing allowances may be recognized by that program as is proposed in the American Clean Energy and Security Act of 2009). Fourth, vintages may be part of borrowing mechanisms in trading systems, though this feature is not yet part of the WCI.

One disadvantage with respect to auctioning future vintages is the ability of liable entities to purchase them. To address working capital constraints from liable entities, the Australian government has agreed to provide deferred payment arrangements which allow entities to make final payment and take receipt of permits over an extended time period after the conclusion of the auction.

Notwithstanding the benefits of selling future vintages, the decision to sell them is independent of the actual design of the auction and will be considered by Partner jurisdictions a later date. We assume that vintages exist for the purposes of this section.

Other vintage questions to be considered by Partner jurisdictions are:
How far in advance and how often should allowances be sold and how should their sale relate to the auction of current-period allowances?

Simultaneous or consecutive auctions

Different vintages can be auctioned either simultaneously or consecutively. If a multiple-round auction format is chosen, simultaneous auctions of different vintages can be complicated for bidders to follow. However, it affords the bidders the ability to use information from one vintage auction to inform its decisions on participation in another, thus increasing the efficiency of the auction. It is expected that with clear instructions and adequate training simultaneous auctions will become less complicated for bidders to follow. While consecutive auctions are easier for participants to follow, they do not allow participants the opportunity to execute a plan to minimize costs by substituting certain vintages for others (recall that, with banking, allowances of current or past vintages are interchangeable).

If the auction format is a sealed bid, the complexity of the auction process decreases. While firms may face some challenge in determining what to include in the sealed bid for each auction, the execution of the auction itself is straightforward and is the responsibility of the auctioneer.

e. Lot Size

Lot size refers to the number of allowances bundled together as an auction unit. In the development of an auction design, Partner jurisdictions must consider how many allowances will be offered as a unit for purchase.

Smaller lot sizes allow for more flexibility bidding strategies by allowing bidders to define their offer curves over more price levels than for large lot sizes. Entities that want to participate in the allowance auction, but have relatively small operating budgets may benefit from the flexibility that comes with lower gross pricing resulting from smaller lot sizes.

One consideration in determining the lot size is the emission profiles of compliance entities. By understanding the compliance obligations of participants in the cap and trade program, the number of auctions per compliance period and the lot size can be coordinated to ensure that participants have the opportunity to obtain the necessary allowances to meet their obligation. For example, if there are four auctions per year over a three year compliance period and a lot size of 1,000 - an entity needing 25,000 allowances could spread its purchases over all 12 auctions. If the lot size were larger, perhaps 10,000 allowances or more, the entity would need to purchase three lots and will have an opportunity to do this over a maximum of three auctions. This would be less of a problem if allowances were available on the secondary market in smaller lots.

Another consideration in determining lot size is future plans to reduce the compliance threshold. If the threshold drops to 10,000 tonnes, then the smallest emitters (those with 10,000 allowance obligations) would be more dramatically impacted by a larger lot size. A 10,000 or 5,000 allowance lot size would allow these smaller entities only one or two opportunities to purchase allowances at auction.

WCI Partner jurisdictions should further consider sizes of contracts likely to be traded on private exchanges for compatibility with auction lot sizes. Matching lot sizes to those normally traded in the secondary market could enhance the development of the secondary market and reduce friction overall.

Table 4 highlights the lot sizes of RGGI, the UK ETS and the Carbon Pollution Reduction Scheme.

Table 4: Lot Sizes

Trading Program	**Lot Size**
RGGI	1,000
UK ETS	1,000 in the competitive portion, maximum bid of 10,000 allowances in the non-competitive portion.[5]
Australia: Carbon Pollution Reduction Scheme	To be determined - set low enough to allow participation by some emitters with less than the 25,000 tonne threshold[6].

f. Timing and Frequency of Auctions

The frequency of allowance auctions requires a balance between administrative complexity and flexibility for participants. First, increased frequency can aid in developing liquid forward markets and by providing a stabilized spot market through continuous new supply. In addition, frequent auctions can offer participants a regular price signal from which to inform their decisions. Second, increased frequency is useful if the regulator wants to require a smaller capital commitment for each auction and address cash flow shortages for potential bidders. If auctions are infrequent, emitters that wish to acquire allowances in the primary market need to buy larger proportions of their requirements each time. This would require larger, less frequent outlays which could be a problem for small firms. This was a particular concern in the design of the Australian Carbon Pollution Reduction Scheme.[7] As

[5] If the non-competitive portion is over-subscribed, priority is given to bids of lower than 1,000 allowances, which is the standard minimum lot size on the secondary market. Remainder are allocated on a pro rata basis
[6] The current general threshold for triggering a liability under the Carbon Pollution Reduction Scheme is 25,000 tonnes of CO_2e. This is complicated by the fact that some entities will be liable for their emissions below 25,000 tonne threshold. Lot size is likely to be set low enough to participate at the auction.
[7] Carbon Pollution Reduction Scheme: Australia's Low Pollution Future
http://www.climatechange.gov.au/publications/cprs/white-paper/cprs-whitepaper.aspx

a result, Australia is considering monthly auctions. Third, increased frequency allows bidders to adjust their strategies over time as they gain experience with the process. Of course, holding more auctions is easier when there are a large number of allowances to auction. Fourth, increased frequency has the advantage of making market manipulation difficult, that is, it is more difficult to coordinate, and organize manipulative behavior.

However, auctions are costly endeavors and each one implies additional administrative costs for bidders and sellers alike. There are also scheduling constraints on the number of auctions that can be executed each year. For example, RGGI holds auctions quarterly, but each one has a 60-day lead time. Using the same approach for a monthly auction could be potentially confusing and could create perpetual overlap.

Conversely, offering frequent auctions may serve to keep secondary market prices consistent with the demand schedule revealed during the auction process

The WCI Partner jurisdictions may also consider holding auctions in advance of or after the compliance period. Compliance entities may prefer to purchase allowances once their emissions for the compliance period are known. An auction held after the end of the compliance period but before the reconciliation of emissions and allowances[8] may be beneficial to firms that do not wish to hold allowances for a significant period of time. It could provide a means of addressing compliance needs (other than the secondary market) for firms with emissions in excess of planned allowances, especially if there is an immature and potentially illiquid secondary market.

Another issue for some businesses is assured opportunity, which is access to or ownership of allowances to sign long-term contracts. Assured opportunity is generally necessary to secure new project financing. This is a common issue in the electricity generation industry.

Another timing concern is the perceived need to have some allowances available (e.g., by auction) before the compliance period for which they are issued. An early allowance auction allows businesses to manage risk by securing allowances before producing emissions, and establishes an early price signal to facilitate secondary market activity.

g. Participant Access

A decision regarding which entities may be permitted to, and which entities may be restricted in purchasing allowances is in part related to the design of the overall program as opposed to the auction itself. Most carbon schemes allow non-restrictive access meaning that any entity that can hold an allowance can participate in the auction. However, it is possible to make it more restrictive by dividing access along compliance/non-compliance entity lines.

There are two types of participant access restriction: (1) restricting those who may be permitted to purchase allowances at an auction and (2) restricting access to the auction mechanism itself.

Auction Participation

[8] Commonly called true up, where emitters exceeding the established thresholds are required to relinquish a sum of allowances and credits equal to their emissions of $CO2e$.

One option for making the auction more restrictive is restricted participation. Restricted participation would allow only compliance entities to participate in the auction, as opposed to allowing any entity that can hold allowances to participate. Advocates of restricted participation in the auction tend to believe that the auction price will be more influenced by a larger number of auction participants rather than the overall demand in the markets. Therefore, they suggest that allowing more auction participants might increase allowance demand and drive the price up, whereas limiting auction participation could address concerns of increasing allowance prices (from speculating, non-compliance entities).

Conversely, advocates of unrestricted participation in the auction site several competing views. First, if the desired if a desired outcome from the auction of allowances is an indication of market value for the auctioned good, full market participation in the auction should be pursued in the design. Non-compliance entities can provide a service to the market by reducing price volatility. For example, they could prop up demand for allowances when it would otherwise fall due to broader macroeconomic factors, and release those allowances back into the market when demand rises.

Restricted participation is not typical of other schemes. This may be due in part to the perception that allowing non-compliance entities to participate in the auction can increase market liquidity, and in part because it is difficult to determine who is and who is not a compliance entity.

Auction Access

Notwithstanding the potential restriction on the acquisition of allowances via auction participation limitations, it is possible to restrict access in another way. Regulators can require entities interested in obtaining allowances to submit bids via a smaller group of pre-arranged intermediaries that deal directly with the government in the auction. Where the number of potential participants is large, the administrative burden associated with vetting financial assurance and checking for evidence of money laundering can be significant. In the UK, bidders must either apply to become intermediaries or bid through intermediaries (i.e., have intermediaries act as their proxies at the auction). Importantly, the intermediary approach also shifts the risks associated with non-payment to the intermediaries.

The intermediary approach is not common, possibly due to stakeholder concerns about the revelation of their business strategy to the intermediaries, especially where intermediaries are (potential) competitors. Control of sensitive business information is an important issue to many firms. Furthermore, the use of intermediaries creates a new set of issues for the regulator to monitor, i.e., supervision of the intermediaries.

In addition, the intermediary approach reduces competition at the auction, which may hamper the price discovery of the auction process. Such a strategy should only be used if there is strong evidence that the administrative savings would be large.

Non-Competitive Bids/Uniform-price auctions

A non-competitive bid is where bidders submit a request for a fixed number of allowances prior to the auction, agreeing to pay the auction clearing price.
For the auction to be equitable, all potential bidders must believe they have a legitimate opportunity to obtain allowances. Some entities, in particular small emitters, may not be able to afford the number of allowances that are in the minimum lot size. The UK has taken a direct approach to this issue. Under some of the UK's EU ETS auctions, a maximum of 30

percent[9] of the allowances available are reserved for non-competitive bids. These non-competitive bidders pay the eventual auction clearing price for the number of allowances they wish to purchase.

There is a precedent for this approach in electricity markets. Non-competitive bids are used in some electricity markets by generators that need to be dispatched (i.e., will be generating electricity regardless) and are not price-responsive. The objective is to allow extremely risk-averse compliance entities, especially those without activity in commodity markets, the ability to obtain allowances without quantity risk or risk of overbidding. Setting a quantitative limit on the amount of allowances set aside for the non-competitive bids requires a method of allocating participation if the non-competitive bids are oversubscribed.

The designers of the Australian Carbon Pollution Reduction Scheme decided that a non-competitive bid mechanism was not necessary to protect small or risk-averse bidders. It was judged that an ascending clock auction format would reduce the information asymmetry between large and small bidders, to the extent that one exists.

The non-competitive bid approach used in the UK was used for the first time in the second phase of the EU ETS and based on stakeholder feedback as well as information from the first phase of the auction.[10] Given the current limited information about compliance entities in the WCI, stakeholder input will likely be the most effective approach to understanding auction participation limitations for compliance entities.

Consignment

Allowance holders may also wish to sell allowances using the auction platform designed for primary market distribution.

While the focus throughout most of this paper has been on WCI Partner jurisdictions as sellers of allowances, this need not be the case. Other allowance holders may wish to sell allowances, and some of those may wish to do so without participating in the secondary market. In cases such as this, it is possible that the regulatory entity could sell the other parties' allowances on a consignment basis. This type of transaction is sometimes called a double-sided auction. The EPA offers this service as part of the auction of SO_2 allowances in the Acid Rain Program (see below). A double-sided auction was also proposed for the Australian Carbon Pollution Reduction Scheme.

Generally, this approach is likely to be favored by allowance holders who lack the technical expertise to confidently participate in the secondary market. For these allowance holders, permitting the regulatory body to sell your excess allowances is an attractive option, and one that would likely minimize transaction costs.

Many current systems have not incorporated consignment selling as a design feature in their auctions. Soliciting stakeholder feedback could be useful at this point to better understand the interest in potential consignment opportunities and challenges.

[9] This limit was chosen to strike the balance between the needs of smaller compliance buyers and ensuring that there is enough competition in the 'competitive' stage of the auction, which is what determines the clearing price. The percentage will be kept under review.
[10] UK representative presentation to WCI Markets Task 6. January 9th, 2009

h. Financial Assurance

Many auction programs, including RGGI, require financial assurance to ensure participants are able to cover the value of their bids. Financial assurance usually consists of adequate bond ratings, letters of credit, or similar instruments of comparable quality. Other entities who are unable to meet financial qualifications levels may deposit cash in escrow to cover their bids. The RGGI Auction Platform automatically rejects any bid that violates a bidder's financial security limits. When financial disclosure tools are used, design experts suggest levying penalties against any party that is unable or unwilling to pay for its winning bid[11].

i. Information and Transparency

The collection of information related to auctions along with transparent use and publication of that information plays a central role in building confidence in market-based programs. In general, the greater the level of transparency and disclosure of information, the more trust stakeholders, compliance entities, and others place in the value and integrity of the auction program. However, public disclosure of confidential information that compromises business positions of auction participants diminishes confidence in the allowance market and may have negative consequences outside of the cap and trade program. Decisions regarding what information to collect and eventually publish must balance the interests of transparency and confidentiality.

Clear rules for auction participation and administration lead to greater transparency. The RGGI design team used the following guidance to assist in development of their auction rules: "… auction rules should be transparent and available to everyone who might want to participate. The rules should not discriminate against any potential qualified participants."[12]

In addition to transparent rules, transparency in the auction execution, monitoring and reporting of results further fosters confidence in each auction. To ensure transparency, experts who designed the auction for RGGI suggested that the auction clearing price and the identities of winning bidders be disclosed publicly after each auction. However, RGGI does not disclose the quantity of allowances purchased by each winning bidder to protect proprietary information and tacit collusion by bidders buying fixed shares of available allowances.

To balance the interests of transparency with proprietary or business confidential information, auction operators may also release aggregated information on trading activity to the public. This ensures transparency without compromising an entity's ability to do business. For example, RGGI's independent market monitor provides public information on the percent of purchases going to entities with compliance obligations. RGGI also provides sixty days advance notice before upcoming auctions.

The RGGI auction design team asserts that "the actual value bid by each auction participant…" and "information about losing bidders should not be disclosed."[13] In this vein,

http://www.rggi.org/docs/rggi_auction_final.pdf

not that RGGI's auction results are posted as quickly as possible after the conclusion of an auction.

Partners may also wish to consider the adoption of beneficial ownership disclosure requirements. The RGGI auction rules require all applicants to disclose their direct and indirect corporate associations with other applicants and bidding associations, beneficial relationships to other persons and groups participating in the auction. Information on beneficial ownership is gathered via a thorough on-line application system for participants in the regional auctions and is used, in part, to ensure that participants comply with the 25% purchase limit described in "Preventing Market Manipulation" below. Beneficial Ownership information may be considered proprietary because it has the potential to reveal business strategies outside of the allowance auction and market. The decision to disclose this information publicly must be weighed against potential impacts to confidential business strategies.

j. Avoiding Market Manipulation

Manipulation occurs when market participants engage in activities with the intent to artificially raise or lower the price of allowances. Market manipulation occurs when multiple bidders coordinate their bidding in an attempt to lower the price they pay for allowances at auction.[14] In an effort to deter market manipulation and other forms of broader market manipulation RGGI included the, use of: a single-round sealed-bid uniform-price auction, a limit on the size of purchases at a given auction, and an open and transparent auction program. Auction monitoring is another tool the regulator may use to deter market manipulation.

An open and transparent auction improves competition and limits opportunities for market manipulation. A percentage limit on the number of allowances a single entity may purchase in a single auction "… raises the cost of using the auction to corner the market without placing too stringent a restriction…" on what compliance entities can purchase.[15] It is expected that WCI market participants will have small compliance obligations, relative to the total pool of available allowances, and that new entrants will have access to allowances and offsets through the secondary market. Therefore, setting a percentage limit will not impose an excessive burden on participating firms because WCI does not anticipate that any one entity will have that large a share of the WCI market. In addition, purchasers can access an auction periodically (e.g., quarterly) – which further reduces the inconvenience of a percentage limit. Such a limit can also be a means of protecting inexperienced participants from purchasing more allowances than they will need.

WCI can consider working in partnership with existing and interested agencies in the design of monitoring criteria to guide and regulate the allowance auction program. Existing market monitoring activities by federal and state agencies and provincial agencies could be examined by the WCI Partner jurisdictions to ensure that the appropriate criteria are used for detecting market manipulation and for sharing information regarding the performance of the allowance market and the auction. The Markets Oversight task group is charged with consideration of secondary market monitoring; there may be room for coordination of monitoring for both aspects of WCI program operation through a common market monitor. In addition, auction design elements may be incorporated to reduce the possibility of broader market manipulation. For example, as a means of discouraging hoarding within

[14] Auction Design for Selling CO2 Emission Allowances Under RGGI. Final Report. October 2007.
[15] Auction Design for Selling CO2 Emission Allowances Under RGGI. Final Report. October 2007.

the allowance market, the regulator can set a single auction purchase limit for any applicant or associated applicants.

A number of entities may be able to provide auction oversight or monitoring assistance including[16]:

- Federal Energy Regulatory Commission (FERC)
- Commodity Futures Trading Commission (CFTC)
- Securities and Exchange Commission (SEC)
- The US Environmental Protection Agency (US EPA)
- The Independent System Operators
- Other market monitors hired by WCI

The RGGI auction design team explored coordination opportunities with all of these agencies and organizations. The CFTC currently exercises jurisdiction over derivatives in existing SO_2, NO_X, and CO_2 markets in the U.S., and parallel agencies in the European Union are doing the same for its emissions markets. In future GHG markets, the CFTC could expand its oversight to include new emissions derivatives markets.

RGGI contracted Potomac Economics as an independent market monitor to monitor auction activities and results. This group analyzes auction data including (but not limited to) the clearing price, total allowances sold, the quantity of each vintage sold, the range of prices bid, the number of entities with winning bids, and the percentage of allowances purchased by entities with a compliance obligation.

RGGI definition of principle to… "**Guard against collusion and/or market manipulation:** The allowance auction should be designed in a way that limits opportunities for bidders to actively or tacitly collude to keep prices low. To the extent possible, the auction also should limit opportunities for bidders to bid up the price of allowances above the competitive price, which we refer to as hoarding. Because collusion and hoarding are potential issues in the allowance market, and not just the auction, there may be a limit to the ability of an auction design to limit incentives for hoarding."[17]

[16] Options for Limiting Market Manipulation, Washington State Department of Ecology. November 11, 2008. URL: http://www.ecy.wa.gov/climatechange/2008CTdocs/10102008_LimitingMarketManipulation.pdf
[17] Auction Design for Selling CO2 Emission Allowances Under RGGI. Final Report. October 2007 http://www.rggi.org/docs/rggi_auction_final.pdf

4. Other Jurisdictions

Introduction

Auctioning has long been touted as the best method to allocate allowances in an emissions trading scheme. There are now several examples of the use of auctions in new emissions trading schemes. These include:

- the Regional Greenhouse Gas Initiative (RGGI)
- United Kingdom Emissions Trading Scheme (UK ETS)
- Australia's Carbon Pollution Reduction Scheme
- the United States Environmental Protection Agency's SO_2 (Acid Rain Program) Auction
- Virginia's NO_X auction

The United States Treasury bill auction also provides an example of a well established auction.

Common Features

Most auctions evaluated share at least two criteria or values: fairness and allocative efficiency.

Fairness is important because: (1) the auction itself should not change the playing field for competing firms, (2) the perception of fairness is critical to the acceptance of the auction by all stakeholders: no one will embrace a process that is seen to give an unwarranted advantage to others.

Allocative efficiency is a measure of the degree to which the allowances go to the entities that value them most. Value can be expressed as the return that the firm can generate on the asset, and therefore what it is willing to pay to obtain it.

The auctions examined below also have common approaches to certain aspects of auction design. For example, all the examined auctions have a reserve price. This common adoption reflects a perceived value in establishing a reserve price as a way to create a credible auction and a deterrent to market manipulation.

Another characteristic that is common to all the auction designs reviewed is that they are open to all qualifying bidders. They are not restricted to compliance entities alone.

Regional Greenhouse Gas Initiative

The Regional Greenhouse Gas Initiative (RGGI) is an initiative of ten northeastern states to cap GHG emissions from approximately 200 fossil fuel-fired electricity generation facilities with capacities greater than twenty-five megawatts. The ten states enacted the program with regulations based on a RGGI model rule, but functionally it is a regional compliance market. Each state must allocate at least twenty-five percent of its allowances by auction, although several have chosen to sell more. States may distribute the remaining allowances in a manner of their own choosing.

The overall cap is 188 million tons, with no entity forecast to demand more than 12 percent of available allowances.[18] The first compliance period is 2009-2012; however, the first auctions were held in September and December 2008. The auctions were successful, with significant bidding activity leading to clearing prices ($3.07 and $3.32, respectively), well above the reserve price in both cases.[19] Most allowances (>80%) were purchased by compliance entities but some non-compliance entities bought allowances as well.[20] Demand was high, as both auctions were at least 3.5 times oversubscribed and each saw approximately sixty bidders participating.[21]

Distinguishing Features:

Auction type
- single-round, uniform-price, sealed-bid auction

Advantage
- simple, transparent and provides good price discovery
- familiar to electricity generation companies
- single round restricts the amount of information that is revealed to competing firms that could be used to engage in market manipulation

Reserve price – what level?
- Reserve price set at $1.86 for all auctions to date.

Vintages and lead time (when to sell each vintage)
- RGGI sells future vintages in advance of compliance periods.
- At all four auctions held in 2009 (March, June, September and December), the RGGI states sold 2012 allocation year allowances, the first year of the next compliance period.
- RGGI has committed to sell five percent of its allocation year 2012 allowances by the end of 2009.
- At the March 2010 auction RGGI will offer allocation year 2013 allowances.
- RGGI has committed to sell five percent of its allocation year 2013 allowances by the end of 2010.

Lot size
- The allowances are sold in lots of 1,000 (i.e., 1,000 tons)
- At the December 2009 auction, approximately 28,591 lots were available from the 2009 vintage, while 2,175 lots were available from the 2012 vintage.

Unsold allowances
- All allowances were sold in the first five auctions.
- 573,540 allocation year 2012 allowances were unsold at the December 2009 auction.
- There are State specific regulations on unsold allowances.

Timing and frequency of auctions
- All states are expected to sell at least a portion of their allowances in auctions held quarterly in each of year of the first compliance period.

---
[18] http://rggi.org/docs/Auction%203%20News%20Release%20MM%20Report.pdf
[19] http://www.rggi.org/docs/Auction_3_Auction_Notice_News_Release.pdf
[20] http://www.rggi.org/docs/Auction%202%20Post%20Settlement%20Auction%20Report.pdf
[21] ibid.

- Allowances are made available for sale in an evenly distributed manner during the first control period.
- To prepare the market in advance of the launch of the initiative, RGGI sold some allowances at two advance auctions in September and December 2008.

Method of participant access

- Entities interested in obtaining allowances must be qualified to gain access to the auctions. Once qualification is complete, the applicants submit appropriate financial assurance, and then the registered entities or their agents participate in the online auction directly.

Financial assurance

- All participants in RGGI auctions must submit some form of financial assurance in advance of the auction.
- Depending on the financial sophistication and health of the prospective participant, the three following forms of assurance are accepted: a letter of credit from a US bank, cash, or a bond from a US bank.
- Without this assurance, qualified applications cannot participate in an auction.
- The auction platform is designed to reject bids that exceed a bidder's financial assurance amount

Information and transparency

- After each auction, RGGI releases the results along with an assessment of the auction proceedings, prepared by an independent market monitor.

- The total number of allowances sold and the clearing price are released along with the market monitor auction report. Once settlement is complete, RGGI states release additional details, including:
  - the pre-auction estimate of dispersion of demand for allowances;
  - the dispersion of actual bids;
  - the proportion of allowances purchased by type of bidder (compliance, environmental and other non-compliance);
  - amounts of allowances awarded to bidders (names not released), and
  - a summary of bid prices, showing the minimum, maximum, average and clearing price.

Monitoring

- As indicated above, RGGI has contracted a third party to observe the auctions and, in addition to the actual results, report on the degree to which the auction met RGGI's goals of transparency, effectiveness and, most importantly, any signs of market manipulation.

- In the six auctions already held, there was no sign of either market manipulation.

United Kingdom: European Union Emissions Trading System (EU ETS)

The United Kingdom participates in the EU Emissions Trading system which is one of the key policies introduced by the European Union to help it meet its Kyoto Protocol commitment to reduce emissions to 8 per cent below 1990 levels by 2012. The system covers emissions from electricity generation and the main energy-intensive industries. The EU ETS currently covers approximately 11,500 installations, which account for approximately 45 percent of the EU27's CO2 emissions (2.2 $GtCO_2e$). The EU ETS is currently in its second phase (2008-2012), which followed a three year pilot phase that ran from 2005 to 2007. Prior to the inception of the EU ETS, the UK ran a voluntary domestic emissions trading program from 2002 to 2006.

Before the start of EU ETS Phase II, each member state was required to submit to the European Commission a National Allocation Plan (NAP) in which it described how and to whom it would allocate allowances during the four years of the second trading period. Member states were allowed to auction up to 10% of their allowances each year.

The UK NAP provides for an allocation of 246 million allowances to covered sectors during each year of EU ETS Phase II. It has chosen to auction seven percent of these allowances, equal to 17 million allowances per year, or 85 million over the entirety of Phase II[22] Allowances sold at auction are deducted from the nominal allocation to Large Electricity Producers. The auctions are open to any entity that holds an EU ETS Registry account.

Some UK auctions will have two bidding stages: (1) a non-competitive element, aimed at smaller emitters who need to buy allowances for compliance purposes; and (2) a competitive element. Other auctions will only provide the competitive element. The first auction (competitive only) was held in November 2008 and was four times oversubscribed with a clearing price of €16.15.[23] The most recent auction of 4.4 million allowances on February 4, 2010 was almost seven times oversubscribed and cleared at €12.66.

A centralized EU-wide cap, which will decline annually, on emissions for Phase III (2013 onwards), will mean that there is more ambition, certainty and consistency across the EU. The number of allowances sold at auction will be greatly increased. In 2012, electricity generators in most EU countries will be required to purchase 100% of their allowances at auction, and free allocation to other non-trade-exposed EU ETS sectors will be gradually phased out by 2020. Overall across Europe, at least 60% of allowances will be auctioned by 2020, compared to around 3% in phase II.

Distinguishing Features:

Auction type

Competitive Portion

- Single round (static) uniform-price auction
- Chosen for simplicity and resulting cost effectiveness, but also because of limited incentives for market manipulation

Non-Competitive Portion (proposed)

- up to 30% of allowances available at any auction could be set aside for the non-competitive process[24]
- bidders in this portion of the auction agree to pay the clearing price for any allowances received
- if oversubscribed, government will first fill the smallest orders, in preference of the smaller compliance entities
- stems from government concern that smaller compliance entities may otherwise have problems obtaining allowances in the auction and find it harder to access the secondary market.[25]

---

[22] http://www.dmo.gov.uk/docs/ETS/etspr230209.pdf
[23] http://www.defra.gov.uk/environment/climatechange/trading/eu/operators/auctioning.htm
[24] http://www.defra.gov.uk/environment/climatechange/trading/eu/pdf/phase2-consultation.pdf
[25] http://www.defra.gov.uk/environment/climatechange/trading/eu/pdf/phase2-consultation.pdf

Reserve price - what level?

- Used, but not announced in advance
- If the auction clearing price is less than the reserve price, the reserve price will be the price to be paid for each allowance at auction
- The reserve price is calculated based on the prevalent secondary market price at the time of the auction.[26]
- Government announces whether the reserve price was triggered after the close of each auction.

Vintages and lead time (when to sell each vintage)

- There are no yearly vintages
- Phase II (2008-12) allowances can be used for compliance in phase III (2013 onwards)
- Plans for auctioning in phase III are still in development. The European Commission is expected to publish its proposals for the auctioning rules for phase III soon

Lot Size

- 1,000 in the competitive portion
- maximum bid of 10,000 allowances in the non-competitive portion. No minimum bid size

Unsold allowances

- Unsold allowances sold in future Phase II auctions

Timing and frequency of auctions

- Initially planned for quarterly auctions, but government maintains the option to increase frequency
- For example, the UK Debt Management Office has announced that there will be eight auctions in 2010.

Method of participant access

- In the competitive part of the auction, use of approved intermediaries that collect and submit bids on behalf of bidders is mandatory
- There are currently seven intermediaries also called Primary Participants. All seven intermediaries are investment banks but other organizations that meet the eligibility criteria can apply
- The UK Government believes that intermediaries can best carry out the critical role of implementing checks to guard against potential money laundering activities and providing assurance of the financial standing of bidders.

Financial assurance

- Handled through Primary Participants

Information and transparency

- limited information is released soon after the conclusion of each auction, including:
  - clearing price
  - total bids received
  - number of allowances allocated to competitive bids

Monitoring

- The Treasury contracts and independent third party to monitor the auction and report on its execution.

[26] ibid

- The monitor looks for signs of market manipulation, while observing the transparency of the process. The findings are published soon after the auction's conclusion.

Australia: Carbon Pollution Reduction Scheme

Australia proposes to launch the Carbon Pollution Reduction Scheme in July 2011. For the first year of the scheme (July 1 2011 to June 30 2012) there will be a fixed price operating, that is, permits will be available to liable entities for a fixed charge of $10. This is intended to help companies transition to the scheme. These permits cannot be banked for future use and will be immediately surrendered. During the fixed price period there will be auctions of future vintage permits. Currently Australia intends to auction a portion of 2012-13, 2013-14, 2014-15 vintage permits in 2011-12.
Australia's Department of Climate Change released a White Paper explaining the Scheme details on December 15, 2008.

The aim of the auction is to have a fair, equitable process that aids price discovery. The proposed scheme shares many characteristics with other auction designs, in terms of the reserve price, openness to access and general philosophy. However, Australia will include to two unique features: (1) double-sided auction, allowing those receiving allowances by administrative distribution to sell them in the auction (2) deferred payment, Australian authorities are considering a deferred payment option to help address cash flow concerns expressed by many compliance entities.
The Australian scheme will auction around 70 per cent of the permits, with the rest administratively allocated. With a smaller auction pool, settings such as the reserve price, the frequency of auctions and the auction schedule take on an added significance

Distinguishing Features:

Auction type

- Simultaneous ascending clock auctions used for multiple vintages (option to submit sealed proxy bid)

Benefits

- To further simplify the process for smaller entities, participants will be allowed to submit sealed proxy bids (bidders submit in advance their demand schedule for allowances at various price levels)
- Generates a uniform price for all winning bidders
- Market manipulation less of a concern in Australian scheme because there are many compliance entities with similarly-sized obligations

Reserve price - what level?

- Tool to increase efficiency and speed of auction not intended as a price floor
- Reserve price will be based on, but well below anticipated market price
- Goals are to limit benefits of market manipulation while increasing efficiency of the auction process[27]
- Notify participants of the reserve price prior to auction

---

[27] Carbon Pollution Reduction Scheme: Australia's Low Pollution Future
http://www.cramton.umd.edu/papers2005-2009/australia-carbon-pollution-reduction-scheme-chapter-9-auctions.pdf

Vintages and lead time (when to sell each vintage)

- At least one of the monthly auctions (usually the first) will include the sale of allowances for the current year plus the three following compliance periods.
- This will help facilities plan production and foster the development of the secondary market
- Regulator acknowledges that this will increase the complexity of the auction operation but believes the benefits will outweigh the concerns

Bid restrictions – single entity parcel size

- Bidders will be restricted to 25% of allowances available for a given year at each auction
- Given 16 auctions per vintage, this means that a bidder may win a maximum of 1.6% of the allowances available for any one vintage at any particular auction.

Unsold allowances

- Details are being finalized

Lot Size

- Details currently being finalized

Timing and frequency of auctions

- Auctions will be held monthly
- The last auction of allowances for a given compliance period/year will occur after the year has ended but before the compliance reconciliation period, allowing compliance entities to purchase allowances after they know the actual emissions they need to address
- With the advance auctions, there are 16 scheduled opportunities for bidders to obtain allowances of each vintage

Method of participant access

- Direct access (no intermediaries)
- Subject to financial assurance, the auctions will be open to all
    - Limits market manipulation
    - Fosters development of a secondary market

Financial assurance

- Some form of financial guarantee will be required to participate in the auction
- Details to be confirmed

Information and transparency

- Auction results will be made public as soon as possible after the auction concludes
- In addition to the clearing price, the number of allowances demanded at each price will be published
- Individual bids will not be published

Monitoring

- Regulator will appoint an independent panel to review operation of the Scheme soon after its launch.
- Australian Securities and Investments Commission (ASIC) will have power to investigate and prosecute market manipulation; market will be subject to the same effective safeguards as the bond market.
- Additional rules will protect against individual entities manipulating auctions
- Banking and borrowing provisions intended to act as deterrents to market manipulation as well

- Further protection afforded by measures already contained in the Trade Practices Act.

US EPA: SO_2

The Acid Rain Program was created under the 1990 Clean Air Act Amendments to reduce the adverse effects of acid deposition through reductions in annual emissions of SO_2 and NO_X primarily from fossil-fuel burning electricity generation. The Act calls for SO_2 reductions from all sources of 10 million tons from 1980 emission levels, largely achieved through a cap and trade program which imposes a permanent emission cap on SO_2 emissions from electric generating units (EGUs) at power plants. The program initially affected about 2,500 EGUs (roughly 220 plants), but now encompasses around 560 coal fired plants plus gas fired and fuel oil plants.

This national program has two phases. All Phase I utilities were in the Midwest and on the east coast. Now, Phase II of the program covers the 48 continental states. Phase I auctions started in 1993, Phase II started in 2000. There is an opt-in program (voluntary entry into program), but only about only ten facilities chose to do this.

Auction type

- Single round, discriminatory price
- Regular auction: descending order (Congress specified descending order)
- EPA may sell other entities' allowances on a consignment basis

Auction Awards

- The auctions sell allowances on the basis of bid price, starting with the highest priced bid and continuing until all allowances have been sold or the number of bids is exhausted. EPA may not set a minimum price for allowances from the Auction Reserve.
- Allowances are sold from the Auction Reserve before allowances offered by private holders are sold. Offered allowances are sold in ascending order, starting with the allowances for which private holders have set the lowest minimum price requirements. Offered allowances are sold until the allowance supply is depleted, bids are used up, or the minimum price for the next set of offered allowances exceeds the purchase price of the next bid.

Reserve price - what level?

- No minimum price for auction

Vintages and lead time (when to sell each vintage)

- The SO_2 allowance auction consists of two parts:
  1. a spot allowance auction, in which allowances are sold that can be used in that same year for compliance purposes, and
  2. an advance auction for the sale of allowances that will become usable for compliance seven years after the transaction date, although they can be traded earlier.

Table: Allowances Offered at Auctions

Year of Auction	Spot Auction	Advance Auction*
1998	150,000	125,000
1999	150,000	125,000
2000 and after	125,000	125,000

* Not useable until seven years after purchase.

Lot Size

- Can purchase as little as 1 allowance. 1 allowance = 1 ton

Bid Restrictions

- Bidders must send sealed offers containing information on the number and type (spot or advance) of allowances desired and the purchase price to EPA, no later than three business days prior to the auctions. Each bid must also include a wire transfer, certified check, or letter of credit for the total bid cost.

Unsold allowances

- EPA returns proceeds and unsold allowances from the auctioning of reserve allowances on a pro rata basis to those units from which EPA originally withheld allowances to create the Auction Reserve.

Timing and frequency of auctions

- Once per year – usually the last Monday of March each year

Method of participant access

- The auction was initially meant to be for new entrants, but now it is open to any qualified bidder

Financial assurance

- Participants must complete a Letter of Credit, wire check, or certified check.

Information and transparency

- Philosophy is to share as much data as possible including raw hourly emissions data (limited by capacity and emissions monitoring is quarterly). Data is unit by unit.
- Allowance transactions: details available through on-line queries, allowing access to the allowance tracking database.

Monitoring

- Once per year, there is nothing in the rules that prevents someone from buying all of the allowances. Only 2.8% of allowances are sold via auction.
- It is apparent that market manipulation was not a significant concern; the auction was designed mainly for new entrants into program.

Virginia: NO_X

Under the EPA's NO_X State Implementation Plan (SIP) program to reduce smog in the eastern United States, Virginia received an annual 500,000 tonne cap. Most allowances were distributed free of charge to firms with historical rights to emit. About eight percent of 2004-2005 allowances (1,885 tons per year) were reserved for new sources and auctioned. Revenue for 2004 and 2005 vintages was $10.5 million, 19% above target.

In the Virginia NO_X trading program, allowances are bankable, but there is a form of flow control. If over 10% of allowances surrendered during a given year are from a previous year, previous year allowances are worth only 50% of face value (i.e., vintages are not perfect substitutes for one another). There can be no borrowing against future issuance of allowances.

The primary goal of the commonwealth in the execution of the NO_X allowances auction was to maximize revenue. Simplicity was important, given regulators only had two months to design the auction from the time the decision was made to hold one. Transparency was also

Other Auction Types Considered

- Simultaneous (Combinatorial) Discriminatory Sealed Bid
  - Format: (P_{04}, Q_{04}; P_{05}, Q_{05}) P = Price willing to pay for *up to* Q the stated quantity. Gives the auctioneer some flexibility in awarding vintages.
  - Fairly simple and transparent.
  - Because auction is not iterative there is less chance for market manipulation between participants.
  - May be subject to the winners curse b/c of discriminatory pricing.
- Simultaneous (Combinatorial) Uniform-price English Clock (uniform)
  - Linked clocks auction off vintages simultaneously.
  - Good under elastic demand conditions
  - Involves complicated modifications to let the system handle substitutions of vintages efficiently.

a stated goal of the auction design.

Auction Type

Virginia employed two sequential English clock auctions for the 2004 and 2005 allowances. While their models indicated simultaneous English clock auctions would maximize revenue, the option was dismissed as too complicated given time constraints.

Auction Participation

- The auction attracted both regulated entities (energy companies) and brokerage houses

Frequency

- Only one auction each for vintages 2004 and 2005. The 2004 vintage allowances were sold in a morning auction, 2005 vintages in an afternoon auction.

Information Sharing

- Virginia Freedom of Information Act required that all bid information be released including the identities of winners and losers along with their bids.

US Treasury: Sale of Treasury Bills

The United States Treasury has a long experience auctioning Treasury Bills and other marketable securities. The auctions are open to individuals and institutional investors. To accommodate smaller, less sophisticated investors, the Treasury offers non-competitive access to the securities, but with a $5 million limit on the value of securities that can be obtained in this manner. Prospective buyers can also bid through intermediaries such as brokers. The Treasury offers bills, notes, bonds and Treasury Inflation-Protected Securities (TIPS) at auction.

Distinguishing Features

Auction type

- Sealed bid, uniform price
- Competitive Bidders: submit as many bids as they want stating the quantity they are willing to buy at a given price.
- Non-Competitive Bidders – Place a bid stating the quantity they wish to buy. Pay either the clearing price or the quantity-weighted average of the winning competitive bids.

Auction Awards

- Accept all non-competitive bids
- Accept all bids from federal reserve bank
- Demand of highest price competitive bidders are met until supply is allocated

Bid Restrictions

- Competitive bidders: 35 percent of securities on offer (net long position)
- Non-Competitive bidders: $1 million for bills and $5 million for notes

Timing and frequency of auctions

Examples:

- All bills except 52 week bills and cash management bills are auctioned weekly.

Lot Size

- $100.00

Method of participant access

- Both competitive and non-competitive (Usually 15-20%) bidders

Information and transparency

Through a press release available online the Treasury Department announces the following information:

- The amounts of accepted bids and the amount of securities awarded;
- The range of accepted yields or discount rates;
- The proration percentage;
- The interest rate for a note or bond;
- A breakdown of the amounts of noncompetitive and competitive bids accepted from, and awarded to, the public;
- The amounts of bids tendered and accepted from the Federal Reserve Banks for their own accounts;
- The bid-to-cover ratio; and
- Other information that the Department may decide to include.

Monitoring

- Penalty for non-compliance of the auction rules or failure to pay for issued securities.

Auction Design White Paper Overview

Stakeholder Conference Call

9:00am Pacific, April 29, 2010

Markets Committee Mission

- Coordinate the development of recommendations on issues and elements needed to guide the proper development and operation of a robust allowance and offset credit trading market.

Auction Principles

- The following auction design principles inform decisions regarding the auction and guide the overall WCI market design effort.

The 8 principles for developing the auction design are:

Fairness	*Efficiency*
Effective Oversight	*Transparency & Openness*
Administrative Simplicity and Cost	*Accountability*
Compatibility with other markets	*Conflict of Interest*

Auction Parameters

- following parameters are essential in defining the structure of the auction and are discussed in the White Paper:

The 10 parameters discussed in the white paper are:

Auction Format
Reserve Price
Unsold Allowances
Vintages
Lot Size
Timing and Frequency of Auctions
Participant Access
Financial Assurance
Information and Transparency
Avoiding Market Manipulation

Parameters

Auction Format:

- how participants can bid on allowances, for example:

  a) Sealed Bid Single Round

  b) Ascending/Descending Clock multiple rounds

Reserve Price:

- the minimum allowance price that the seller will accept.
- existing WCI direction is that a reserve price be applied.

Parameters Cont.

Unsold Allowances:

- may occur if the reserve price is higher than the auction market clearing price.
- can be retired, rolled forward, or held as a contingency.
- Existing WCI position: partners will retire a fraction of the unsold allowances, the remaining fraction retained for distribution in future compliance periods consistent with WCI partner direction.

Vintages:

- vintage allowances are sold prior to the compliance period for which they become valid.
- vintages help with price discovery but also increase the complexity of auction.

Parameters Cont.

Lot Size:

- refers to the number of allowances bundled together for offering as an action unit.
- smaller lot size allows flexibility in the bidding strategy and makes auction participation more affordable for non-compliance entities.

Timing and Frequency of Auctions:

- advantage of frequent auctions: market liquidity, price stabilization and discouraging collusion.
- disadvantage of frequent auctions: increase in administrative costs.

Parameters Cont.

Participant Access:

- restricting access to the auction may benefit compliance entities by decreasing the number of overall bidders thereby influencing the auction price.
- open access supports market liquidity.

Financial Assurance:

- required from bidders to ensure they are able to cover the value of their bids (e.g., bonds, letters of credit).
- prequalification of participants is essential to the integrity of the auction.

Parameters Cont.

Information and Transparency:

- transparency increases the integrity of the auction program.
  - Mitigate collusion

Avoiding Market Manipulation:

- there are several ways to minimize collusion, manipulation and hoarding. For example:
  - Encourage many bidders to participate in the auction.
  - auction monitoring, single round bidding, sealed bidding and uniform price method.
  - limit amount of allowances that can be obtained at a single auction.
  - Maintaining an open and transparent auction.

Other Jurisdictions

- Regional Greenhouse Gas Initiative (RGGI)
- United Kingdom – European Trading System (UK ETS)
- Australia: Carbon Pollution Reduction Scheme
- US Environmental Protection Agency: SO_2
- US Treasury: Sale of Treasury Bills

Jurisdictional Review:

Regional Greenhouse Gas Initiative

Auction Format	Single round, uniform-price sealed-bid auction
Reserve Price	$1.86 (set initially by modelling, then based on secondary market price)
Unsold Allowances	There are state specific regulations on unsold allowances.
Vintage	Sells future vintages
Lot Size	1,000 tons
Timing and Frequency	Auctions are held quarterly, in each year of the compliance period
Participant Access	Interested entities must be qualified to gain access to auctions.
Financial Assurance	Participants must submit financial assurance before the auction. Three forms of assurance are accepted: letter of credit, cash or bond.
Information and Transparency	After each auction, results and auction assessment are released. Latter is produced by a third party
Monitoring	Third party observation

Jurisdictional Review Cont.

UK Emissions Trading System (EU ETS)

Auction Format	Single round, uniform price auction and a non-competitive bid process
Reserve Price	Used but not announced in advance. Based on a prevalent secondary market price at time of auction.
Unsold Allowances	Unsold allowances are sold in future phase II auction
Vintage	No yearly vintages
Lot Size	1,000 in the competitive portion. Max bid of 10,000 allowances in the non-competitive portion. No min bid.
Timing and Frequency	Quarterly initially. Has increased frequency
Participant Access	Mandatory use of primary participants (also called intermediaries)
Financial Assurance	Handled through primary participants
Information and Transparency	Limited information released after the auction: clearing price, total bids, number of allowances sold in competitive bid.
Monitoring	Independent third party monitors the auction and reports on the execution

Jurisdictional Review Cont.

Australia: Carbon Pollution Reduction Scheme

Auction Format	Simultaneous ascending clock auction
Reserve Price	Below anticipated market price. Participants will be notified of the RP before the auction.
Unsold Allowances	Details being finalized
Vintage	One of the monthly auctions will sell allowances for the current year plus the three following compliance periods
Lot Size	Details being finalized
Timing and Frequency	Held monthly, 16 auctions per vintage
Participant Access	No intermediaries, open to all (subject to financial assurance)
Financial Assurance	Required. Details to be confirmed
Information and Transparency	Auction results will be made public: incl. clearing price & number of allowances at each price.
Monitoring	Independent panel to review operation after it launches. Market manipulation will be investigated and prosecuted

Jurisdictional Review Cont.

US Environmental Protection Agency SO_2

Auction Format	Single round discriminatory price. Descending order
Reserve Price	No reserve price
Unsold Allowances	EPA returns unsold allowances to those the EPA originally withheld allowances from.
Vintage	Both spot allowance auction and an advance auction
Lot Size	Can purchase as little as 1 allowance. 1 allowance = 1 ton
Timing and Frequency	Occurs once per year
Participant Access	Open to any qualified bidder
Financial Assurance	Three options: a wire transfer, certified check or letter of credit for the total bid cost
Information and Transparency	Share as much data as possible. Details are available through online queries
Monitoring	No rule preventing a buyer from purchasing all allowances sold via auction

Jurisdictional Review Cont.

US Treasury: Sale of Treasury Bills

Auction Format	Sealed bid uniform price. Competitive and non-competitive bids.
Reserve Price	N/A (treasury bills typically sold at a discount from the par amount)
Unsold Bills	N/A
Vintage	N/A
Lot Size	$100.00
Timing and Frequency	All bills except 52-week bills and cash management bills are auctioned weekly
Participant Access	Competitive and non-competitive bidders (Corporation, Government-related entity, trust or fiduciary estate, individual, foreign and international monetary authority, other)
Financial Assurance	Depends on bidding method. Treasury direct requires debit entry to a deposit account or submission payment with a bid
Information and Transparency	Results of all public auctions are released in a press release after each auction. Available on website
Monitoring	Penalty for non-compliance of the auction rules or failure to pay for issued securities

COVERING EMISSIONS FROM IMPORTED ELECTRICITY: AN ADMINISTRATIVE APPROACH

May 2010

Introduction

The point of regulation for electricity imported into a WCI jurisdiction is the First Jurisdictional Deliverer (FJD)[1] using the individual boundary approach, which is the recommended approach for all Partner jurisdictions.[2] The FJD approach ensures appropriate price signals are maintained in WCI jurisdictions for imported electricity.

The Partners tasked the Electricity Team to also explore how regulation of imported power covered by the cap-and-trade system could be accomplished through an administrative approach.[3] The administrative approach is less preferred, but is recognized as potentially necessary to address individual Partner jurisdiction circumstances. In particular the administrative approach may be best suited to jurisdictions with low levels of imports. This paper describes and evaluates this way to implement coverage of emissions associated with imports, explains how the two different approaches will interact, and recommends that the administrative approach be available to Partner jurisdictions where appropriate.

The Administrative Approach

The Electricity Team has developed an administrative approach to address import emissions. The administrative approach would establish a mechanism for reserving allowances for retirement to "cover" emissions attributable to imported power. The mechanism would be established and operate as follows:

---

[1] http://www.westernclimateinitiative.org/the-wci-cap-and-trade-program/design-recommendations.
[2] http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/Announcement-Regarding-the-FJD-Approach.
[3] http://www.westernclimateinitiative.org/component/remository/Electricity-Team-Documents/Formation-of-the-Electricity-Team.

- Emissions for imported electricity consumed in the Partner jurisdiction are forecasted and included in the jurisdiction's allowance budget in addition to the jurisdiction's internal emissions, beginning with the 2012 best estimate emissions forecast and are trued up to actual emissions in 2012.[4]

- The jurisdiction places the imported electricity allowances in a reserve equal to forecasted imported electricity emissions.

- The jurisdiction monitors and tracks emissions from imported electricity for each compliance period.

- At the end of each compliance period, the jurisdiction retires allowances from the reserve equal to total imported electricity emissions for the compliance period.

- In the event that the number of allowances placed in the reserve pool based on the forecast exceeds the number of allowances needed to cover emissions attributable to imported electricity, those allowances will be retired. This will avoid over-inflating the jurisdiction's emissions cap due to the overestimation of import emissions.

- In the event that emissions from imported electricity exceed the number of allowances in the reserve pool, however, the jurisdiction must increase the number of allowances deposited into the reserve pool using allowances otherwise intended for use by sources with a compliance obligation under the cap-and-trade program.

Unlike the FJD approach, the administrative approach does not impose a compliance obligation on the first deliverer of electricity originating outside the Partner jurisdiction's boundary. Instead, the jurisdiction retires allowances on its own from the reserve pool, thereby ensuring that the emissions attributable to imported electricity are "covered" and the integrity of the emissions cap is maintained.

Addressing Competitiveness in the Absence of a Price Signal

The administrative approach does not attach a price signal to imported emissions, and as a result it would give a price advantage to imported electricity over electricity generated within the jurisdiction. The resulting market distortion can be minimized by other requirements. An Emissions Performance Standard, for example, would restrict the displacement of cleaner sources within the jurisdiction by more emissions-intensive imports. Long term contracts for generation also provide stability in the market and would prevent displacement for the covered generation. A Renewable Portfolio Standard provides for a minimum quantity of renewable power in the overall generation supply, and may play a role in restricting displacement. Jurisdictions predominantly supplied by low emission and low operating cost generation such as

[4] Starting budgets for partners that commence their cap-and-trade programs later than 2012 would have to be adjusted.

hydro, wind and nuclear are inherently protected against displacement from other higher operating cost generation, such as coal and gas-fired generation, since the higher cost generation is not competitive in their market.

The Electricity Team recommends that a jurisdiction implementing the administrative approach give consideration to the potential for an advantage to imports and implement additional measures as appropriate.

Interaction of Administrative and FJD Approaches

Because it is contemplated that some Partner jurisdictions will implement the FJD approach while others will implement the administrative approach, the Electricity Team has considered how the two approaches will interact. One possible concern is that there could be an incentive to flow power through an administrative jurisdiction and subsequently into an FJD. If power is moved into the administrative jurisdiction in one transaction, and then moved into an FJD jurisdiction in another transaction, the party moving the power could avoid incurring an allowance obligation and gain a price advantage. A method to address this would entail the FJD jurisdiction imposing an allowance obligation on all power entering from the administrative approach jurisdiction, unless the importer can show that the imported power already incurred a direct allowance obligation.

In some cases it could be possible for a load serving entity in an administrative jurisidiction to arrange to meet their load with imported power and transfer the domestic generation to an FJD jurisdiction, for a net profit[5]. The power would meet the test of the FJD jurisdiction since it was generated in a WCI jurisdiction and could demonstrate an allowance obligation. This incentive could lead to increased imports into the administrative jurisdiction, putting pressure on their reserve pool. It could also lead to a reduced price signal in the FJD jurisdiction. To address these circumstances, mutually acceptable arrangements between jurisdictions using the two approaches could be employed. A possible approach would be to identify such transactions so an allowance obligation can be imposed on the importer by the FJD jurisdiction, rather than drawing down the reserve pool in the administrative approach jurisidiction. Alternatively an administrative approach jurisdiction may be able to restrict the actions of their load serving entities or remove the profit incentive from such transactions through regulatory actions.

[5] Example: consider an FJD jurisdiction (A), administrative approach jurisdiction (B) and non-WCI jurisdiction (C). Each jurisdiction has gas-fired generation which can generate at a cost of $50/MWh. The allowance cost in A and B amounts to $10/MWh for gas-fired generation. Transmission tariffs amount to $2/MWh between each jurisdiction. The prevailing market price will be $60/MWh in A and B, and $50/MWh in C.
A load-serving entity in B has a long term contract for 1000 MWh of B generation daily. The current cost of 1000 MWh is $60,000, and the entity recovers $65,000 from customers for a net revenue of $5,000.
Now the load-serving entity arranges to import 1000 MWh from C at a cost of $50,000 plus $2,000 tariff to meet its load. B must account for the emissions by reducing its reserve pool – the entity faces no direct cost. The entity then bids its 1000 MWh of contracted generation into A for $59/MWh (underbid to ensure the power is taken). The bid is accepted and the entity receives the prevailing price of $60/MWh. In total, the entity now realizes [revenues of $65,000 from customers plus $60,000 from A] less [contracted power cost of $$60,000 and imports of $50,000 and transmission tariffs of (2 x $2,000)] for a net revenue of $11,000. Note that if the bid of $59/MWh set the market price in A, then the entity would still be ahead, realizing a net revenue of $10,000. The price signal in A would now be weakened.

The team has concluded that the two approaches are compatible, provided that (a) the jurisdiction accurately monitors and tracks emissions from imported electricity for each compliance period; (b) power entering an FJD jurisdiction from the administrative approach jurisdiction incurs an allowance obligation unless the importer can prove a previous obligation; and (c) mutually acceptable arrangements are in place as necessary to address other circumstances.

Emissions Monitoring and Reporting under the Administrative Approach

Ideally, jurisdictions implementing the administrative approach would implement full reporting of emissions related to electricity imports. Full reporting may not be necessary, however, to carry out the administrative approach. Under the administrative approach it is only necessary to calculate emissions for aggregate electricity imports that "sink" in the jurisdiction. Some jurisdictions have the authority to require their utilities to report imports indirectly. For example, Washington and Oregon require all utilities to disclose annually their fuel mix for electricity sales to end users in their jurisdiction. Utilities are also required to identify the source of their fuels.

Partners can collect information through the Energy Information Agency (EIA) in the US and the National Energy Board in Canada, the Western Interchange Pool, e-tags and other sources to quantify and assess trends in imported electricity. Canadian provinces also typically have a single system operator for the province, which can provide a further source of information on imported electricity.

The OATI work product analyzing data from the Western Electricity Coordinating Council (WECC) is designed to estimate historical electricity imports into each WCI member jurisdiction in WECC from non-member areas and provides an example of a potential approach in answering this question. It provides records of aggregate 2005-2008 transactions from one balancing authority to another within WECC.

Thresholds for Applying the Administrative Approach

The Electricity Team was asked by Partners to consider the implications of applying an emissions and/or imports threshold as a condition to implementing the administrative approach rather than the FJD approach. The Partners recognize that the administrative approach does not remove the incentive to import electricity created when in-Partner generators are placed under the cap. While other measures can reduce the resulting displacement potential, thresholds could also be used to ensure that market effects are limited.

Partner jurisdictions with small imports or relatively minor emissions from imported electricity could use the administrative approach without significant market effects, provided imports and emissions remain below threshold levels.

For jurisdictions with low marginal cost generation as described previously, thresholds would not be necessary to address internal generation displacement. Thresholds based on historical import levels could form part of a mutually acceptable agreement as a means of tracking market effects and identifying the need for further measures.

Western Climate Initiative

To All Interested Parties:

The Western Climate Initiative Partners have expressed an interest in effective market oversight to ensure an efficient and transparent carbon market. The WCI's Markets Committee issued a Market Oversight White Paper in November, 2009, and Draft Recommendations April 1, 2010. The Committee requested comment on the Draft Recommendations by April 30, 2010.

The Draft Recommendations document identified twelve market oversight policy decisions. One of the identified decisions was whether or not to implement "holdings limits," limits on the number of allowances or offset certificates any entity could control. WCI Partners commissioned a consultant's report on this issue, to review the history, theory, and use of similar limits in other markets, as well as recommendations on their use in a regional cap-and-trade program. The Partners contracted with Dr. Jeffrey H. Harris of the University of Delaware to provide the report and recommendations. His work is attached, and available at the WCI website (http://www.westernclimateinitiative.org/component/remository/Markets-Committee-Documents/Report-on-Holdings-Limits/).

The WCI Partners intend to release final recommendations, including a recommendation on holdings limits, by June 30, 2010. To facilitate its deliberations, the Committee requests comment on the commissioned report by June 4, 2010. Dr. Harris will present his work and be available to answer questions during a webinar on May 25, 2010, at 11:00 a.m. Pacific Time. For audio, dial 1-800-868-1837 and use participant code 659 537#. To view the presentation, go to https://www.accuconference.com/customer/join/, enter the same conference number and participant code and a screen name. Comments may be submitted to the WCI website at http://www.westernclimateinitiative.org/public-comments/document/31.

Sincerely,

The Western Climate Initiative Markets Committee

Report on Holdings Limits

To the Western Climate Initiative Markets Committee

ii Executive Summary

1 Manipulation and Market Power

8 Manipulation and Contract Design

10 Market Regulation and Holding/Position Limits

13 Determining Holding/Position Limits

16 Holding Limit Recommendations

Executive Summary

The Western Climate Initiative (WCI) Markets Committee aims to coordinate the development of recommendations on issues and elements needed to guide the proper development and operation of a robust allowance and offset credit trading market.

This report puts forth recommendations to the WCI Market Committee regarding the adoption and implementation of holdings limits for the proposed allowance and offset credit trading markets. The report discusses holdings limits in the broader context of efficient and effective market regulation, with an emphasis on how holdings limits might serve to mitigate manipulation in the secondary market for allowances and credits.

Key observations of this report are as follows:

- Market manipulation should be a concern for cash-settled contracts such as allowance and offset credit trading markets.
- Market manipulation reduces participation in the market, inhibiting trading volume, reducing market depth and adding to market volatility.
- The size of an individual trader holdings relative to the size of the market (contracts outstanding) or to the size of the market float (contracts available for trade) are appropriate metrics for monitoring/inhibiting market manipulation.
- Excessive trading can also be used to manipulate allowance and offset markets.
- Since trading behavior changes even with the threat of market manipulation, regulators in the allowance and offset credit markets should employ proactive market surveillance policies.
- Allowances and offset credits issued via primary market auctions and traded in a secondary market are susceptible to manipulation in both the auction and secondary markets.
- Auction design and secondary market trading are linked. Frequent auctions with broad-based access (and participation) can help to minimize manipulation in the secondary market.
- Extant theory on position limits requires an estimate of the price change tolerance of the regulator and a measure of illiquidity in the secondary market for trading of allowances. In this regard, theory is of little practical use to the nascent (prospective) market.
- Nevertheless, most derivative markets apply a form of holdings limits in deference to the real and active manipulation from various market participants.

In this light, and in consideration of the myriad components that contribute to the application of holdings limits, ***this report recommends that the WCI Market Committee apply holdings limits in the allowance and credit trading markets be set as 10 percent of the first 25,000,000 allowances issued plus 2.5 percent of any additional allowances issued each year.***

Section I. Manipulation and Market Power

In financial markets, manipulation involves actions that change market prices such that prices do not reflect the true fundamental value of the financial asset. When manipulation occurs, market participants may lose faith in the prices determined in the marketplace. In this light, participants may scale back or even cease to participate in markets subject to manipulation. Thus, a direct consequence of manipulation is that market quality suffers—when participation drops, trading volume falls, transaction costs increase, liquidity is diminished and the volatility of prices rises as well. In fact, the mere threat of manipulation can undermine confidence in market prices and therefore will have similar consequences.

Potential market manipulators, like other economic actors, respond to incentives in the marketplace. Manipulators typically reap economic gains (at the expense of other traders) as a result of their manipulative actions. Active market surveillance that sheds light on and imposes costs on manipulators can inhibit market manipulation. To the extent that manipulators seek economic rewards from their activities, market structures and surveillance cannot fully eliminate manipulation. Proper policies, however, can serve to tilt the balance of costs and benefits toward the goal of minimizing manipulation in the market.

This paper discusses holdings limits, one dimension of market design that can assist in limiting market manipulation. Importantly, holdings limits should be integrated with comprehensive market design, surveillance and penalty structures to be effective.[1] Indeed prospective holdings limits depend crucially on market regulators having both accurate holdings information and the authority to influence market participant holdings. Properly designed, holdings limits can tilt the power balance away from manipulators in favor of robust and efficient allowance and offset credit trading markets.

A. Forms of Market Manipulation

Manipulation can take on many forms. Manipulation may involve direct trading in the market to move prices or more indirect actions such as releasing erroneous information to other traders (whose trades, in turn, may push prices away from fundamental values). To inhibit manipulation in the former case, markets can establish rules regarding trading activities. To inhibit manipulation in the latter case, markets must implement more costly surveillance tools because actions taken away from the exchange are more difficult (and expensive) to monitor.

Although perhaps not directly related to the issue of holdings limits, various types of market manipulation are worthy of mention. In fact, a comprehensive set of rules

[1] A broad literature discusses whether various U.S. markets deter manipulation effectively and efficiently (see e.g. Abolafia (1985), Easterbrook (1986), Edwards and Edwards (1984), Fischel (1986), Fischel and Grossman (1984) and Fischel and Ross (1991)).

governing holdings limits should fit within an overarching market surveillance scheme, some of which relate more closely to these various manipulative strategies.

One form of manipulation, disclosure manipulation, involves information releases. Disclosure manipulation occurs when a market participant propagates false or misleading information regarding the value or volume of a security to other participants. In greenhouse gas markets, for instance, an end user may manipulate the market through false disclosures. Consider, for example, a major factory operator that anticipates (unbeknownst to the market) falling short of the necessary allowances in the near term. The factory operator might falsely release information that they have already adequately purchased the requisite number of allowances, thereby sending a false demand signal to the market. If the market believes that demand is lower than anticipated, market prices might fall, affording the opportunity for the manipulator to purchase the allowance shortfall at discounted prices.

Although large holdings may not indicate manipulation *per se*, large holdings may (even if inadvertently) convey misleading information to other traders in the market. Large holders, for instance, may be perceived as more credible (or more informed) to other market participants. To this extent, the holdings of market participants may be of interest to market regulators who are interested in deterring manipulative disclosures. And, as with most other manipulative schemes, traders with large holdings stand to benefit the most from successful manipulative efforts.

Action-based manipulation should also concern market regulators. Action-based manipulation involves deeds performed to affect the value of an asset by means other than trading. In the greenhouse gas market, for instance, an action-based manipulation scheme may involve an end user of allowances taking other less transparent actions to offset greenhouse gas emissions (such as planting trees) to reduce their demand for allowances while selling off allowances in the market. If these less transparent actions are not disclosed to market participants before the allowances are sold, the end user benefits from selling at artificially high prices. The market only partially learns of the decrease in demand when the allowances are sold. The full reduction in demand is only completely known with full disclosure of the alternative offset program.

Of course, actions are typically more costly for manipulators than are information releases (the tree planting program, for instance, may be quite expensive). The added expense of action-based manipulation is therefore likely to make these manipulative schemes less common, but they cannot be ignored altogether. As with other prospective manipulative schemes, a comprehensive surveillance program will consider the prospect when monitoring market participants.

Indeed, as with other types of manipulation, the size of holdings in the marketplace may not be directly related to the prospects of action-based manipulation. However, to the extent that large holdings are positively associated with a greater number of activities that could affect the secondary market for trading allowances (more diverse business activities, for instance), large holders may have greater opportunities to attempt and execute these schemes. Likewise, to the extent that action-based manipulation schemes create greater net benefits to large holdings, large holders should be monitored accordingly.

A form of action-based manipulation involves active trading in financial markets. Trade-based manipulation, for instance, has been modeled by Hart (1977), Jarrow (1992), Kumar and Seppi (1992), Allen and Gale (1992), and Chakraborty and Yilmaz (2004, 2008). In this form of manipulation, a trader can cause artificial price fluctuations simply by buying and selling an asset in hopes that other market participants follow suit. To the extent that large holdings convey the appearance of an information advantage to others in the market, traders with large holdings may be better able to induce others to follow suit on any manipulative trading strategy employed.

Although disclosure and action-based manipulations should concern market regulators, these forms are only tangentially related to holdings limits. They link to holdings limits only in the sense that large positions largely benefit the most from manipulative strategies, so that smaller holdings limits will necessarily reduce the prospective gains from manipulation. Market power is the primary concern of holdings limits, which we discuss in more detail below.

B. Market Power and Manipulation

The Federal Trade Commission defines market power as the ability of a firm to alter the market price of a good or service from competitive levels for a significant amount of time. In a perfectly competitive market, no participant possesses market power so that all market participants can be sure that prices observed in the marketplace represent the fair value for the good or service provided. Perfect competition can be predicated on a market having infinite numbers of buyers and sellers, on no barriers to entry, on perfect information (known to all participants), on zero transaction costs, on homogenous products and on firms consistently behaving as profit maximizers.

Of course, real world conditions dictate that markets commonly reflect less-than-perfect competition. No market can have large numbers of (let alone an infinite number of) buyers and sellers at all points in time, for instance. When markets are less-than-perfect, some participants can have market power, an advantage over others. Market participants that have market power can be alternatively referred to as "price makers," while those without market power are “price takers.”

Market power traditionally results from a participant’s control of a significant portion of or information about the market. These participants may be able to erect barriers to entry and/or gain proprietary information that is not known to others, creating further impediments to a perfectly competitive market. Ultimately those holding market power and setting prices might profit at the expense of others, discouraging price takers from participating. Market regulators, therefore monitor and surveil market participants in an effort to foster competition and limit market power that may distort fair prices for all.[2]

The Lerner (1934) and Herfindahl-Hirshman (HHI) indexes are commonly used to measure market power within specific product markets. In the area of antitrust, the HHI is used to evaluate the effect of proposed mergers on social welfare, industry prices and output. The HHI metric can capture the welfare loss (relative to perfect competition) of various industry structures. Importantly, the metric is typically applied to product markets where market power or collusive agreements can reduce output.

Regulatory Point #1: In allowance and offset markets, market concentration (large holdings) can create distortions in market prices.

In the context of allowance and offset credit markets (and financial markets more generally), market concentration might also create distortions in pricing. There is a tradeoff between market liquidity and the risk of holding large positions. Market makers have to be compensated for holding larger positions (Grossman and Miller (1988)). If any single trader demands liquidity that exceeds the supply of liquidity available from market makers, this liquidity demand may push prices higher.

For the allowance and offset credit market, the potential for price distortions is a real and tangible threat. Holders of allowances and credit offsets are likely to be more interested in holding (and perhaps even encouraged to hold) for the long term rather than in providing liquidity. For this reason these traders are unlikely to be induced to contribute liquidity to the market during periods when liquidity is in short supply until prices change quite substantially.

To illustrate the potential for short-term price distortions, consider a common manipulation scheme known as "banging the close" in which a large trader might take advantage of an illiquid market. Traders with relatively larger trading positions have a greater incentive to influence closing prices (which typically serve as price benchmarks to the investing public) since the cost of affecting closing prices is the same for all traders, but the gains to changing closing prices are proportional to the trader's position.[3] To "bang the close" a trader would engage in uneconomic trading to influence closing prices to their advantage. For instance, a trader holding a long position may buy substantial quantities leading up to the close in order to raise the value of the rest of their holdings (even if there were no other reason to buy).

If manipulation schemes like "banging the close" are of concern, then potential holdings limits would best be defined in terms of market share—that is, holdings limits should be set proportional to the number of outstanding allowance and offset credits. Large holders have a greater incentive to manipulate the market since they stand to benefit

[2] Market power can also be a result of collusion by multiple market participants, so that regulatory oversight should not simply focus on individual firms, but should also include dimensions to oversee interactions among multiple market participants.
[3] For this reason, larger positions (or large traders more generally) are typically monitored more closely than small positions (traders).

most from existing holdings. In addition, since larger markets are generally characterized by greater liquidity, small holders are unlikely to affect market prices. Therefore, the relevant regulatory concern is the size of an individual trader's holdings relative to the size of the market.[4]

Regulatory Point #2.1: The size of individual trader holdings relative to the size of the market should be the focus of regulation in allowance and offset markets.

1. Market Power-based Manipulation Theory

A number of market power-based manipulation theories demonstrate that manipulation can occur in both continuous trading markets and auction markets. Many of these models are relevant to the question of holdings limits in greenhouse gas markets, given that they rely on the relative market share or market power held by individual (or groups of) traders. Market manipulation affects asset prices and, by extension, derivative prices that are based on asset prices. In the economic sense, manipulation drives prices to levels that do not reflect intrinsic economic value (often referred to as fundamental value). Pirrong (1995) articulates the detriments of market power-based manipulation. He notes that market power-based manipulation is bad for the market and impedes the price discovery and risk management purposes of financial derivatives markets by distorting patterns of trading and consumption. Indeed, market participants other than the manipulator are victimized by losses when they transact at prices other than fundamental value.

One common form of market power based manipulation involves a market squeeze. Market squeezes occur when a long trader holds a position representing a quantity that is larger than what might be reasonably supplied to the market without distorting prices. When demand or supply do not immediately adjust to traders wishing to trade a large number of contracts, market squeezes can also distort prices in the short run (see Figlewski (1984) and Merrick (1988)). Sustained squeeze-generated price distortions dissipate the economic role of futures and forward markets (and, by extension, to other hedging instruments) by significantly reducing the effectiveness of a contract for hedging. In this regard, manipulation of derivative markets arising from market power can also generate social costs by diminishing or even eliminating hedging opportunities.

The cash settlement feature of allowance and offset markets minimizes the potential for market squeezes, since the cost for cash settlement is typically much lower than for physical settlement. Agricultural products, for instance, involve significant storage and transportation costs which are largely irrelevant to allowance markets. However, squeezes may be possible in allowance markets as well, if individual trader positions exceed the quantity available for purchase or sale.

---

[4] Indeed, more than one trader might simultaneously attempt to change prices, so that a measure of aggregate concentration may also be relevant. In two-sided markets, the disparity of concentration between the long and short sides might be most relevant. With high concentrations on each side of the market, traders attempting to move prices upward would be met with an equal and opposing set of traders attempting to move prices downward, with the net effect on prices perhaps close to zero.

Pirrong (2008) notes that there is a difference between the total number of allowances or offset credits issued and the number readily available for purchase or sale. In economic terms, the available supply of contracts is known as the float. In theory, as noted above, the size of individual trader positions relative to the size of the market should be the focus of regulation. However, although perhaps not immediately evident, the size of the market for allowance and offset credits is not necessarily the same as the market float. In that the float more adequately describes liquidity available to the market, the potential for market manipulation may be more likely related to the relative size of individual trader positions to the float (rather than to the number of contracts outstanding).

Regulatory Point #2.2: The size of individual trader holdings relative to the size of the float in the market should be the focus of regulation in allowance and offset markets.

Some theories focus on how manipulators can use an excessive number of trades to exert market power to their benefit. Leoni (2008), for instance, examines how a single "strategic agent" can use market power in financial markets to strategically affect the market prices.[5] In this model, other market participants make forecasts about the ability of the strategic agent to exert market power and account for these forecasts when they trade. In this framework, the strategic agent uses high levels of trading volume to create the opportunity to *indirectly* control market prices. These theories provide some incentive for regulators to not only consider holdings limits, but to also limit excessive trading.

Regulatory Point #3: Excessive trading can also be used to manipulate allowance and offset markets.

Pirrong (2008), building on Pirrong (2004), examines various market power based manipulations scenarios in futures markets. He demonstrates that short traders who have information that a dominant long trader has market power will rationally partially (or entirely) liquidate positions prior to expiration to avoided being squeezed. In this regard, even the threat of manipulation in the allowance and offset markets can change trading behavior. In fact, the prospect of manipulation alone can increase trading costs for other participants as some traders will pay a premium for protection against manipulation. To the extent that market regulation can deter manipulative schemes, effective regulation reduces the premium paid for protection, making most other participants better off while encouraging greater market participation.

Regulatory Point #4: Even the threat of manipulation can change trading behavior so regulators should also be proactive in market surveillance activities.

[5] This work builds on Sandroni (2005).

Auction markets can also be manipulated. Inspired by the Salomon Brothers' Treasury note manipulation episode of 1991[6], Chatterjea and Jarrow (1998) determine that market power-based manipulation can occur when an auction market is accompanied by secondary market trading in the same product—conditions that exist in the allowance and offset credit markets.

In the Chatterjea and Jarrow model, a potential manipulator observes order flow in the forward market to assess demand and then overbids in the primary auction market to obtain a dominant market share and market power. The manipulator, holding a dominant long position, then profits from short traders who need to deliver in the forward market. Importantly, Chatterjea and Jarrow document that this type of manipulation depends on the structure of the auction. Manipulation is possible in a discriminatory auction format in which the winner pays the price of their bid but likely would not occur in a uniform price auction where all winners pay the price of the last accepted winning bid.[7]

Nyborg and Strebulaev (2004) revisit the topic of multiple unit auctions and short squeezes. They conclude that there is a tradeoff when designing an auction format: discriminatory auctions will generate more revenue for the party holding the auction but are more susceptible to short squeezes while uniform auctions will neutralize the effectiveness of a market power based manipulator.[8]

Regulatory Point #5: In allowance and offset markets, information from order flow in the secondary market can be used to manipulate the primary auction market. The manipulator gains market power from large holdings generated in the auction.

The design of the auction market has implications for the potential for market manipulation along other dimensions as well. An auction that is limited to participants that produce greenhouse gases directly will, by definition, have a smaller market float. As noted above, markets with relatively smaller market float are more susceptible to manipulation so that a prudent auction design (intended to minimize manipulation) includes broad-based access to the allowance auction process.

2. Empirical Evidence on Market-power Based Manipulation

Examples of market power-based manipulation incidents abound in a host of markets around the world.[9] Most existing empirical work on manipulation relies primarily on

---

[6] Salomon bid aggressively in the May 1991 auction for two-year Treasury notes and ultimately controlled 94% of the securities. Using market power Salomon squeezed short traders in the pre-auction forward market, causing significant losses for others (US Government (1992)).
[7] Jarrow (1994) also notes that cash markets accompanied by derivative trading also create the opportunity to manipulate.
[8] See also empirical evidence from the 1991 Treasury auctions in Nyborg and Sundaresan (1996).
[9] Recent international examples include the 1997 squeeze of the London International Futures and Options Exchange's Italian Government Bond futures contract and the 1996 Tokyo Stock Exchange market power manipulation of Japanese government debt. A partial list of high-profile events within the U.S. include the 1991 Salomon Brothers T-note squeeze noted above and manipulation attempts in oil

price data (see, for instance the empirical analysis of squeezes in Jegadeesh (1993) and Jordan and Jordan (1996)). In a notable exception, Merrick et al. (2005) combine trader position data with price data to develop a more richly-detailed view of an attempted delivery squeeze in the U.K. gilt bond futures contract. They document that prices become distorted from their fundamental values as a result of the attempted squeeze. Market depth is also diminished by the attempted squeeze, demonstrating that other traders actively respond to attempted manipulation schemes to the detriment of market quality.

Regulatory Point #7: Market manipulation reduces participation in the market, inhibiting trading volume, reducing market depth and adding to market volatility.

Section II. Manipulation and Contract Design

Various contract design features affect the level of concern about potential manipulation. In addition to the auction features, settlement terms, the frequency of allocative auctions, and rules for banking/contract expiration can each affect manipulation in greenhouse gas allowance and offset markets. The following discusses settlement terms and the frequency of auctions/banking terms in more detail.

A. Cash vs. Physically Settled Contracts

There are two major types of settlement that exist in derivatives markets. Physical settlement requires the delivery of the underlying asset of the contract. The seller normally transfers the physical asset to the exchange, which in turn transfers it to the buyers of the contract. Physical delivery is commonly practiced in the commodity and bond markets although actual delivery of the underlying asset rarely occurs in practice as traders typically offset their positions in the market before the delivery date. Cash settlement involves a cash payment based on the underlying reference rate, such as an index or asset value. Counterparties settle by paying/receiving the loss/gain related to the contract at expiration.

Much of the literature on manipulation distinguishes between cash and physical settlement since these contract terms affect the manipulator's incentives. Although much of this research does not directly apply to holdings limits, contract settlement terms often affect the risk faced by traders. Holding the benefits of manipulation constant, a potential manipulator facing lower risk from settlement terms may be more likely to act nefariously.

Physical settlement has been criticized in the literature since physical settlement creates an opportunity for market power and delivery manipulation to occur.[10] Physical

(1996), tin (1980-1981, 1984-1985), silver (1979-1980), and soybean (1977) markets. See Jarrow (1992) and Pirrong (1995) for additional episodes.

[10] In fact, some investment funds are not allowed by rule to establish positions in physically-settled markets because they risk being left with the underlying asset. Garbade and Silber (1983) argue that the

settlement also puts more a strain on exchanges which have to organize, monitor and maintain a fair and orderly delivery process. Lien (1989) analyzes the hedging effectiveness of cash and physically settled contracts. While largely disregarding factors like market manipulation and the accuracy of prices in the cash market, he illustrates that cash settlement is generally preferable to physical settlement.

Two events in the derivative markets generated a relevant strand of literature that empirically compares the performance of financially and physically settled contracts. The first event involved the switch from physical to cash settlement for the feeder cattle futures contract trading on the Chicago Mercantile Exchange (CME). The second is the switch from cash to physical settlement for Australian individual share futures contracts.

For CME feeder cattle, Rich and Leuthold (1993) examine robust cash prices from 27 reporting stations to show that markets are uniformly more stable (and resistant to manipulation) under cash settlement terms.[11] Lien and Yang (2004) examine a move in the opposite direction--the switch from cash to physical settlement for Australian individual stock futures traded on the Sydney Futures Exchange. Employing robust econometric techniques, they find consistent results that cash settlement terms provide more robust market prices--both spot and futures market variability are higher with physical delivery.

Although cash settlement may make markets more robust to manipulation in a relative sense, research shows (see e.g. Jones (1982), Garbade and Silber (1983) and Cornell (1997)) that market manipulation can still disrupt, and perhaps render impractical, cash-settlement of derivatives contracts. Indeed, as Cornell and Kumar and Seppi (1992) point out, illiquid assets do not make good candidates for cash-settlement terms since illiquid assets are more prone to market manipulation. For instance, manipulation of a physically-settled contract may involve relatively expensive delivery of the underlying asset.

Kumar and Seppi (1992) build upon Kyle (1985) and model manipulation in cash-settled markets within a two-period setting with asymmetric information. They demonstrate that cash settlement inhibits corners and squeezes in derivatives markets, but manipulation can still exist in the spot market.

The cash-settlement feature of the proposed Western Climate Initiative allowance and offset credit market should help mitigate concerns about market manipulation. Jones

---

high cost of delivery for physically-delivered contracts induces short investors to take precautionary actions to prevent squeezes, perhaps skewing market prices. Additionally, long investors who want to avoid costly delivery may flock out of the market simultaneously, also affecting market prices.

[11] Elam (1988) first examines the effect of change in settlement procedures in feeder cattle markets. Schroeder and Mintert (1988) expand the Elam hedge ratio model to Texas, Kansas, Missouri and Illinois feeder cattle cash markets while Kenyon et al. (1991) examine the Oklahoma City and Southwest Virginia markets. Subsequently, Schmitz (1997) and Lien and Tse (2002) show reduced risk for live cattle warehouse certificate delivery and cash market feeder cattle delivery markets (relative to physical delivery).

(1982) notes that financially settled contracts are also superior to physically settled contracts for convergence (a measure of effective pricing between spot and derivative assets) if, among other things, the underlying cash market is immune to manipulation. Generally speaking, the literature suggests that cash settlement improves market quality and provides relatively lower risks during the settlement period.

B. Auction Frequency and Banking Allowances

The design of the greenhouse gas allowance and offset market has implications for the propensity for these markets to be squeezed. For example, it is likely that the regular issuance of new allowances will create incentives for traders to attempt a squeeze when new allowances are forthcoming. It may be optimal for traders to sell off positions in advance of these auctions, even when allowances have no expiration date and might be carried over/banked from period to period (Pirrong (2008)). As traders sell off positions, the market may become less liquid and more prone to market squeezes.

The ability to carry over allowances across auction cycles may help to bolster liquidity in the period leading up to new auctions. The caveat, of course is that simply having more allowances outstanding does not ensure that liquidity will be added into the market. As discussed above, the market float of allowances does not always equate to the number of outstanding allowances. If long-term participants are not induced to provide liquidity without sufficient price incentives, the ability to carry allowances forward may not bolster liquidity. However, other things being equal, market liquidity can be no worse off with the ability to bank allowances.

Section III. Market Regulation and Holding/Position Limits

It is often difficult to differentiate between legitimate economic trades and manipulative trades. In fact, it is even more difficult to differentiate accurately in a timely fashion, that is, either during or shortly after a manipulative event. Pirrong (1996) argues that this difficulty is best addressed by applying severe *ex post* penalties on manipulative behavior. In this light, strong punitive measures can help to deter potential manipulation. However, as Pirrong (1996,1997) notes, strong *ex post* penalties have not always been effectively imposed by U.S. courts and markets. These facts perhaps explain why markets have applied various other regulatory tools (including holding/position limits) to deter market manipulation.

In the interest of preserving fair market prices for all, many financial market regulators use a combination of reporting thresholds, position limits, position accountability levels and market surveillance activities to monitor the trading of individual market participants and groups of market participants. In order to best monitor trader behavior, many markets require periodic reporting of trading positions to a market regulator and/or market operators. Reporting thresholds typically balance the cost of reporting with position sizes so that relatively small positions may not have to be consistently reported. Given the fixed cost of reporting, small positions are commonly exempt from reporting.[12] As a rule, however, market surveillance activities depend critically on the availability of accurate trading and position data.

Given the availability of position data, position limits can serve to complement market surveillance activities in financial markets. Indeed position limits can be applied differentially across time and across markets. In U.S. futures markets, for instance, different position limits are applied to the spot (delivery) month and across both individual contract months and for all months combined. For cash-settled contracts, the settlement period is an important time. During the settlement period transitory volatility may result when hedged traders unwind positions without enough liquidity available in the market.

Position accountability levels represent a somewhat less restrictive regulatory tool. Accountability levels are typically set for large positions that hold the potential for manipulative market behavior. In this sense, a trading position rising to an accountability level may trigger greater reporting requirements or may require enhanced interactions between market regulators and the trader. Accountability levels typically do not serve as hard and fast limits, but rather as thresholds that signal to regulators the potential for market manipulation. The market regulator typically reserves the right to greater control over the trader's positions when accountability levels are crossed. As the name suggests, a position accountability level typically triggers greater accountability from traders exceeding the level. For instance, a trader holding a position that exceeds and accountability level may be forced to report more details about their trading intent, may be precluded from adding to their position, or may even be forced to liquidate a portion of their position as the regulator sees fit.

In this context, holdings limits serve as one tool among many for market regulation. At one end of the spectrum, position reporting serves as a baseline for collecting appropriate position data. Accountability levels serve to trigger differential regulatory oversight to various positions. Holdings limits more strongly prohibit trader positions from exceeding a given size. Each can be valuable tools among the many strategies employed by market regulators in applying efficient and effective surveillance mechanisms to ensure market integrity.

A. Holding/Position Limit Theory

Extant theory on holding/position limits remains relatively sparse, particularly theory applied to cash-settled contracts. Nevertheless, the disruptive trading of manipulators in cash-settled derivatives markets is typically thought to be isolated at or near the time of cash settlement. Although there is little theory on applying a timeframe for position limits, markets typically consider short horizons (of a few days, or perhaps a week) prior to settlement as candidates for limits.

[12] The U.S. Commodity Futures Trading Commission (CFTC), for instance, sets reporting thresholds individually by market to ensure that their Large Trader Reporting System includes 70-90 percent of open interest in each futures contract.

For physically-delivered contracts, Kyle (1984) develops a theoretical model where position limits can be effective in limiting the ability of traders to manipulate the market. This model analyzes market manipulations, specifically squeezes in the deliverable contract month, and draws conclusions as to how more general policy applications might be utilized to reduce price distortions that result from market squeezes. The Kyle model can be applied to analyze a variety of policy applications, including delivery differentials, additional deliverable supply, cash settlement, and position limits. As his theoretical model pertains to position limits, Kyle concludes that effective position limits can be devised to reduce market manipulation at contract expiration for physically settled contracts. He notes, however, that successful position limit policies would also need to address the difficulty and ineffectiveness of monitoring positions owned by different traders actually managed collectively.

Dutt and Harris (2005) note that cash-settled contracts can also be subject to manipulation schemes, particularly from disruptive trading of large positions near the settlement date. In light of the fact that optimal position limits depend on information that is not available in practice, they devise a general model of *prudent position limits* as a function of:

- the market regulator's tolerance for price changes,
- a contract multiplier (a measure of the size of the contract) and
- the illiquidity of the underlying instrument.

Dutt and Harris begin by modeling a trader's incentive to manipulate the market. That is, they presume that the benefits of manipulation will be proportional to the aggregate size of manipulative trades while the cost of the manipulation will be proportional to the square of the aggregate size of manipulative trades. As the manipulator trades, prices are pushed further away from true economic value so that costs increase faster than the benefits. Eventually then, a manipulator faces the tradeoff between the cost of being discovered and the benefits reaped by manipulative trading. When the costs exceed the benefit, the manipulator will cease trading.

Ultimately, and more specifically, Dutt and Harris determine that prudent position limits are dictated by the regulator's price change tolerance divided by an illiquidity measure. We discuss applications of this model to allowance and credit markets in Section IV below.

B. Empirical Evidence

Research papers by Gastineau (1992), Telser (1993) and Grossman (1993) each question the wisdom of imposing position limits to address manipulation concerns. For the most part, these papers typically note that effective surveillance programs make positions limits unnecessary. Gastineau and Telser specifically propose that surveillance should be favored over limits, while Grossman states that position limits can force trading into alternative markets. While thought-provoking and provocative, these studies simply argue their case and do not provide empirical support for their claims.

Importantly, however, Dutt and Harris (2005) take their model to the data using empirical limits from cash-settled derivatives markets like equity index futures and options markets. Using data from the Chicago Mercantile Exchange, the Chicago Board of Options Exchange, the Philadelphia Stock Exchange and American Stock Exchange, Dutt and Harris find that existing position limits far exceed the prudent position limits that their model proscribes for most equity index futures and options products. In fact, they find almost no correlation between their prudent limits and those applied by these exchanges.

Nevertheless, the Dutt and Harris framework provides a framework for assessing prospective holding limits. They demonstrate that the liquidity of the market is an important determinant of limits. For example, contracts based on narrow indices of illiquid securities may benefit more from position limits than contracts based on liquid securities.

This research highlights, more generally, how position limits can minimize manipulation by limiting the size of derivative positions and notes that, compared to the costs of added surveillance, these benefits are potentially achieved at a lower cost. The authors find that current derivative index limits are not consistent with the limits proposed by the model, which suggests possible sources of economic inefficiency.

Section IV. Determining Holding/Position Limits

In practice, holding/position limits have been utilized in conjunction with other regulatory mechanisms such as market surveillance activities, large trader reporting requirements, and position accountability levels. In U.S.-regulated futures markets, position limits have been set for single month contracts, for specific products (all months combined) and for the delivery month. Jurisdiction for setting position limits in the U.S. is typically delegated to the futures exchange except for agricultural products, where Federal position limits are set and administered by the CFTC.

Most of these limits include exemptive relief for *bona fide* hedging purposes. Commercial entities engaged in the market for hedging purposes are typically exempt from limits since their holdings are presumed to relate to risk management activities emanating from the operation of commercial activities. Notably, however, exemptions are typically granted and monitored by the market regulator to ensure that the trading activities of these commercial firms do indeed represent risk management. In this regard, greenhouse gas emitters might also be considered for exemptions, but should be subject to reporting requirements and regular review by the regulator.

In determining position limits by market, the regulator typically weighs the benefits of developing market liquidity with the potential harm that might result from manipulation by large position. Federal limits on agricultural products are currently set by formula, using a two-tier structure. Federal limits are set as 10 percent of the lagged (by one year) open interest in contracts up to 25,000 contracts and 2.5 percent of open interest thereafter (see Table 1).

The two-tier structure allows for greater market share in less liquid markets, allowing traders to aggregate up to 10 percent market share in order to facilitate market liquidity when the market is realtively small. For markets that develop and expand beyond 25,000 contracts, liquidity concerns are mitigated while the concern for manipulation is increased. With the second tier limits imposed, the allowable positions shrink as a percentage of market share. For instance, with a 50,000 contract market, limits are set at 3,125 contracts (10 percent of the first 25,000 plus 2.5 percent of the next 25,000), representing just 6.25% of market share.

The CFTC revisits the position limits annually in order to adjust limits based on the formula. Indeed, although these Federal limits are reassessed annually to reflect the current size and liquidity of the market, the CFTC does not necessarily apply the formula mechanically. When the formula calls for an increase in position limits, the CFTC commonly asks for public comment. Consistent with the Dutt and Harris (2005) model, the CFTC appears to exercise judgment in their tolerance for higher position limits. Given concerns about agricultural prices, for instance, most agricultural position limits have not been adjusted upward in the past three years, despite a marked growth in open interest. This results in most current agricultural position limits to be somewhat below the limits that would otherwise be dictated by the Federal formula.

In the realm of European carbon trading, there are two notable exchanges: Bluenext, a Paris-based climate exchange offering spot and futures contracts and the European Climate Exchange (ECX), a U.K.-based climate exchange offering spot, futures and options contracts. Bluenext lists contracts for European Union Allowances (EUAs) , which are allotted by member states and Certified Emission Reductions (CERs) while the European Climate Exchange lists contracts on CERs. EUAs are now issued via a uniform price auction of 400,000 allowances amounting to 10% of global supply. Derivatives traded in Europe are physically settled.

Volume on the two exchanges has increased in notional value from €2.1 billion in 2005, to €68 billion in 2009. With contracts listing on ICE Futures Europe, the ECX has the lion's share of trading volume among global climate exchanges. Figure 1 below presents global exchange volumes.

Investors in the ECX include compliance-based traders who have emissions to offset (e.g. Industrials, Utilities), intermediaries/investors (e.g. Banks, long only funds), project developers, and speculators.

The contracts traded on the ECX fall under the regulation of the U.K.'s Financial Services Administration (FSA) and follow a similar compliance structure that applies to other products on ICE Futures Europe including Brent Crude Oil and West Texas Intermediate Crude Oil contracts. All market participants have daily trading limits in place determined by their Clearing Member. The ICE Futures Europe compliance department constantly monitors the level of open interest per market participant as well. Although no specific position limits are applied in advance, if a position is suspicious then the participant will be contacted for accountability. If deemed necessary, traders will be asked (or perhaps forced) to reduce the size of the position.

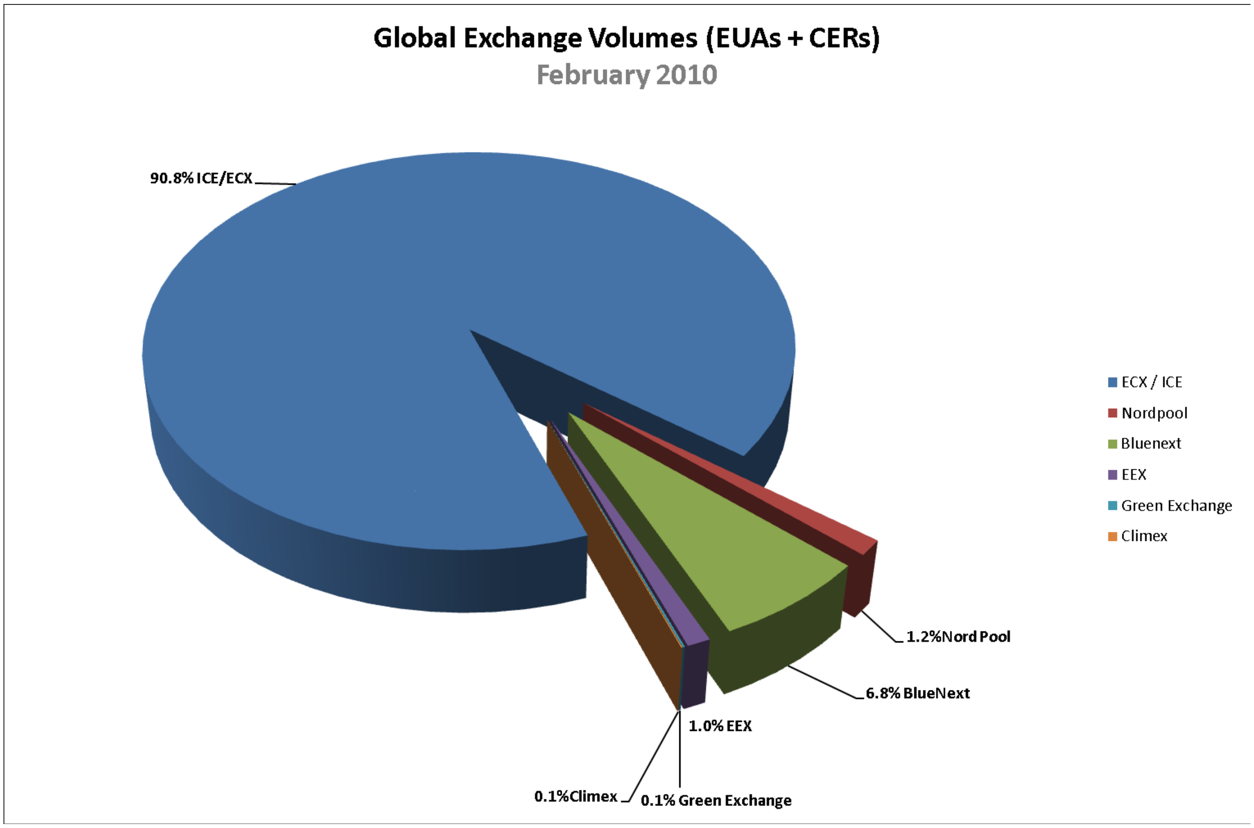

Figure 1: Global Exchange Volume of European Union Allowances (UARs) and Certified Emission Reductions (CERs)
Source: European Climate Exchange

In addition, the exchange applies a "bust range" of €0.50 to ECX contracts. The bust range limits bids and offers to prices no lower or higher, respectively, than €0.50 from the last traded price. The bust range was lowered in 2009 from €0.85 as a precautionary measure to prevent high/low ticking (which would be classified as market manipulation).

Both theory and practice can help guide in determining the optimal level of holding limits that might be applied in greenhouse gas allowance and offset trading markets. Theory (Dutt and Harris (2005)) dictates that both the market regulator's tolerance for price changes and the illiquidity of the underlying instrument should play a role. Unfortunately, for a market with only prospective trading and nascent regulation, theory offers little practical advice since neither component is known.

However, empirical work in the stock market presented in Dutt and Harris suggests a common risk tolerance might be to allow for a three percent change in prices. Likewise, they present stock illiquidity measures ranging from below 27 to above 752, with a mean near 150.[13] Empirically, then, this model suggests an extremely wide range of prudent position limits differing by a magnitude of thirty or more (the ratio of 752 over 27).

Once trading begins in the market, an empirical estimate from allowances can be attained (although since market liquidity can vary over time, an average illiquidity measure can only approximate an optimal position limit level). In the meantime, we are left with existing practice as a guide. Given that the FSA does not publicly disclose position limits, the CFTC limits must suffice along this dimension.

Section V. Holding Limit Recommendations

Theory suggests that limits on trader holdings can be combined with more costly surveillance activities to effectively regulate markets. As discussed above, market regulators can apply a myriad of contract terms, market mechanisms, surveillance activities, and trading rules in order to best minimize the prospects of manipulation in allowance and offset credit markets. Any recommendations for applying holdings limits should not only be grounded in theory, but should also be anchored to the specific characteristics of the market that also relate to manipulation.

In terms of contract design, we know that cash-settled contracts are less prone to manipulation relative to physically-settled contracts.

In terms of market design, we know that participation in the primary auction for allowances can have an impact on potential manipulative activities. To the extent that allowance auctions are open and accessible to a wide variety of participants, this feature makes the secondary market less prone to manipulation.

However, since the market float can be a significant factor in manipulative schemes, the ability for participants to bank allowances from year to year might reduce market float and increase the potential for manipulation.

Unfortunately, extant theory (Dutt and Harris (2005)) on position limits requires an estimate of the price change tolerance of the regulator and a measure of illiquidity in the secondary market for trading of allowances. In this regard, theory is of little practical use to the nascent (prospective) market with no trading history and limited regulatory experience.

Additionally, most markets apply some degree of holdings limits to contracts, recognizing the real possibility of manipulation in derivatives markets.

In this light, it would be prudent to recommend that greenhouse gas allowance and credit markets implement holdings limits be set with the two-tier structure applied to futures markets. Namely, holdings limits should be set as 10 percent of the first

[13] ITG Inc. and Goldman, Sachs graciously shared illiquidity measures for this exercise. Notably, illiquidity measures from the two sources overlap, but differ substantially at the extremes.

25,000,000 allowances issued plus 2.5 percent of any additional allowances issued each year. This two-tier structure allows for greater market share as the nascent market develops liquidity, and scales back (in terms of market share) as the market grows and matures.

To illustrate, assume an initial allocation of 250,000,000 allowances in the first year of the program. Traders not allocated allowances for commercial greenhouse gas emissions would be limited to holdings that do not exceed 8,125,000 allowances during this first year (10 percent of 25,000,000 plus 2.5 percent of the next 225,000,000), representing just 3.25 percent market share. Assuming the cap-and-trade program expands in the second year to an allocation of 300,000,000 allowances, traders would be subject to holdings limits of 8,750,000 allowances (or 2.9 percent market share).

These holdings limits should be applied to any entity that is not allocated allowances to offset commercial emissions of greenhouse gases. The holdings of commercial entities (firms which are allocated allowances) will be dictated by rules governing annual allocations and the banking of allowances from year to year.

Importantly, this report recognizes that the adjustment and maintenance of holdings limits is a dynamic process and this recommendation should be viewed in that light. In a new market with little information, the recommendation falls back on tried and true mechanisms that have been applied successfully in U.S. futures markets. As the nascent market for allowances and credits matures, these limits should be reassessed for an appropriate fit.

Table 1: Summary of Current Position Limits on Various Futures Exchanges

Panel A: Chicago Board of Trade-listed Contracts

CBOT			
Contract	**Spot Month**	**Single Month**	**All Months Combined**
Corn	600	13,500	22,000
Oats	600	1,400	2,000
Wheat	600	5,000	6,500
Soybeans	600	6,500	10,000
Soybean Oil	540	5,000	6,500
Soybean Meal	720	5,000	6,500

Panel B: Chicago Mercantile Exchange-listed Contracts

CME			
Contract	**Spot Month**	**Single Month**	**All Months Combined**
Live Cattle	450	5,400	
Lean Hogs	950	4,100	
Pork Bellies	100	800	1,000
Feeder Cattle	300	1,600	

Panel C: New York Mercantile Exchange-listed Contracts

NYMEX					
	Position Limits			**Accountability Levels**	
Contract	**Spot Month**	**Single Month**	**All Months Combined**	**Single Month**	**All Months**
Cocoa	300			6,000	6,000
Coffee	100			5,000	5,000
Cotton	50	2,500	5,000		
Sugar	100			9,000	9,000
Crude Oil	3,000			10,000	20,000
Natural Gas	1,000			6,000	12,000
Heating Oil	1,000			5,000	7,000
Gasoline Blendstock (RBOB)	1,000			5,000	7,000

Panel D: Intercontinental Exchange-listed Contracts

ICE					
	Position Limits			Accountability Levels	
Contract	Spot Month	Single Month	All Months Combined	Single Month	All Months
Cocoa	1,000	3,500	5,000	6,000	6,000
Coffee	500			5,000	5,000
Cotton	300				
Sugar	5,000			10,000	15,000

Panel E: COMEX-listed Contracts

COMEX			
	Position Limits	Accountability Levels	
Contract	Spot Month	Single Month	All Months
Gold	3,000	6,000	6,000
Silver	1,500	6,000	6,000

Panel F: Treasury Contracts

Treasuries	
Auction Award Limit	35% of auction - Net Long Position

Panel G: Listed Option Exchanges

OCC Option Exchanges Dependent on underlying stock trading volume (Net Position)
250,000
200,000
75,000
50,000
25,000

Public Announcement
Treatment of Renewable Energy Certificates in the WCI Cap-and-Trade Program

Several states have passed renewable portfolio standards that require electricity load-serving entities to include a minimum amount of renewable electricity in the portfolio of electricity sources used to serve their customers. Most of these programs use Renewable Energy Certificates (RECs) to track compliance and ensure that no renewable megawatt hours are double-counted.

Many states with renewable portfolio standards allow RECs to be sold separately from the generated electricity. The electricity from which RECs have been separated is often referred to as “null” power. In order to prevent double counting of the zero-GHG attribute of renewable electricity in greenhouse gas (GHG) cap-and-trade programs, either the null power or the RECs should carry the zero-GHG attribute. If RECs carry the attribute, they could be bundled with electricity from other sources to negate or reduce the compliance obligation associated with the electricity. Under this approach, WCI Partner jurisdictions would then have to attribute emissions to the null power in order to maintain accurate GHG accounting; otherwise, reported emissions would be lower than actual emissions.

The WCI Partners recommend that RECs have no role in the WCI Partner jurisdictions’ mandatory GHG reporting and compliance protocols. Under this approach, the compliance obligation of first jurisdictional deliverers of electricity would be based only on the actual GHG emissions occurring as a result of generating electricity (as described in the Design Recommendations for the WCI Regional Cap-and-Trade Program). First jurisdictional deliverers with a GHG compliance obligation would not be able to use RECs to reduce their compliance obligations, and null power would not have GHG emissions attributed to it.

Western Climate Initiative News

May 17, 2010

This status report is issued monthly from WCI Partner jurisdictions to all interested stakeholders via the WCI list server and website.

Upcoming Events

May 19: Benchmarking Symposium in Seattle

The WA State Department of Ecology and the WCI will host a GHG Benchmarking Symposium from 8:30 am to 4:30 pm at The Westin in downtown Seattle. Speakers, panelists, and participants will discuss what benchmarks are, how they can be constructed, and the leading policy approaches for using benchmarks to reduce GHG emissions. Click here to register your attendance (there is no fee) or to obtain an agenda, webinar, and other meeting information.

May 20: Partners Meeting in Seattle

Stakeholders are invited to attend the next WCI Partners meeting in-person or via teleconference on May 20 at The Westin in downtown Seattle. There is no charge to participate in the meeting, but participants planning to attend in-person are asked to register to ensure sufficient capacity. To join the meeting via teleconference, dial 1-800-868-1837, and enter code 659 537# (1-404-920-6440 for outside the U.S. and Canada). The agenda is posted here.

Québec Announces Funding for Climate Change Adaptation

British Columbia Introduces Updates to Its Cap and Trade Act and a New Clean Energy Act

Updates to BC's Cap and Trade Act, first introduced in 2008, were recently introduced to the BC Legislative Assembly. The amendments further clarify existing statutory power to enable implementation of details of the cap-and-trade program that BC has been developing in collaboration with its WCI partners. A vote is expected prior to the adjournment of the legislative session in the first week of June and will be followed by intentions papers to consult on proposed regulations.

BC's new Clean Energy Act was introduced on April 28. The legislation would enable BC Hydro, the provincially-owned crown corporation, to aggregate clean and renewable energy and offer customers outside BC the opportunity to secure long-term agreements for clean power at competitive prices to assist them in meeting their climate action and renewable energy objectives.

WCI Partners Recommend Renewable Energy Certificates Have No Role in Compliance With Their Cap-and-Trade Program

May 25: Stakeholder Call to Discuss Consultant Report on Allowance and Offset Holding Limits

A stakeholder conference call to discuss this report (see adjacent column) will be hosted on May 25 at 11:00 am Pacific Time. To join the call, dial 1-800-868-1837, and enter code 659 537# (1-404-920-6440 for outside the U.S. and Canada). To view the presentation as it is being discussed, click here and enter the same phone number, participant code, and screen name.

Several states have passed renewable portfolio standards that require electricity load-serving entities to include a minimum amount of renewable electricity in the portfolio of electricity sources used to serve their customers. Most of these programs use Renewable Energy Certificates (RECs) to track compliance and ensure that no renewable megawatt hours are double-counted.

Many states with renewable portfolio standards allow RECs to be sold separately from the generated electricity. The electricity from which RECs have been separated is often referred to as "null" power. In order to prevent double counting of the zero-GHG attribute of renewable electricity in greenhouse gas (GHG) cap-and-trade programs, either the null power or the RECs should carry the zero-GHG attribute. If RECs carry the attribute, they could be bundled with electricity from other sources to negate or reduce the compliance obligation associated with the electricity. Under this approach, WCI Partner jurisdictions would then have to attribute emissions to the null power in order to maintain accurate GHG accounting; otherwise, reported emissions would be lower than actual emissions.

The WCI Partners recommend that RECs have no role in the WCI Partner jurisdictions' mandatory GHG reporting and compliance protocols. Under this approach, the compliance obligation of first jurisdictional deliverers of electricity would be based only on the actual GHG emissions occurring as a result of generating electricity (as described in the Design Recommendations for the WCI Regional Cap-and-Trade Program). First jurisdictional deliverers with a GHG compliance obligation would not be able to use RECs to reduce their compliance obligations, and null power would not have GHG emissions attributed to it.

WCI Markets Committee Releases Consultant Report on Allowance and Offset Holding Limits

In its Market Oversight Draft Recommendations (see article below), the Markets Committee identified twelve policy decisions, including whether or not to implement "holdings limits," limits on the number of allowances or offset certificates any entity could control. The WCI Partners commissioned a consultant's report on this issue, to review the history, theory, and use of similar limits in other markets, as well as recommendations on their use in a regional cap-and-trade program. The Partners contracted with Dr. Jeffrey H. Harris of the University of Delaware to provide the report and recommendations

To facilitate deliberations on final recommendations for holding limits, the Committee requests comment on the commissioned report by June 4, 2010. Dr. Harris will present his work and be available to answer questions on May 25, 2010 at 11:00 Pacific Time. Click here for details on the webinar.

WCI Markets Committee Issues Draft Recommendations for Market Oversight

On April 5, the WCI Markets Committee issued draft recommendations to ensure that the allowance and offset credit trading market is organized properly to operate reliably and prevent or minimize manipulation. The Committee identified twelve policy decisions and examined the background, options, and pros and cons for each. A public stakeholder conference call was hosted on April 20 to discuss the draft recommendations, and written comments were due April 30. Next steps include public release and input on the Committee's consultant report on holding limits (see above article) and final recommendations by the WCI Partners.

WCI Markets Committee Issues Auction Design White Paper

The WCI Design Recommendations for a Regional Cap-and-Trade Program call for a portion of the emission allowances to be auctioned. This white paper, released April 15, is the first step in developing recommendations on auction design. It identifies design decisions to be made and assesses their inherent tradeoffs. A public stakeholder conference call was hosted on April 29 to discuss the white paper, and written comments were due May 7. Next steps include draft recommendations from the Committee on the auction design.

WCI Offsets Committee Releases Draft Recommendations for Offsets System Essential Elements

Released on April 13, these draft recommendations define offsets and essential criteria to ensure that all offset credits issued or accepted by WCI Partner jurisdictions are real, additional, verifiable, and enforceable. The draft recommendations are based on stakeholder feedback and Partner input since the Committee's release of its offset definition and criteria white paper in July 2009. Public stakeholder conference calls were held on the draft recommendations on April 22 and May 5. Next steps include review of stakeholder comment and finalization of the recommendation by WCI Partners.

WCI Offsets Committee Releases Consultant Report Reviewing Current Offset Protocols

On April 13, the WCI Offsets Committee released a report for public comment that evaluates how each of several existing offset protocols correspond to the WCI draft offset definition and criteria (see article above), meets the relevant requirements described in the ISO framework, and is applicable to the geographies of the Partner jurisdictions. The report was prepared by Det Norske Veritas (DNV) and focuses on protocols in the agriculture, forestry, and waste management sectors, which are identified as priority project types in the Design Recommendations for the WCI Regional Cap-and-Trade Program. Next steps include modifications to existing protocols or developing new protocols where suitable ones do not exist. Stakeholder input will be sought in this process.

Québec Announces Funding for Climate Change Adaptation

On April 30, 2010, the Government of Québec announced that it would spend $8,725,000 over three years to combat heat islands. A total of 14 projects will be funded in four different regions: Montréal, Québec City, Montérégie, and Lanaudière. The projects will lessen the impact of climate change on public health by improving air quality and by decreasing smog episodes. They will also increase vegetation density, create shade zones, and protect against high ambient temperatures and ultraviolet radiation. Selected in a public request for proposals process, the 14 projects will be funded out of a $30 million budget managed by the Ministère de la Santé et des Services Sociaux, as part of the 2006-2012 Climate Change Action Plan.

SYMPOSIUM ON UNDERSTANDING THE VALUE OF BENCHMARKING

Westin Hotel – Fifth Ave Meeting Room, 1900 5th Ave., Seattle, WA
Wednesday, May 19, 2010

WASHINGTON STATE DEPARTMENT OF ECOLOGY

WESTERN CLIMATE INITIATIVE

Call-in: (800) 868-1837, passcode 659 537# (Outside U.S. and Canada, dial: (404) 920-6440)
Webinar: https://www1.gotomeeting.com/join/115725897 *(Questions will be collected via the webinar interface)*

**Morning Objectives - ** Address the following questions:
What are benchmarks?

How are benchmarks constructed?

What are the leading policy approaches for using benchmarks to reduce GHG emissions?

8:30 am **Registration**

9:00 am **Welcome and Symposium Overview**

- Janice Adair, Washington State Department of Ecology
- Michael Gibbs, US Co-Chair of WCI, California EPA
- Bill Ross, Ross & Associates, Facilitator

9:15 am **Overview of Current Efforts in Industry Benchmarking to Improve Industrial Performance**

- **Michael Lazarus, Stockholm Environment Institute (SEI)**
  Michael Lazarus, co-author of the SEI *White Paper* on greenhouse gas benchmarking, will provide an overview of current efforts in industry greenhouse gas benchmarking and introduce the *White Paper* under development for the Department of Ecology.

9:30 am **A Look into Existing Policy Approaches that Use Benchmarking to Improve Industrial Energy Performance**

- **James Bradbury, World Resources Institute**
  Industry Benchmarking and Federal Climate Legislation
  James Bradbury will provide a status update of the use of greenhouse gas benchmarks in proposed federal climate legislation, including the Waxman-Markey and Kerry-Graham-Lieberman bills.
- **Judi Greenwald, Pew Center on Global Climate Change**
  Using Benchmarks to Develop Regulatory Performance Standards
  Judi Greenwald will provide an overview of possible approaches to developing and using benchmark-based GHG performance standards under existing environmental law.
- **Betsy Dutrow, US EPA ENERGY STAR Industrial Sector Partnership**
  "A Voluntary Approach: ENERGY STAR® Benchmarking of Industrial Plant Energy Performance"
  Betsy Dutrow will provide an overview of EPA's approach for benchmarking industrial plant energy performance and will review the successes and challenges of benchmarking plant performance.
- Panel Discussion / Q&A

10:45 am **Break**

11:00 am **Methods for Constructing Benchmarks**

- **Hauke Hermann, Öko Institute**
  Data-driven, Benchmark Curve Approach and Lessons from the European Union's Emissions Trading System
  Hauke Hermann is a consultant to the EU, and will discuss the process underway to establish industry GHG benchmarks for carbon-intensive, trade-exposed industries under the EU's cap-and-trade program.
- **Gale Boyd, Duke University** (*via phone*)
  The ENERGY STAR® Approach to Developing Benchmarks of Industrial Plant Energy Performance
  Gale Boyd, as part of EPA's ENERGY STAR® Industrial Team, constructs the models that form the basis for benchmarking the energy performance of industrial plants in the U.S. He will describe the data, methods, and challenges of benchmarking these plants.
- **Peter Erickson, SEI**
  Issues and Options for Benchmark Development in the U.S.
  Peter Erickson, co-author of the SEI *White Paper* on greenhouse gas benchmarking, will describe key issues and options for developing GHG benchmarks in Washington and the U.S.
- Panel Discussion / Q&A

12:15 pm **Lunch break (on your own)**

Afternoon Objectives - Address the following questions:
What are the benefits and challenges of developing and applying benchmarks?

What data constraints limit benchmarking and how might they be overcome?

How do responses to these questions differ depending on how benchmarks are used?

1:30 pm Key Issues for Industry GHG Benchmarking

- **Ken Martchek, Alcoa**
  Ken Martchek will provide a national perspective of considerations in addressing this session's key topics: benefits and challenges of benchmarking, data constraints, and striking a balance between detail and aggregation in benchmarks across industry sectors.
- **Industry Panelists:**
  - Pam Barrow, Northwest Food Processors Association
  - Anthony Chavez, Weyerhaeuser
  - Jeff Jacobson, Cardinal Glass
  - Curtis Lesslie, Ash Grove Cement Company
  - Ken Martchek, Alcoa
- **Research Panelists:**
  - James Bradbury, World Resources Institute
  - Betsy Dutrow, US EPA ENERGY STAR
  - Peter Erickson, Stockholm Environment Institute
  - Judi Greenwald, Pew Center
  - Hauke Hermann, Öko Institute
- Bill Ross, Moderator
- Michael Lazarus, SEI, Co-Moderator

3:30 pm Break

3:45 pm Observations and Next Steps for the Benchmarking Project

- Janice Adair, Washington State Department of Ecology

4:30 pm Adjourn

To view the draft White Paper, please visit: http://www.ecy.wa.gov/climatechange/GHGbenchmarking.htm
Comments on this draft are requested by Friday, June 4, 2010 to benchmarking.wa@sei-us.org

Issues and Options for Benchmark Development

Peter Erickson

Stockholm Environment Institute – US, Seattle

WA Ecology/WCI Symposium on Understanding the Value of Benchmarking, May 19, 2010, Seattle, WA

STOCKHOLM ENVIRONMENT INSTITUTE

Overview

- Key benchmark design decisions
- Other issues
- Path forward

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Key Design Decisions

- **Ambition** – average, best available, top percentile?
- **Scope and boundaries** – direct only or total, including indirect?

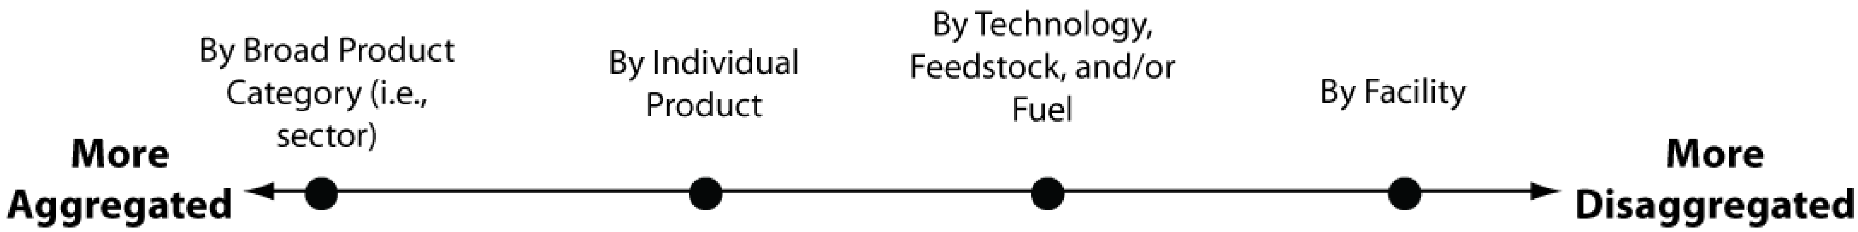
$$\textbf{Benchmark} = \frac{\textbf{Emissions}}{\textbf{Unit of Output}}$$

- **Level of aggregation**: Balance between aggregation & specificity
- **Data** sources

All facets influenced by benchmark application

STOCKHOLM ENVIRONMENT INSTITUTE

Sample Levels of Aggregation



Aluminum	Cast aluminum, rolled aluminum	Anode type	e.g., Intalco, Ferndale
Cement	Clinker (white or grey)	Wet vs. dry kiln	e.g., Ash Grove Cement, Seattle
Glass	Flat, container, fiber glass	Fraction of recycled cullet used	e.g., Cardinal Glass, Winlock
Paper	Newsprint, writing paper, market pulp	Mechanical versus chemical pulp	e.g., Norpac, Longview
Steel	High-alloy steel, hot-rolled steel, EAF steel	EAF vs. BOF, integrated versus rolling mill	e.g., Nucor Steel, Seattle

Level of Aggregation

- Need balance between:
  - **Specificity**: enables meaningful comparisons across facilities; and
  - **Aggregation**: enables broad application, provides big enough pool for benchmark to provide incentive effect
- Benefits and challenges exist for each level of aggregation

Benefits and Challenges of Aggregation

- Broad product category
  - Benefits: Simplicity
  - Challenges: Intermediate products
- Product-specific
  - Benefits: Rewards top-performers, provides long-term incentive
  - Challenges: Data, defining products
- Facility-specific
  - Benefits: recognizes site-specifics
  - Challenges: Limited incentive for best performance

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Aggregation Depends on Policy Context!

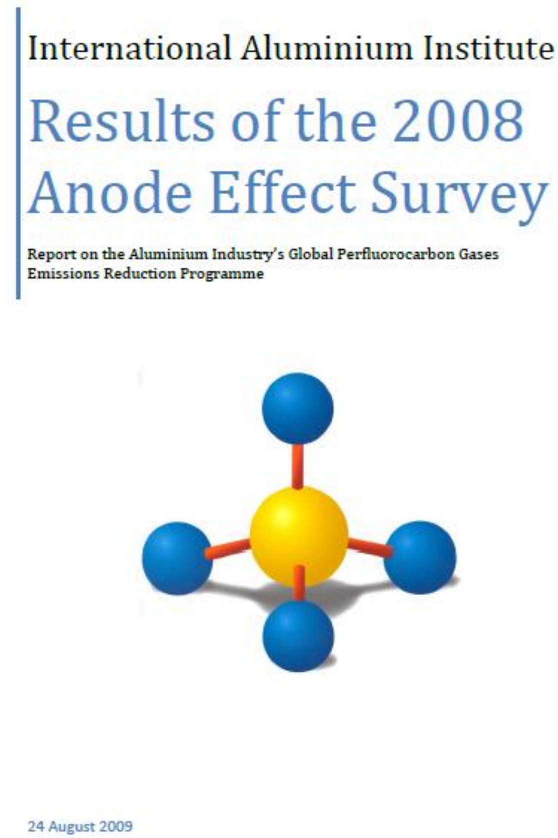
- **Cap-and-trade:**
  - Intent of output-based allocation is to avoid carbon leakage while retaining CO_2 price signal
  - Some level of aggregation may be okay (e.g., "one product, one benchmark")
- **Regulatory**
  - Benchmark directly determines level of emissions and plant viability
  - Differentiation / disaggregation may be appropriate
- **Voluntary**
  - Differentiated benchmarks may encourage participation

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Data Sources

- Four types
  - Industry groups and associations
  - Government surveys
  - Air permits
  - Mandatory GHG reporting rules
- Need for improved data is widely recognized
- Consistent, rigorous protocols should be applied equally for benchmark construction and application

Data: Industry Sources



SEI STOCKHOLM ENVIRONMENT INSTITUTE

Data: Government Surveys

- MECS

U.S. Energy Information Administration
Independent Statistics and Analysis

Home > Households Buildings & Industry > Manufacturing Energy Consumption Survey (MECS) > 2006 Data Tables

2006 Energy Consumption by Manufacturers--Data Tables

Released June 2009

- Census

U.S. Census Bureau

Annual Survey of Manufactures (ASM)

- USGS

USGS
science for a changing world

2008 Minerals Yearbook

Each source has only a piece of the puzzle

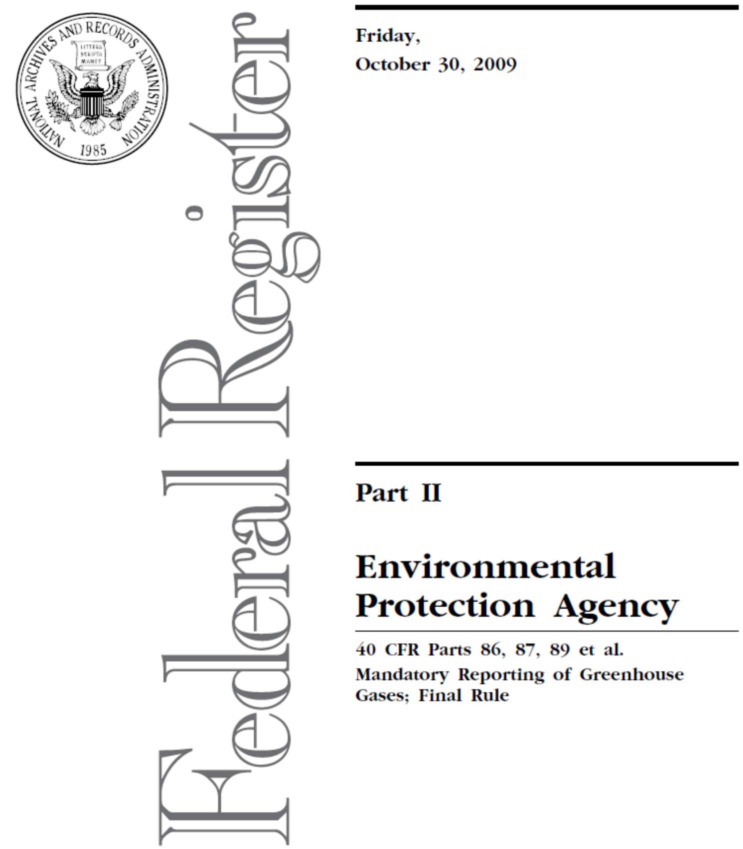
SEI STOCKHOLM ENVIRONMENT INSTITUTE

Data: Air Permits

- Some air agencies use permit data to estimate GHGs
- Ecology and local air agencies use permit information on facility production and other data to estimate GHGs
- Large number of disparate data sources complicates use

Data: GHG Reporting Rules

- All facilities in some sectors
  - E.g., aluminum, cement
- Most sectors if:
  - > 25,000 tCO_2e nationally
  - > 10,000 tCO_2e in Washington State
- Data due Oct 2010 in WA State, March 2011 nationally



Federal Register

Friday,
October 30, 2009

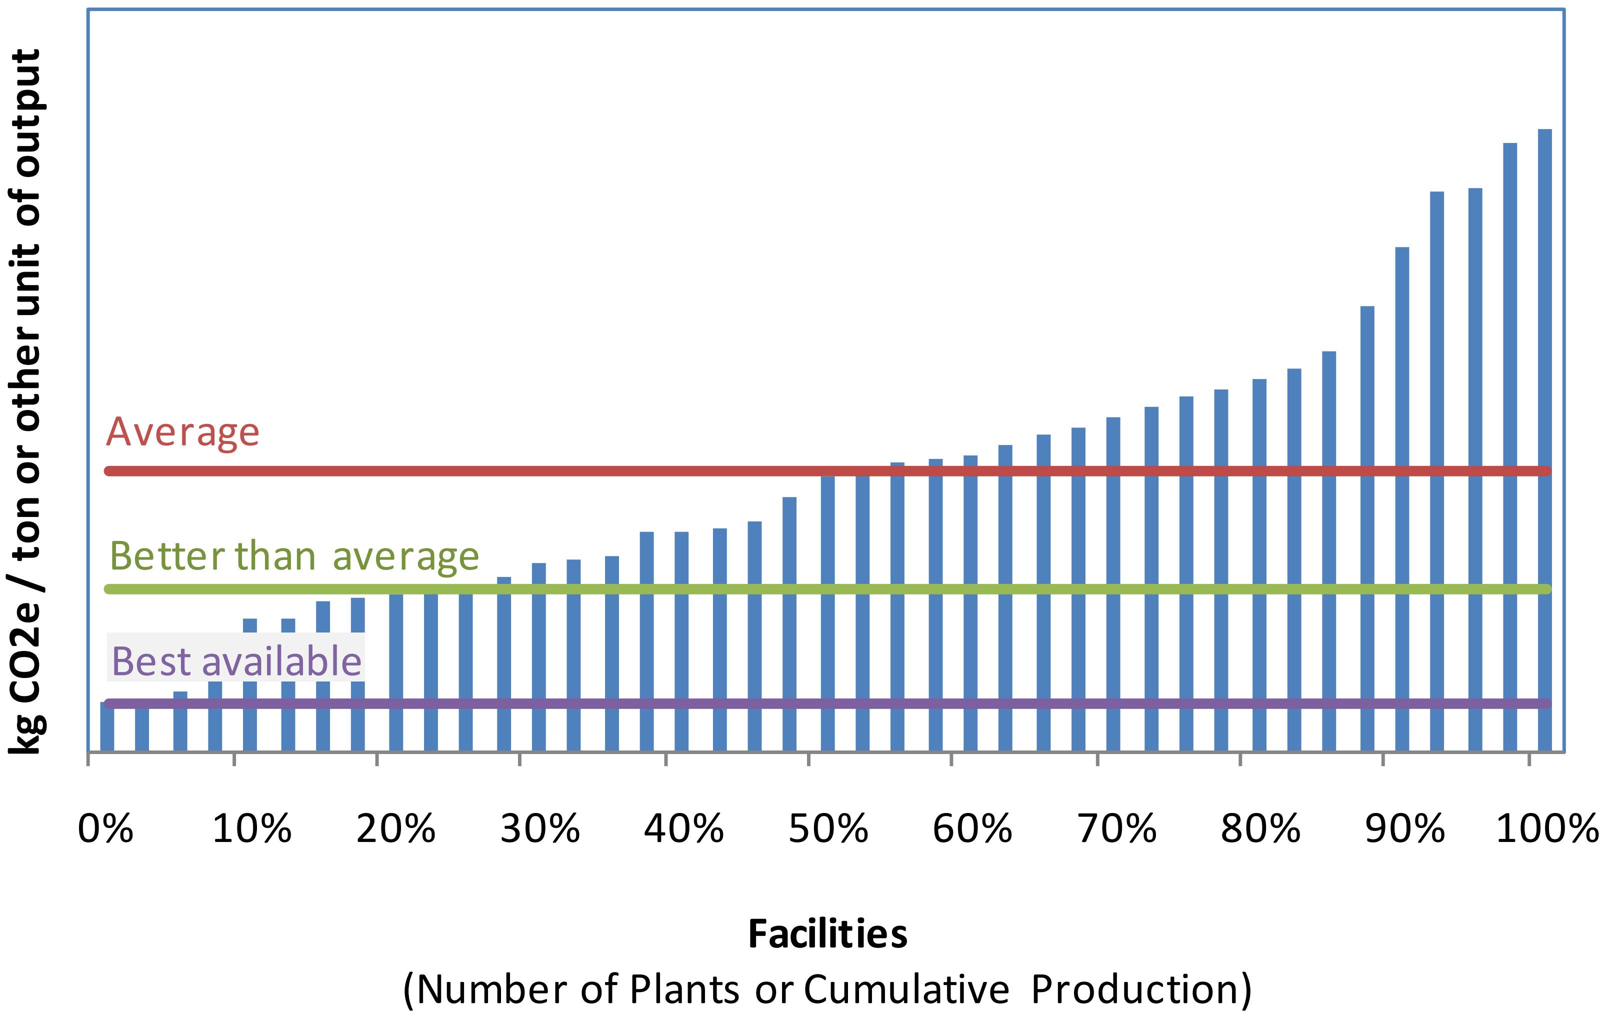
Part II

Environmental Protection Agency

40 CFR Parts 86, 87, 89 et al.
Mandatory Reporting of Greenhouse Gases; Final Rule

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Benchmark Ambition



Ambition Depends on Policy Context, Too!

- **Cap-and-trade:**
  - What level of output-based rebate appropriate to address leakage and competitiveness?
  - Average industry performance (as in draft US legislation) or best practices (as in EU's top 10%)?
  - Insights from economic modeling (e.g., US Interagency Report on Competitiveness and Leakage)
- **Regulatory**
  - Benchmark sets allowable emissions level and may determine plant viability
  - More ambitious benchmarks where abatement less expensive?
- **Voluntary**
  - Differentiation of benchmark ambition can help distribute costs across sectors

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Ambition in Washington State

- Governor Gregoire’s Executive Order 09-05 calls for benchmarks developed by the Department of Ecology to “be based on industry best practices, reflecting emission levels from highly efficient, lower emitting facilities in each industry sector.”

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Scope / Boundaries

- Direct emissions only
  - Benefits: Simpler, aligns best with cap-and-trade and reporting rules
  - Challenges: Could encourage "leakage", if it induces switching from fuel use to purchased electricity or steam
- All (including indirect) emissions:
  - Benefits: Includes more emission-causing activities over which facilities have control (e.g. electricity use); captures emission impact of switching to/from electricity
  - Challenges: Data needs and complexity
- Considerations for Scope also vary by policy approach

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Other Issues

- **Combined heat and power**, or use of waste gases (paper and pulp, steel, and others)
- **Feedstock quality and quantity**: Use and quality of recovered/recycled feedstock (glass, aluminum, steel)
- **Facilities that produce multiple products** (paper or steel mills)
- **Integrated vs. non-integrated facilities** (paper and pulp and steel)
- **Alternative definitions of the final product** (e.g. cement or clinker)

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Potential Elements of a Path Forward on Benchmarking

- Build Data Sets
  - GHG Reporting rules
  - Industry partnerships
  - Federal – State partnerships for MECS, Census, other data?
- Pick one or more policy contexts for further benchmark analysis/development
  - Disaggregation, Ambition, Scope All Depend on Policy Context!
- Pilot in select sector(s)

SEI STOCKHOLM ENVIRONMENT INSTITUTE

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Benchmarking in the EU

Symposium on understanding the value of benchmarking

Hauke Hermann

Seattle, May 19, 2010

Disclaimer

- The views and opinions presented in this presentation are partly based on results from research commissioned by the German Federal Environment Agency and the European Commission.
- The contents of this presentation does not necessarily reflect any official position.

Overview

- Target functions of benchmarks and consequences for the design
- The history: How were benchmarks used in the EU ETS from 2005-2012?
- The future: How will benchmarks be used in the EU ETS from 2013 onwards?
- Conclusions

The EU Emissions Trading Scheme
Some background information

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **The EU ETS is a multi-national ETS**
  - 27 EU Member States, 2.2 (2005) → 2.4 bn t CO2e (2013)
  - Linking: CDM & JI, Norway, Iceland, Liechtenstein, etc
- **The EU ETS is a downstream ETS**
  - Power generation
  - Combustion installations > 20 MW
  - Other installations in energy-intensive industries (cement, iron and steel, glass, ceramics, refineries, etc)
  - From 2013: N2O emissions from large industrial point sources
  - From 2011: aviation included
- **The EU ETS is a multi-period scheme**
  - Pilot phase 2005-2007
  - Second phase 2008-2012
  - Third phase 2013-2020

Benchmarking
Definitions and specifications

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **Benchmarking is an approach to assess performance based on objective and transparent criteria and indicators**
- **The design of benchmarks and benchmarking strongly depends on the specific purpose** (… not all existing benchmarking approaches are suitable to the needs of an ETS and not all benchmarking approaches are suitable to all targets)
  - Voluntary approaches
  - Regulatory approaches
  - Emissions trading schemes (ETS)
- **Target functions of benchmarking within the EU ETS**
  - Compensation (especially during the phase-in; 2005-2007)
  - Rewarding early action (especially during the phase-in; 2005-2007)
  - Preventing (operational and/or investment) leakage; from 2013 onwards

Different target functions lead to different designs

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **Target functions in an ETS**
  - Preventing leakage is the main objective for continued free allocation within the EU ETS
  - At the same time Benchmarking as an approach for free allocation should minimize distortions of the carbon price signal
- **Target functions for voluntary approaches**
  - Comparing the efficiency of different installations
  - Showing the abatement potential (e.g. in a technology class)
- **Target functions for regulatory approaches**
  - Incentivize emissions abatement below the benchmark
  - Fair distribution of abatement costs might make a technology differentiation necessary

Example: the role of indirect emissions

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **Do the target function influence the treatment of indirect emissions from electricity consumption?**
- **The benchmarks in the EU ETS are only based on direct emissions**
  - There will be a separate financial compensation for electricity intensive process with a carbon leakage problem
  - No need to take indirect emissions into account as the carbon price is included in the electricity price
- **Benchmarks for voluntary approaches and regulatory approaches should take indirect emissions into account**
  - Not taking indirect emissions into account might lead to the perverse incentive to increase the use of electricity

Some history

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **Emissions trading started in January 2005 in the EU:**
  - **Grandfathering** based on historic emissions in the years 2000 to 2002 for **incumbents**
  - Main question: How to allocate to **new entrants** (installations starting after 2005)?
  - **Benchmarks for new entrants** were developed for electricity, heat, **cement**, bricks and glass based on best available technology (BAT)
- **From 2013 onwards:**
  - **Benchmarking for incumbents and new entrants based on the 10% most efficient installations**

The allocation formula in the EU

- **Allocation is more than one benchmark**

Allocation formula

$A = BM_e \cdot P\ [\cdot \alpha_{cap}]$

A	free allocation [EUA]
BM_e	emission benchmark [t CO_2/t product]
P	historic production
α_{cap}	adjustment factor to adjust allocation to the cap

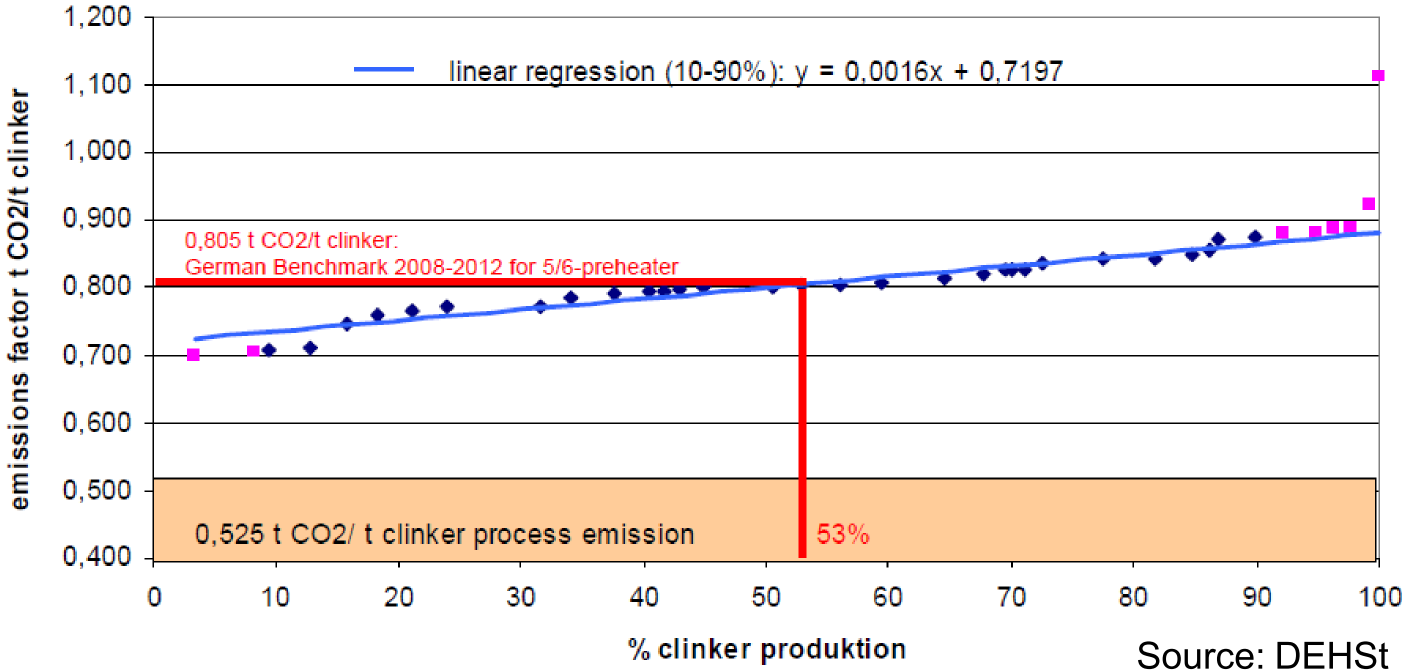
History: Benchmarking for cement

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **Case study: benchmarking for cement in Germany**
  - Derived from the textbook
  - Benchmark was aimed to reflect emissions of best available technology
  - German new entrants benchmark (2005-2012)
    0.805 …0.845 t CO2 per t clinker (depending on chosen technology) + 7500 full load hours
  - Process emissions 0.53 t CO_2 / t clinker + 3 GJ / t clinker * fuel mix of coal = 0.805 t CO2 per t clinker
  - 7500 full load hours

German Benchmarking curve for cement clinker (2007)

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology



Source: DEHSt

- **Looking at real data:**
  - The BAT benchmark was not really BAT (high share of waste fuels used)
  - Perverse incentives due to the technology differentiation
  - Actual full load hours were only 5400 h and not 7500 h

Future: Cooperation with industry

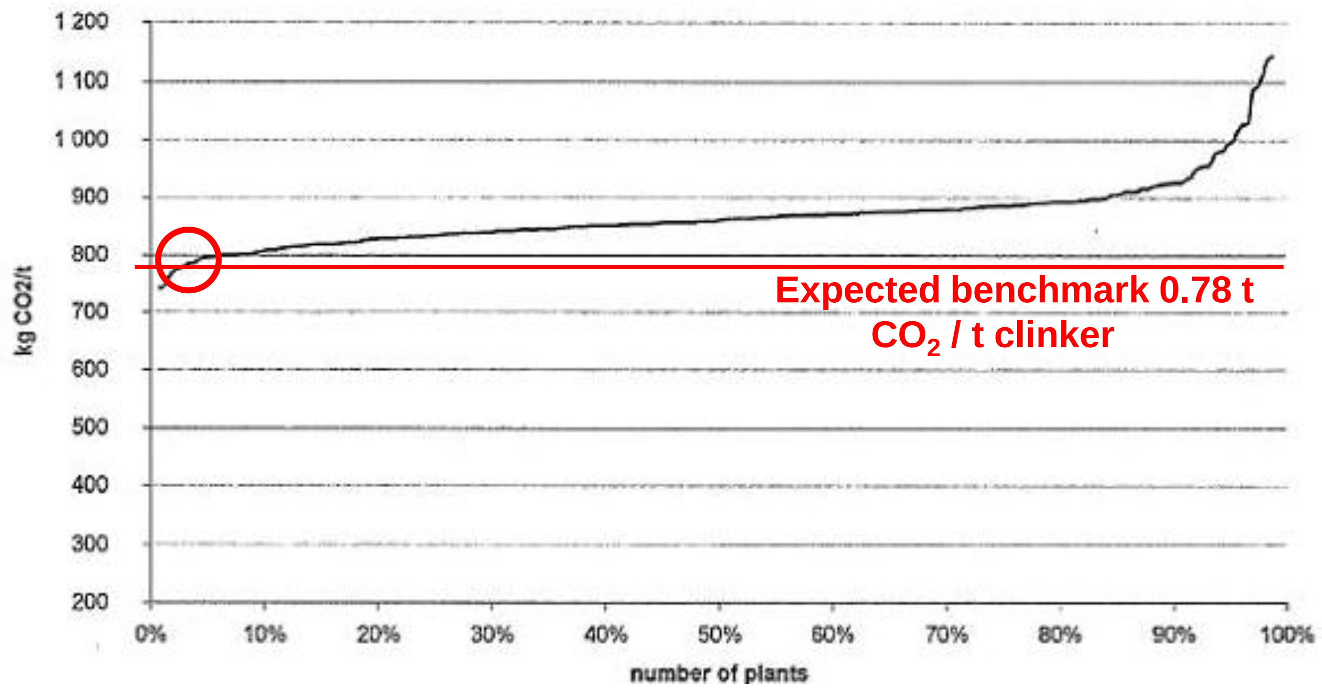
- **Benchmarks for free allocation from 2013 onwards**
  - Benchmarks will be decided in the EU until end 2010
  - Benchmarks will be developed for all major industrial processes listed in the Annex of the ETS directive
  - Sector organisations were asked to construct benchmark curves based on the specific emissions in 2007-2008
  - Benchmarking curves are submitted (first via consultants and now directly) to the European Commission and externally verified

- **Number of Benchmarks**
  - Sector organisations were asked if they want to develop additional product benchmarks (e.g. sugar, starch, were under discussion)
  - No additional product benchmarks are developed in the EU, most sector organisations decided to go for the heat benchmark instead

Example: Benchmarking curve for cement clinker for the EU-27

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **Improved approach from 2013 onwards:**
  - Construct benchmarking curve including all installations
  - Benchmark for free allocation is set at the efficiency of the average 10%



Source: Ecofys/ISI/Öko (2009), Preliminary graph based on data for 2006

How to set up benchmark curves

- **Benchmark curves**
  - Specific emissions are calculated by dividing emissions by production in a reference period (e.g. 2007-08)
  - No correction of the benchmarking curve for outliers, but
    - imports and exports of heat are corrected with the emission factor of natural gas (a paper mill with outsourced heat supply would have zero emission, this needs to be corrected in the benchmarking curve)
    - Imports and exports of waste gases (mainly relevant for iron and steel) are corrected with the emission factor of natural gas
  - The curve should consist of the specific emissions all installations in a region (e.g. US)

- **Data quality**
  - The same monitoring method should be used to set up benchmarking curves and to monitor emissions in an ETS

Conclusions (1)

- **Work with Industry, use real monitoring data for production and emissions to construct benchmarking curves**
- **Use an integrated assessment of CO_2 / t of product (and not energy efficiency and fuel mix separately)**
- **Use the 10% approach to determine the ambition of benchmarks (this lowers transactions costs for negotiations about availability of fuels and achievable efficiency)**
- **BM must maintain a non-distorted CO2 price signal and BM must avoid distortions within the EU**
  - one benchmarking curve per product (cement clinker, glasses, papers)
  - Focus on important basic processes (no benchmark for cars or planes)
  - No consideration of process, raw material, country, regional or other specifics
- **But, under regulatory / voluntary approaches benchmarking curves might be differentiated according to technology**

Conclusions (2)

Öko-Institut e.V.
Institut für angewandte Ökologie
Institute for Applied Ecology

- **BM design must avoid perverse incentives with regard to carbon leakage**
  - Cement clinker facility vs. final product cement (output of grinding plant which is not regulated by the EU ETS – and possibly imports cement clinker)
  - → BM should be implemented at the point of regulation (e.g. based on clinker)

Thank you very much

White Paper

Issues and Options for Benchmarking Industrial GHG Emissions

Submitted to: the Washington State Department of Ecology

PRELIMINARY DRAFT May 12, 2010

STOCKHOLM ENVIRONMENT INSTITUTE

With support from:

Öko-Institut

Ross & Associates Environmental Consulting, Ltd.

Acknowledgments

This report was commissioned by the Washington State Department of Ecology and supported in part by the Energy Foundation. The report and underlying research were completed by the Seattle office of the Stockholm Environment Institute U.S. (SEI-US) with assistance from Öko-Institut and Ross & Associates Environmental Consulting, Ltd. The authors gratefully acknowledge contributions from the following individuals.

1. Introduction and Context

Industrial activity remains a cornerstone of modern economies, as well as a major source of emissions of heat-trapping greenhouse gases (GHGs). Industrial processes and energy use account for 20% of direct greenhouse gas emissions globally (Metz et al. 2007) and in Washington State (Center for Climate Strategies 2007). Many industries, such as aluminum production, are highly reliant on electricity use; when the emissions associated with generating electricity for industry are included, the share rises to a quarter of global emissions, and an even larger share of energy-related CO_2 emissions. A handful of energy-intensive industries – iron and steel, aluminum, chemicals, petroleum refining, minerals (e.g., cement, lime, and glass), and pulp and paper – account for over 80% of global industrial energy use, and a large majority of industrial GHG emissions (Metz et al. 2007).

These same industries could also play central roles in a transition to a low-carbon economy. Aluminum can reduce transportation energy needs by "lightweighting" vehicles. New low-carbon transportation and energy infrastructure, from public transit systems to wind turbines, may require significant amounts of steel and cement. Advanced low-emissivity ("low e") glass is a key component of ultra-low energy buildings. Sustainably harvested forest products offer the potential for carbon sequestration in the built environment as well as a low-carbon energy source. In short, a few key energy and GHG emissions intensive industries – most of which are represented here in Washington State and operate in a highly competitive international markets – are central to tackling climate change.

With these considerations in mind, state and federal policymakers are considering a range of approaches to address GHG emissions from industrial activity. Approaches under consideration for emissions-intensive industry sectors include voluntary agreements or incentives, inclusion of industry in an economy-wide cap-and-trade program, and direct regulation through performance standards. A common theme to all three such approaches is the use or development of GHG benchmarks, which enable the assessment of GHG emissions performance across facilities or against a common standard.

GHG benchmarks are typically expressed as a quantity of emissions per unit of output, as in the following simple equation, and may in some contexts be called *emissions intensity*. [1]

$$GHG\ Benchmark = \frac{Emissions\ (tons\ CO_2e)}{Unit\ of\ Output\ (tons, \$, or\ other\ metric)}$$

Policymakers can use GHG benchmarks in any of at least three policy approaches:

- **Voluntary performance goals,** in which participating companies commit to achieving a particular emissions benchmark by a particular year;
- **Allocation of allowances in a cap-and-trade program**, where emissions allowances are freely allocated to industry sectors based on a benchmark level of emissions performance and in proportion to the output of each facility;[2] and
- **Regulatory GHG performance standards,** where individual facilities are required to meet an emissions performance standard that may be set using a benchmark approach.[3]

With this range of possible purposes in mind, Washington Governor Gregoire issued Executive Order 09-05 in 2009, directing the Washington State Department of Ecology to develop emission benchmarks in consultation with industry and other interested stakeholders to be delivered to the Governor, per the Executive Order, by July 1, 2011. Specifically, the Executive Order calls for the Director of the Department of Ecology to:

[1] A common unit of emissions benchmarks is kilograms of carbon dioxide equivalent per ton of material processed or produced.
[2] For example, H.R, 2454 in the 111th Congress (the "Waxman-Markey" bill) included a rebate to certain energy intensive and trade-exposed sectors based on the average level of emissions per output of the sector.
[3] Other approaches to setting emissions performance standards also exist, such as defining particular technologies that must be installed.

"In consultation with business and other interested stakeholders, develop emission benchmarks, by industry sector, for facilities the Department of Ecology believes will be covered by a federal or regional cap-and-trade program. The Department of Ecology shall support the use of these emission benchmarks in any federal or regional cap-and-trade program as an appropriate basis for the distribution of emission allowances, and as a means to recognize and reward those businesses that have invested in achieving emission reductions. These benchmarks shall be based on industry best practices, reflecting emission levels from highly efficient, lower emitting facilities in each industry sector. The benchmarks shall be developed to allow their application as state-based emissions standards, should they be needed to complement the federal program, or in the absence of a federal program."

Benchmark Basics

Industry efforts to compare and track GHG emissions performance have been underway for several years. Many global and North American industry associations have collected data from member companies on greenhouse gas emissions and production and distributed corresponding greenhouse gas intensity statistics. For example, the petroleum industry has been engaged for more than 20 years in benchmarking the dozens of processes that occur in petroleum refineries. Petroleum industry actors have compiled a global database of energy use, and have developed a widely adopted benchmarking approach.[4] Other industry associations in other sectors – both globally and regionally – have also developed greenhouse gas intensity metrics, or benchmarks.[5]

Approaches to benchmarking can vary substantially by sector. Some sectors (e.g., cement) have processes and products that are relatively simple and uniform. In such sectors, the task of defining which emissions to include – and what products and/or processes to benchmark – can be relatively straightforward. In other sectors, the task can be much more difficult. For example, the presence of dozens of unique processes and wide variation between facilities in the petroleum refining sector can make the task of developing meaningful benchmarks much more challenging and time-consuming. Regardless, an important consideration in developing benchmarks is to balance the need to obtain emissions and production data from a large enough group of facilities to be representative against the need for each benchmark to be consistent with the circumstances of the facilities it is intended to help assess.[6]

Figure 1 below presents a hypothetical benchmarking curve of emissions intensity data for a fictional industry sector.[7] In this chart, each individual facility, knowing its emissions intensity, could compare its emissions performance (kg CO_2e/ton) to each other facility anonymously, as well as to the average intensity (displayed here as a red horizontal line). Facilities with emissions intensities below the red line are outperforming the average, while facilities with emissions above the red line are underperforming the average and emitting more emissions per each ton of product.

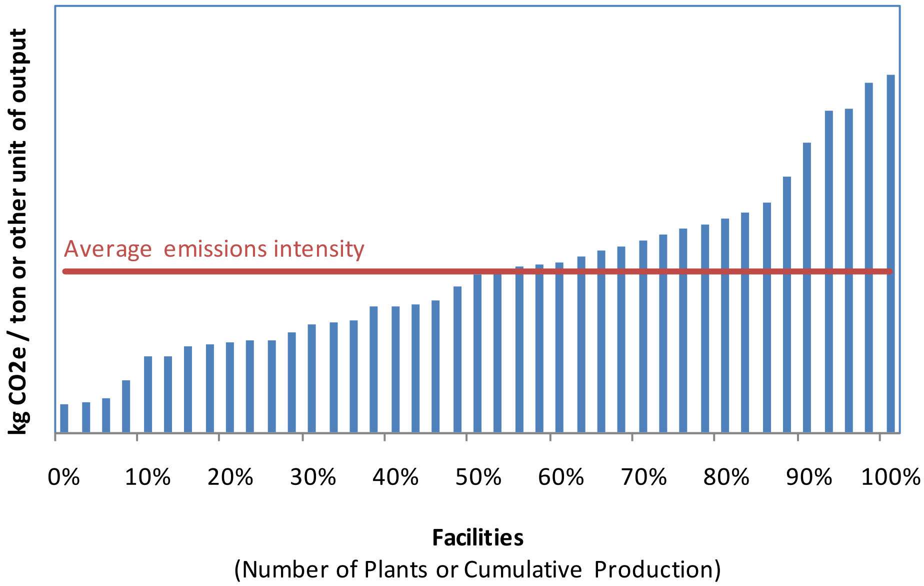
[4] The benchmarking approach developed for the refinery industry by Solomon Associates, Inc. has been widely adopted among the world's refineries and is also likely to form the basis for the European Union's approach to benchmarking refineries in the third phase of its Emissions Trading Scheme, discussed in greater detail later in this paper.

[5] Several industry efforts rely, and have contributed to, the Greenhouse Gas Protocol of the World Business Council for Sustainable Development and the World Resources Institute. In addition, the US EPA ENERGY STAR program for industry uses Census Bureau and industry-provided data to develop energy benchmarks called Energy Performance Indicators. Facilities that score in the top 25% energy efficiency are eligible to be awarded the ENERGY STAR label by EPA.

[6] Current industry efforts have tended to use kg CO_2e as the numerator of the benchmark (and participated in collaborative exercises to establish protocols, such as the GHG Protocol, for measuring such emissions) and tons of product (usually an output, but sometimes an input, as for refining) as the denominator. Industry associations are much less uniform, however, concerning the level of ambition of the benchmark. A common approach employed by several industry associations is to report average greenhouse gas intensity metrics for their respective members.

[7] Curves like that presented in Figure 1 are common in developing benchmarks for energy and emissions. For example, US EPA develops similar curves in its ENERGY STAR Energy Performance Indicators for Industry, including in spreadsheet tools made freely available on its website, www.energystar.gov.

Figure 1. Hypothetical Benchmark Curve: Comparing Facility Emission Intensities in a Given Sector or Subsector [8]



Benchmarks need not be set at the average emissions intensity, however. A benchmarking curve (and its underlying data) can also be used to develop more ambitious benchmarks. For example, a benchmarking curve can be used to understand the best achieved level of emissions performance (i.e., the column furthest to the left in the chart above), to set a goal for a specified improvement over the current average (e.g., a 20% improvement in emissions intensity by a certain year), or to select a definition of top-performing plants (e.g., the plants in the top 25th percentile of performers). As we discuss in Section 3, setting the ambition of a benchmark becomes particularly important in regulatory systems for reducing greenhouse gases, including both cap-and-trade and performance standards approaches.

Roadmap of the White Paper

In this *White Paper*, we discuss issues and options for developing emissions benchmarks, starting with a brief summary of the possible policy approaches in Section 2. We then provide an assessment of key issues and options for developing benchmarks in Section 3, including a discussion of how the issues and options may differ for three commonly applied policy approaches. We include a discussion of considerations specific to several industrial sectors (e.g., aluminum, cement, steel) in Section 4. In Section 5, we assess possible paths forward for Washington State in developing benchmarks to fulfill Governor Gregoire's Executive Order.

This *White Paper* and the associated GHG benchmarking symposium on May 19, 2010 mark the first phase of the Department of Ecology's research and stakeholder consultation on benchmarking. The second phase, starting in July 2010, will entail the development of recommendations on industry benchmarks and their appropriate use in achieving the state GHG emission reduction targets: to reduce emissions to 1990 levels by 2020, 25% below 1990 levels by 2035, and 50% below 1990 levels by 2050.[9]

---

[8] In this chart, each vertical bar represents an individual facility, with facilities organized from least emissions intensive on the left to most emissions intensive on the right. The horizontal (x-axis) can be defined simply as the cumulative number (or percent) of facilities, the cumulative production, the cumulative emissions, or the cumulative energy, depending on the intent of the benchmarking curve. The curve here is depicted as if the axis is cumulative share of facilities, which, if all the facilities produced the same quantity of output, would also equal cumulative production.

[9] As specified in Revised Code of Washington (RCW) 70.235.020 (2008): http://apps.leg.wa.gov/RCW/default.aspx?cite=70.235.020

We intend the primary audience for the *White Paper* to be policymakers, industries to which GHG benchmarks may apply, and other interested stakeholders. While we place a particular focus on the needs and opportunities with respect to Washington State, much of the discussion may also apply to broader policy dialogues and decisions in the Western Climate Initiative and U.S.

This *White Paper* is currently in draft form. We invite your comments on this draft by Friday, June 4, 2010. Please send comments via email to benchmarking.wa@sei-us.org. This document will be finalized by late June 2010.

2. Summary of Current Policy Approaches

Broadly speaking, greenhouse gas benchmarks are metrics that enable the assessment of GHG emissions performance across facilities or against a common standard. Benchmarks have been used in each of three leading policy approaches to reducing industrial GHG emissions: voluntary performance goals, cap-and-trade programs, and emission performance standards. This section describes these policy approaches and how benchmarks have been developed and applied in each approach.

Voluntary Performance Goals

Voluntary industry efforts to benchmark and reduce greenhouse gas emissions have been underway for several years at international, national, and local levels. For example, major players in the global cement industry, organized as the Cement Sustainability Initiative, share data on emissions released per ton of cement (or clinker, a key component) so that they may compare their performance against other plants, or against an average or high-performing plant (CSI 2009). Similarly, the international aluminum industry collects and shares data on emissions of perfluorocarbon (PFC), a highly potent greenhouse gas, and has recently pledge to reduce PFC emissions by at least 50% by 2020 as compared to 2006 (International Aluminum Institute 2009).

Voluntary programs may take one of several forms (Lyon 2003):

- initiatives undertaken by industry alone (e.g., self-regulation), such as the goals announced by the Cement Sustainability Initiative and the PFC reduction goals of the International Aluminum Institute;
- negotiated agreements between government and industry, such as the US EPA's Climate Leaders program; or
- public voluntary programs (e.g., ENERGY STAR) in which governments provide technical assistance and publicity to companies that adopt and meet certain goals.

Table 1 provides a summary of examples of the latter two types of voluntary programs recently active in the U.S. Benchmark methodologies in these programs have varied widely.

Table 1. U.S. Government Programs with Voluntary GHG or Energy Performance Goals

Program	Type of Goal	Sample of Participating Organizations with Facilities in Washington State	Benchmark Methodology
US DOE Climate VISION	Sector-wide improvement in energy or emissions intensity relative to value in some base year	▪ American Chemistry Council ▪ American Forest and Paper Association ▪ American Iron and Steel Institute ▪ Portland Cement Association	Unclear. Appears to be defined by each participating industry association.[10] Not a true benchmark since no comparison between facilities, though progress tracked in terms of emissions (or, in some cases, energy) per unit of physical or economic output.
US EPA Climate Leaders	Company-specific absolute GHG reduction that significantly outperforms a pre-defined sector benchmark[11]	▪ Alcoa ▪ Ash Grove Cement ▪ Boeing Company ▪ ConAgra ▪ Kimberly-Clark Corporation ▪ Lafarge North America ▪ Saint-Gobain Containers ▪ Tyson Foods ▪ Wafertech LLC	EPA calculates benchmark based on current and projected future GHG intensity of sector based on Department of Energy and Bureau of Labor Statistics data and models.
US EPA ENERGY STAR	Depends on individual facility. Facilities that are in the top 25th percentile nationally for energy performance receive the ENERGY STAR label / designation	▪ Ash Grove Cement ▪ ConAgra ▪ Simplot	EPA conducts a statistical analysis to determine energy use per normalized facility; specific benchmark value not available.
US EPA Performance Track (no longer active)[12]	Depends on individual facility. GHG reduction goals were common as are goals to reduce energy use by at least 10%.	▪ Wafertech LLC	Unclear. Appears to have been defined or negotiated by each participating facility.[13]
Northwest Food Processors Association and US DOE partnership	Reduce industry-wide energy intensity by 25% in 10 years and 50% in 20 years	49 facilities in Oregon and Washington (facility names and locations undisclosed)	Still under development. Completed energy audits and tested baseline methodologies in 2009.

Europe also has significant experience with voluntary GHG reduction goals particularly those agreements negotiated between governments and industries. For example, the German government and industrial sector organizations agreed to emission reduction targets in 2000.

Belgium and the Netherlands have also developed voluntary industrial covenants. These countries negotiated reduction targets with industry on a company level. By 2012, companies are to achieve an energy efficiency target comparable to the 10% most efficient installations worldwide. The companies must enact energy efficiency plans, which are subject to external verification, and report their progress annually. Table 2 summarizes the German, Dutch, and Flemish voluntary industry benchmarking programs.

[10] Per www.climatevision.gov.
[11] From 2002 to 2009, goals could be absolute or intensity-based.
[12] EPA's Performance Track program operated between 2000 and 2009.
[13] The EPA Performance Track program concluded in 2009. Methodology details could not be located on the EPA website.

Table 2. European Government Programs with Voluntary GHG or Energy Performance Goals

Program	Type of Goal	Sample of Participating Organizations	Benchmark Methodology
Voluntary commitment of German industry of 9th November 2000	Sector-wide improvement in emissions intensity relative to historic emissions / specific emissions depending on sectors	▪ Federation of German Industries ▪ Steel Industry ▪ Chemical Industry ▪ Power production	Not technically benchmarks, since sector-wide goal relative to historic emissions. Emission reductions are not reported on a company level, but by the sector organization.
Energy Efficiency Benchmarking Covenant (Dutch Benchmarking Committee 1999)	Company-should reach the energy efficiency of the best international standard (defined as energy efficiency of the top 10 %)	▪ Netherlands Chemical Industry Federation ▪ Netherlands Iron and Steel Producing Industry Association ▪ Non-Ferrous Industry Association ▪ Petroleum Industry Association	▪ Determination of the best international standard regarding energy efficiency. ▪ Companies draw up energy efficiency plans. ▪ Checked by independent authority. Annual reporting of companies to competent authority.
Flemish Energy Benchmarking Covenant (Flemish Benchmarking Commission 2010)	As in the Netherlands	As in the Netherlands	As in the Netherlands

Voluntary approaches have generally been perceived as being more acceptable to industry actors than regulatory or even market-based approaches to reducing greenhouse gases. Analyses of the success of voluntary environmental programs, however, have found that in general they have not and cannot attain levels of emissions reduction comparable to market-based or regulatory approaches (Lyon 2003; Morgenstern and Pizer 2007). When voluntary efforts have failed to meet their goals, some governments have pursued other policy approaches. For example, in the German voluntary program described above, when GHG reduction targets were not met in 2003 and 2004, Germany introduced a more ambitious cap into its cap-and-trade program in 2006 (German Federal Ministry of the Environment 2006). Despite their limitations, voluntary programs can help build technical capacity and early action towards eventual transition to a more comprehensive policy approach.

Market-Based Approaches

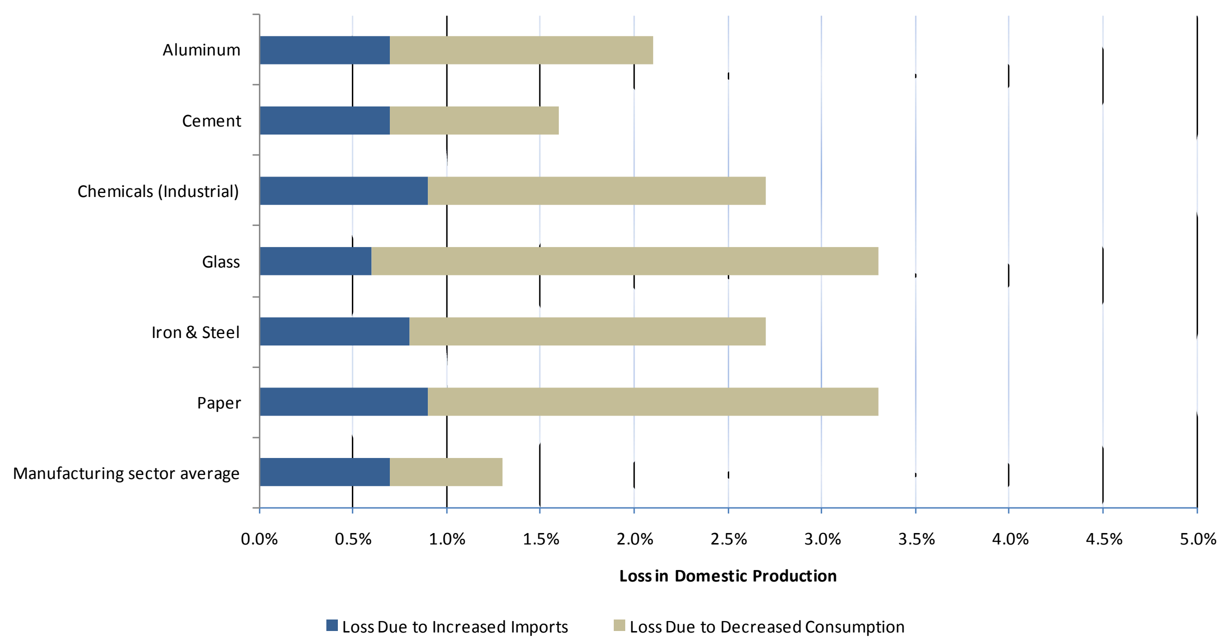
A cap-and-trade program is a market-based program to limit greenhouse gas emissions. These types of programs are being implemented in the U.S. East Coast and Mid-Atlantic states through the Regional Greenhouse Gas Initiative (RGGI), in Europe, through the EU Emission Trading System (EU ETS), and in the state of New South Wales, Australia through its Greenhouse Gas Abatement Scheme. The Western Climate Initiative, which comprises four Canadian provinces and seven U.S. states including Washington, is currently developing the detailed design for a regional cap-and-trade system, as are the states involved in the Midwest Greenhouse Gas Reduction Accord (MGGRA).

At the national level, proposed federal legislation that would establish a cap-and-trade system for large GHG emitters has been under consideration for many years, most recently in a Senate bill drafted by Senators Kerry, Graham, and Lieberman that is currently being evaluated by US EPA in preparation for possible debate on the Senate floor in late spring or early summer 2010. While the RGGI system currently covers only electric generators, most of the other GHG cap-and-trade programs proposed or underway also include large industrial sources.

Some industries – particularly those that are energy-intensive and sell their products in highly global markets – have raised concerns that a cap-and-trade program could disproportionately increase their costs and, in turn, potentially impact their competitiveness in the global marketplace. Furthermore, if implementation of a cap-and-trade program led industry to relocate its activities or investments to other regions or countries without comparable greenhouse gas regulations, emissions "leakage" could occur, compromising the environmental effectiveness of the greenhouse gas cap.[14] For example, recent economic modeling suggests that unless some counteracting policy was implemented, a cap-and-trade program on greenhouse gases in the U.S. could lead to declines in domestic production of between 0.5% and 1.0% for several industrial sectors due to international competition (Aldy and Pizer 2009). This shift of production to other countries would also result in increased emissions in those countries and possibly to increased global emissions if the emissions intensity of production in that other country was higher than in the U.S.

Economists have developed predictions of competitiveness impacts for several energy-intensive sectors. We display one such set of predictions in Figure 2, which indicates that a $15 carbon price in 2012 is predicted to lead to a 0.5-1.0% loss of domestic production in favor of foreign imports in some industry sectors. Economists also predict that a cap-and-trade program would decrease consumption of these energy-intensive goods, since some fraction of the carbon price could be expected to be passed on to consumers. As displayed in Figure 2, reduced consumption is expected to have a greater effect on industry production levels than is increased competition from foreign imports, with total impacts from both increased competition and decreased consumption less than 3% in most sectors.

Figure 2. Predicted Impacts on Industrial Production Resulting from a $15 per ton CO_2 Allowance Price in 2012 without Output-Based Rebates (Aldy and Pizer 2009)



As seen in Figure 2, economists expect the effects of increased costs on domestic production to vary by industry. Among the factors that help explain these differences are (US EPA, US EIA, and US Treasury 2009) are:

- Production cost advantages: differences among countries in terms of access to inexpensive raw materials, highly skilled or low-cost labor, or advanced technologies that may provide cost advantages greater than any increased cost of production resulting from the cap-and-trade program;

[14] Emissions "leakage" would occur if implementation of a greenhouse gas policy (e.g., cap-and-trade legislation) were to induce industry sectors to replace domestic production with imports or to relocate production to foreign countries. If that were to occur, emissions would increase in the other country, resulting in emissions "leaking" from the domestic to the foreign country (Dröge et al. 2009).

- Large, fixed, capital investments: the extent to which increased production costs in the US might influence where new manufacturing facilities are located; and
- Transportation costs: the degree to which transportation costs for inputs and outputs influence the competitive position of the industry.

Benchmark-based Allowance Allocation in Proposed U.S. Cap-and-trade Legislation

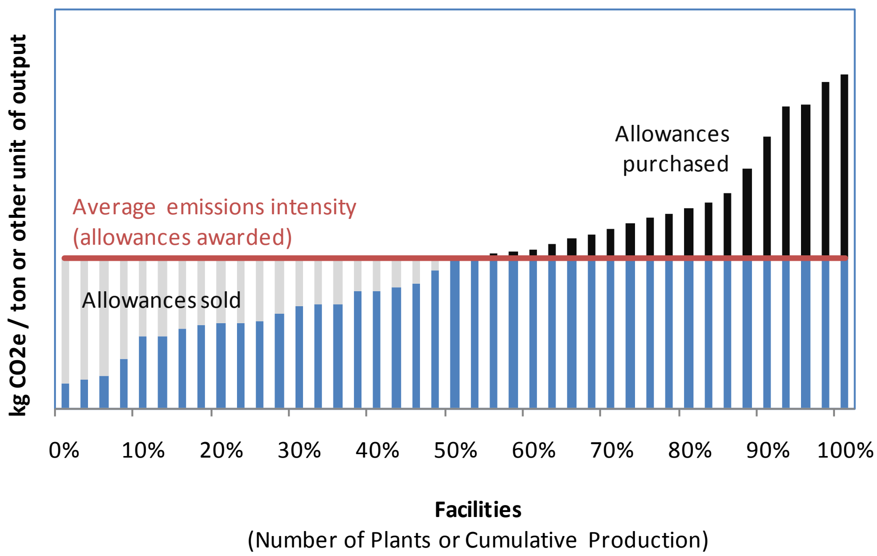
To help address concerns regarding industrial competitiveness, some observers have suggested that emissions allowances, the tradable commodity in a cap-and-trade system, be freely allocated to emissions-intensive, trade-exposed (EITE) industries. The *American Clean Energy and Security Act* (i.e., "Waxman-Markey"), which passed out of the U.S. House of Representatives as H.R. 2454 in June 2009, provides for allowances to EITE industries on the basis of a benchmark emissions level defined as the sector's average direct emissions per unit of production output.[15] Allowances are also rebated for indirect emissions (i.e., emissions released to produce purchased electricity or heat) based on a similar sector-average calculation.[16] The Senate bill drafted (but not introduced at the time of this writing) by Senators Kerry, Graham, and Lieberman is expected to include some similar provisions. Each individual facility in an EITE sector would receive free allowances based on the facility's output times the average emissions intensity of the sector (the benchmark).[17] Facilities with an emissions intensity below the average (more efficient or lower emitting facilities) would receive more allowances than they would need to cover their emissions and would therefore have extra allowances to sell. As shown in Figure 3, facilities with emissions above the average (less efficient or higher emitting facilities) would need to purchase allowances.

[15] See Section 761, page 1081, of H.R. 2454 as passed by the House of Representatives. In H.R. 2454, benchmarks are called "carbon factors." A similar approach to benchmarking was included in the Kerry-Boxer bill passed out of committee in the U.S. Senate in fall, 2009.

[16] Direct emissions are those released by sources owned or controlled by an entity, for example by the combustion of fossil fuels to fuel a boiler or the release of $CO_2$from limestone calcinations at a cement kiln. Indirect emissions are those released as a consequence of the activities of an entity but occur at sources not owned or controlled by the company (WBCSD and WRI 2004). The most commonly tracked source of indirect emissions is electricity production.

[17] The Waxman-Markey and Kerry-Boxer bills include allowance rebates to energy-intensive, trade-exposed (EITE) industry. EITE eligibility is determined according to criteria of energy or greenhouse gas intensity and trade intensity. Energy intensity is equal to a sector's energy expenditures divided by the dollar value of its shipments; GHG intensity is calculated the same way except that GHGs are monetized at $20/ton. Any sector that has an energy or GHG intensity of 20% or more is automatically an EITE industry. Otherwise, sectors that have an energy/carbon intensity greater than 5% and a trade intensity (defined as the sum of the value of imports and exports divided by sum of value of shipments and imports) greater than 15% are considered EITE. The actual benchmark value is calculated as the average direct and indirect emissions per unit of output (tons or a similar physical measure of output) for all entities in each eligible sector over the prior four years. Eligible entities are awarded allowances based on this benchmark multiplied by the average output in the two years preceding the allowance distribution. For further details on how EITE sectors are defined, benchmarks calculated, and allowances allocated, see EPA, EIA and Treasury (2009), Schneck, Murray, Mazurek and Boyd (2009), Tonkonogy (2009), or Bradbury (2009), or Section 764 of the final version of H.R. 2454 as passed by the House of Representatives in June 2009.

Figure 3. Simplified Diagram of Benchmark-based Allowance Allocation to EITE Industry Sectors in H.R. 2454 for a Given Sector or Subsector

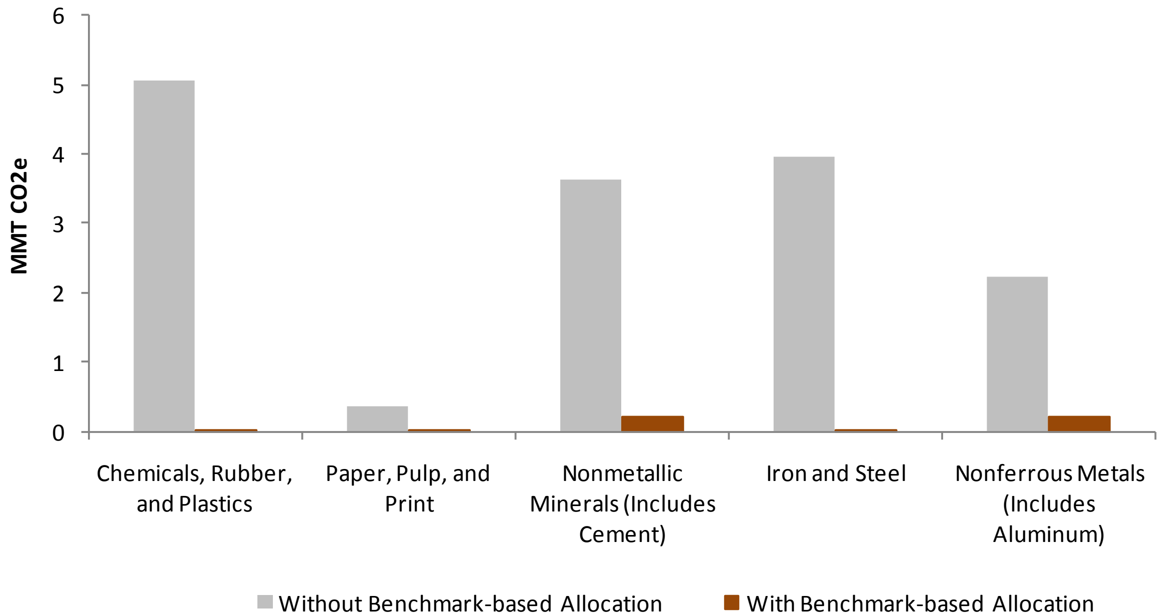


Economic modeling suggests that such output-based, or benchmarking, approaches to freely allocating allowances can effectively address industry competitiveness concerns, negating the potential impacts discussed above and summarized in Figure 2 (US EPA, US EIA, and US Treasury 2009; Fischer and Fox 2007; Fischer and Fox 2009). Analyzing the EITE provisions of H.R. 2454, a U.S. interagency report found that the free, output-based allocation of allowances "can eliminate almost all – and, in some cases, potentially more than all – of those cost impacts, as well as the resulting changes in net imports and emissions leakage"(EPA, EIA, and Treasury 2009).

Figure 4, below, displays results from the interagency study for five industrial sectors. Without the benchmark-based allocation (and companion free allowance allocation to electricity and natural gas local distribution companies), emissions leakage to developing countries is predicted to be many millions of tons of GHGs.[18] With the allocation, this leakage is predicted to be almost completely eliminated.

[18] The authors of the U.S. interagency report focused on leakage to developing countries based on the assumption that other major OECD trading partners (e.g., Canada, Mexico, Europe) would adopt comparable regulations, minimizing risks of leakage to and from these countries.

Figure 4. Estimated Emissions Leakage to Developing Countries from U.S. Energy-intensive Trade-Exposed Industries under H.R. 2454 without and with Benchmark-based Allowance Allocation (US EPA, US EIA, and US Treasury 2009)[19]



Despite the apparent benefits of free allocation of allowances via output-based benchmarks, tradeoffs do exist. In particular, freely allocating allowances to industry can substantially diminish the price signal to firms to reduce GHG emissions, the central goal of the cap-and-trade program (Schneck et al. 2009; Matthes et al. 2008). Freely allocating allowances also foregoes the opportunity to use that allowance value for "other uses, including support for low income consumers, clean energy technology, or deficit reduction" (US EPA, US EIA, and US Treasury 2009).

As an example of a benchmark-based allocation to an energy-intensive, trade-exposed industry, consider the cement sector. H.R. 2454 calls for emissions benchmarks to EITE sectors to be calculated "every 4 years, using an average of the four most recent years of the best available data" (Waxman and Markey 2009, 1111). Table 3, below, shows estimated emissions and production data for the U.S. cement industry for the four most recent years for which data are available as of the writing of this *White Paper*. The table includes both direct and indirect emissions for the cement sector as calculated by EPA, EIA, and Treasury in their Interagency Report (2009) from the national U.S. GHG inventory and the Energy Information Administration's Manufacturer Energy Consumption Survey. These underlying data sources – and the subsequent calculations in the Interagency Report – are calculated at an aggregate sector level and include significant assumptions and uncertainties. Nevertheless, we use these data here to provide a numerical example based on publicly available information. Actual benchmark development would likely require facility-level data to increase accuracy and enable construction of benchmark curves (as in Figure 1) or other statistics that would enable comparison across facilities.

Using the requirements in H.R. 2454 and these data, we estimate that the benchmark for direct emissions (i.e., process CO_2 and combustion-related GHGs) for the U.S. cement sector would therefore be approximately 0.78 tCO_2e per metric ton of cement produced.[20] The calculation of indirect emissions intensity would be a more

[19] The Waxman-Markey bill also includes free allocation to electricity and natural gas local distribution companies (LDCs) that would benefit energy-intensive and trade-exposed industries. In Figure 4, these LDC allocations are included in the results labeled "with benchmark-based allocation" and not in the results labeled "without benchmark-based allocation."

[20] Note that this benchmark calculation is denominated in metric tons of cement per the specifications of H.R. 2454 (page 1092). However, many stakeholders and analysts have recommended that benchmarks be based instead on clinker, the key, energy-intensive component of cement. Note also that data points in Table 3 are taken from public sources and in some cases are estimated. Since these may not be the exact same data sources or years ultimately used under any U.S. climate legislation, this calculation is approximate and for demonstration purposes only.

complicated calculation involving national average energy intensity multiplied by the GHG-intensity of each facility's electricity supply and is not displayed here.

Table 3. Sample Benchmark Calculation for Cement Sector under Waxman-Markey (H.R. 2454)

Year	GHG Emissions (MtCO2e)					Cement Production	Direct Emissions Intensity
	Process[21]	Combustion[22]	Total Direct	Indirect [22]	Total Direct + Indirect	Million Metric Tons[23]	tCO2e per ton of cement
2005	46	32	77	8	85	99	0.78
2006	47	31	78	8	85	98	0.79
2007	45	30	75	7	82	95	0.78
2008	41	27	68	7	74	86	0.78
						Direct Emissions Benchmark (Average over Four Years):	**0.78**

Under a cap-and-trade program with benchmark-based allocation similar to H.R. 2454, each individual facility would receive an allocation of allowances equal to its level of production (averaged over the two years preceding the distribution) multiplied by this direct emissions benchmark. For example, suppose that allowances were to be distributed in the year 2012,[24] that the benchmark value was 0.78 tCO_2e per ton of cement (as in Table 3), and cement production at a cement production facility averaged 400,000 metric tons in 2010 and 2011 (the two years preceding the distribution in 2012). This cement facility would therefore receive an allowance allocation as follows:

Benchmark value *(0.78 tCO_2e/ton cement) x* ***Production*** *(400,000 tons) =* ***Allocation*** *(312,000 allowances).*

The number of allowances allocated (312,000) may be more or less than the actual emissions released by the plant. If more, then the facility would have extra allowances to sell; if less, it would have to buy allowances. For example, suppose that this cement facility emitted 350,000 tCO_2e of emissions in 2012. With a free allocation of 312,000 allowances, the facility would need to purchase the remaining 38,000 allowances from the cap-and-trade market (or else reduce emissions by a corresponding amount). If, on the other hand, the facility emitted 300,000 tCO_2e, then the facility would have an extra 12,000 allowances to sell or bank for use in future years.[25]

The benchmark-based allocation for indirect emissions would be similar. Under H.R. 2454, the indirect emissions benchmark is calculated as the sector-wide average electricity intensity multiplied by an entity-specific electricity emissions factor. Using national (rather than facility-specific) data, this value would be expected to average about 0.08 tCO_2e per ton of cement (i.e., 7 $MtCO_2e$ divided by 86 million tons in 2008 per Table 3). The allocation is then calculated by multiplying by the production level (in this example, 400,000 tons).

In addition to proposed federal climate legislation, the State of California has proposed implementation of a cap-and-trade program. Its state-appointed Economic and Allocation Advisory Committee recently recommended output-based free allocation, which would require the development and use of benchmarks to the extent needed for the purpose of addressing emissions leakage associated with energy-intensive trade-exposed industries (EAAC 2010).[26]

---

[21] Process emissions from cement production are taken from EPA's *Inventory of Greenhouse Gas Emissions and Sinks: 2000-2008* (2010c).
[22] Combustion and indirect emissions for the cement sector in 2006 are taken from US EPA, US EIA, and US Treasury (2009). Emissions for 2005, 2007, and 2008 are estimated here by SEI based on adjusting the 2006 values based on estimated annual energy intensity improvements for the U.S. cement industry reported in Dutrow et al (2010).
[23] Per the USGS Annual *Mineral Commodity Summary*: http://minerals.usgs.gov/minerals/pubs/commodity/cement/mcs-2010-cemen.pdf. Cement production here includes cement produced using imported clinker.
[24] The Waxman-Markey bill proposed to include most industrial sources beginning in 2014, but we use 2012 here for simplicity.
[25] Note that since the allocation is based on production in the two years prior to the distribution, an increase in production in the year of the distribution would not be figured into the allocation and could leave even the average producer with fewer allowances than emissions in that year. Similarly, a decline in production would result in too many allowances.
[26] In addition, the Portland Cement Association (PCA) has proposed that California adopt a "Cement Intensity Factor" as a tradable performance standard (Portland Cement Association 2009). Under a tradable performance standard, plants with performance less than the carbon intensity factor would generate a tradable credit, while plants with performance above the carbon intensity factor would have to purchase credits

Benchmark-based Allowance Allocation in the European Union

Benchmarks will be the basis for distributing free allowances to industry in the upcoming third phase of the European Union's Emissions Trading System, which begins in 2013. The EU-ETS Directive, adopted in late 2008, sets the broad framework for establishing these benchmarks. The Directive specifies that the benchmarks be based on "the average performance of the 10% most efficient installations in a sector or sub-sector" in the years 2007 and 2008 (European Union 2008).[27]

The EU will decide on final benchmark values for the EU-ETS in 2010. In order to facilitate the development of these benchmarks, the European Commission has developed a set of benchmarking criteria. For example, the criterion "one product, one benchmark" means that among facilities that produce the same product, there will be no disaggregation according to technology, process, fuel choice, or age of facilities. Prior to 2012, the EU will decide on the measure of physical output to use in conjunction with these benchmarks in order to determine the number of allowances each facility will receive.[28]

Emissions Performance Standards

While EPA and many stakeholders have expressed a preference for a market-based approach to reducing greenhouse gases (e.g., cap-and-trade), regulatory emissions performance standards continue to be considered and advanced as a "backstop" policy, should market-based approaches fail to be implemented (Alsalam 2009; Richardson, Fraas, and Burtraw 2010). In particular, EPA's December 2009 finding that greenhouse gases "endanger both the public health and the public welfare of current and future generations" may ultimately require EPA to regulate greenhouse gases from industrial facilities and other stationary sources under the Clean Air Act (Richardson, Fraas, and Burtraw 2010; US EPA 2009c). Accordingly, below we briefly describe possible means of developing and applying greenhouse gas emissions performance standards in a regulatory context.

Broadly speaking, regulations on GHG emissions from stationary, industrial facilities could be developed using one of two approaches. The first approach is to identify particular, sector-specific emissions benchmarks in terms, such as of tons CO_2e per unit of output, that must not be exceeded. This approach has already been taken in Washington State for baseload electric generation, per Senate Bill 6001 in 2007, which imposed an emissions performance standard (a benchmark of 1,100 pounds CO_2 per megawatt hour) that has to be met by all qualifying facilities. The second approach is to define a particular set of technological controls – such as best available control technology (BACT) – that must be implemented by a specific facility. These approaches are not mutually exclusive. For example, a BACT may be defined as a specific technology based on that technology's ability to meet a particular emissions benchmark. Below we discuss the possible development and application of the GHG benchmark-based approach under EPA's existing permitting systems. Box 1 describes the relationship of how this process could require a technology-specific approach under determinations of BACT.

Section 111 of the Clean Air Act authorizes EPA to set New Source Performance Standards (NSPS) for emissions from *new* or substantially modified sources based on best demonstrated technology (Alsalam 2009; Nordhaus 2007; Parker and McCarthy 2009). Section 111(d) also authorizes EPA to require states to regulate emissions from certain kinds of *existing* sources (covering non-criteria, non-hazardous air pollutants) for which it has promulgated an NSPS. In this case, EPA issues guidelines for these sources that are implemented by states. Accordingly, EPA and states could require both new and existing facilities, including power plants, refineries, and other industrial facilities, to achieve compliance with specific emissions limitations – for example, a benchmark quantity of GHG

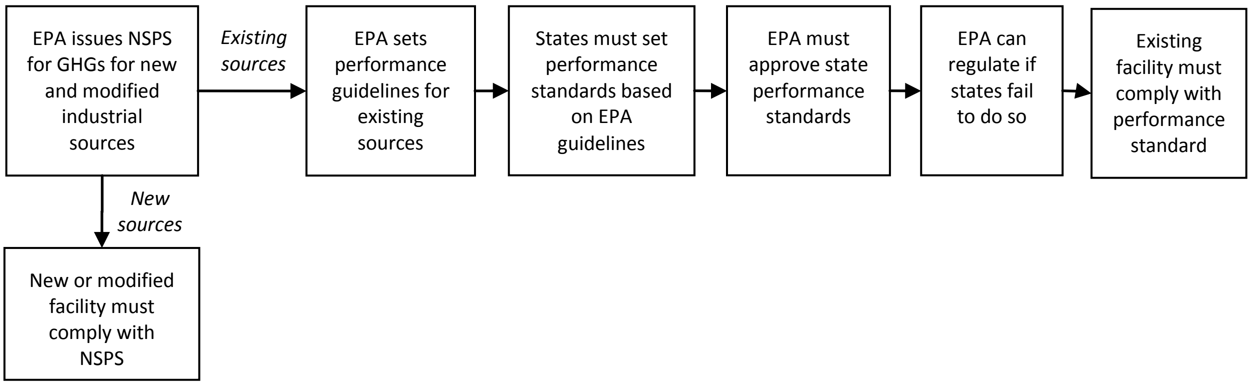
(Fischer 2003). In the absence of a cap, however, overall emissions could rise over time under a tradable intensity standard approach, if and as production increases.

[27] This level of ambition of the benchmark was agreed very early in the process. Since that time, the debate has focused on key methodological issues.

[28] In the EU, benchmarks will be in units of emissions per physical output (e.g., tons) and calculated based on performance of the 10% most efficient installations in 2007 and 2008 (European Union 2008). To translate this benchmark into an annual allocation of allowances, the benchmark must be multiplied by annual physical output. The rules for calculating physical output have not yet been agreed. The current proposal is use average production from 2005 to 2008 as the basis for "physical output."

emissions per unit of physical output of the facility (US EPA 2008b). Figure 5 displays the steps in the process of how the issuance of an NSPS for GHGs for an industrial source could translate into regulations on existing facilities.

Figure 5. Regulating GHGs from Industrial Facilities Under Section 111(d) of the Clean Air Act
Adapted from Richards, Fraas, and Burtraw (2010)



Section 111 of the Clean Air Act gives EPA significant flexibility in defining NSPS, including who is subject to the standards, when the regulations are phased in, the units and stringency of the standard, and, potentially, what emission-control systems are required. Accordingly, the process for developing greenhouse gas NSPS for industrial facilities is not immediately clear. EPA has stated that they "would need to consider how to develop a metric for measuring and benchmarking" GHG emissions "in terms of the facility's output production (e.g., amount of GHG per unit of production for a given facility)" (US EPA 2008b).[29] Whether EPA takes such an approach for greenhouse gases remains to be seen. EPA has shown a tendency to move towards more output-based standards under NSPS. For example, EPA has proposed, in its updates to the Portland cement NSPS, to switch the NSPS from being based on tons of input to tons of output (clinker): "Adopting an output-based standard avoids rewarding a source for becoming less efficient, i.e., requiring more feed to produce a unit of product, therefore promoting the most efficient production processes" (US EPA 2008c, p. 34076).

EPA is statutorily required to review NSPS every eight years. Development and inclusion of emissions performance standards for greenhouse gases would likely occur during these reviews (US EPA 2008d). In 2010, EPA is revising its NSPS for cement, expected in June. Some observers have speculated that EPA will include greenhouse gas emissions in the revisions (Bravender 2009). EPA has requested budget from Congress for funds to develop GHG NSPS for stationary sources, suggesting they do intend to develop NSPS for GHGs in the near future.[30] EPA staff have suggested that the June revisions to the Portland Cement NSPS will not include actual GHG standards for cement kilns, but instead will include some general statement about EPA's views on GHGs (EPA Office of Air and Radiation staff, personal communication, April 2010). If EPA does not include GHGs in the revised cement NSPS, some observers expect a legal challenge, as was the case in 2008 when EPA did not include GHGs in its updated NSPS for petroleum refineries (Richardson, Fraas, and Burtraw 2010).

Federal New Source Performance Standards set a performance floor for permitting in the New Source Review program under Section 111 of the Clean Air Act. Implementation of the New Source Review permitting program (involving case by case determination of best available control technology, or BACT) is carried out by state and local air pollution control agencies, such as the Washington State Department of Ecology and the Puget Sound Clean Air Agency. The Department of Ecology and most local air agencies in Washington have adopted most of the federal New Source Performance Standards covering other pollutants by reference. Washington State and local air

[29] EPA also discussed potential approaches in individual sectors. For example, regarding the petroleum refining sector, EPA states, "We are aware of proprietary metrics that exist that are used by refiners to benchmark their operations with respect to GHG emissions; however the use of a proprietary metric is problematic from a rulemaking perspective. We believe that a more transparent metric is desirable that could be used to describe the amount of GHG per unit of production for a given refinery" (US EPA 2008b, 21). For a list of existing NSPS for other pollutants, see: http://www.epa.gov/ttn/atw/nsps/nspstbl.html.
[30] See http://www.whitehouse.gov/omb/budget/fy2011/assets/environmental.pdf.

agencies in the state have adopted several output-based performance standards for other pollutants, as summarized in Table 4, indicating a precedent for such an approach in Washington.[31]

Table 4. Sample of Existing Output-based Emissions Performance Standards for Industrial Facilities in Washington
(Including examples from both State regulations and local permits)

Sector	Pollutant	Sub-sector or Process	Benchmark	Jurisdiction	Source of Regulation or Permit
Aluminum	Particulate matter (PM)	Primary aluminum	7.5 grams PM per kilogram of aluminum produced	Washington Department of Ecology	WAC 173-415-030
Electricity	Greenhouse gases ($CO2_e$)	Baseload thermal-electric generation facilities	1,100 lb CO_2e per MWh	Washington Department of Ecology	WAC 173-407-130
Glass	Particulate matter (PM)	Container glass (St. Gobain Containers)	0.5 lb PM_{10}/ton of glass produced	Puget Sound Clean Air Agency	Puget Sound Clean Air Agency Order of Approval No. 5193 and 5289
Iron & steel	Nitrous oxides	Electric arc furnace (Nucor Steel)	0.48 lb NO_x per ton of steel produced	Puget Sound Clean Air Agency	Puget Sound Clean Air Agency Order of Approval 9669
Pulp & paper	Sulfur dioxide (SO_2)	Sulfite pulping mills that incinerate spent sulfite liquor	10 g SO_2 / kg pulp produced[32]	Washington Department of Ecology	WAC 173-410-040

As discussed above, federal NSPS apply only to new and modified sources. Section 111(d) of the Clean Air Act also allows EPA to regulate *existing* sources under the NSPS program.[33] Under Section 111(d), the Clean Air Act would require EPA to set performance guidelines (similar to, but likely less stringent, than NSPS) for existing sources and then for the states (or EPA if a state were to fail to act) to create actual performance standards and submit plans to implement the standards (Richardson, Fraas, and Burtraw 2010). If as part of the NSPS proposal for cement plants, EPA were also to issue an emission guideline that addresses GHG emissions from existing facilities, then the state would have to adopt the guideline as a rule, develop a substitute state rule, or wait for EPA to issue the an EPA-implemented rule.

[31] Performance standards are not always based on output (i.e., benchmarks). Instead they can be in terms of concentration of pollutant from a stack. For example, WAC 173-415-030 specifies that SO_2 emissions from primary aluminum facilities must not exceed one thousand parts per million in any gas, in addition to specifying a benchmark-based standard of 30 g SO_2 per kg aluminum produced.
[32] Air dried, unbleached pulp.
[33] The authority to regulate existing sources using performance standards only applies if the pollutant is not regulated under the National Ambient Air Quality Standards (NAAQS) or as toxic pollutants under Section 112 of the Clean Air Act. Each of these has been discussed as an alternative or complementary pathway to regulating GHGs but are generally considered less feasible than NSPS. Nevertheless, this restriction on applying NSPS to existing sources may limit options for integrated approaches that combine regulation under different provisions of the. Clean Air Act (Richardson, Fraas, and Burtraw 2010).

Box 1. New Source Performance Standards and Best Available Control Technology (BACT)

New Source Review is the process for obtaining construction permits for new and modified stationary sources under the Clean Air Act and is sometimes also called Prevention of Significant Deterioration (PSD). Under the New Source Review (NSR) program:

1. **EPA establishes New Source Performance Standards (NSPS) for new and modified sources**.
2. **A new or modified facility emitting more than the pollutant threshold applies for a permit to a state or local air agency and must undergo preconstruction review and permitting.** EPA's proposed "tailoring rule" (US EPA 2009a) would raise the threshold to 25,000 tons CO_2e annually and shield small stationary sources. EPA Administrator Lisa Jackson has since proposed that this limit be raised to a "substantially higher" threshold and that the "smallest sources" not be subject to permitting before 2016 (Jackson 2010).
3. **The state or local air agency determines Best Available Control Technology (BACT) on a case-by-case basis**, taking into account energy, environmental, and economic impacts. Determinations of BACT must be at least as stringent as the NSPS.

Determination of BACT for GHGs will soon be required under the NSR program. In April 2010, EPA issued final rules that set GHG emissions and mileage standards for cars and light trucks (US EPA and US DOT 2010). These rules trigger regulation of GHGs for stationary sources under NSR and will require that major new or modified sources install BACT (Pew Center on Global Climate Change 2010). EPA has stated that limits (or related "work practice standards") for GHGs will be required in PSD permits for stationary sources on January 2, 2011 (US EPA 2010b).[1]

The definition of BACT for greenhouse gases at stationary sources is a major unknown, and defining what technologies qualify as BACT could be an enormous challenge. The normal process for determining BACT is to:

1. Identify all control options
2. Eliminate technically infeasible options
3. Rank remaining control options
4. Eliminate control options based on evaluation of collateral impacts
5. Select BACT

The difficulties of this task for GHGs were pointed out in a report from an EPA advisory committee. The interim report, by thirty-five representatives from industry, state and local governments, and environmental and public health non-profit organizations, identified several areas of contention on defining BACT for GHGs, including how tightly to draw the boundary around what emissions are regulated, criteria to use to determine whether a technology is feasible, and criteria for eliminating particular control technologies from consideration (Clean Air Act Advisory Committee 2010).

Some initial lessons may be drawn from the first facility in the U.S. to undergo a BACT determination for GHGs: the Russell City Energy Center, a combined cycle natural gas-fired power plant in Hayward, CA, which underwent the 5-step process above (Calpine 2010). In particular, that facility defined BACT as a net energy efficiency value expressed as a benchmark value of emissions (1100 lb CO_2/MWh, the California GHG emission performance standard for power plants). This value was not the maximum possible efficiency but was instead a level that could be consistently maintained under all operating conditions.

In addition, EPA is also considering means of providing incentives for continuous improvement and energy efficiency within definitions of BACT for greenhouse gases. These enhancements are being considered to help encourage performance beyond what is required by BACT and between upgrades to the definition of BACT.

Summary: Benchmarks in the Three Policy Approaches

Emissions benchmarks are used in each of the three policy approaches discussed above. For example,

- Member companies of the International Aluminum Institute (IAI) have committed to operate by 2020 with perfluorocarbons (PFC) emissions per ton of aluminum no higher than the 2006 global median level for their technology type. Alcoa, for example, is a member of the IAI, and its Washington facilities already exceed these targets. The IAI goals are an example of a voluntary, unilateral initiative undertaken by industry to reduce emissions of one highly potent GHG below a benchmark level.
- The Waxman-Markey bill, which passed out of the U.S. House of Representatives in June 2009, would allocate allowances to energy-intensive, trade-exposed industries at the level of a sector-average benchmark. For example, cement kilns would receive a number of allowances for each ton of cement produced to cover their direct emissions. This is an example of the use of benchmarks in a cap-and-trade program.
- Washington State has set a limit on the release of sulfur dioxide emissions from sulfite pulp mills of 10 grams of SO_2 per ton of pulp produced. This is an example of a mandatory performance standard on emissions.

The process for developing benchmarks such as these in the three different policy contexts share many common traits, issues, and options. In the following section, we describe several issues and options for constructing greenhouse gas benchmarks for industry and assess how these factors – and the process for constructing benchmarks – might differ according to the policy approach selected.

3. Benchmark Construction: Issues and Options

In this section, we discuss and assess several key issues and options for constructing GHG benchmarks for industry. These include:

- **Definition of product or sector being benchmarked**, including factors to consider in determining whether benchmarks are assigned at a sector-wide level (e.g. pulp and paper) or instead for particular products, processes (e.g., sulfite pulp), or other facility-specific factors;
- **Measurement protocol and boundaries**, such as whether to focus benchmarks on direct emissions only or all emissions (including the indirect emissions associated with purchased energy, such as electricity);
- **Units for normalizing the benchmark**, meaning alternative choices for benchmark denominator, such as tons of output, dollars of output, or tons of input;
- **Benchmark ambition**, or whether to make the benchmark based on an average across facilities or instead some better-than average value; and
- **Data sources** that may support development of benchmarks.

At the end of the section, we reflect on how the different policy approaches described in Section 2 – voluntary goals, output-based allocation in a cap-and-trade program, and emission performance standards – might affect how benchmarks are constructed. We also describe a potential alternative to benchmarking particular products or sectors: benchmarking heat production, an activity that extends across sectors.

Definition of Product or Activity Being Benchmarked

Benchmarks can be developed for entire industries (e.g., the global steel industry) or for individual plants with particular fuel choices and feedstocks (e.g., a steel plant with an electric arc furnace that uses 100% scrap steel). The choice of scale at which to define the benchmark – that is, the level of aggregation across subsectors, product types, technologies and other plant circumstances – is a critical design choice for ensuring that the benchmark provides an appropriate and effective incentive for reducing emissions.

Benchmarks based on an entire class of products (e.g., steel or cement) will tend to give the industry maximum long-term flexibility in reducing emissions. Under an industry-wide benchmark, industry actors could adapt by increasing the efficiency of existing plants, switching fuels from coal or oil to natural gas or low-carbon electricity, phasing out more GHG-intensive technologies in favor of less GHG-intensive technologies, or using a higher fraction of secondary (recovered) feedstock.

Consider the U.S. steel industry. The American Iron and Steel Institute reports that the U.S. steel industry emits an average of 1.24 tCO_2e per ton of steel produced (US EPA 2008a). Of the two primary types of steel mills, integrated (e.g., basic oxygen furnace or BOF) mills tend to produce much higher emissions than this average, in part because they must first convert iron to steel rather than rely on scrap steel. Electric arc furnaces (that rely on scrap steel as feedstock) produce much lower emissions (IEA 2008). Accordingly, implementing a policy approach based on a single industry-wide benchmark of 1.24 tCO_2e per ton of steel could provide a significant incentive to increase production at electric arc furnaces at the expense of production at integrated mills, provided that increased quantities of scrap steel were available to supply the electric arc furnaces.[34] Such an incentive – even as it allows maximum flexibility to the industry to make investments that cost-effectively reduce emissions – would not allow for site- or market-specific considerations and could lead to the closure of smaller, older manufacturers that cannot as readily upgrade, replace capital stock, or access supplies of alternative (e.g., recovered) feedstocks.

By contrast, a benchmark based on the specifics of individual plants may help recognize particular, site-specific conditions, but provides less incentive for larger-scale restructuring of the industry. For example, if individual benchmark-based regulatory performance standards were developed for each type of facility, each fuel choice, each type or quality of feedstock, and other site-specific parameters (such as the availability of recovered feedstocks), then the benchmark would provide relatively little (if any) incentive to alter these factors to reduce GHG emissions, leaving process efficiency improvements or minor retrofits as the only option. If site-specific benchmarks were developed in a cap-and-trade setting, then each facility would receive an allocation roughly equivalent to historic emissions, at least for the first allowance distribution period.[35] Allocating based on historic emissions ("grandfathering") has been criticized for not rewarding those facilities that have undertaken "early action" to reduce emissions before the start of the cap-and-trade program (EAAC 2010; Raymond 2003).

To address the tension between benchmark aggregation and specificity, one approach could be to develop individual benchmarks for each type of unique product produced by an industry. This approach has been employed in the European Union's cap-and-trade program, where it is has been called "one product, one benchmark." Under such an approach, only one benchmark would be developed for each product. Separate benchmarks would not be developed for different production technologies, fuel choices, type or quality of feedstock, local climate circumstances, product color, or other facility-specific factors.

For example, a benchmark on the production of writing paper would recognize the unique processes used to produce writing paper instead of another paper grade (e.g., newsprint). Separate benchmarks for different paper products would avoid incentivizing the production of one type of paper at the expense of another that could result if only one benchmark for all paper grades were applied. Even under a "one product, one benchmark" approach, however, many challenges would still remain in defining what constitutes a unique product. Although writing paper is clearly different from newspaper, cases could be made for distinguishing more specific grades of some types of paper (e.g., coated versus uncoated papers, or different types of containerboard). Similar decisions exist in most other sectors, including steel, aluminum, and chemical sectors. An additional challenge with the "one

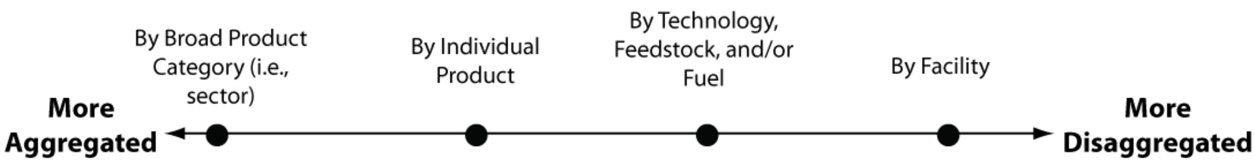
[34] The emissions benefits of an electric arc furnace (EAF) rely strongly on the use of scrap steel, of which supplies are limited. The alternative (virgin) feedstock for an EAF is direct reduced iron (DRI). According to the International Energy Agency, production of steel from DRI can be more or less emissions intensive than producing steel in a basic oxygen furnace depending on whether coal or natural gas, respectively, are used to produce the DRI (IEA 2008).

[35] Since still based on output, allocations in future years would depend on the facility to continue producing..

product, one benchmark" approach is how to develop benchmarks for facilities that produce many different products from the same process units.

Figure 6, below, displays the continuum of levels of benchmark disaggregation along with samples of the choices at each level.

Figure 6. Choices of Benchmark Disaggregation Lie along a Continuum
(With Sample Choices by Sector)



Aluminum	Cast aluminum, rolled aluminum	Anode type	e.g., Intalco, Ferndale
Cement	Clinker (white or grey)	Wet vs. dry kiln	e.g., Ash Grove Cement, Seattle
Glass	Flat, container, fiber glass	Fraction of recycled cullet used	e.g., Cardinal Glass, Winlock
Paper	Newsprint, writing paper, market pulp	Mechanical versus chemical pulp	e.g., Norpac, Longview
Steel	High-alloy steel, hot-rolled steel, cold-rolled steel	EAF vs. BOF, integrated versus rolling mill	e.g., Nucor Steel, Seattle

In a cap-and-trade program, a "one product, one benchmark" approach could help preserve a clear price signal to firms to make investments in reducing emissions. Under cap-and-trade programs like the EU-ETS and the program proposed in H.R. 2454, the program administrator would freely allocate or rebate emissions allowances to each firm according to the benchmark value. Facilities that emit more than the benchmark level would have the flexibility of purchasing allowances from the market to cover their additional emissions, while facilities that emit less than the benchmark value would have allowances to sell. Analysis conducted to support the EU's benchmark development process has found that benchmark-based allocation based on the "one product, one benchmark" concept (but not including consideration of technology or process type, fuels, or feedstock variations) best preserves the price signal to individual firms (Neelis et al. 2009).

Unlike in a cap-and-trade program, a "one product, one benchmark" approach may not be as applicable in a regulatory system using performance standards, however, unless some degree of trading or crediting was provided to the facilities to provide flexibility in meeting the benchmark.

Benchmark Disaggregation in the Three Policy Approaches

The type and extent of disaggregation for setting benchmarks can have important implications for how well the underlying policy can achieve its objectives. For example, in seeking to reduce GHG emissions, policymakers may also strive to maximize the economic efficiency of emission reductions attained, to avoid emissions leakage, and/or to manage cost burdens in an equitable manner. From an economic perspective, the rationale for disaggregating benchmarks by technology, feedstock, or fuel can differ by policy approach, as follows.

- **Cap-and-trade programs use benchmark-based allowance allocation to avoid carbon leakage while retaining an overall CO_2 price signal to incentivize lower-emissions production.** An aggregated benchmark (e.g., uniform across the industry sector) sends the same CO_2 price signal to all installations, irrespective of size, fuel, technology or age. If the benchmarks were instead highly differentiated by facility-specific factors, total economic costs of attaining a particular reduction in GHG emissions would **increase** total economic costs, since overall GHG abatement is determined by the emissions cap and awarding free allowances to facilities based on their individual circumstances diminishes the price signal to shift production from more GHG-intensive technologies, feedstocks, or fuels to less GHG-intensive technologies, feedstocks, or fuels. In other words, and in most cases, the benchmark value does not control the level of abatement. Rather, it helps avoid carbon leakage while attempting to preserve appropriate price signals to individual facilities.

- **In contrast to allowance allocation, regulatory performance standards directly determine the level of abatement. Since a performance standard also acts as a go/no-go threshold, the level of the benchmark will more directly determine whether new facilities are constructed or existing facilities continue to operate.** If the costs of abatement are different for different technologies, feedstocks, or fuels, it may be appropriate to consider more ambitious benchmarks for those with low abatement costs, and a less ambitious benchmark where abatement costs are higher. In this case, allowing for disaggregation by technology, feedstock, or fuel could **reduce** the total economic costs to achieve a given level of abatement. This outcome is more likely for existing facilities with long-lived capital investments and high switching costs. With new facilities the case for disaggregation may be less compelling.

- **In voluntary approach, the differentiating among technologies, feedstocks or fuels might encourage greater participation, especially by those companies with long-lived investments in technologies for which abatement options are more limited or costly.** Similar to regulatory performance standards, it may make sense to differentiate benchmarks if the costs of abatement are different between technologies. In this way, allowing for disaggregation can **reduce** total economic costs.

In summary, from an economic perspective, it may make more sense to disaggregated benchmarks by technology, feedstock, or fuel under voluntary and regulatory approaches, than for allowance distribution under a cap-and-trade system.

Considerations for Intermediate Products

Benchmarks are typically set on a measure of final product output, such as tons of steel or paper produced. Yet the choice of what constitutes a product is not always as easy as it seems. In some contexts, developing separate benchmarks for intermediate products (such as iron used to make steel, or pulp used to make paper) that are energy-intensive and commonly traded between firms and installations may help advance program goals.

In particular, in a cap-and-trade system, the primary motivations for free benchmark allocation is to avoid carbon leakage, while preserving the price signal and rewarding top performers that have undertaken “early action.” If the benchmark were based only on the final product, then companies could instead import the emission intensive intermediate product from non-regulated regions, therefore potentially increasing the risk of carbon leakage. To address this risk, benchmarks can be developed for emissions-intensive intermediate products that are traded between firms and internationally.

Such an approach could (but need not necessarily) be employed under a regulatory or voluntary approaches as well. Defining the benchmark on the final product only would help incentivize GHG emission reductions along the whole supply chain (including the intermediate products), allowing for greater flexibility (and, in turn, lower abatement costs) and potentially also for more ambitious benchmarks. On the other hand, calculating benchmarks for the full life-cycle emissions of an industry or facility’s products could introduce new extra methodological complexity for sectors where a significant fraction of an energy-intensive feedstock is traded between firms. For example, if paper mills were responsible for the emissions of the pulp they purchase from other facilities, new market data systems would be needed to allow pulp sellers to measure and communicate the emissions intensity of their pulp to paper makers purchasing this pulp on the market.

Table 5, below, summarizes the benefits and challenges of different levels of benchmark disaggregation discussed above.

Table 5. Benefits and Challenges of Benchmark Disaggregation

Level of Disaggregation	Benefits	Challenges
Broad product category (i.e., sector-wide) Benchmarks developed for an entire sector's output (e.g. pulp and paper)	Can be simpler than more disaggregated benchmarks. Provides maximum flexibility to industry in reducing emissions.	Smaller, older manufacturers performing far from the sector-wide average may be less able to upgrade, replace capital stock, or access alternative feedstocks. Does not recognize trade of intermediate products.
Product-specific Benchmarks developed for particular products (e.g., cardboard) but not for individual facilities	Provides greater flexibility and incentive to industry to reduce emissions than do facility-specific benchmarks, particularly in cap-and-trade context.	Determining what constitutes a unique product (including intermediate products) can be very challenging. Requires confidential data on product output. May not be as applicable in performance standard or voluntary context since does not recognize facility-specific conditions.
With consideration for technology, feedstock, and/or fuel	Can recognize long-lived investments or particular market conditions, possibly increasing flexibility in a voluntary program	Potentially large administrative burden. Distorts price signal.
Facility-specific Individual benchmarks developed for each facility (e.g., a particular paper mill)	Can tailor benchmarks to individual sites and set more ambitious benchmarks for facilities with greater GHG-reduction opportunities, thereby potentially increasing economic efficiency, at least in a regulatory or voluntary context	Potentially huge administrative burden to develop benchmarks for each individual facility. Erodes incentive for larger-scale restructuring of the industry (distorts price signal).

Measurement Protocol and Boundaries

To ensure that all relevant emission sources are included and produce effective benchmarks, policymakers and administrators need common guidelines, tools, and methods to measure or estimate greenhouse gas emissions and production at the facility level.[36] Fortunately, several GHG measurement protocols have already been established. For example, the World Business Council on Sustainable Development and World Resources Institute, working in partnership with industry groups, developed the GHG Protocol, which has been used widely for the past decade. Recently, US EPA established protocols to guide mandatory reporting of greenhouse gas emissions for all facilities in certain sectors (e.g., aluminum, cement) and for facilities that emit more than 25,000 tons CO_2e annually in most other sectors. The rule will also require reporting of production volumes for those industrial sectors required to report. Washington State will be harmonizing the reporting methodologies for its Greenhouse Gas Reporting Rule, which will cover facilities that emit at least 10,000 tons CO_2e, with those of EPA. Ideally, the same measurement protocol should be used for constructing benchmarks and for monitoring the emissions to which the benchmark will apply.

Include Indirect Emissions?

A critical question in developing GHG benchmarks will be whether and how to account for indirect emissions, in particular the emissions associated with electricity or heat purchased by industrial facilities.

The decision depends in part on the policy context of the benchmark development. In case of voluntary performance goals, including both direct and indirect emissions puts facilities on a more equal footing, and avoids meeting emission reduction goals simply by substituting purchased heat or electricity for on-site fuel combustion. While such a shift might reduce direct on-site emissions, it would increase emissions outside the facility boundary if fossil fuels were used to produce the purchased heat or electricity.

For cap-and-trade systems, however, the choice is less obvious. Under a cap-and-trade system that covers both electricity and industrial facilities, power producers would need to secure allowances for the emissions associated with electricity sold to industrial facilities. Therefore, there is no need to separately account for indirect emissions from electricity purchased by industrial facilities.

[36] Secure and robust data systems must be put in place to maintain confidence and, where needed, confidentiality.

However, industrial facilities could experience cost impacts due to any increase in the cost of electricity resulting from the price of allowances. Accordingly, some cap-and-trade program design (including of H.R. 2454 and Australia's proposed cap-and-trade system) provide further cost support to industry through benchmark-based allowance allocation for indirect emissions similar to the allocation for direct emissions.

For performance standards, the choice of whether to include direct and indirect emissions may be even yet more complex. The concern about a facility switching from fossil fuel to electricity with little or no reduction in overall (direct + indirect) emissions still exists, but is difficult to address given that NSPS and BACT are designed to address direct emissions, not indirect emissions or total energy use. Nevertheless, EPA has been exploring means of encouraging energy efficiency through provisions in BACT to potentially also address indirect emissions. Further research is necessary on means of addressing indirect emissions in a performance-standard approach.

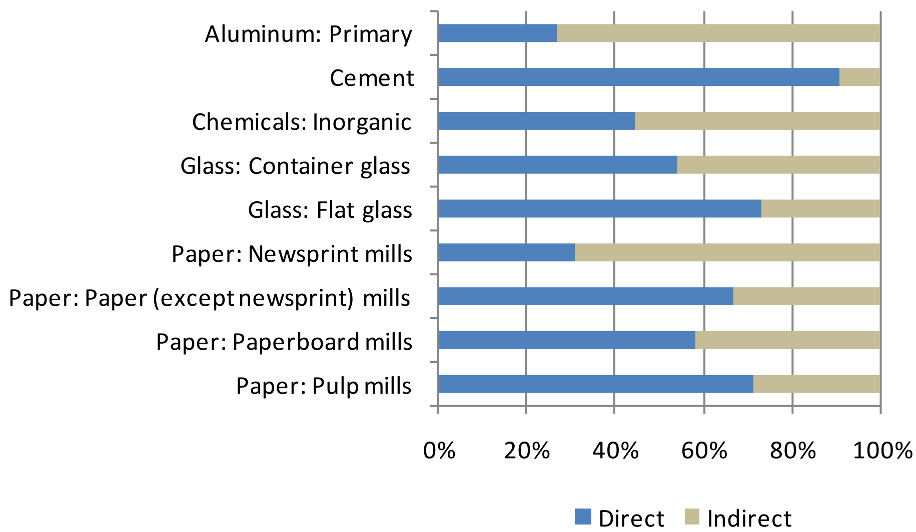
Table 6. Benefits and Challenges of Including Direct or All Emissions in Benchmark Construction

	Voluntary	Allowance Rebate in Cap-and-trade	Performance Standards
Direct only	▪ **Benefits**: simpler ▪ **Challenges**: might encourage emissions "leakage" to electricity sector	▪ **Benefits**: aligns well with basic structure of cap-and-trade ▪ **Challenges**: none	▪ **Benefits**: simpler ▪ **Challenges**: could encourage emissions "leakage" to electricity sector
All (Direct + Indirect)	▪ **Benefits**: includes more sources of emissions over which facility has control ▪ **Challenges**: greater data needs and methodological complexity	▪ **Benefits**: can help offset any added costs to industry from higher electricity prices ▪ **Challenges**: greater data needs and methodological complexity	▪ **Benefits**: includes all sources of emissions over which facility has control ▪ **Challenges**: BACT not designed to address indirect emissions; greater data needs and methodological complexity; might need to regulate electricity or heat purchases as a proxy for indirect emissions.

The relative importance of direct versus all (direct +indirect) emissions also varies by sector. Some sectors (particularly cement) release far more emissions directly than indirectly. For many others (e.g., aluminum), a significant fraction of the sector's emissions are released indirectly through electricity production. Figure 7 displays the overall fraction of direct versus indirect emissions for select industry sectors in the U.S. If a similar graph were produced for the northwestern U.S., the relative amount of direct and indirect emissions would change for many of the sectors, due to the region's relatively higher reliance on low-carbon hydroelectricity.

Even more critical than the balance of direct and indirect emissions is the relative substitutability of electricity and fossil fuels within a sector and the emissions-intensity of that electricity. For example, it could be argued that the electricity-dependent electric arc furnaces and the fossil-fuel-dependent (and more emissions-intensive) basic oxygen furnaces produce equivalent products and should be compared using the same benchmark. If that were the case, such a benchmark would be likely to incentivize the use of electric arc furnaces due to their lower emissions intensity, even considering the emissions used to produce the electricity.

Figure 7. Relative Overall U.S. Fraction of Direct and Indirect GHG Emissions in Select Energy-Intensive, Trade-exposed Sectors (US EPA, US EIA, and US Treasury 2009).



Another complicated issue is the use of combined heat and power (CHP), or cogeneration. With CHP, power and heat are produced by boilers or turbines at industrial facilities, and power or heat may be used internally, or sold to the grid or to other facilities. CHP requires approximately 25% less energy than separate heat and power systems and thus can help facilities meet emissions benchmarks (IEA 2008). Because CHP's two products – heat and electricity – may alternately be used internally or transferred to other facilities, the task of allocating emissions to the respective facilities can be difficult. As a result, how CHP is considered is an important consideration in developing and applying emissions benchmarks. [Research is ongoing; we will speak to options to address CHP in the subsequent version of this *White Paper*.]

Units for Normalizing

As described in the introduction to this paper, GHG benchmarks are typically expressed as a quantity of emissions per unit of output, as in the following simple equation:

$$GHG\ Benchmark = \frac{Emissions\ (tons\ CO_2e)}{Unit\ of\ Output\ (tons, \$, or\ other\ metric)}$$

The denominator of this equation – the *unit of output* – is often a physical unit of product output (e.g., a ton of cement, steel, or aluminum). However, the denominator could instead be a unit of input (e.g., a ton or barrel of crude oil refined), or some other metric, such as production capacity or a monetary output (e.g., net value added or revenue of product shipped). Benchmarking can also utilize a combination of factors, expressed in terms of an equation, as in the method of the US EPA ENERGY STAR program. This section discusses the rationale and tradeoffs with alternate choices of benchmark denominator, or the units for normalizing the benchmark.

Most, but not all, existing benchmarking efforts use physical product output as the benchmark denominator. For example, the formulas for constructing sector-average benchmarks in the U.S. Waxman-Markey bill (H.R. 2454), existing emissions performance standards in Washington State (e.g., NO_X from steel mills, SO_2 from sulfite pulp mills), and most of the voluntary efforts summarized in Section 2 of this White Paper all rely on a weight-based, physical unit of output. Physical units are not affected by cyclical variations in prices or other economic fluctuations and link more directly to technology performance and efficiency than do monetary denominators.

Furthermore, a physical unit of *output* (rather than input) will tend to better enable assessment of technology performance and efficiency. If a unit of *input* was used, the benchmark performance (emissions per ton or per unit of heat input) could provide a perverse incentive to use input feedstocks less efficiently, since using more input to produce the same unit of output would drive up the benchmark denominator and therefore improve the apparent GHG performance of the facility. By contrast, basing the benchmark on output provides an incentive to increase production – a goal that, while it may also have unintended consequences, does support manufacturing within the benchmark region and may help address industry competitiveness concerns, particularly in a cap-and-trade context. Still, for some industry sectors basing the benchmark on a unit of input may be desirable if defining and quantifying output-based benchmarks is too onerous. The petroleum refining industry is one sector where benchmarking based on inputs (e.g., barrels of crude oil) is commonly discussed and implemented.

Table 7, below, summarizes benefits and challenges associated with alternative choices of physical versus monetary and input versus output in selecting benchmark denominators.

Table 7. Benefits and Challenges of Alternative Choices of Benchmark Denominator

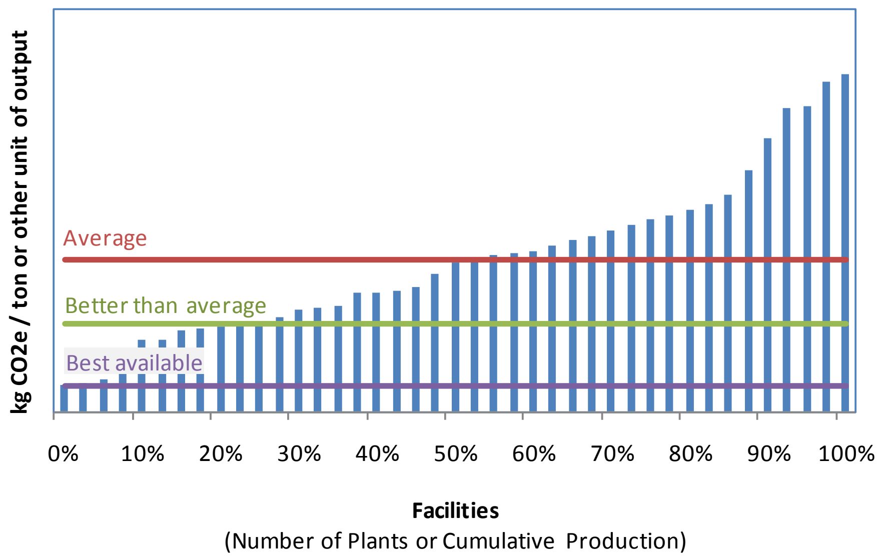
	Benefits	Challenges
Physical Input	Can be well-suited to industry sectors where the products are far more complicated than the inputs (e.g., petroleum refining)	Fails to reward efficient use of raw material feedstock in producing a product and can lead to perverse incentives
Physical Output	Links directly to technology performance and efficiency and therefore can more directly be used to help identify improvements possible through new technologies. Can enable comparisons between world regions regardless of the structure of each region's industry and economic data.	Requires data on product output, which is generally confidential, though will be supplied under mandatory GHG reporting in most instances
Monetary Input	None identified	Would require confidential information on each facility's expenditures on raw materials yet would not provide any physical unit (e.g., barrels of crude oil) on which to assess plant efficiency
Monetary Output	Some such data already exist, at least at the sector-wide level, through existing sources (e.g., U.S. Census Bureau). Can create a common denominator across sectors.	Using a monetary unit can introduce other types of variation (price or currency fluctuations) that would obscure the underlying technical performance of the plant

Benchmark Ambition

The choice of an emissions benchmark – whether average, better-than-average, or best available – depends on the intended use. If the goal is to assess performance relative to average emissions practices, a simple average can be sufficient, particularly when coupled with a curve such as was presented in Figure 1.

A benchmarking curve (and its underlying data) can also be used to assess potential benchmarks with ambitions other than a simple average performance. For example, a benchmarking curve can be used to understand the best achieved level of emissions performance, to set a goal for a specified improvement over the current average (e.g., a 20% improvement in emissions intensity by a certain year), or to select a definition of top-performing plants (e.g., the plants in the top 25th percentile of performers). In Figure 8, below, the green horizontal line depicts the emissions intensity of the top 25th percentile of plants and the purple horizontal line depicts the best-performing plant for a fictional industry sector.

Figure 8. Hypothetical Benchmark Curve: Choice of Benchmark Ambition



How ambitious to make the benchmark depends on the policy context and goals of the program. Under regulatory performance standards and voluntary programs, the level of benchmark ambition directly determines the level of greenhouse gas abatement and each sector's share of the costs of meeting a particular regional emissions target, as was discussed on page 18. When used for allowance allocation, on the other hand, the ambition of the benchmark does not itself determine the level of abatement but instead helps avoid carbon leakage while preserving price signals to individual facilities. Economic modeling, as in the U.S. Interagency Report (US EPA, US EIA, and US Treasury 2009), can be used to estimate the benchmark level that would be likely to avoid emissions leakage (as well as to avoid subsidizing domestic production if set too high) in individual industries.

Governor Gregoire's Executive Order 09-05 specifically calls for benchmarks developed by the Department of Ecology to "be based on industry best practices, reflecting emission levels from highly efficient, lower emitting facilities in each industry sector." This language suggests that benchmarks should be set at emission rate that lies below the average level.

Data Sources

Despite the potential for use of benchmarks to help address greenhouse gas emissions from industry, relatively few comprehensive data sources exist to develop and set benchmarks. In general, four types of data providers exist:

- **Industry groups and associations**, such as the Cement Sustainability Initiative, International Aluminum Institute, Northwest Food Processors Association, or National Council for Air and Stream Improvement. These organizations tend to have (or are developing) the most detailed and comprehensive data on production, energy use, and emissions at the level of individual facilities. However, none of these efforts are known to make their facility-level data publicly available.[37] Furthermore, comparable efforts do not exist in all sectors. Still, benchmarking curves with facility-level resolution have been published by the Cement Sustainability Initiative (CSI 2009) and the International Aluminum Institute (International Aluminum Institute 2009) and could serve as the basis for a benchmarking effort for these sectors.
- **Government surveys,** such as the Energy Information Administration's Manufacturing Energy Consumption Survey (MECS) or the US Census Bureau's Annual Survey of Manufactures and Economic

[37] In some cases, compiled information with facility identifiers removed can be acquired for a fee.

Census.[38] These sources cover some but not all applicable sectors or emissions sources. They also do not provide emissions estimates, but rather fuel use and production data that can be used, with standard emission factors, to estimate emission levels. Physical production data may be limited[39], and use of such data is typically restricted, even for government analysts (Schneck et al, 2009). Following strict procedures to maintain confidentiality, EPA uses Census Bureau data in developing energy benchmarks for industry in the agency's ENERGY STAR program. H.R. 2454 also lists these data as sources for determining industry eligibility for EITE provisions.[40]

- **Air permits held by state and local air agencies.** Air permits and other agency sources (e.g., information on fuel type) sometimes contain production levels and other data sufficient to perform reasonably accurate estimate of GHG emissions. For example, the Puget Sound Clean Air Agency has estimated process CO_2 emissions from both the Ash Grove and Lafarge cement kilns in Seattle based on clinker production data (Puget Sound Clean Air Agency 2008). Compiling data from air agencies around the country or region in order to develop benchmarking curves could be prohibitively difficult, given the sheer number of such agencies and potentially disparate and inconsistent data they may hold.[41]
- **Mandatory GHG reporting rules.** Data from state and federal mandatory reporting rules on GHGs are likely to provide the best source of data for benchmarking, however, these data are not yet available. US EPA's Mandatory Reporting of Greenhouse Gases rule will require all facilities that emit at least 25,000 tons CO_2e and all facilities in some sectors (e.g., aluminum, cement, several chemical industry sectors) to report greenhouse gas emissions and production volumes for year 2010 by March 31, 2011 (US EPA 2009b). Washington State's Mandatory Greenhouse Gas Reporting Rule takes effect in 2010 for facilities with at least 25,000 tons CO_2e of 2009 emissions. Facilities that emit at least 10,000 tons of GHGs must start reporting in 2011 for year 2010 emissions. The reporting methodologies for both the federal and Washington State rules will be harmonized.

The need for more comprehensive production, energy, and emissions data for developing greenhouse gas benchmarks –at least for benchmarks to be used in a cap-and-trade or performance standard setting – is clear. This need is recognized by national and regional policymakers. Notably, the recent interagency analysis of the competitiveness and leakage provisions of H.R. 2454 concluded that implementation of any mechanism to use output-based allocations would require "data from facilities on output levels, electricity use, and emissions associated with electricity use (in addition to data already planned via the Mandatory Reporting Rule)" and also require that "such data can be generated at a sufficiently disaggregated level for EPA to develop meaningful benchmarks for output-based allocations"(US EPA, US EIA, and US Treasury 2009). Facility-level data on physical production or sales is generally considered confidential information and not available to most analysts, regardless of whether the data are collected and held by industry groups (e.g., the Cement Sustainability Initiative) or government sources (e.g., the U.S. Census Bureau). Still, some industry groups (e.g., the international aluminum and cement industries) have voluntarily released GHG benchmarking curves or worked with government partners (e.g., the European Union) to develop and publicize GHG benchmarking curves which display, but do not identify, individual facility-level GHG intensity values. Lastly, monetary sales data are generally available in the U.S. at an aggregate industry level (e.g., six-digit NAICS code).

Table 8, below, displays an assessment of existing possible data sources for GHG benchmarking.

[38] An additional possible source of data is EPA's triennial national emission inventory (NEI), which includes company and state emission estimates for criteria and hazardous pollutants and production and fuel usage information that may be applicable for benchmark development.
[39] One potential source of production data is the US Geological Survey's (USGS) annual Minerals Yearbook, which reports some national and regional production volumes but facility-specific data are very limited (e.g., the USGS reports production capacity at Alcoa's Ferndale and Wenatchee facilities but not actual annual production) (USGS 2009).
[40] For the ENERGY STAR program, EPA relies on a sworn Census agent at the Triangle Research Data Center at Duke University to conduct these analyses.
[41] One potential source to facilitate such data collection is EPA's RACT/BACT/LAER Clearinghouse, which compiles facility-specific information on "best available" air pollution technologies. Since this system (http://cfpub.epa.gov/rblc/) is designed to collect permitting decision information rather than emissions and production information, it does not include the level of detail for the Ash Grove and Lafarge cement plants that is on the Puget Sound Clean Air Agency's own website, suggesting that the Clearinghouse may not an appropriate tool for consolidating relevant GHG benchmarking data. EPA does intend to modify the system to include permit limit data for greenhouse gases.

Table 8. Assessment of Possible Data Sources for GHG Benchmarking

Data Source	Level of Disaggregation (e.g., facility, product)	Types of Data	If Includes GHGs, Uses Accepted Protocol?	Geographic Coverage (& Country Resolution)	Threshold for Coverage	Scope (Direct / Indirect)	Publicly Available at Disaggregated Level	Years of Data Available	Other Considerations
Industry Groups and Associations									
Cement Sustainability Initiative	Facility	▪ CO_2 ▪ Energy ▪ Clinker and cement	Yes, WBCSD/CSI	Global down to North America; low coverage in developing countries (e.g., China)	CSI member companies only	Direct + Indirect	In benchmarking curve	1990-2007	
International Aluminum Institute	Facility	▪ PFCs ▪ Primary aluminum	Yes, IPCC	Global (60% of production);low coverage in China	All facilities	Direct	In benchmarking curve	1990-2008	
Government Surveys									
MECS	Facility	▪ Energy	N/A	U.S.	All but the smallest producers in each covered sector	Direct (fuels) + Indirect (electricity)	No	1991, 1994-2006 in 4-year increments	Does not cover all sectors; only sworn Census agents can access
Census Bureau Economic Census and ASM	Facility	▪ Value of shipments	N/A	U.S.	All facilities	N/A	No	Annual	Only sworn Census agents can access
USGS	Facility (for U.S. data)	▪ Production of metals and minerals	N/A	Global (175 countries) and U.S.	All facilities	N/A	No (country or region only)	1932-2008	
Air Permits From Local Air Agencies									
Puget Sound Clean Air Agency (as example)	Facility	Varies. May include GHGs and production	Varies	Limited to facilities in each individual air agency	Only those facilities required to be permitted for other (non-GHG) pollutants	Direct	Yes but data limited	Varies	Local air agencies may not use consistent methods for estimating GHGs
Mandatory GHG Reporting Rules									
WA GHG Reporting Rule	Facility	▪ 6 GHGs ▪ Production	Yes, US EPA	Washington State	Facilities that emit more than 10,000 tons CO_2e	Direct	Yes (emissions only)	2009 on	Data first reported in Oct. 2010
US GHG Reporting Rule	Facility	▪ 6 GHGs ▪ Production	Yes, US EPA	U.S.	All facilities in certain sectors (e.g., aluminum, cement); others if over 25,000 tCO_2e	Direct	Yes (emissions only)	2010 on	Data first reported in March, 2011

How Different Policy Approaches Might Affect Benchmark Construction

In the discussion above, we describe and assess several issues and options with benchmark construction and application. A few of these issues and options (e.g., what units to use for normalizing the benchmark) remain relatively consistent and apply equally regardless of policy approach. Several others, however, imply very different incentives or outcomes in different policy approaches. In Table 9 below, we summarize how different policy approaches – voluntary goals, output-based allocation in a cap-and-trade program, or emission performance standards – might affect how benchmarks are constructed and used. A key lesson is that disaggregating benchmarks by feedstock type, fuel, or technology distorts the price signal in a cap-and-trade program but may be necessary (or even desirable) in a regulator performance standard or voluntary framework.

Table 9. How Benchmark Application May Affect Benchmark Construction

	Allowance rebates in Cap-and-trade	**Regulatory Performance Standard**	**Voluntary**
Disaggregation by Feedstock type / fuel/ technology / other factors	Disaggregation should be minimized in order to provide the incentive to adopt to more efficient technologies and practices.	Some disaggregation might be necessary to consider cost-effectiveness and achievability, particularly for existing facilities	Some disaggregation might be necessary to distribute abatement costs between companies.
Disaggregation by specific product type	Disaggregation is desirable to extent that products are non-substitutable, and there is sufficient number of distinct facilities producing them to develop a meaningful benchmark	Similar to above	Similar to above
Consideration of indirect electricity emission factors	Indirect emissions do not have to be taken into account as the carbon price signal is part of the electricity price and automatically incentivizes an optimal use of fuel and electricity.	Indirect emissions should be taken into account in order to avoid perverse incentives to use more (carbon free) electricity instead of fuel.	Indirect emissions should be taken into account in order to avoid perverse incentives to use more (carbon free) electricity instead of fuel.
Point of regulation	In order to avoid carbon leakage the benchmark should be based on the point of regulation. This means that the benchmark should be set for the (intermediate) product leaving the installation.	In order to incentivize all abatement options the benchmark should be derived for the final product.	In order to incentivize all abatement options the benchmark should be derived for the final product.

Box 2. An Alternative to Product-specific Benchmarks: Benchmarking Heat Production

In several industries, the main source of emissions is the production of heat (as steam or hot water) in a boiler. That is, while many industrial sectors (e.g., aluminum, cement, glass, and steel) emit large quantities of greenhouse gas emissions directly from the a production process or from burning of fossil fuels to directly heat materials (e.g., in furnaces), others (e.g., food processors and some chemical industry companies) generate most of their emissions from the burning of fossil fuels to produce steam or hot water. Heat could therefore be considered as the product of the boiler and benchmarked accordingly, at least for facilities where other product-specific benchmarks are not applied. The EU has taken this approach in the development of its cap-and-trade program by developing a "fall-back" benchmark approach for sectors and facilities that generate and use heat but are not assigned product-specific benchmarks. The main advantage of applying a benchmark on heat is the simplicity and the potential application across sectors.

Three factors influence GHG emissions from combustion processes that generate heat as steam or hot water: the choice of fuels, the efficiency of the heat production, and the efficiency of heat end use (Ecofys, Fraunhofer Institute, and Öko Institut 2009a). A benchmark on heat production would account for the first two factors but not the third. As a result, one issue in benchmarking heat (at least relative to alternative approaches, such as benchmarking end products) is that a heat benchmark would not encouraged increased efficiency of the *use* of that heat in producing a final product such as paper, a food product, or chemicals.

An important question is whether a heat production benchmark should be differentiated by sector. Different industrial sectors may use different boiler technologies (with varying efficiencies) or rely historically on different fuels, factors that may suggest the use of differentiated benchmarks by sector, at least in a voluntary or regulatory approach. Under a cap-and-trade program, disaggregation by sector may be less appropriate as the goal is to encourage long-term technology and fuel transitions and facilities can purchase or sell allowances depending on whether they are emitting above or below the respective benchmarks.

Table 10 summarizes some benefits and challenges of benchmarking heat as opposed to developing individual product benchmarks.

Table 10. Benefits and Challenges of a GHG Benchmark on Heat Production

Benefits	Challenges
▪ Can be simpler than product-specific benchmarks for some sectors (e.g., food processing) ▪ Incentivizes low-GHG heat production through fuel choice and boiler efficiency ▪ Potentially applicable across a variety of industrial and commercial users, since many use boilers ▪ Does not require confidential production data (e.g., tons of frozen french fries, pulp, chemical product) other than steam/hot water production and fuel input data, which may be less sensitive	▪ Does not directly encourage efficient *use* of heat in producing a final product ▪ Differentiating heat production benchmarks by sector, may be desirable, which would limit the benefit of applying a single benchmark across multiple sectors ▪ Does not apply to process emissions, which are large in some sectors. ▪ Harder to apply to direct-heating applications (e.g., furnaces) than boilers

US EPA has conducted some initial research on possible GHG performance standards for heat production from industrial and commercial boilers. Federal New Source Performance Standards (NSPS) for other pollutants already exist for industrial boilers, and thus EPA may be required to develop GHG performance standards for boilers. [42]

[42] EPA reports that a first step in developing an NSPS for GHGs for industrial boilers would be to "consider how to develop a metric for measuring and benchmarking boiler GHG emissions in terms of the facility's output production" (US EPA 2008b). US EPA also has a GHG offset protocol for quantifying emission reductions from projects in industrial boilers: http://epa.gov/stateply/documents/resources/industrial_boiler_protocol.pdf

4. Focus on Particular Industry Sectors

This section provides a deeper dive into the particular issues and options for benchmarking in key industrial sectors: aluminum, cement, chemicals, food processing, glass, paper and pulp, and steel. We selected these sectors for further examination because they (or closely related sectors) are present in Washington State and are relatively energy-intensive and trade exposed. In addition, we discuss steam production as its own sector. Several other sectors generate most of their greenhouse gas emissions through the production of steam as an intermediate product in their operations, suggesting that a focus on steam could provide benefits to several industry sectors.

Research on each of the sectors has helped inform the issues and options discussed in Section 3, which generally apply across sectors. For example, the level of benchmark disaggregation and availability of comprehensive, facility-specific, publicly available data sources are key considerations in each sector. In this section, we instead focus primarily on key issues and options that are unique to each sector, such as the treatment of waste-derived fuels in the cement sector, availability and quality of recycled cullet in the glass sector, and whether separate benchmarks are needed for integrated versus non-integrated mills in the pulp and paper sector. In addition, this section also provides a review of the emission sources, production processes, and corresponding benchmarks already developed in each sector. For a review of upcoming mandatory GHG reporting data under federal and state rules, please see Appendix A.

As the Washington State Department of Ecology (Ecology) proceeds in the second phase of its work on industry GHG benchmarks under Executive Order 09-05, the agency may choose to focus to develop emission benchmarks for some subset of industries in the state. Accordingly, Ecology may choose to develop criteria to guide selection of sectors. Such criteria may include, for example, minimum thresholds of the following:

- **Energy-intensiveness and trade-exposure**. Industries that are particularly energy-intensive and exposed to global trade may have a greater risk of competitiveness impacts from domestic cap-and-trade legislation. Accordingly, such industry sectors may have a greater need for free allocation of allowances, potentially suggesting a benchmarking approach. For example, as discussed in Section 1, H.R. 2454 includes allowance rebates based on a sector being classified as an energy-intensive, trade-exposed (EITE) industry according to criteria of energy or greenhouse gas intensity and trade intensity. Since GHG benchmarks are often considered well suited to such energy-intensive and trade exposed industries in a cap-and-trade program, a criterion could be whether the industry sector in Washington is included as an EITE sector in federal legislation.
- **Contribution to Washington's annual GHG emissions**. The higher the industry's contribution to the state's total GHG releases, the greater the opportunity to develop approaches such as benchmarking for reducing those emissions. Accordingly, one criterion could be the fraction of the state's total annual GHG emissions (94.8 million metric tons CO_2e in 2005) contributed as direct emissions by the sector.
- **Experience with GHG benchmarking.** The process of developing benchmarks for use in a cap-and-trade system can be complex and time-consuming and may not be appropriate for all industry sectors. The process of assessing issues and options for benchmarks in Washington State may be facilitated by focusing on sectors where relevant data, or benchmarks themselves, have already been developed, and corresponding challenges addressed. For example, the international aluminum and cement industries have made significant strides in data collection and GHG benchmarking methodologies, and the Northwest Food Processors Association is embarking on an energy benchmarking effort. An additional source of research is the European Union, which is currently developing an approach to benchmark-based free allocation of emissions allowances, in coordination with industry associations, and where benchmarks are in their final stages of development, scheduled for release in mid- 2010.

Table 11. Potential Criteria for Selecting Industry Sectors to Benchmark, below, presents a preliminary assessment of industry sectors against these three criteria.

Table 11. Potential Criteria for Selecting Industry Sectors to Benchmark

Sector	NAICS Codes	**Energy-intensive, trade-exposed** (as covered by EITE Provisions in Federal Legislation) [43]	Estimated Contribution to Washington's Annual GHG Emissions [44]	Sector Experience with Benchmarking
Aerospace	336411	No	Low	
Aluminum (Primary)	331312	Yes	Medium	IAI*, EU
Aluminum (Secondary)	331314	No	Low	EU
Cement	327310	Yes	High	CSI*, EU
Chemical[45]	325188 325199	Yes	Low	EU
Electricity	221112	No	High	
Fertilizer	[Many]	Yes[46]	Low	EU
Food Processing	[Many]	Partial[47]	Medium	NWFPA*
Glass	327211 327212 327213	Yes	Low	EU
Gypsum	327420	No	Low	EU
Lime	327410	Yes	Low	EU
Natural Gas Transmission	486210	No	Medium	
Natural Gas Distribution	221210	No	High	
Oil refineries	324110	No[48]	High	EU
Pulp and Paper	322110 322121 322122 322130	Yes	High	EU
Semiconductors / solar	334413	No	Medium	
Steel	331111	Yes	Low	EU

CSI = Cement Sustainability Initiative
NWFPA = Northwest Food Processors Association
EU – European Union Emissions Trading System

[43] For a comprehensive, national list of industrial sectors likely to be considered EITE under H.R. 2454, see EPA, EIA et al (2009).
[44] These categorizations are based on the Department of Ecology's estimates (Washington Dept. of Ecology 2009). A rating of *Low* indicates the sector is estimated to contribute 0.2% or less of the State's total GHG emissions, a rating of *Medium* indicates the sector is estimated to contribute between 0.2% and 1%, and a rating of *High* indicates an estimated contribution of more than 1%.
[45] The chemical industry is very diverse. Sectors listed here qualify for EITE rebates per EPA, EIA and Treasury (2009), but other sectors may not.
[46] Per EPA, EIA and Treasury (2009), "Nitrogenous fertilizer manufacturing" (NAICS 325311) is included.
[47] The only food processing subsectors that appear to be included are "malt manufacturing (NAICS 311213), "wet corn milling" (311221), and "rendering and meat byproduct processing" (311613) per EPA, EIA and Treasury (2009)
[48] Petroleum refining receives its own free allocation of allowances under Sections 782 (j) and 787of H.R. 2454 and so is explicitly excluded from the EITE provisions of H.R. 2454. Under the definition of EITE industries, petroleum refining may not have qualified as energy- or emissions-intensive. Because H.R. 2454's intensity criterion uses value of shipments in the denominator (instead of value added, as in the EU), and since the value of crude oil purchased is high, the denominator is great enough that the energy- or emissions-intensiveness of the petroleum refining may not meet the 5% (Bradbury 2009).

Aluminum

Aluminum is produced in one of two ways. In primary aluminum production, alumina is produced from bauxite and then processed to aluminum via electrolysis. In secondary aluminum production, aluminum is refined or remelted from scrap.

In the North America, over half of the aluminum supply is from primary production, about a third is from secondary production, and the remainder is imported as ingot or partially assembled components (Aluminum Association 2009). Historically, most aluminum production in Washington State has been primary and has benefited from relatively inexpensive, abundant hydroelectricity. In recent years, increases in energy prices and a drop in world aluminum markets have led to a decline in the state's aluminum industry, including the closing of primary aluminum smelters.

In Washington, aluminum-producing facilities include two primary aluminum smelters: Alcoa facilities in Ferndale and Wenatchee; and the Kaiser Aluminum secondary aluminum facility in Spokane.[49]

Overview of Production Process and Emissions Sources

Primary aluminum is produced in the following process:

- **Bauxite mining.** Most of the bauxite used in North American aluminum refineries is mined in other countries, with Jamaica, Guinea, Brazil, Guyana, and Sierra Leone being significant suppliers (USGS 2009).
- **Alumina refining.** Alumina (aluminum oxide) is produced from bauxite using the Bayer process in which bauxite is digested and then alumina is clarified, precipitated, and then dried and calcined. The bauxite digestion process uses significant quantities of (usually fossil fuel) energy to heat the caustic soda, as does the calcining of alumina (IEA 2009). The end product of alumina refining is a fine white powder.
- **Anode manufacturing**, in which coal tar pitch and petroleum coke is ground pressed into green anodes, and then baked[50] at high temperatures in gas-heated furnaces (Worrell et al. 2008). Anodes can either be made onsite at the smelter or in separate, specialized plants. The Alcoa facilities in Ferndale and Wenatchee both use pre-baked anodes made on-site. The Ferndale facility uses "side worked pre-bake" anodes and the Wenatchee facility uses "center work pre bake" anodes.
- **Aluminum smelting.** In aluminum smelting, known as the Hall-Héroult process, alumina is dissolved in an electrolyte bath under a strong electric current. The electric current separates the aluminum oxide molecules by pulling the oxygen ions towards the carbon anode, where they react with carbon, leaving molten aluminum behind. Smelting uses significant quantities of electricity.
- **Aluminum casting and forming.** Molten aluminum is shaped into forms and semi-finished products via casting of ingots, hot and cold rolling, extrusion, drawing, finishing, and cutting.

Producing secondary aluminum from scrap requires much less energy than primary production. Steps in the production of secondary aluminum include:

- **Scrap collection and processing.** Scrap aluminum needs to be collected, sorted, cleaned, and shredded. Sources of scrap aluminum include both post-consumer products (e.g., used beverage cans, old automobile parts, windows and doors) as well as post-industrial production scrap.
- **Remelting and refining,** which can occur via one of several processes, including reverbatory furnaces, rotary furnaces, or induction technology.
- **Aluminum casting and forming**, similar to that described above for primary aluminum.

The table below summarizes the major processes in aluminum production and sources of emissions.

[49]Per the Department of Ecology (2009) and http://www.ecy.wa.gov/programs/swfa/industrial/facilities.html.
[50] In a Soderburg aluminum smelter, the anodes are not pre-baked. Instead the heat from the aluminum reduction cell provides the heat to 'bake' the anodes at the same time it is being consumed in the smelting process.

Table 12. Summary of Aluminum Production Processes, Emission Sources, and Existing Benchmark Sources

Step	Dominant Emissions Sources	Proposed or Existing GHG Benchmarks under Cap-and-trade	Other Benchmarks or Best-Practice Values	Key Issues / Options
Primary				
Bauxite mining	▪ Fossil fuel burning for equipment	▪ None known	▪ None known	
Alumina refining	▪ Fossil fuel for heat generation	▪ Proposed EU benchmark on alumina ▪ H.R. 2454 (Waxman-Markey), passed in the US House of Representatives in 2009, included a formula for constructing an average benchmark for alumina refining	▪ Worrell et al (2008) list world best-practice energy benchmarks for alumina production	▪ Few installations produce alumina and with a wide spread of emissions, complicating benchmark development
Anode manufacture	▪ Fossil fuel for furnace ▪ Process CO_2 from anode baking	▪ Proposed EU benchmark on pre-baked anodes	▪ Worrell et al (2008) list world best-practice energy benchmarks for anode manufacture	
Aluminum smelting	▪ Fossil fuel for heat generation ▪ Process CO_2 from consumption of carbon anodes ▪ Perfluorocarbons (PFCs) from the anodes ▪ Electricity production for electrolysis	▪ Proposed EU benchmark on primary aluminum smelting ▪ H.R. 2454 (Waxman-Markey), passed in the US House of Representatives in 2009, included a formula for constructing an average benchmark for primary aluminum smelting	▪ Worrell et al (2008) list world best-practice energy benchmarks for aluminum smelting ▪ International Aluminum Institute has published benchmark curves for PFC emissions (International Aluminum Institute 2009)	▪ Choice of carbon anode type (e.g., pre-baked anodes versus Söderberg) can affect energy and process CO_2 emissions greatly ▪ In the EU, the aluminum industry has argued for a separate benchmark for primary cast houses with adjustment factors for degree of secondary remelting and homogenization
Aluminum casting and forming	▪ Fossil fuel for production machinery ▪ Electricity production to run machinery	▪ Proposed EU benchmark on primary cast aluminum ▪ EU has proposed using the separate "fall-back" approach for products from rolling plants, extrusion plants, and foil plants	▪ Worrell et al (2008) list world best-practice energy benchmarks for aluminum casting	
Secondary				
Scrap collection	▪ Fossil fuel and electricity to operate equipment	▪ None known	▪ None known	
Scrap processing	▪ Fossil fuel and electricity to operate equipment	▪ Proposed EU benchmark on secondary aluminum	▪ Worrell et al (2008) list world best-practice energy benchmarks for secondary aluminum	▪ See above if secondary aluminum remelting occurs in a primary cast house ▪ In EU, stakeholders have argued that production from low-quality scrap may be more energy-intensive than production of high-quality scrap and may deserve its own benchmark
Remelting and refining	▪ Fossil fuel for furnace ▪ Electricity production (if electric furnace used)			
Aluminum casting and forming	▪ Fossil fuel for production machinery ▪ Electricity production to run machinery			

Key Issues in Benchmarking Aluminum

As with all sectors, the data availability and level of benchmark disaggregation are key issues. This is discussed in detail in Section 3 of this *White Paper*. In addition, some stakeholders have suggested that quality of recovered scrap may be an issue for the secondary aluminum industry (Ecofys, Fraunhofer Institute, and Öko Institut 2009b). The quality of recovered scrap can affect energy required for production of secondary aluminum. However, under a cap-and-trade system on greenhouse gases, differentiating the benchmark based on aluminum scrap quality may be less appropriate, since the entity could use the savings realized from purchasing less expensive, lower-quality scrap to secure additional emissions allowances.

Cement

Cement is the binding agent in concrete and most mortars, and is generally produced from a feedstock of limestone, clay, and sand. In the United States, 118 cement plants produce about 85 million metric tons of cement annually.[51] In Washington State, the largest cement plants are Ash Grove Cement and Lafarge Cement, both located in Seattle. Together, these facilities emit about 900,000 tons CO_2e of GHGs annually in the course of producing about one million tons of cement (Washington Dept. of Ecology 2009).

Overview of Production Processes and Emission Sources

The production of cement involves four sequential production processes (Matthes et al. 2008):

- **Raw material extraction**, in which limestone and clay, sand, or other materials are quarried. Neither cement kiln in Washington State operates its own quarry; both import limestone from Texada Island in British Columbia, from which the limestone is transported by barge to the plants.
- **Raw material preparation,** in which a raw mixture of limestone (approximately 90%) and other materials (e.g., clay, sand) are crushed and ground into a mixture with a specific chemical composition. This step can occur either as a dry process, in which the product is a fine dry powder, or in a wet process, where the crushed material is mixed into a slurry prior to grinding. Over 75% of cement produced in the U.S. uses the dry process (Worrell and Christina Galitsky 2008).
- **Clinker production**, in which the fine powder or slurry is heated to over 2,500˚F in a kiln. The heating first transforms the ground limestone ($CaCO_3$) into lime (CaO), releasing CO_2, in a process called calcination, and then into solid pellets called clinker, the material which gives cement its binding properties. Two major kiln types exist: vertical shaft kilns, and the more-efficient rotary kilns. Few (if any) vertical shaft kilns remain in the U.S. Of rotary kilns, the wet kilns are less efficient because they require more energy to produce clinker due to the need to evaporate the slurry water prior to calcination. No new wet kilns have been built in the U.S. since the 1970s (US EPA 2008a). The Lafarge plant in Seattle (a wet kiln) has recently announced intentions to stop manufacturing clinker at the end of 2010.[52]
- **Cement grinding and blending**, in which clinker is mixed with other ingredients to produce cement. To make Portland cement, only about 5% gypsum is added. Other, “blended cements” can be made by mixing in other materials with cementitious properties, especially byproducts from other industries, such as fly ash from coal power plants or blast-furnace slags.

The table below summarizes the major processes and sources of emissions in cement production.

[51] Per USGS (2009) and the Portland Cement Association (www.cement.org).
[52] http://www.westseattleherald.com/2010/04/30/news/update-lafarge-cement-forced-make-changes-its-seattle-plant

Table 13. Summary of Cement Production Processes, Emission Sources, and Existing Benchmarks

Step	Dominant Emissions Sources	Proposed or Existing GHG Benchmarks under Cap-and-trade	Other Benchmarks or Best-Practice Values	Key Issues / Options
Raw material extraction	▪ Fossil fuel for extraction equipment and transport from mine to plant ▪ Electricity for conveyors	▪ None known	▪ None known	
Raw material Preparation	▪ Fossil fuel and/or electricity production for machinery to crush, grind, and dry (if necessary) the raw meal	▪ None known (emissions from this phase are included in clinker production phase in the EU benchmark)	▪ Worrell et al (2008) list world best-practice energy benchmark for raw materials preparation	▪ Higher moisture content and hardness of the limestone increase energy use.
Clinker production	▪ Process CO_2 released in the calcination reaction ▪ Fossil fuel burning for kiln heating ▪ Electricity production for machinery, including fans, kiln drive, cooler, and material transport	▪ EU has proposed benchmark on clinker production[53]	▪ Cement Sustainability Initiative (2009) lists global and regional average GHG intensities ▪ Worrell et al (2008) and IEA (2008) list world best-practice energy benchmark for clinker production ▪ US EPA ENERGY STAR has an energy benchmarking tool that compares energy per ton of clinker	▪ The choice of whether to benchmark based on clinker or cement is the most significant issue. Basing the benchmark on cement incentivizes blending with clinker substitutes (thereby reducing the emissions associated with clinker), but can create a perverse incentive to import clinker or else to restructure the industry to create companies that only grind clinker and do not make cement ▪ Treatment of biomass and wastes as heating fuels for the kiln can affect benchmark development ▪ Some have argued that different benchmarks should be created for grey versus white cement, but the possible applications (if not the aesthetics) are the same[54]. Both cement kilns in Washington produce grey cement.
Cement grinding and blending	▪ Fossil fuel needed for heat for drying of additives, if necessary ▪ Electricity for equipment for blending and grinding of additives and final product	▪ H.R. 2454 (Waxman-Markey), passed in the US House of Representatives in 2009, included a formula for constructing an average benchmark for cement (not clinker) production	▪ Cement Sustainability Initiative (2009) lists global and regional average GHG intensities ▪ Worrell et al (2008) list world best-practice energy benchmark for grinding and blending	

Key Issues in Benchmarking Cement

Based on review of benchmarking and related efforts in the cement sector, key questions to address in developing benchmarks for the cement sector would include:

- **Whether to benchmark based on cement or clinker.** A benchmark based on clinker helps drive kiln and process efficiency upgrades but fails to incentivize the use of clinker substitutes (such as fly ash and slag) in blending to reduce emissions. A benchmark based on cement provides incentive for blending of clinker substitutes but could lead to restructuring in the cement industry. In particular, if the benchmark were only applied to cement, cement facilities may choose to no longer make emissions-intensive clinker themselves, instead importing it or else purchasing it from facilities that only grind clinker and do not

[53] Information pertaining to benchmarking of cement from the EU is taken largely from Ecofys, Fraunhofer Institute, & Öko Institut (2009c). Final benchmarks are being developed in the EU in the first half of 2010.

[54] The EU has recommended that no separate benchmarks be developed for white versus grey cement (European Commission 2010). In Washington State, both cement kilns produce grey cement.

make cement (therefore potentially exempting themselves from the cement-based benchmark). Such a restructuring would provide little or no overall decrease in cement industry emissions.

- **Treatment of wastes and biomass as fuels,** in particular, how emissions from these fuels are calculated and included in the benchmark, including treatment of fuels such as used tires.

In addition, the cement system would also face issues similar to all sectors – such as what data are available and how many products to distinguish. Note that EPA is currently revising its NSPS for cement, expected in June 2010. Some observers have speculated that EPA will include greenhouse gas emissions in the revisions (Bravender 2009).

Chemicals

The chemical industry is a diverse, energy-intensive sector that generates products such as plastics, fertilizers, cleaners, pharmaceuticals, and numerous other products from feedstocks of natural gas, crude oil, and sometimes coal or other materials. The U.S. chemical industry is the largest in the world (Worrell et al. 2000). From an energy and emissions perspective, the three most significant subsectors of the chemical industry include (IEA 2008; Worrell et al. 2000):

- **Petrochemicals**, in which firms convert oil and natural gas feedstocks into chemical building blocks used to produce polymers, plastics, synthetic rubbers, solvents, and other organic chemicals. Petrochemical producers use large quantities of heat to power distillation columns and other processes, such as steam-cracking, the process used to produce ethylene (the most widely used petrochemical intermediate compound nationally and globally) and other chemicals.
- **Fertilizers** and related products, where the production of ammonia is the most energy-intensive production step. Ammonia is produced by a reaction of hydrogen and nitrogen. Most ammonia is converted to other compounds to be utilized as fertilizer.
- **Inorganic chemicals,** which include the energy-intensive chemicals chlorine, caustic soda (sodium hydroxide), carbon black, and soda ash, among others.

Major sources of greenhouse gas emissions from chemical manufacturers include direct combustion of fossil fuels to produce heat and non-combustion process emissions that occur from the use of fossil fuels as feedstocks and the use of other raw materials (US EPA 2008a).

In Washington State, the chemical industry includes numerous small companies that manufacture a variety of chemicals. Larger facilities include Solvay Chemicals and Emerald Kalama Chemicals. Solvay makes hydrogen peroxide (an inorganic chemical) from hydrogen it produces in a steam-methane reformer. The process of reforming methane (CH_4) to hydrogen (H_2) releases CO_2 as a process emission. Emerald Kalama Chemicals makes petrochemical additives for the food industry; the firm's primary source of emissions would likely be fuels used to heat the multiple boilers.

The huge diversity of the chemical industry, and many thousands of products made, complicate efforts to discuss production processes and greenhouse gas emission sources. A number of benchmarking efforts are underway globally, however, and may help inform possible benchmark development in other regions. These include efforts by the EU to develop benchmarks for the upcoming third phase of the EU Emissions Trading System (Ecofys, Fraunhofer Institute, and Öko Institut 2009d); development of a benchmarking approach for steam crackers (used to make ethylene and other petrochemicals) developed by the consulting firm Solomon Associates; documentation of world "best practice" energy intensity values for ammonia and ethylene production (Worrell et al. 2008); efforts to document best available techniques in the chemicals sector (European Commission 2003); and global average or typical energy and GHG emission intensities for production of several particular chemicals (IEA 2008). These efforts focus on the chemicals that comprise a large fraction of the worldwide chemical sector's energy consumption and emissions releases, and in most cases focus little attention on the chemicals produced at scale in Washington State: hydrogen (and then hydrogen peroxide) and food additives. The EU study (Ecofys, Fraunhofer Institute, and Öko Institut 2009d) does specifically address hydrogen and therefore may be relevant to Solvay Chemicals. That study includes a proposed benchmark value on hydrogen production that was developed in part through data provided by the European Industrial Gases Association (EIGA) as well as elements of the Solomon Associates approach.

In addition, H.R. 2454 ("Waxman-Markey"), passed out of the U.S. House of Representatives in June 2009, included a formula for constructing average, sector-wide benchmarks for several energy-intensive and trade-exposed subsectors of the chemical industry. The benchmarks were to be used to issue allowance rebates to these industry sectors.[55] Inorganic chemicals (NAICS 325188), a sector that includes Solvay Chemicals, and organic chemicals (NAICS 325199), a sector that includes Emerald Kalama chemicals, are both included in the proposed benchmarking approach to output-based rebates.

Key Issues in Benchmarking Chemicals

In general, key issues in developing GHG benchmarks in the chemicals industry include the large number of chemicals produced (which could, in theory, require hundreds of benchmarks), the rapidity by which come facilities can change the chemicals they produce in response to market demand, data availability (even for those chemicals that are dominant from an energy or emissions perspective, such as ammonia or ethylene), and the treatment of imported heat (generally in the form of steam) given that different types of facilities produce or import varying degrees of heat depending on individual plant needs and the product made.

Food Processing

Food processing facilities in Washington manufacture diverse products such as frozen french fries, juice, and dairy products. Together, large food processing facilities in Washington emit approximately 300,000 metric tons of greenhouse gases per year (Washington Dept. of Ecology 2009).

Overview of Production Processes and Emission Sources

Major sources of greenhouse gas emissions from food processing facilities include fossil fuel combustion for heating, cooking, drying, and other processes; non-combustion processes, such as methane emissions from onsite wastewater treatment plants and hydrofluorocarbon emissions from refrigeration; and purchased electricity (US EPA 2008a). Although difficult to generalize given the wide variety of food processing facilities, steps involved in food processing often include (Masanet et al. 2008):

- **Inspection, grading, and washing**, involving a variety of electrical equipment including motors, conveyors, and pumps;
- **Processing,** including any of a wide variety of activities that can include peeling, blanching, juice extraction, filtering, pasteurization, and others, depending on the particular product being made;
- **Freezing or canning**, in which the products are frozen (using large quantities of electricity) or canned (often using large quantities of heat); and
- **Packaging**, in which the products are placed in their final packaging for shipment.

Few efforts are known to benchmark greenhouse gas emissions in the food processing industry, although regional and national efforts are underway to benchmark energy performance. These include the US EPA's ENERGY STAR program for frozen french fry manufacturers and juice processing plants and a regional effort by the Northwest Food Processors Association. More specifically:

- **ENERGY STAR** released tools in 2009 to evaluate energy performance at frozen potato and juice processing plants. Two frozen fried potato facilities in Washington have since been awarded the ENERGY STAR: the JR Simplot plant in Quincy and the ConAgra plant in Othello. EPA estimates that these two plants are in the top 25th percentile in terms of energy efficiency performance and use about 20% less energy than similar plants throughout the nation (US EPA 2010a).
- **Northwest Food Processors Association (NWFPA)** members adopted a goal to reduce industry-wide energy intensity by 25% in 10 years and 50% in 20 years. In February 2009, NWFPA signed a

[55] For more information, see the discussion of benchmarking in the context of cap-and-trade legislation that begins on page 6.

Memorandum of Understanding (MOU) with the US Department of Energy supporting that goal. To date, 49 NWFPA-member facilities have documented energy intensities for 2006 through 2009. NWFPA is establishing an industry-wide baseline for 2009 against which industry progress toward achieving the energy intensity reduction goal can be tracked.[56] Other activities include expanding data collection to include the 180 or so member facilities, benchmarking energy intensities by subsectors (at the six digit NAICS level), and developing a "roadmap" to guide efforts to achieve the 2020 energy intensity goal.

The diversity of the food processing industry, and many products made, complicate efforts to provide a more detailed overview of production processes and greenhouse gas emission sources as provided in this report for other industries.

Glass

Broadly speaking, four types of glass are manufactured in the U.S.: flat glass (e.g., windows), container (hollow) glass, fiberglass, and specialty glass. Glass is made primarily from silica sand with lime, soda, cullet (recycled glass), and other ingredients added. In the United States, glass manufacturers produce approximately 20 million tons of glass annually (Worrell et al. 2008). In Washington State, the largest glass plants are Cardinal Glass, a flat glass manufacturer in Winlock (near Chehalis), and St. Gobain Containers, a glass bottle manufacturer in Seattle. Together these facilities emit approximately 150,000 metric tons of greenhouse gases annually (Washington Dept. of Ecology 2009). Accordingly, the container glass and flat glass segments of the industry will be the focus of this section. Several producers of fiberglass-reinforced plastics, as well as a variety of smaller specialty glass products, also exist in Washington State and are not addressed here.

Overview of Production Processes and Emission Sources

The production of glass involves four sequential steps (Worrell et al. 2008):

- **Batch preparation and mixing,** in which silica (sand), soda, potash, and (in some cases for container manufacture) cullet are combined with stabilizers lime, magnesium oxide, and aluminum oxide. Refining agents may be added to help remove air bubbles in the subsequent melting step. Other additives are included here to give the glass the desired color and other properties.
- **Melting and refining**, in which the raw materials are fired in a furnace (usually a "tank" furnace) heated either by combustion or electricity or a combination of both, and sometimes using oxygen instead of regular combustion air to increase efficiency and reduce nitrous oxide emissions. Refining, which involves removal of bubbles, and homogenization, also occur in the furnace. In the U.S., most glass furnaces are fired by natural gas and some use electric boosters, as glass is a conductor at high temperatures. In such cases, electricity can represent up to 30% of the energy input to the furnace.
- **Conditioning and forming**, in which glass is transferred out of the furnace into a forehearth, where it is conditioned to have the desired temperature distribution, and then delivered to the forming equipment, where it is either shaped continuously (e.g., the float or rolled glass processes used to make flat glass) or separated into individual portions ("gobs") for blowing or pressing into containers.
- **Finishing**, in which various processes and treatments may be applied to affect glass characteristics. These steps may include annealing (reheating and cooling of the glass to remove stresses), toughening (also accomplished by a reheating, followed by rapid cooling with air jets), and coatings (e.g., mirrors).

The table below summarizes the major processes and sources of emissions in glass production.

[56] Personal communication between Eli Levitt, Washington Department of Ecology and NWFPA staff, March 24, 2010.

Table 14. Summary of Flat and Container Glass Production Processes, Emission Sources, and Existing Benchmarks

Step	Dominant Emissions Sources	Proposed or Existing GHG Benchmarks under Cap-and-trade	Other Benchmarks or Best-Practice Values	Key Issues / Options
Batch preparation and mixing	▪ Electricity production or natural gas combustion for equipment operation	E.U. has proposed benchmarks on: ▪ Flat glass ▪ Hollow glass[57] H.R. 2454 (Waxman-Markey), passed in the US House of Representatives in 2009, included a formula for constructing a average benchmarks for: ▪ Flat glass ▪ Pressed / blown glass ▪ Glass containers	▪ IEA (2008) reports some average and best-practice energy-intensity values ▪ European Commission (2009) reports energy and CO_2 levels of typical and "best available techniques" for different types of glass production ▪ US EPA ENERGY STAR has an energy benchmarking tool that compares energy per ton of glass sand input (for flat glass) or glass sand plus cullet (for container glass)[58]	▪ Use of cullet can reduce energy use and process emissions in the manufacture of container glass, but availability and quality of cullet can vary substantially by region depending on local recycling programs, which can complicate assumptions about default rate of cullet use in development of benchmark ▪ The potential substitutability of natural gas and electricity can complicate a benchmark based on direct emissions only ▪ High degree of consolidation in the glass industry complicates data availability for benchmark development
Melting and refining	▪ Natural gas for firing the furnace ▪ Production of electricity used for boosting furnace, if applicable ▪ Process CO_2 emissions resulting from the decarbonization of soda ash and lime			
Conditioning and forming	▪ Natural gas burning or electricity production for heating of the forehearth ▪ Electricity production or natural gas combustion for equipment operation			
Finishing	▪ Electricity production or natural gas combustion for equipment operation	None known	▪ IEA (2008) reports some average and best-practice energy-intensity values	

Key Issues in Benchmarking Glass

As with all sectors, the data availability and number of products to distinguish (e.g., whether to develop separate benchmarks by container shape or color) may be key issues. In addition, two issues particular to the glass industry are:

- **How to treat use of cullet (recycled glass)**, particularly in container glass production. Use of cullet can reduce energy use and process emissions, but its availability and quality can vary substantially by region depending on local recycling programs, such that areas with more-developed recycled glass collection and processing infrastructures may have significant advantages in meeting a benchmark level. However, under a cap-and-trade system on greenhouse gases, differentiating the benchmark based on cullet usage or quality may be less appropriate, since the goal is to encourage the use of lowest-GHG processes and feedstocks and facilities have the flexibility to purchase allowances or offsets. Under a regulatory or voluntary framework, some level of accounting for cullet quality and availability may be desirable, assuming facilities are asked to meet a particular benchmark and do not have flexibility to purchase allowances or offsets to meet the benchmark.
- **Relative ease of substitution between electricity and natural gas** in many glass furnaces could complicate benchmark development and application. If the benchmark was based only on direct emissions, then the facilities that are more reliant on electricity would appear to fare much better, regardless of overall GHG intensity (including the emissions released in electricity production).

[57] The EU has also proposed a benchmark in continuous filament fibers that is not discussed here because the focus is on flat and container glass (Ecofys, Fraunhofer Institute, and Öko Institut 2009e)
[58] Cardinal Glass has been a participant in an EPA Work Group as part of the ENERGY STAR program: http://www.energystar.gov/index.cfm?c=in_focus.bus_glass_manuf_focus.

Pulp & Paper

With extensive forests, the Pacific Northwest (and Washington State in particular) has historically been a leader in the pulp and paper industry. In recent decades, the state's industry has contracted due to increased competition and decreased prices due to rising global production capacity (particularly in Asia), increased energy prices, and decreased supply of raw materials (e.g., wood chips). However, many pulp and paper mills remain in the state, with most being integrated mills, meaning they produce both pulp and paper. Together these large pulp and paper emitted approximately 850,000 metric tons of greenhouse gases in 2007 (Washington Dept. of Ecology 2009).

Table 15, below summarizes the active pulp and/or paper mills in Washington State.

Table 15. Active Pulp & Paper Mills in Washington State[59]

Facility	City	Mill Type	Pulp Type	Products
Boise*	Wallula	Integrated	▪ Kraft	▪ Bleached paper ▪ Coated paper ▪ Corrugating medium
Georgia Pacific*	Camas	Integrated	▪ Kraft	▪ Bleached kraft paper ▪ Tissue ▪ Paper towels
Grays Harbor Paper	Hoquiam	Non-integrated	▪ Recycled paper and Kraft (purchased)	▪ Writing paper
Inland Empire*	Spokane	Integrated	▪ Mechanical ▪ Deinked recycled	▪ Newsprint
Kimberly Clark*	Everett	Integrated	▪ Sulfite (ammonia-based)	▪ Tissue
Longview Fibre*	Longview	Integrated	▪ Kraft	▪ Container board
Nippon Paper	Port Angeles	Integrated	▪ Mechanical pulp and recycled paper	▪ Telephone directory paper
Ponderay Newsprint	Usk	Integrated	▪ Thermomechanical	▪ Newsprint
Port Townsend Paper*	Port Townsend	Integrated	▪ Kraft and recycled OCC	▪ Unbleached kraft pulp ▪ Lightweight linerboard ▪ Corrugating medium ▪ Unbleached converting grades
Simpson Tacoma Kraft*	Tacoma	Integrated	▪ Kraft	▪ Unbleached kraft pulp ▪ Bleached and unbleached packaging paper ▪ Linerboard
Sonoco	Sumner	Integrated	▪ Recycled cardboard and magazine-type papers	▪ Recycled paperboard
Weyerhaeuser Co.*	Longview	Integrated	▪ Kraft ▪ De-ink (recycled) ▪ Thermomechanical	▪ Paperboard ▪ Corrugating medium ▪ Newsprint ▪ Fine papers

*These facilities are estimated to emit at least 25,000 tons CO_2e annually (Washington Dept. of Ecology 2009)

One of the most significant distinctions between mills is the production process used to create pulp. The main pulp processes are chemical pulping (including the kraft and sulphite processes), mechanical pulping, or paper recycling, with mechanical pulping being the most greenhouse-gas intensive. The type of process used in each of Washington's mills is noted in Table 15 and described in more detail below.

[59] Summarized from the Department of Ecology's industrial section web page (http://www.ecy.wa.gov/programs/swfa/industrial/facilities.html) and individual company web pages.

Overview of Production Processes and Emission Sources

The production of pulp and paper involves four main processes:

- **Raw material harvest or collection**, in which either virgin wood is harvested and chipped or post-consumer or post-industrial paper feedstocks are collected and sorted.
- **Virgin pulp production**, in which the wood chips are broken down into their raw cellulose fibers by one of three dominant types of processes:
    - Kraft (sulfate) pulping, in which fibers are released by dissolving the wood chips in a high-temperature sulfate chemical solution (the cooking process) and which produces black liquor, a waste product that contains a significant quantity of lignin;
    - Sulfite pulping, in which the cooking process uses a bisulfate liquor in a pressurized vessel. Sulfite pulping is rare and is used mainly for specialty papers, and produces a byproduct called "green liquor."
    - Mechanical pulping, in which wood fibers are mechanically separated. One type of mechanical pulping is the groundwood process, in which wood is ground to produce relatively short fibres (e.g., for newsprint) in an electricity-intensive process. Mechanical pulping can also involve pre-softening with steam (thermo-mechanical pulping) or with chemicals (chemi-mechanical pulping), either of which can involve more use of fossil fuel than other mechanical-based pulps.

  Methods of recovering energy are possible in all three types of pulping. In the kraft process, black liquor can be combusted to recover substantial quantities of energy from the lignin, even producing more heat than is needed in the pulping process.[60] Similar energy recovery is possible from green liquor produced in sulfite pulping. In mechanical pulping, heat generated from the application of mechanical energy (only a fraction of which is used to separate the cellulose fibers) can also be recovered as hot water or steam.

  In all of the pulping processes, bleach may or may not be applied depending on the desired brightness of the finished product.
- **Recovered paper processing**, which involves collecting and sorting post-consumer and pre consumer waste as feedstocks, cleaning and de-inking. Use of recovered paper requires energy but tends to lower the overall energy and emissions intensity of paper production.
- **Paper production**, in which the pulp is fed into the paper making machine, screened, vacuumed of water, pressed by rollers, and dried. If necessary, sizing (to affect absorption and wear) and coatings are then applied.

Table 16 summarizes the major processes and sources of emissions in pulp and paper production.

[60] Lime can also be recovered from the kraft pulping process.

Table 16. Summary of Paper Production Processes, Emission Sources, and Existing Benchmarks

Step	Dominant Emissions Sources	Proposed or Existing GHG Benchmarks under Cap-and-trade	Other Benchmarks or Best-Practice Values	Key Issues / Options
Raw material harvest or collection	▪ Fossil fuel for extraction equipment	None known	None known	
Virgin pulp production	▪ Fossil fuel for heat or steam (particularly for start-up if recovering energy from waste liquors) and to power the lime kilns in the kraft process ▪ Process emissions from production of lime in the kraft process ▪ Electricity production (particularly for mechanical pulping)	▪ EU has proposed benchmark for kraft pulp (for lime kiln operation only)[61] ▪ H.R. 2454 (Waxman-Markey), passed in the US House of Representatives in 2009, included a formula for constructing an average benchmark for pulp production (NAICS 322110)	▪ Worrell et al (2008) and IEA (2008) list world best-practice energy and "best available technology" benchmarks, respectively, for virgin pulp production	Heat at the mill can be produced using feedstocks that are either: ▪ Inherent to the pulping process (e.g., black or green liquor recovery or from heat recovery from mechanical pulping), in which case heat recovery can exceed that needed for the pulping process and the facility can be a net exporter of heat; no benchmark may be needed (as in the EU) ▪ Unrelated to the pulping process (e.g., bark or wood residues, wastewater treatment, and short fiber sludges), which in the EU is left outside the pulp benchmark system boundary since it is not directly related to the performance of pulp making; this heat production may still receive a benchmark under the allocation for cross-facility heat flows
Recycled paper processing	▪ Fossil fuel and electricity for processing equipment, particularly for pulping and deinking	▪ EU has proposed a benchmark on processed recovered paper	▪ Worrell et al (2008) and IEA (2008) list world best-practice energy and "best available technology" benchmarks, respectively, for recovered pulp production	▪ Use of a separate benchmark for processed recovered paper avoids the need to derive an assumed ratio of recycled fibers to virgin pulp in paper benchmarks
Paper production	▪ Fossil fuel for dryers, heaters (for production of coated papers), and other equipment ▪ Electricity production for equipment, including rollers, presses, motors, and pumps	EU has proposed benchmarks on: ▪ Recycled paper ▪ Newsprint ▪ Uncoated fine paper ▪ Coated fine paper ▪ Tissue ▪ Container board ▪ Carton board ▪ Other papers H.R. 2454 (Waxman-Markey) included formulas for calculating benchmarks for: ▪ Newsprint, NAICS 322122 ▪ Paperboard, NAICS 322130 ▪ Other Paper, NAICS 322121	▪ Worrell et al (2008) and IEA (2008) list world best-practice energy and "best available technology" benchmarks, respectively, for numerous paper grades	▪ Benchmarks developed based on integrated mills may be too low for non-integrated mills that buy market pulp (and therefore don't have pulp residuals available as fuels), but splitting emissions in integrated mills between pulp and paper making is very difficult. ▪ The EU reports that containerboard, carton board, and other papers may need further disaggregation but that data are insufficient:[62]

[61] The EU has not proposed benchmarks for heat consumption for kraft, sulfite, or mechanical pulp because the recovery of waste products from these processes can produce more than enough heat to supply to the pulping process (Ecofys, Fraunhofer Institute, and Öko Institut 2009f) The allocation for lime production is for the fossil fuel use only, not for the process CO_2, because the process CO_2 here is from a biomass source, unlike in normal lime production (Neelis et al. 2009).

[62] A subsequent finding by the European Commission (European Commission 2010) suggests separate benchmarks for two types of containerboard: kraftliner and testliner/fluting.

Key Issues in Benchmarking Pulp & Paper

Three issues particular to the pulp and paper industry are:

- **How to treat use of recycled pulp or recovered paper**. Since use of recovered paper affects the GHG intensity of paper production, benchmark construction may need to either assume a default rate of recovered paper (or recycled pulp) use or else develop a separate benchmark for use of processed recovered paper, as is currently being explored in the EU.
- **Whether paper benchmarks based on integrated mills can be applied to non-integrated mills.** Integrated mills make paper from their own pulp and have pulping residuals (e.g., black liquor) left over to use as fuel in the boiler. Accordingly, non-integrated mills that buy market pulp or produce pulp by recycling papers may not be able to meet benchmarks based largely on emissions from integrated mills. Differentiating the benchmark for integrated and non-integrated mills may be particularly relevant for benchmarks in a regulatory or voluntary context. However, under a cap-and-trade system on greenhouse gases, such differentiating may be less appropriate, since the goal is to encourage the lowest-GHG processes and facilities have the flexibility to purchase allowances or offsets.
- **How to treat heat production and possibility for cross-facility heat flows**, especially since recovery of black liquor from the kraft pulping process can result in production of excess heat that could be sold to another facility or used to make electricity. In such case, some researchers (Ecofys, Fraunhofer Institute, and Öko Institut 2009f) have considered (but generally discarded due to methodological complexity) whether a *negative* benchmark might be considered to account for the heat that could be sold and exported as a separate product. Regardless, the question of how to account for cross-facility heat or power flows will need to be carefully considered.

Steam

Many industrial processes use heat (as hot water or steam) produced in boilers, many of which are fired using fossil fuels. Nationally, EPA estimates that the approximately 45,000 industrial boilers in use nationally emit 1,250 $MtCO_2e$ annually, or approximately 20% of the national U.S. greenhouse gas inventory (US EPA 2008b). Boilers are also used in commercial and institutional settings such as hospitals, schools, and shopping malls. Boiler sizes exist along a continuum from small residential-scale units to factory-built intermediate-sized units to large site-built units. While the differing boiler sizes can be subject to similar emission reduction options and benchmarking considerations, this *White Paper* addresses only boilers used at industrial sources.

The use of boilers and generation of steam applies across many of the industry sectors discussed in this *White Paper* (including pulp and paper, chemical, and food processing sectors), as well as many other sectors not discussed in detail (e.g., petroleum refining). More specifically, use of boilers is particularly common in the following sectors (Energy and Environmental Analysis, Inc. 2005; IEA 2008):

- **Pulp and paper**, with about 3,400 boilers nationally, and where the dominant fuel is black liquor, a byproduct of the chemical pulping process, and where bark, wood chips, and production wastes are other common feedstocks.
- **Chemicals**, with about 12,000 boilers nationally, many of them smaller than the 10 MMBtu/hour threshold for Clean Air Act standards, and where dominant fuels are natural gas, by-products, and coal or coke.
- **Petroleum refining**, with 1,200 (generally large) boilers nationally, and where the dominant fuels are crude oil, natural gas, and residual fuel oil.
- **Food processing,** where boilers are generally fueled by natural gas or residual fuel oil.
- **Wood products,** where the boilers are generally fueled by wood wastes.
- **Miscellaneous industrial products,** where the boilers are generally fueled by what fuel is available, was lowest cost at time of initial installation of the boiler, or is allowed in an air permit.

Accordingly, steam is not an industry *per se*,[63] but instead is an intermediate product produced and used by several industry sectors – a product that is usually generated and consumed in the same facility but is sometimes sold or transferred between facilities. Because many different types of facilities produce and use steam, some existing or proposed benchmarking efforts have considered developing separate benchmarks based on heat or steam production in addition to or instead of other benchmarks. These include the EU's effort to develop industry benchmarks for the third phase of its Emissions Trading System, where a heat production benchmark has been recommended as a "fall-back" approach for sectors or products where product-specific benchmarks are not developed and applied (Ecofys, Fraunhofer Institute, and Öko Institut 2009a). Additionally, US EPA has considered developing benchmark-based performance standards for industrial boilers as it has evaluated alternative possibilities for regulating greenhouse gases under the Clean Air Act (US EPA 2008b) and has also developed a protocol for measuring reductions in greenhouse gas emissions from industrial boilers (US EPA 2008e).

Overview of Production Processes and Emission Sources

The production and use of steam in industrial processes involves four sequential steps (LBNL and Resource Dynamics 2004):

- **Generation.** Steam is produced either in a boiler or in a system to recover heat from another industrial process. In either case, steam is produced by transferring heat to water, which when heated to the boiling point, produces steam. The temperature and pressure of the steam produced in a boiler is influenced by the boiler design and by the ultimate uses of the steam produced.
- **Distribution.** Under pressure, steam flows from the generator into distribution lines, which carry the steam to the points of end use and which involve various types of valves to regulate pressure.
- **End Use.** Steam can be used for process heating, mechanical drives via turbines, moderation of chemical reactions, drying of paper products, fractionation of hydrocarbons in petroleum refining, or used directly as a hydrogen feedstock in a steam-methane reformer (e.g., at Solvay Chemicals.)
- **Recovery.** Wet steam or condensed steam used in process heating is returned to the boiler area where it is cooled in a heat exchanger and collected in a boiler feedwater tank. From the collection tank, the water is pumped to a deaeretor, where it is stripped of oxygen and non-condensable gases and fed back into the boiler along with any makeup water needed to repeat the cycle.

Release of greenhouse gases occurs in the generation stage as a result of burning of fuels used to heat the boiler. Fuels used include the fossil fuels coal, oil, refiner gas (petroleum refining), and natural gas; waste products such as bark or wood chips, pulping liquors (pulp and paper sector), or landfill gas; plus other fuels. Boiler efficiency can vary tremendously by boiler age, size, and design. Coal and natural gas fired boilers are typically about 80 to 85% efficient, whereas a boiler fired by spent pulping liquors is approximately 70% efficient (Energy and Environmental Analysis, Inc. 2005). Significant losses of efficiency can also arise in the distribution system. According to the International Energy Agency, the best opportunity to increase efficiency of a steam system is through a combined heat and power (CHP) system (IEA 2008).

Key Issues in Benchmarking Steam

Three factors influence GHG emissions from combustion processes that generate steam: the choice of fuels, the efficiency of the heat production, and the efficiency of heat end use (Ecofys, Fraunhofer Institute, and Öko Institut 2009a). A benchmark on steam production would easily account for the first two factors, but the third would be harder to include. As a result, one issue in benchmarking steam (at least relative to alternative approaches, such as benchmarking end products) is that a steam benchmark would not account for the efficiency of the *use* of that steam in producing a final product such as paper, a food product, or chemicals, or heating buildings. To address this limitation, the EU has considered whether an adjustment factor may be applied to the benchmark to account for potential end-use efficiency improvements (Ecofys, Fraunhofer Institute, and Öko Institut 2009a). In other

[63] Unless the steam is the product of a specialized area heating/cooling facility that provides steam to heat office buildings in the area around the plant. The Seattle Steam plant in downtown Seattle is an example of such a facility.

words, for sectors with large end-use efficiency opportunities, the benchmark value could be adjusted to help encourage pursuit of the end-use efficiency opportunities.

The biggest issue with benchmarking steam, however, may be whether to differentiate a steam benchmark by sector. Different industrial sectors may use different boiler technologies (with varying efficiencies) or (as described above) rely historically on different fuels, factors which may suggest the use of differentiated benchmarks by sector or by fuel and boiler design, at least in a voluntary or regulatory approach. The U.S. Department of State, for example, has written "the efficiencies of industrial boiler applications in the U.S. are dictated by operational and emission requirements making no single emissions performance value applicable for the variety of industrial boilers in use in the U.S. (US Department of State 2010). Under a cap-and-trade program, developing different steam benchmarks for each sector may be less appropriate as the goal is to encourage long-term technology and fuel transitions and facilities can purchase or sell allowances depending on whether they are emitting above or below the respective benchmarks.

Finally, how emissions from biomass and waste fuels, as well as cross-boundary (versus within-facility) heat flows are treated in benchmark development and application is very important in ensuring that the benchmark sends the appropriate incentive. [Our research on cross boundary heat flows and combined heat and power (CHP) is ongoing.]

Steel

Crude steel is produced from both virgin materials (primary iron, which is made from iron ore) and secondary materials (scrap). The steel industry employs two distinct production technologies to make steel: the basic oxygen furnace (BOF), which is integrated with the production of pig iron, and the electric arc furnace (EAF), in which steel is produced by the melting of scrap or direct reduced iron with the help of electric arcs. Globally, about two-thirds of steel is produced via the first process, which uses mostly iron ore as its feedstock (with small amounts of scrap). In the U.S., more steel is produced in the electric arc furnaces, which is generally less greenhouse-gas intensive than production via basic oxygen furnace (IEA 2008).[64] Other technologies, including the outdated open-hearth furnaces, account for a very small fraction of steel making. The industry, in collaboration with researchers at the Massachusetts Institute of Technology, is also investigating new steelmaking technologies, such as molten oxide electrolysis, that would generate zero direct carbon emissions, but that would require large quantities of electricity (IEA 2009).

In Washington State, the only producer of crude steel is Nucor Steel in Seattle, an electric arc furnace that uses scrap (recycled) steel to make steel rebar, flat bar, channel, and other similar products. We cover both BOF and EAF technologies here, however, as basic oxygen furnaces have existed in Washington previously, and they continue to be major producers of steel in other parts of the country.

After crude steel is cast, additional processes convert the steel to finished products at forges. One forge, Jorgenson Forge, is based in Tukwila, WA. Together, Nucor Steel and Jorgensen Forge release an estimated 135,000 tons CO_2e of greenhouse gases each year(Washington Dept. of Ecology 2009).

Overview of Production Processes and Emission Sources

Production of steel occurs in five distinct steps (Ecofys, Fraunhofer Institute, and Öko Institut 2009g; Neelis and Patel 2006):

- **Mining and treatment of raw materials.** Two significant raw materials are used to make steel: iron ore and coal. Coal is converted to coke by heating in the absence of oxygen to remove the volatile components and tars. Iron ore is sintered, a process in which iron ores of different grain sizes (particularly finer-grained ore) are agglomerated together with additives (e.g., limestone) to make a consistent feedstock for the blast furnace.

[64] The exception would be if the electric arc furnace is fueled by direct reduced iron produced using coal, in which case total emissions per ton of steel can be higher than from a basic oxygen furnace (IEA 2008).

- **Iron making**, in which iron ore is smelted with coke in a blast furnace and iron oxides are reduced to liquid pig iron. Alternatively, iron ore can instead be reduced, below its melting point and retaining its original shape, into direct reduced iron (DRI) (also called "sponge iron") for use in an electric arc furnace.[65]
- **Steel making.** In the basic oxygen furnace, oxygen is blown through the molten pig iron, oxidizing the carbon, silicon, and phosphorus in the pig iron and producing steel. Some amount of scrap may be added at this stage to help control the reaction and aid in cooling. In an electric arc furnace, as in the Nucor facility in Seattle, melting of scrap (recycled steel) and direct reduced iron occurs in a bath at high temperatures attained with the help of an electric arc.
- **Casting**, in which liquid steel is cast into large ingots, billets, or, semi-finished products such as slabs. In the Nucor facility in Seattle, steel is cast into a billet.
- **Rolling and finishing,** in which the steel is converted to finished steel products via various foundry, rolling, pickling, annealing, welding, or other steps.

Table 17 summarizes the major processes and sources of emissions in iron and steel production. Note that the first two processes: raw material treatment and iron-making, do not occur in Washington State.

[65] Washington's only steel mill, Nucor Steel, an electric arc furnace, does not use direct reduced iron.

Table 17. Summary of Iron and Steel Production Processes, Emission Sources, and Existing Benchmark Sources

Step	Dominant Emissions Sources	Proposed or Existing GHG Benchmarks under Cap-and-trade	Other Benchmarks or Best-Practice Values	Key Issues / Options
Mining and treatment of raw materials	▪ Fossil fuel burning for coking and sintering ▪ Direct CO_2 emissions from residue materials and from limestone calcinations ▪ Direct CO_2 and CH_4 emissions from coke-making (usually transferred as a waste gas to the blast furnace) or sinter making	EU has proposed benchmarks for: ▪ Coke ▪ Sinter	▪ Worrell et al (2008) list world best-practice energy benchmarks for pellets	▪ Treatment of waste gases from the coke oven, blast furnace, and basic oxygen furnace can be used in internal processes or transferred to other installations. Benchmarks for these waste gases could be established and allowances allocated (if in a cap-and-trade setting) to either producer or consumer of them (or split between them).[66] ▪ EU states that a separate benchmark for iron ore pellets (an alternative to sinter) may be warranted if data are sufficient
Iron making	▪ Fossil fuel burning to fire blast furnaces ▪ Direct CO_2 emissions from use of coke as a reducing agent in a blast furnace	None known (In the EU, emissions for producing pig iron are included in the hot steel benchmark)	▪ Worrell et al (2008) list world best-practice energy benchmark for ironmaking, including direct reduced iron	Arguments exist both for and against having a separate benchmark for pig iron: ▪ For: it can be traded as its own intermediate product ▪ Against: Rarely is cooled and sold as its own product; could create perverse incentives for altering ratio or quality of pig iron use; separate pig iron and hot metal benchmarks would likely be impossible for an integrated facility to simultaneously attain.[67]
Steel making	▪ In a BOF, fossil fuel burning and direct CO_2 emissions from oxidizing the carbon in the pig iron ▪ In an EAF, direct, process CO_2 emissions from carbon from electrodes and scrap oxidizing, as well as emissions from production of electricity	EU has proposed benchmarks for: ▪ Hot steel ▪ EAF steel H.R. 2454 (Waxman-Markey), passed in the US House of Representatives in 2009, included a formula for constructing average benchmarks for: ▪ Steel from integrated mills ▪ EAF steel	IEA (2008) lists global averages for ▪ EAF steel from scrap ▪ EAF steel from direct reduced iron ▪ BOF steel Worrell et al (2008) list world best-practice energy benchmarks for steelmaking and casting US EPA (2008a) reports U.S. average 1.24 tons of CO_2 per ton of steel, including both direct and indirect emissions, based on AISI data	▪ Treatment of waste gases can be critical (see above under treatment of raw materials) ▪ EAF high-alloy steel may warrant its own benchmark as it may be considered a distinctly different product, but in the EU data were insufficient ▪ The substitutability of electricity and fossil fuel in EAFs may be debated ▪ A key decision may be in what casting steps to include in a steel benchmark versus to treat downstream with a separate benchmark (perhaps using a fall-back approach given limited data)
Casting	▪ Fossil fuel burning or electricity production			
Rolling and finishing	▪ Fossil fuel burning or electricity production for equipment	EU treats with a fall-back approach	▪ Worrell et al (2008) list world best-practice energy benchmarks for rolling and finishing	▪ EU considering separate benchmarks for foundry products and warm rolling if products are similar enough

[66] For a lengthy discussion of waste gases in the iron and steel sector, including stakeholder comments, see Ecofys, Fraunhofer Institute, and Öko Institut (2009g)
[67] For a full discussion, see Ecofys, Fraunhofer Institute, and Öko Institut (2009g).

Key Issues in Benchmarking Steel

As with all sectors, the data availability and number of products to distinguish may be key issues. In addition, three issues particular to the steel industry are:

- **Treatment of waste gases,** which can either be used internally as furnace fuel or to generate electricity. To what extent these waste gases are counted when the benchmark is constructed, and whether they are counted under the producer or consumer (if applicable) of these gases, can be important questions (Ecofys, Fraunhofer Institute, and Öko Institut 2009g).
- **Treatment of intermediate products.** Coke, sinter and hot metal are important intermediate products that can be traded between installations. How to account for these possible trades can be an important question. The EU proposed to develop benchmarks for these intermediate products (Ecofys, Fraunhofer Institute, and Öko Institut 2009g).
- **Substitutability of electricity and fossil fuel in an electric arc furnace.** In an electric arc furnace, oxy-fuel burners can also be used to provide heat to the furnace. Within certain limits, and depending on the product being made, the fraction of heat supplied by the oxy-fuel burner can be altered. Accordingly, a benchmark based only on direct emissions could tend to favor electric arc furnaces that use a lower fraction of heat from the oxy-fuel burner, regardless of overall (direct + indirect) GHG intensity. However, this issue would be less of a concern under a cap-and-trade program that also included electricity, since the cost of emissions from electricity production would be reflected in the price of the electricity.

5. Summary of Preliminary Findings and Potential Next Steps

Executive Order 09-05 directs the Department of Ecology to both to “develop emission benchmarks” and to deliver “recommendations on industry benchmarks, and the appropriate use of these benchmarks in achieving the state emission reduction targets” to the Governor by July 1, 2011.

Ecology has divided benchmarking work under the Executive Order into two phases. This report presents findings of the first, exploratory Phase I on key issues and options in benchmark development. Phase II could involve the development of benchmarks and will involve developing specific recommendations on their appropriate use. This section begins by reviewing our preliminary findings for Phase I, and then presents some possible paths forward under a Phase II.

Industries in Washington State and throughout the world use benchmarking to compare their performance to others in their own benchmarked industry sector using best practices and/or industry averages. Use of benchmarks to improve energy efficiency is well established, while benchmarking to reduce GHG emissions is increasingly explored and in some instances, practiced. Internationally, the cement and aluminum industries, for example, have made significant in-roads in developing GHG benchmarks and using these to set GHG performance targets.

As discussed in this paper, benchmarking is incorporated in most of the key efforts to address industrial GHGs :cap-and-trade programs, voluntary initiatives and agreements, and regulatory performance standards. From a climate policy perspective, industrial benchmarking is most advanced in the EU, where benchmarks have been used for voluntary agreements between national governments and industrial sectors or individual companies, and where detailed benchmark development is well underway for allowance distribution under the third phase of the EU’s Emission Trading System. However, as described in Section 2, GHG benchmarking is gaining ground in the U.S. as well. Benchmarking provides a tool for developing GHG performance standards under the Clean Air Act, and the possible basis for distributing allowances under a cap-and-trade system.

It is important to note that developing meaningful benchmarks will require collecting and comparing performance data across a significant proportion of product markets. The development of GHG benchmarks is thus most relevant at a regional, national, or international level, even as such benchmarks may be applied at more local (e.g., state) levels. This has implications for Ecology’s work in Phase II.

The construction of benchmarking presents a number of challenges, such as:

- The appropriate level of disaggregation by technology, feedstock, fuel or other facility-specific factors; The ability to differentiate by specific product type;
- Whether and how to include indirect emissions from purchased electricity and heat;
- How to address cogeneration (combined production of heat and power);
- Whether to develop and use a more generic heat production benchmark;
- What data sources to use, including how many facilities are needed to yield a meaningful data set for benchmarking; and
- The level of ambition to which the benchmark should be constructed to inform/motivate industry actors;

As described in Section 3, the policy context – cap-and-trade allowance distribution, regulatory performance standards, or voluntary targets – will influence how each of the challenges is resolved. Executive Order 09-05 calls for Ecology specifically to "develop emission benchmarks, by industry sector, for facilities the Department of Ecology believes will be covered by a federal or regional cap-and-trade program" and to "support the use of these emission benchmarks… as an appropriate basis for the distribution of emission allowances." At the same time, the Executive Order is also clear that benchmarks "shall be developed to allow their application as state-based emissions standards, should they be needed to complement the federal program, or in the absence of a federal program." Regardless of the ultimate policy approach – cap-and-trade or regulatory performance standards – there is some common work to do collect and analyze sectoral benchmarking data.

Indeed, benchmarking is a highly data-intensive exercise, and comprehensive and consistent facility-level greenhouse gas emissions data are only just now beginning to emerge, especially here in the U.S., through mandatory reporting rules and industry-led efforts. Benchmarking data can also be sensitive or difficult to procure, since the production data used to index performance are often considered confidential business or production information. As we note in Section 3, however, a number of sources can be utilized to analyze and gauge emissions, production, and other data needed to develop benchmarks. The timing of policies that will depend on benchmarks will determine the data sources that can be relied upon for benchmark construction, which in turn will influence how the benchmarks can be designed. If benchmarks are needed by July 1, 2011, for example, then they will be able to rely upon, at most, one year of comprehensive U.S.-wide mandatory reporting data.

In keeping with the Executive Order, and as reflected in this paper, Ecology is currently proceeding with an approach to benchmarking that leaves open how benchmarks might ultimately be used: for allowance distribution in a cap-and-trade system or for emissions performance standards. Such an approach enables Washington State agencies and industries to be prepared for, and be involved in shaping, a climate policy landscape that is currently highly uncertain. It allows Ecology to proceed with certain elements of benchmark development, such as data collection and analysis, that do not depend on policy context. However, as we illustrate in this paper, other elements of benchmark development, such as levels of ambition and disaggregation, are likely to depend upon whether benchmarks are used for allowance rebates, performance standards, or other applications.

As a path forward, Ecology could continue to cover all the bases with a comprehensive effort would involve developing benchmarking data and methodologies, and constructing proposed benchmarks, that are appropriate for each policy context. This path forward would require significant resources and would depend on finding ways to overcome possible data limitations, especially if all potentially relevant sectors are covered. Pursuing such an approach would maintain maximum flexibility and could include the greatest possible share of industrial GHG emitters in the state, but could forego the opportunity to use limited resources to develop a path forward tailored to policy approaches or industry sectors for which benefits are likely to be the greatest.

Alternatively, Ecology could choose more focused paths, for instance, by doing one or more of the following:

- Concentrate on one benchmark context alone, such as output-based allowance distribution. Doing so would allow Ecology to contribute to more detailed methodology development (with potential broader influence) yet would require the implementation of a national or regional cap-and-trade program to actually implement the use of benchmarks in this manner.

- Select one or more sectors for initial benchmark development. As a first step, Ecology could establish and use criteria upon which such a selection could be made. Section 4 of this report discussed particular industry sectors and how they might be evaluated under some potential criteria, such as energy-intensiveness or trade exposure, level of emissions in Washington State, data availability, and experience with benchmarking.
- Dive more deeply on a) resolving specific benchmarking questions, such as the feasible and desirable levels of product differentiation (e.g. writing paper, newspaper, or all paper within the pulp and paper sector) or technology or other differentiation in benchmarks for selected sectors, or b) collecting and analyzing performance data, rather than developing actual benchmark values.

The direction and extent of Phase II work will depend on a number of factors, from available resources at Ecology to policy developments occurring beyond the state's borders. With federal climate policy in considerable flux, and regional efforts (i.e., WCI) still under development, Ecology could take such an incremental approach, undertaking some of the steps noted above during the last half of 2010, and then re-evaluating whether and how to proceed with benchmark development in the first half of 2011.

Other steps that Ecology may consider, regardless of the path taken as outlined above, would be to:

- Partner with other interested jurisdictions in the WCI, MGGRA, or RGGI on data collection, analysis, and benchmark design;
- Establish a collaborative agreement with EPA and/or industry associations and facilities to gain better access to data and to pilot specific benchmarking methods; and/or
- Convene expert groups to review and evaluate benchmark methodologies for their relevancy to the Washington state context and the Governor's Executive Order.

As noted in the introduction, this report is a preliminary draft. Building on the insights gained from the benchmarking symposium (May 19, 2010) and stakeholder input, we will issue a final draft in late June. We invite your comments on this draft, submitted via email to benchmarking.wa@sei-us.org by Friday, June 4, 2010. Our recommendations on how Ecology might undertake Phase 2 will be detailed more fully in the final draft.

Appendix A. Expected GHG Reporting Data

In Section 3 of this White Paper, we assess possible sources for emissions and production data that could enable construction of benchmark curves. One of the most promising – but as yet unavailable – sources of data will be mandatory greenhouse gas reporting rules. This appendix describes the data that will be submitted under the federal and Washington State reporting rules as well as other sector-specific data sources (e.g., the Cement Sustainability Initiative).

US EPA's Mandatory Reporting of Greenhouse Gases rule will require facilities to report greenhouse gas emissions for year 2010 by March 31, 2011 (US EPA 2009b). All facilities in the primary aluminum and cement sectors will need to report emissions, as will facilities in several other sectors without a significant presence in Washington State (e.g., chemical industry sectors adipic acid, ammonia, HCFC-22, nitric acid, phosphoric acid, and others). In most other sectors, all facilities that emit more than 25,000 ton CO_2e annually will be required to report. Emissions data will be public. Reporting of production data is also required. While a determination of the confidentiality of the production data is still forthcoming, these data are not expected to become public but may be used by agency staff (EPA staff, personal communication, April 2010).

The State of Washington's Mandatory Greenhouse Gas Reporting Rule takes effect in 2010 for facilities with at least 25,000 tons CO_2e of 2009 emissions. Facilities that emit at least 10,000 tons of GHGs must start reporting in 2011 for year 2010 emissions. The reporting methodologies for both the federal and Washington State rules have been harmonized.

Following is a discussion of reporting rule specifics for each sector that we addressed in Section 4 of the main body of this White Paper.

Aluminum

Reporting requirements for the aluminum sector are summarized in Table 18. Most of the emission sources below apply only to primary aluminum. For secondary aluminum, the major sources of direct emissions are fossil fuel combustion for the furnace (if applicable) and equipment.

Table 18. Summary of Required Federal GHG Reporting for the Aluminum Sector (US EPA 2009b)

Sources Addressed	▪ Aluminum smelting via electrolysis using either prebake or Söderberg anodes ▪ Baking of anodes for pre-bake anodes ▪ Stationary combustion of fossil fuel
GHGs Required to be Reported	▪ PFC – Perfluoromethane (CF_4) and perfluoroethane (C_2F_6) – emissions from anode effects ▪ Carbon dioxide (CO_2) emissions from anode consumption during electrolysis in all prebake and Søderberg cells. ▪ All CO_2 emissions from onsite anode baking ▪ CO_2, nitrous oxide (N_2O), and methane (CH_4) emissions from each stationary combustion unit
Methodology Highlights	▪ Perfluorocarbon emissions (CF_4) and perfluoroethane (C_2F_6) emissions calculated based on frequency and duration of anode effects, monthly aluminum production, and a pre-determined coefficient that estimates emissions from these parameters ▪ Process CO_2 emissions calculated based either on installing and operating a continuous emissions monitoring system (CEMS) or a mass-balance calculation ▪ Process CO_2 emissions during anode baking of prebake cells estimated based on mass balance calculation ▪ Carbon dioxide (CO_2) emissions from each fuel combustion unit calculated using one of the four tiered methods outlined in the rule, as well as methane (CH_4), and nitrous oxide (N_2O).
Required Reporting	▪ Annual GHG emissions ▪ Annual aluminum production in metric tons ▪ Type of smelter technology used ▪ Annual fuel use ▪ Various parameters used to support calculations of process emissions

Other Data Sources in the Aluminum Industry

Internationally, the International Aluminum Institute (IAI) collects data on the specific emissions of PFC emissions from primary aluminum production. The IAI publishes plant specific data for most of the aluminium production plants worldwide (International Aluminum Institute 2009). Unfortunately, only very few installations from China reported their emissions. With the data of the reporting installations (representing approximately 60% of all installations worldwide) a benchmarking curve can be constructed and is depicted below as Figure 9.

Figure 9. Benchmarking curve for PFC emissions from primary aluminum production
(X-axis is fraction of plants)

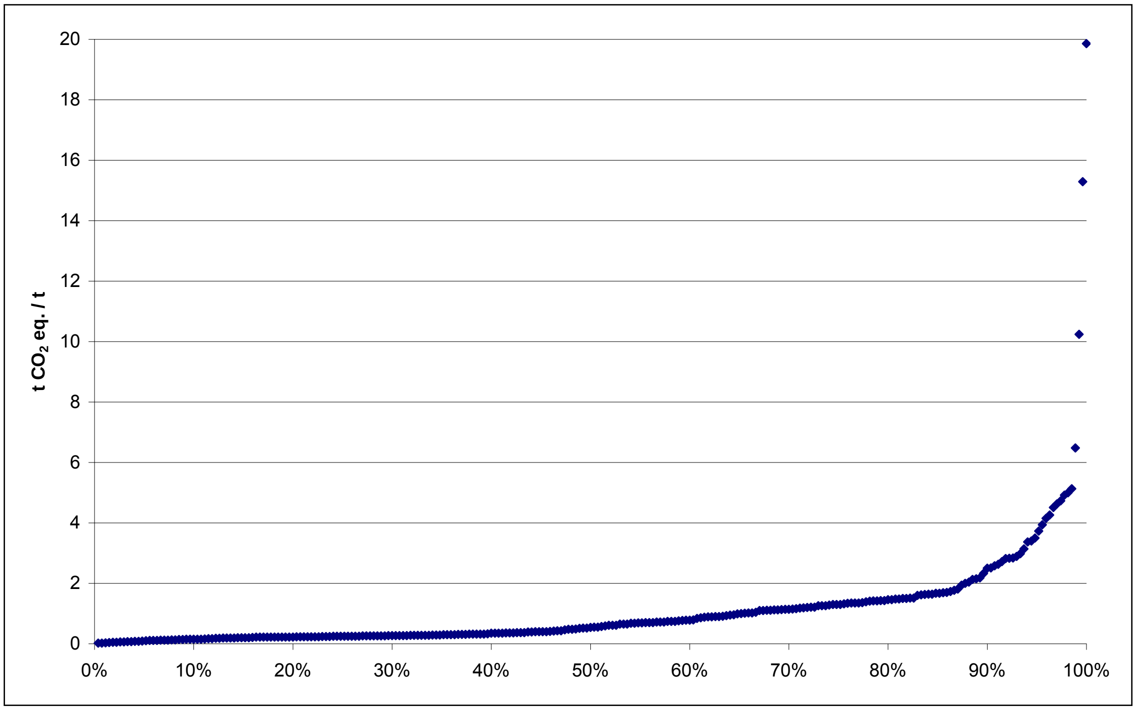

Figure Source: *Calculations by Öko-Institut based on specific emissions reported by 270 primary aluminium smelters published by IAI 2009*

In addition, the IAI's 2009 publication *Results of the 2008 Anode Effect Survey* includes additional detailed benchmarking data and curves that depict the performance of facilities with different anode technologies.

Cement

For the cement sector, the rules will require reporting of GHG emissions and clinker and cement production, as summarized in Table 19.

Table 19. Summary of Required Federal GHG Reporting for the Cement Sector (US EPA 2009b)

Sources Addressed	▪ Each kiln and each inline kiln / raw mill at any Portland cement manufacturing facility ▪ Stationary combustion of fossil fuel
GHGs Required to be Reported	▪ CO_2 process emissions from calcinations at each kiln ▪ CO_2, methane (CH_4), and nitrous oxide (N_2O) emissions from combustion at each kiln or combustion unit other than kilns
Methodology Highlights	▪ For process CO_2 emissions, either operate and maintain a continuous emissions monitoring system (CEMS, as in Tier 4) or calculate process CO_2 emissions based on clinker production and kiln-specific emission factors ▪ For fossil fuel combustion, calculate CO_2 emissions from each fuel combustion unit using one of the four tiered methods outlined in the rule and also report methane (CH_4), and nitrous oxide (N_2O) emissions
Required Reporting[68]	▪ Annual GHG emissions ▪ Monthly clinker and cement production ▪ Number of kilns and number of operating kilns ▪ Annual fuel use ▪ Additional, other data on cement kiln dust and raw material usage, as used to support calculations of process emissions if CEMS not used

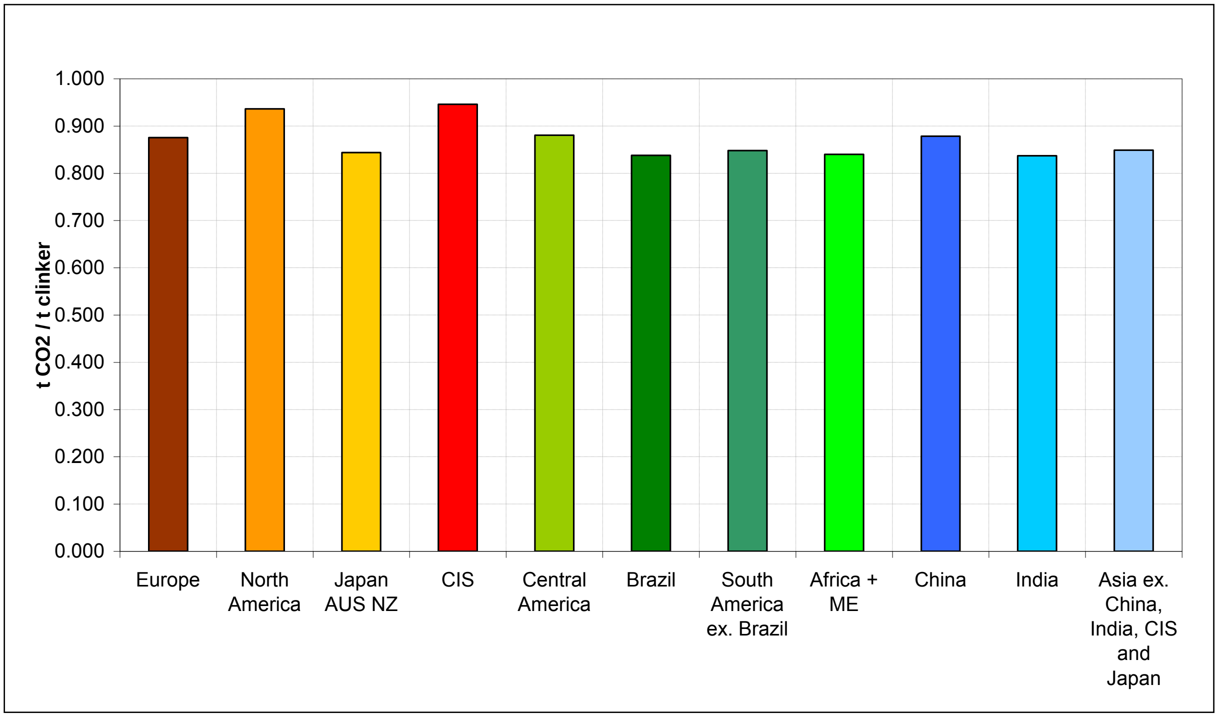
Other Data Sources in the Cement Industry

The Cement Sustainability Initiative (CSI) collects GHG benchmarking data for the global cement industry. To provide an example of possible benchmark curve construction based on these data, we calculated emissions for cement clinker production based on direct emissions and production using data from the Cement Sustainability Initiative (CSI 2009). These data include statistics from (mainly) multinational companies that represent 40% of the world's cement production. Direct emissions are influenced by the following two components: CO_2 intensity of the fuel used and specific fuel consumption per ton of product. Data on clinker production was used to calculate specific emissions from direct emissions from clinker production and illustrates how the CO_2 emissions associated with the production of a ton of clinker varied amongst the different countries. Figure 10 displays these results based on Cement Sustainability Initiative data.

The fact that for China and India relatively low specific emissions are reported can be explained by the fact that only the rather new and efficient plants of multinational companies are reporting under CSI.

[68] Additional data are required to support the methodology chosen.

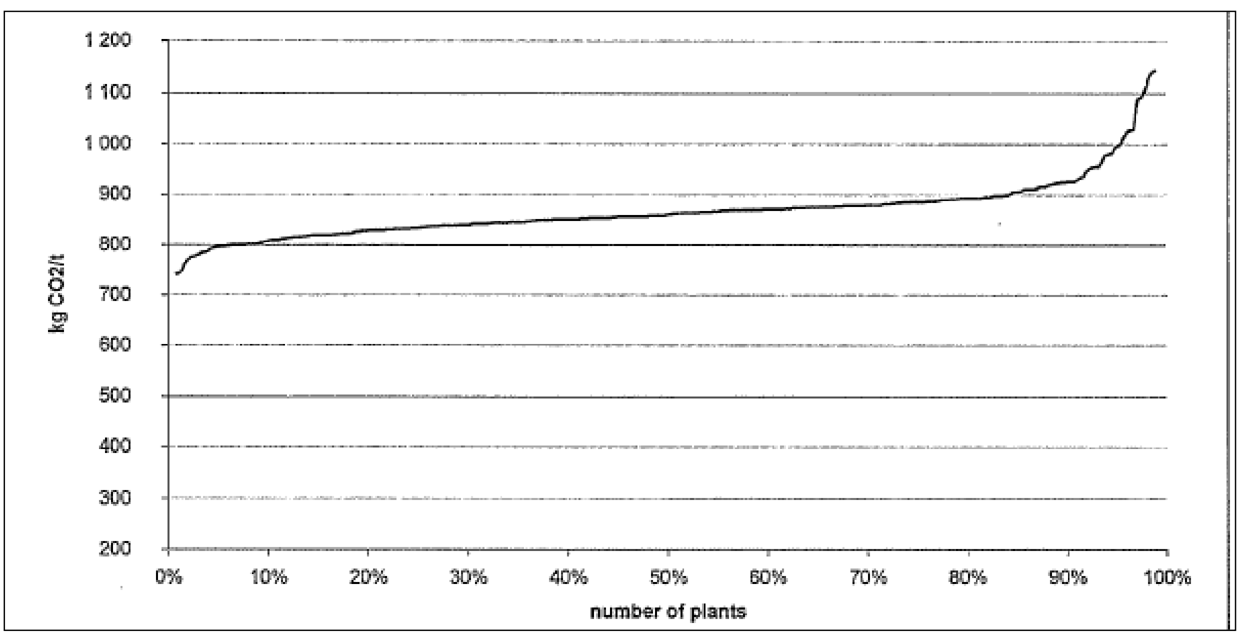
Figure 10. Average direct specific CO_2 emissions of clinker production in the year 2007 of those companies reporting under the CSI



Source: *Öko-Institute based on CSI (2009).*

In the EU, the preliminary benchmark for the third phase of the EU Emissions Trading System, derived from the average specific emissions of the 10 % most efficient installations, is about 0.78t CO_2 / ton of clinker (based on data in 2006, Figure 11). The final benchmark will be based on data for the years 2007 and 2008.

Figure 11. Benchmarking curve for cement clinker in the EU for the year 2006.



Source: *Ecofys, Fraunhofer Institute, and Öko-Institut (2009c)*

Chemicals

The federal GHG reporting rule requires facilities in several chemical industry sectors to report emissions regardless of size. Other sectors (including hydrogen production) must only report if emissions exceed 25,000 tons CO_2e annually. Since Solvay Chemicals produces hydrogen in Washington, Table 20, below, summarizes the reporting requirements for the hydrogen production sector. Emerald Kalama chemicals, which produces petrochemical food additives, would be required to report under the general requirements for facilities that emit at least 25,000 tons CO_2e from boilers and possibly also due to the petrochemical requirements.

Table 20. Summary of Required Federal GHG Reporting for the Hydrogen-production Sector (US EPA 2009b)

Sources Addressed	▪ Process units that produce hydrogen by reforming, gasification, oxidation, reaction, or other transformation of feedstock
GHGs Required to be Reported	▪ CO_2 process emissions from each hydrogen production process unit ▪ CO_2, methane (CH_4), and nitrous oxide (N_2O) emissions from combustion at each hydrogen production process unit ▪ CO_2 either collected and used on-site or transferred off site
Methodology Highlights	▪ For process CO_2 emissions, either operate and maintain a continuous emissions monitoring system (CEMS) or calculate process CO_2 emissions based on fuel and feedstock usage and fuel- and feedstock-specific emission factors
Required Reporting	▪ Annual GHG emissions ▪ Fuel and feedstock consumption ▪ Annual quantity of hydrogen produced (metric tons) ▪ Annual quantity of ammonia produced, if applicable (metric tons) ▪ Additional data to support other calculations, as specified in the rule

Food Processors

Food processors are not in an industry sector specifically addressed in the federal greenhouse gas reporting rule (US EPA 2009b) nor in federal legislation passed out of the U.S. House of Representatives in June 2009 (the Waxman-Markey bill, H.R. 2454, but with the exception of malt manufacturing, wet corn milling, and rendering and meat byproduct processing, which were included in the benchmark-based allowance rebates to energy-intensive, trade-exposed industry sectors). Nevertheless, where facilities emit more than the minimum thresholds for reporting (25,000 tons CO_2e in the federal reporting rule and 10,000 tons CO_2e in the State reporting rule, SB 6373), then food processing facilities will need to report GHG emissions.

Glass

For the glass sector, the federal rule will require reporting of GHG emissions from continuous glass melting furnaces, as summarized in Table 21.

Table 21. Summary of Required Federal GHG Reporting for the Glass Sector (US EPA 2009b)

Sources Addressed	▪ Continuous glass melting furnaces that manufacture flat, container, pressed or blown glass, or wool fiberglass
GHGs Required to be Reported	▪ CO_2 process emissions from each continuous glass melting furnace ▪ CO_2, methane (CH_4), and nitrous oxide (N_2O) emissions from combustion at continuous glass melting furnace or other fuel combustion units
Methodology Highlights	▪ For process CO_2 emissions, either operate and maintain a continuous emissions monitoring system (CEMS) or calculate process CO_2 emissions based on usage of carbonate raw material (e.g., lime), mass fraction of carbonate in the raw material, and fraction of calcinations achieved ▪ Carbon dioxide (CO_2) emissions from each fuel combustion unit calculated using one of the four tiered methods outlined in the rule, as well as methane (CH_4), and nitrous oxide (N_2O).
Required Reporting	▪ Annual GHG emissions ▪ Fuel and feedstock consumption ▪ Annual quantity of each carbonate-based material used (tons) ▪ Annual quantity of glass produced (tons) ▪ Number of continuous glass melting furnaces ▪ Additional data to support other calculations, as specified in the rule

Pulp and Paper

For the pulp and paper sector, the federal rule will require reporting of GHG emissions from facilities that produce market pulp, manufacture pulp and paper (i.e., integrated mills), produce paper from purchased pulp, produce secondary fiber from recovered paper, convert paper into paperboard products, or operate coating and laminating processes(US EPA 2009b). Reporting requirements for pulp and paper facilities are summarized in Table 22.

Table 22. Summary of Required Federal GHG Reporting for the Pulp and Paper Sector (US EPA 2009b)

Sources Addressed	▪ Chemical recovery furnaces at kraft and soda mills (including recovery furnaces that burn spent pulping liquor produced by both the kraft and co-located semichemical process). ▪ Chemical recovery combustion units at sulfite mills. ▪ Chemical recovery combustion units at stand-alone semichemical mills. ▪ Systems for adding makeup chemicals ▪ Lime kilns at kraft and soda pulp mills.
GHGs Required to be Reported	▪ CO_2, biogenic CO_2, methane (CH_4), and nitrous oxide (N_2O) emissions from each chemical recovery furnace at kraft and soda mills and from each chemical recovery combustion unit at sulfite or stand-alone semichemical mills ▪ CO_2, biogenic CO_2, methane (CH_4), and nitrous oxide (N_2O) emissions from combustion of fossil fuels in each kraft or soda pulp mill lime kiln ▪ CO_2 from stationary fuel combustion units calculated using one of the four tiered methods outlined in the rule, as well as methane (CH4), and nitrous oxide (N_2O).
Methodology Highlights	▪ Methods generally involve measurement of fossil fuels, spent liquor fuels, and makeup chemicals and application of default or site-specific emission factors
Required Reporting	▪ Annual GHG emissions ▪ Annual fuel consumption ▪ Annual mass of spent liquor solids fired at the facility (short tons) ▪ Annual steam purchases (pounds of steam per year) ▪ Annual quantity of makeup chemicals (metric tons) ▪ Annual production of pulp and/or paper products produced (metric tons)

Steam

US EPA's Mandatory Reporting of Greenhouse Gases rule will require facilities that emit at least 25,000 tons CO_2e from stationary fuel combustion sources (e.g., boilers) to report greenhouse gas emissions. Facilities that must report only because of stationary fuel combustion (for example, several food processing sectors but not other sectors that are specifically required to report) are required to also report) are not required to report production output, potentially limiting the utility of these data for benchmarking purposes.

Steel

For the iron and steel sector, the rule will require reporting of annual GHG emissions from both electric arc furnaces and basis oxygen furnaces (e.g., integrated mills), as summarized in Table 23. Note that to be consistent with the discussion above, this table addresses both integrated (BOF) and EAF steel. Only EAF steel is produced in Washington State.

Table 23. Summary of Required Federal GHG Reporting for the Steel Sector (US EPA 2009b)

Sources Addressed	▪ Taconite iron ore processing ▪ Integrated iron and steel manufacturing (production of steel from iron ore or iron ore pellets) ▪ Coke making not co-located with an integrated iron and steel manufacturing process. ▪ Electric arc furnace (EAF) steelmaking not co-located with an integrated iron and steel manufacturing process
GHGs Required to be Reported	▪ CO_2 process emissions from each taconite indurating furnace, basic oxygen furnace, nonrecovery coke oven battery combustion stack, coke pushing process; sinter process, EAF, argon-oxygen decarburization vessel, and direct reduction furnace. ▪ For fossil fuel combustion, calculate CO_2 emissions from each fuel combustion unit using one of the four tiered methods outlined in the rule and also report methane (CH_4), and nitrous oxide (N2O) emissions ▪ CO_2, CH_4, and N_2O emissions from flares (e.g., coke oven gas and blast furnace gas.)
Methodology Highlights	One of three methodologies: ▪ Operate and maintain a continuous emissions monitoring system (CEMS) for process and combustion CO_2 ▪ Calculate the mass emissions rate using a carbon balance method ▪ Use a site-specific emissions factor based on a performance test that measures CO2 emissions from all exhaust stacks and processes
Required Reporting[69]	▪ Annual GHG emissions ▪ Annual production quantity (metric tons) for taconite pellets, coke, sinter, iron, and raw steel. ▪ Annual fuel use

[69] Additional data are required to support the methodology chosen.

Statistical Energy Benchmarking for Manufacturing Plants: The Energy Star Energy Performance Indicators (EPI)

Gale Boyd, PhD

presented to the

Western Climate Initiative

Symposium on Understanding the Value of Benchmarking

Seattle WA, May 19, 2010

DUKE UNIVERSITY
DEPARTMENT of ECONOMICS

Philosophy of the EPI

Analysis of the range of actual performance

"Observed Best Practice"

Plant/System (fence boundary) rather than process level

"Bird's Eye View"

Statistical approach - stochastic frontier / linear regression

"Black Box"

"Is performance close (or far) from my competitors?"

Digging a Little Deeper..

- The Energy Star manufacturing plant EPI is a facility level comparison of energy use in "similar" manufacturing plants.
  - Plants are distinguished based on
    - The products produced for final shipment and
    - The materials used to produced those products
    - External factors (e.g. climate) that drive energy use
  - A statistical model is used to normalize for differences
- Since some activities may be "too different," the scope of the analysis is on plants in specific production sectors.
- How the model "works"
  - A statistical analysis computes weights applied to shares of products, materials, and other factors to compute MMBtu per ton for the plant.
    - Weights are computed so as to best represent (fit) the most energy efficient plant (lowest MMBtu/ton) producing that product (mix).
    - The difference between actual MMBtu/ton and the benchmark from the product weights is the EPI measure of inefficiency.

Plant level data is key

- Analysis typically uses confidential plant level data from two sources
  - Center for Economic Studies (CES), U.S. Bureau of the Census
  - Data provided by trade associations and (occasionally) directly from industry
- Data from CES includes the non-public, plant-level data which is the basis of the government statistics on manufacturing
  - Title 13 of the U.S. Code protects this data,
    - CES allows researchers with Special Sworn Status to access these confidential micro-data at a Research Data Center (RDC).
    - Confidentiality prevents the disclosure of any information that would allow for the identification of a specific plant or firm's activities.
  - Duke University is an institutional partner with CES which provides access to this research project to this confidential data and CES has reviewed and approved the use of the data for this purpose.
- Advantage of using available data
  - No new reporting requirements; all plants; confidentiality assured
- Disadvantage is that the data were not collected specifically for this purpose and may not have all the details we would like.

Approach considers four major factors

- Product mix
- Physical plant size or productive capacity
- Process inputs
- External variables, such as
  - weather and
  - utilization rates

Product mix

- Segment the industry into natural product categories.
  - No overlap between plants that produce the various products
  - Each sub-group is treated as a separate industry
  - The glass industry is a good example, since
    - flat, container, and fiberglass are distinct products and
    - each sector can be treated in a "stand alone" manner
- Specialty products may require different energy use
  - ASTM I is the most common, but masonry cement is more energy intensive
  - Corn refiners have a common process of separation of gluten from starch.
    - animal feed by-products result in similar energy demands
    - differences arise from the treatment of the cornstarch.

      It may be dried as a final product,
      further processed and "modified,"
      used as a feedstock for sugar (e.g. HFCS, glucose, etc) or
      ethanol production.
- Statistical modeling can measure these differences.

Plant size or capacity

- To include size in the EPI a meaningful measure of size or capacity is needed. This can be measured by
    - inputs (corn refining – tons of corn),
    - outputs (auto assembly – number of autos produced),
    - or physical size (pharmaceuticals – square feet).
- Possible advantages to larger scale of production, i.e. economies of scale with respect to energy use.
    - This was not found to be the case for auto assembly or pharmaceuticals.
    - For cement it was found that larger kilns are an advantage, but larger numbers of kilns are not.

Process Inputs

- Materials, labor, or production hours may be proxy measures of production when measures of output are not available
  - Corn refining is an example of a sector where the energy use per unit of material input, i.e. corn processed, is used.
  - When production data is not available, materials may be used, e.g. sand and cullet are common inputs to glass manufacturing.

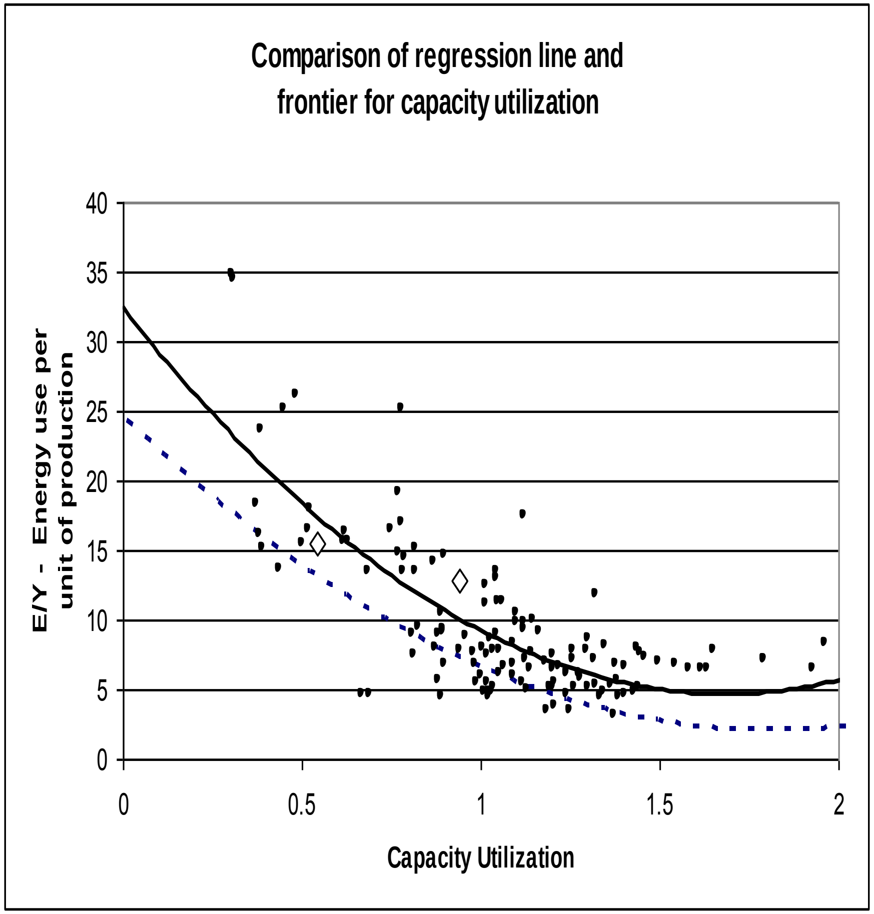
- When levels of materials or outputs are not available, production labor or hours of operation may be used to measure production activity and utilization
  - These alternatives are only used when they show a statistically significant relationship to energy, i.e. "when then work."

External Factors

- There are many things under the control of a plant or energy manager, but one they cannot control is "the weather."
- The approach that has been taken for all sectors is to include heating and cooling degree days (HDD and CDD) into the analysis to determine how much "weather" impact energy use.
  - For sectors like automobile, pharmaceutical, and some food manufacturing the approach finds statistically significant impacts of HDD and CDD on energy use.
  - For sectors like cement, glass, food processing, and corn refining we have not been able to estimate any impact so these factors are treated as de-minis for the purposed of annual, plant level benchmarks.

Stochastic Frontier is a Modified Regression

- Linear regression computes the "typical" performance by finding the line which "goes through the middle" of the data.
- Stochastic Frontier Regression (SFR) finds the best-performing by finding the line which "envelopes the frontier" of the data
- The frontier regression estimates the distribution of efficiency separately from the statistical error distribution and allows us to get a normalized percentile score for efficiency.



Statistical Frontier Model for Auto Assembly

- Stochastic frontier regression separates energy intensity into
  - Systematic effects,
  - Statistical (random) error
  - Inefficiency

$$E/Y_i = \beta_1 + \beta_2 Util + \beta_3 Util^2 + \beta_4 WB$$

$$\beta_5 HDD + \beta_6 HDD^2 + \beta_7 CDD \times AT + \beta_8 CDD^2 \times AT + u_i - v_i$$

E = total site energy use in mMBTU (1 kwh=3412 BTU)

Y = number of vehicles produced

Util = plant utilization rate, defined as output/capacity

HDD = heating degree days for the plant location and year

CDD = cooling degree days for the plant location and year

AT = dummy variable if plant is air-tempered is 1, otherwise 0

WB= wheelbase of the primary product

β is the vector of parameters to be estimated, $v \sim N(0, \sigma^2)$, and $u \sim \Gamma(\theta, P)$.

Why use SFR for benchmarking?

- The distribution of energy efficiency may not be "Bell shaped" curve, but may have a skewed distribution.
- We test whether a normalizing factor should be included
- The response of energy use to a factor, as measured by the estimated slope, may differ for average plants versus the best plants.
  - The best building may perform well in both cold and temperate climates, so it "less sensitive" to heating degree day differences.
  - The best plant may have better startup and shutdown procedures, so it "less sensitive" to differences in utilization.
- This method has 30 years of literature behind it used to measure productivity and other types of performance.

Benchmarking is an art, because...

- It is about developing tools that balance
  - Measures that are readily available
- Against
  - Information one can obtain from a particular approach
  - The specific needs of the application
  - The ability to meaningfully interpret the results
- Since there are often multiple needs for different types of information, a tool box is always better than any single tool

If the only tool you have is a hammer, then

everything looks like a nail…

Benchmarking Industrial Plant Energy Efficiency

How EPA's ENERGY STAR® Program Helps Industry Improve Energy Efficiency

Elizabeth Dutrow
US Environmental Protection Agency
ENERGY STAR Industrial Partnership
May 19, 2010

ENERGY STAR

- Voluntary government partnership
  - ***Goal: reduce carbon dioxide emissions***
  - Introduced by EPA in 1992 to enable companies to improve in energy efficiency
- The national symbol of energy efficiency and environmental protection
  - Awareness exceeds 70% of U.S. households
  - A brand owned and managed solely by the government
- Focused on improving energy efficiency of:
  - Products
  - Homes
  - **Plants & buildings**
- For industrial businesses, EPA helps manufacturers improve strategic energy management.

ENERGY STAR & Industry

- EPA’s goals:
  - ***“Shift the curve” of energy performance for manufacturing industries***
  - Identify the transformative practices to achieve top energy performance
  - Help companies succeed in achieving top performance

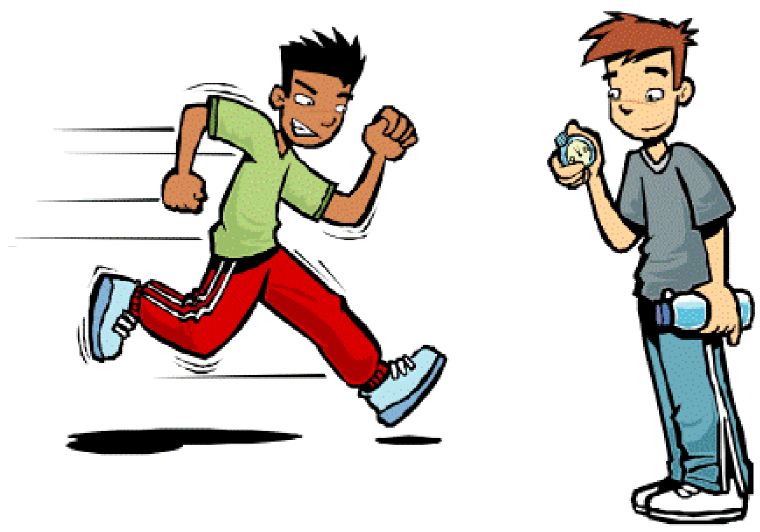
ENERGY STAR designed to address the barriers

Barrier

- Lack of a bearing on efficiency

Solution

- Benchmarking is an objective measurement method



ENERGY STAR provides business a clear pathway to succeed

1. Evaluate risks, prepare energy strategy with senior management

2. Build company-wide energy program, using ENERGY STAR

3. Look to suppliers and customers

Let's get on the same page

- Benchmarking
  - The process of comparing to something similar or the best
- ***Energy*** benchmarking
  - The process of comparing the energy performance of facilities, processes or equipment to something similar or the best

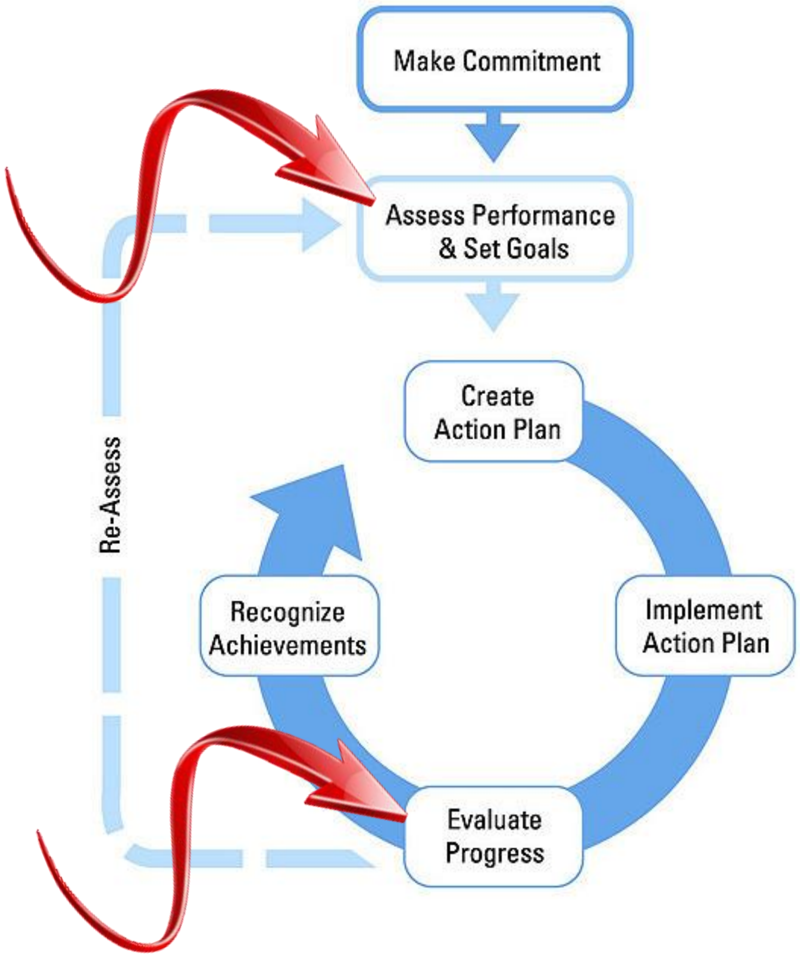
Types of benchmarking

- **Internal**
  – compares performance against internal baseline or benchmark
- **External**
  – compares performance against a metric “outside” of the organization
  – identifies “Best in Class” performance
- **Quantitative**
  – data-driven; compares actual numbers
- **Qualitative**
  – based on best practices; compares actions

Benchmarking's place in energy management

- Fundamental practice
- Energy reductions and project measurement are nice but only benchmarking proves improvements have had an effect
- Can be based on comparison of management practices or energy data
  - ***practice*** benchmarking gives an idea of where to improve by identifying best energy management practices
  - ***energy data*** benchmarking informs how well an entity might perform and improve and the position of that entity in terms of energy performance

ENERGY STAR Guidelines for Energy Management



Variety of benchmarking in energy management

Energy Management Objective	Scope		
	Scale	**Focus**	**Time Frame**
Assess equipment efficiency	Equipment or process	Internal – comparison against other owned equipment or process External – comparison to industry standard or cooperative study with other organizations	•Peak demand period •Three month sample •Weekly •Monthly •Annual •Continuous from baseline
Assess facility performance	Whole facility or sub-metered portion	Internal – comparison of single facility over time. Comparison of similar facilities within single organization External – comparison of facility against national performance rating	•Continuous from baseline •Monthly •Quarterly •Annual
Assess department or divisional energy use	Facilities or sub-metered portions of facilities	Internal – comparison against internal sub-divisions	•Continuous from baseline •Weekly •Monthly •Quarterly •Annual
Assess organizational performance	All facilities	Internal – comparison over time or towards goal. External – Comparison of portfolio average against a national performance rating	•Continuous from baseline •Monthly •Quarterly •Annual

ENERGY STAR benchmarks

- External
- Define “best in class” for an industry or building type
- Industry sector-specific at 6 digit NAICS code (or more refined)
- Energy data at the whole facility level
- Source energy intensity
- Normalized for key variables

ENERGY STAR Industrial Focuses

Developing specific industrial plant benchmarks

ENERGY STAR's industrial sector-specific focuses

Collaborative process to develop:

- ✓ **Energy Performance Indicator (EPI) to benchmark/rate plant energy performance**
- ✓ Energy Guide

Facilitates:

- ✓ Sharing of best practices
- ✓ Networking
- ✓ Development of stronger company energy programs

Results in:

- ✓ **Sophisticated plant benchmarking tool**
- ✓ Recognition for energy-efficient plants with the ENERGY STAR
- ✓ Increased momentum for continued improvement
- ✓ Improved efficiency within an industry sector
- ✓ Prevention of carbon emissions

Benchmarking drives performance

Answers: *"If all plants in the industry use energy as this one, what percent of plants in the country would be better, and what percent would be worse?"*

Standardized measurement: the plant EPI

- Plant energy performance indicators (EPI)
  - Enable a higher level of energy management
    - Compare how efficiently a plant uses energy relative to those of its industry
    - Enable goal setting
    - Empower management to require greater energy performance from plants
    - Score plants on a **percentile basis (0-100),** normalized to a plant's unique configuration
      - ENERGY STAR defines score of 75 or above to be energy-efficient; 50 is average
  - www.energystar.gov/epis
  - www.energystar.gov/industrybenchmarkingtools

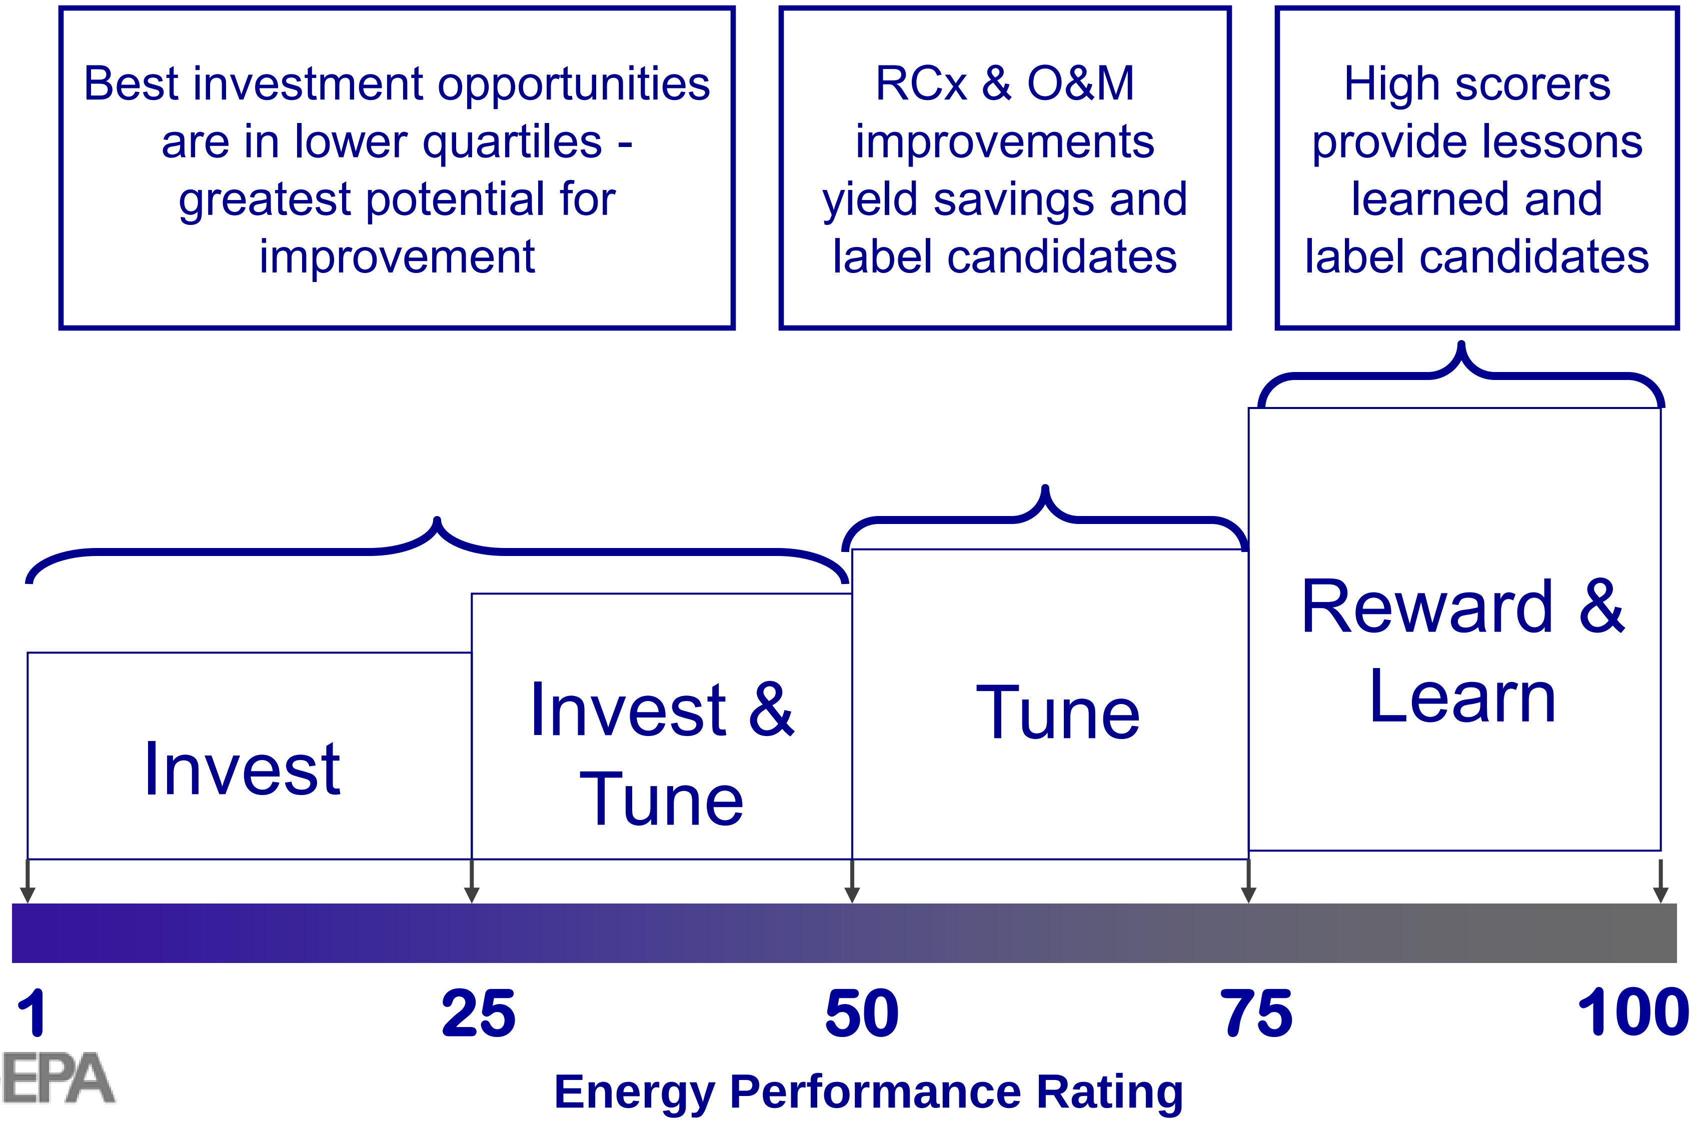
What EPA's national level plant energy benchmarking accomplishes

- Empowers industry to **shift the curve of energy performance**
  - For most companies, the ENERGY STAR EPI is the first time they are able to see how their plants' energy performance compares to that of their industry

- Enables companies in the benchmarked industry to **set competitive goals** for plant improvement

- Enables **EPA to gauge improvement** of an industry's energy performance over time

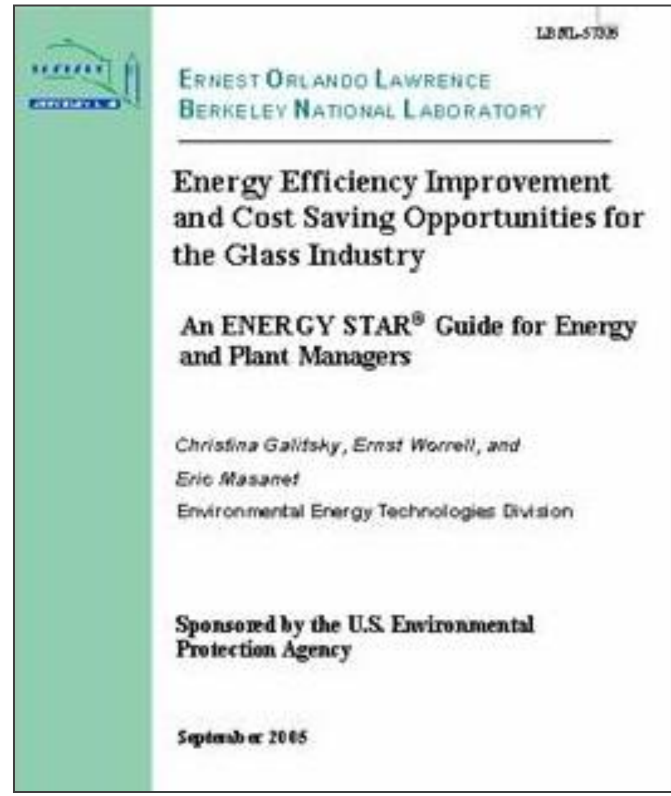
Enabling companies to make informed energy investment decisions



More help to improve: Energy Guides

Practices and technologies available now to improve energy efficiency in an industry

- **Identify existing & promising emerging technologies**
  - provide brief overview of technology or practice
    - review its limitations
    - quantify potential energy and cost savings
    - estimate payback periods
    - provide case study from application
    - highlight industry success stories



Ernest Orlando Lawrence Berkeley National Laboratory

Energy Efficiency Improvement and Cost Saving Opportunities for the Glass Industry

An ENERGY STAR® Guide for Energy and Plant Managers

Christina Galitsky, Ernst Worrell, and Eric Masanet

Environmental Energy Technologies Division

Sponsored by the U.S. Environmental Protection Agency

September 2005

Case study

- Example: U.S. cement plant
- Initial cement plant ENERGY STAR EPI score: **61**
- Upgraded in 2002, EPI verified energy reductions of 40%
  - Energy efficiency improved by 2.5 mmBtu/short ton of clinker
- Commercially available technologies employed (described in Energy Guide) :
  - Improved grinding mills
  - Roller mills
  - Improved preheaters
  - Indirect firing
- New ENERGY STAR EPI score: **98**
  - national energy efficiency scoring system demonstrated this plant is now one of the most efficient cement plants in the U.S.

Results – EPA experience with US auto assembly plants

- Based on ENERGY STAR benchmarking of auto assembly plants, EPA has seen fuel usage in the industry improve by 12 percent over a five year period.
- The level of inefficiency has also dropped by 1.0 mmBtu/vehicle.
- The range of performance has also narrowed.
  - This means that while the best auto assembly plants have improved, the others have more than "kept up" with this improvement.

ENERGY STAR benchmarking resources

- **Plants** use ENERGY STAR's **Energy Performance Indicators** (EPIs)
- **Commercial Buildings** use ENERGY STAR's **Portfolio Manager**

Industrial EPIs
Motor Vehicle Assembly
Wet Corn Milling

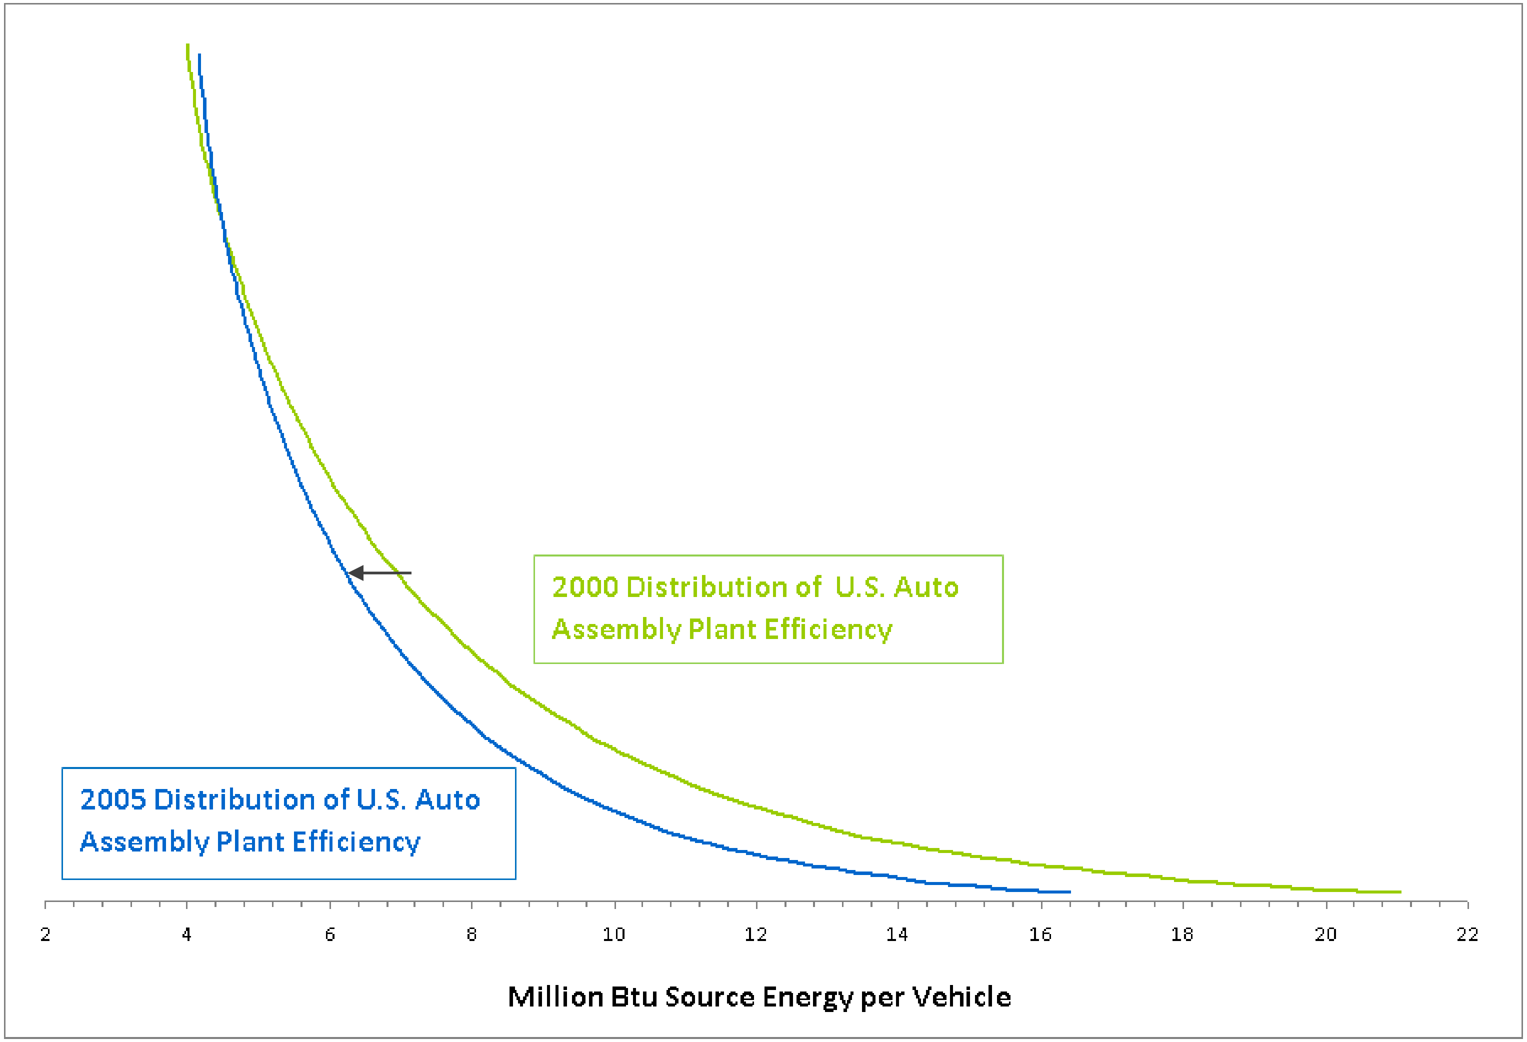
Supermarkets
Retail Stores
Warehouses
Bank Branches
Residence Halls
Waste Water Treatment
Court houses
Medical Office Buildings

ENERGY STAR Benchmarking: Auto Assembly 2000-2005



EPA, Duke University

Lessons

- It is possible to benchmark plants and help industry improve
- Benchmarking takes data (lots of it) and time
- Benchmarked entity should be homogeneous.

ALCOA

Key Issues for Industry GHG Benchmarking

Ken Martchek
Alcoa Inc.

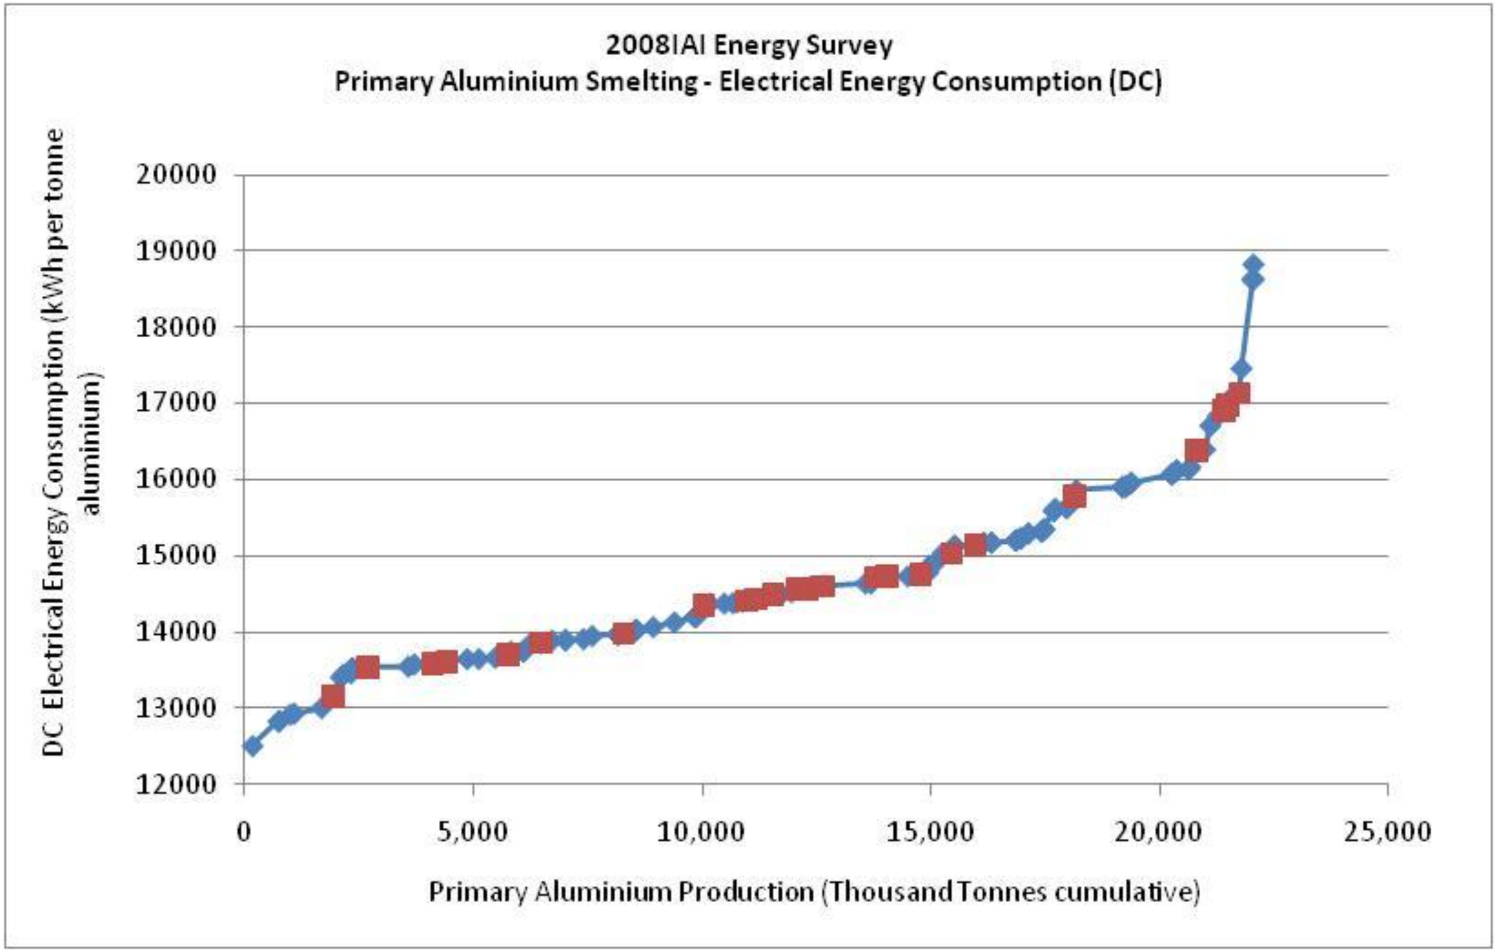
ALCOA

Afternoon Panel Objectives

<u>Address the following questions:</u>

- What are the benefits and challenges of developing and applying benchmarks for industry?
- What data constraints limit benchmarking and how might they be overcome?
- At what level of detail / disaggregation are benchmarks helpful or needed?
- How do responses to these questions differ depending on how benchmarks are used?
- What other information and perspectives are important for Washington State to consider in developing industry benchmarks?

Example of Industry Benchmarking



Benefits and Challenges to Industry

Benefits

- Drive process and energy improvements
- Set achievable objectives
- Etc.

Challenges

- Time and expense of data gathering, analysis, review, & communications
- “Apples” vs. “Oranges”

Clear Reporting Guidelines - Example

PFC EMISSIONS FROM PRIMARY ALUMINIUM SMELTING IAI FORM PFC001

Reporting Guidelines

1. Data are reported by technology category and, preferably, by potline. Data for different technology categories should not be mixed.

2. If anode effect data are not available then data for technology category, cell technology, feed type, primary aluminium production and average number of cells operating per day are still reported. Anode effect frequency data should be reported, if available, even though anode effect duration or overvoltage data are not available.

3. Technology category is reported as:
   a. PFPB - where cell technology is Centre Worked Prebake with a Point Feed System.
   b. CWPB - where cell technology is Centre Worked Prebake with a Bar Break Feed System.
   c. SWPB - where cell technology is Side Worked Prebake.
   d. HSS - where cell technology is Horizontal Stud Søderberg.
   e. VSS - where cell technology is Vertical Stud Søderberg.

4. Cell technology is the particular cell technology used (RA-300, SY300, AP18, Reynolds P19 etc.)

5. Potline number is the reference number or letter used to identify the potline. If data from two or more potlines are combined, then all relevant reference numbers or letters relating to the combined data are shown.

6. Feed type is reported as:
   a. PF - where a Point Feed System is applied to Prebake or Søderberg technologies.
   b. BF - where a Bar Break Feed System is used.
   c. SF - where a manual Side Feed System is used.

7. Primary aluminium production is molten (liquid) aluminium as tapped from the pots. It is reported in tonnes (metric tons) and is that production relevant to the anode effect and cell technology type data being reported.

8. Anode effect measurements are reported to two decimal places if possible. If the reported average anode effect duration is estimated, then this is indicated by adding the letter "E" against the reported figure. When data from two or more potlines are combined, the reported average anode effect frequency, average anode effect duration and averaged anode effect over-voltage are production-weighted averages.

9. Averaged anode effect over-voltage in millivolts is only reported for Alcan Pechiney cell technology types AP18, AP30, growth versions of these two cell technologies (e.g. AP33, AP35) and applicable Alcan Pechiney technology SWPB (Side Worked Prebake) potlines. Over-voltage can also be reported as integrated anode effect over-voltage in units of mv.day per cell day. Over-voltage is reported as either positive or algebraic according to the following definitions:
   a. Positive Anode Effect Over-voltage is the sum of the product of time and voltage above the pot target operating voltage (corresponding to the target resistance), divided by the time over which the data are collected (hour, shift, day, month etc.).
   b. Algebraic Anode Effect Over-voltage is the sum of the product of time and voltage above and below the pot target operating voltage (corresponding to the target resistance), divided by the time over which the data are collected (hour, shift, day, month etc.).

10. Section 3 is completed only if PFC emissions have been directly measured and the resulting CF_4 emissions coefficient and C_2F6/CF_4 weight fraction are applicable for production for the year being reported (in accordance with the USEPA/IAI *Protocol for Measurement of Tetrafluoromethane (CF4) and Hexafluoroethane (C2F6) Emissions from Primary Aluminum Production* - **http://www.epa.gov/aluminum-pfc/documents/measureprotocol.pdf**. The directly measured emissions, and hence also the calculated emission coefficients, are to take account of both duct and fugitive emissions. Emission rates and emission coefficients are reported to two decimal places.

11. If Anode Effect and PFC Emissions Measurement data (where appropriate) has been verified by a Third Party (e.g. auditor, regulatory authority) then please fill in details of the verifying body (fields a-d). If third party verification of the data has not occurred then please request internal verification of the data submitted by a senior manager and fill in their details in fields (a, b & d).

Enablers and Issues

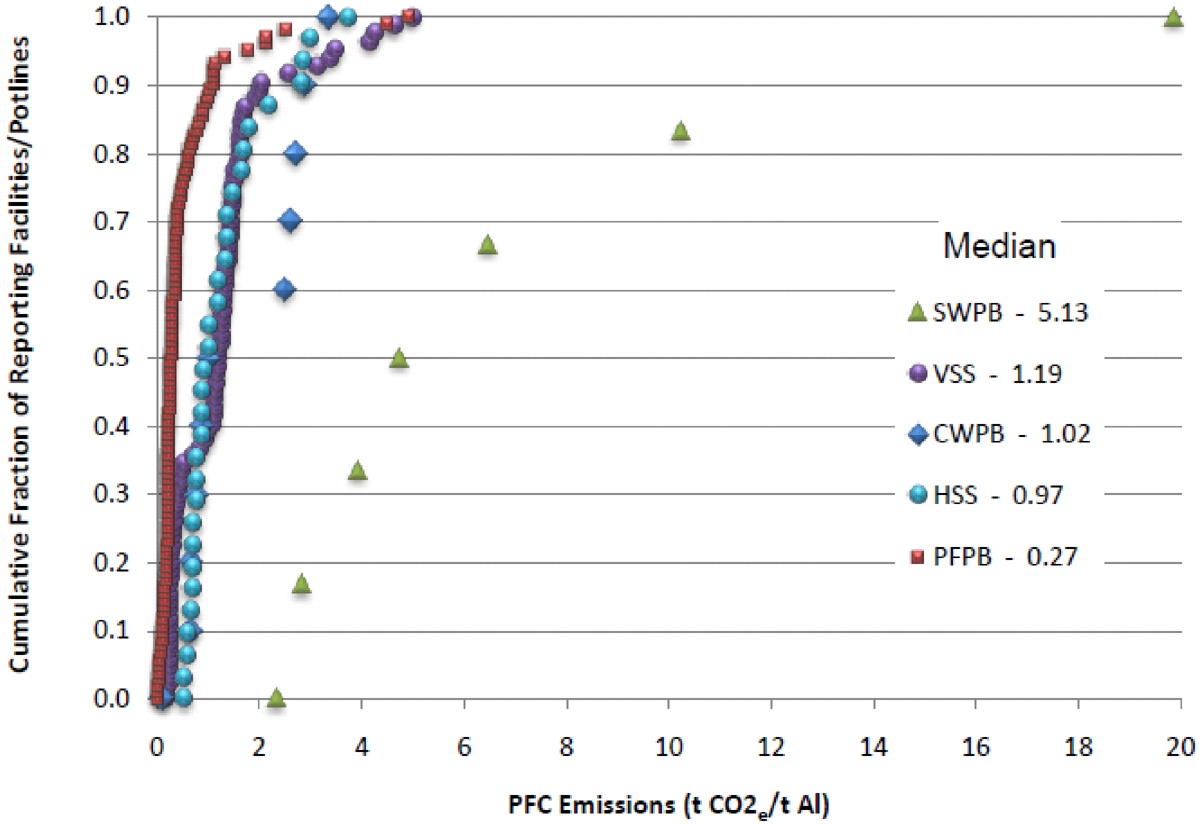
Enablers

- Reporting Guidelines
- Common Boundaries
- Written Industry Specific Protocols

Issues

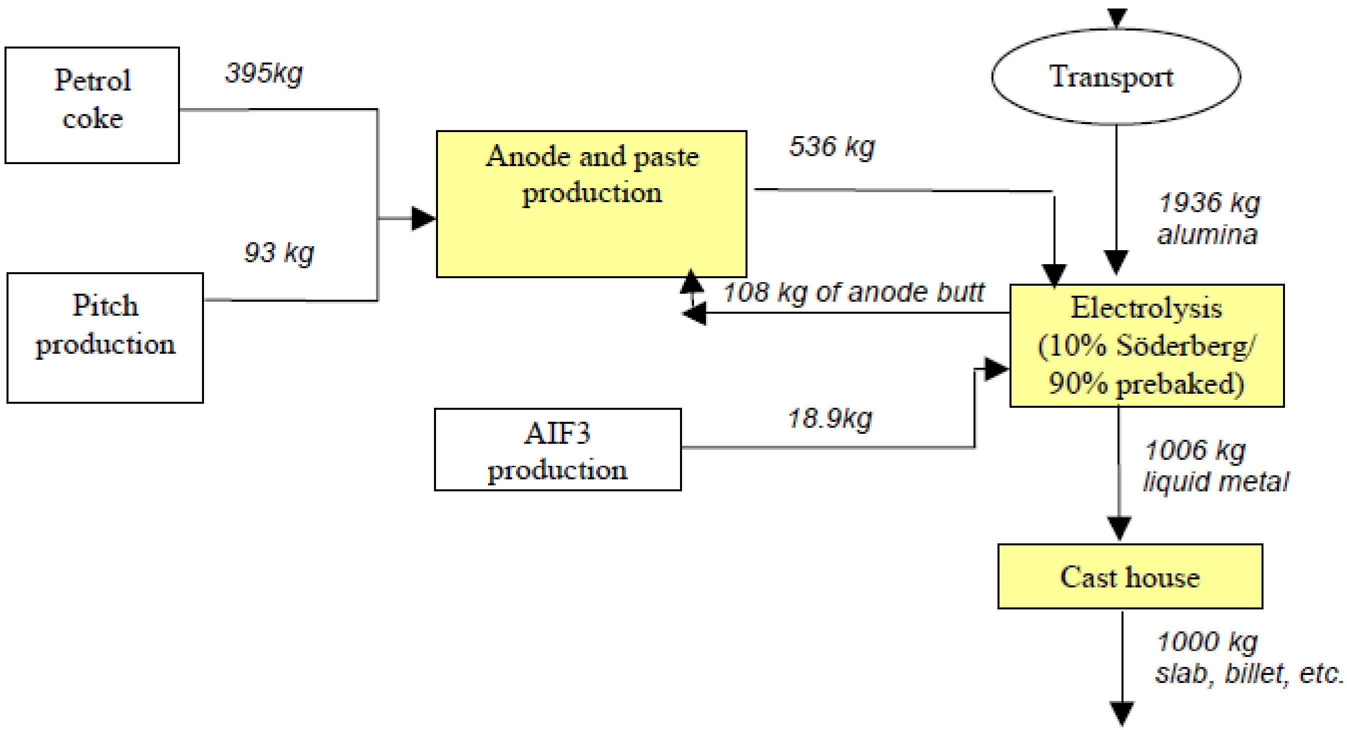
- What is appropriate benchmark subset?
  - World best practice (Worrell)
  - Best in North America? Europe?
  - Best in USA?
  - Best in Washington State?
- Best 10%?, Top quartile?
- Very small sub-sets
- Need to be technology specific

Different Technologies – Different Benchmarks



Level of Detail/ Disaggregation

- Each sub-process in a sector has different emissions
- Not all operators have all of the sub-processes



Conclusion

Also for Discussion Today

- How do responses to these questions differ depending on how benchmarks are used?
- What other information and perspectives are important for Washington State to consider in developing industry benchmarks?

Carbon Leakage Provisions Proposed in US Federal Climate Legislation

SYMPOSIUM ON UNDERSTANDING THE VALUE OF BENCHMARKING

Seattle, WA

May, 2010

James Bradbury

Senior Associate

Climate and Energy Program

World Resources Institute

jbradbury@wri.org

http://www.wri.org

W R I

Recent US Federal Policy History

- *Jun. 2008*, **Boxer-Lieberman-Warner**
  - letter from 10 Senate Democrats opposed bill, citing competitiveness concerns ("Gang of 10")
- *Sep. 2008*, **Inslee-Doyle** (HR 7146; HR 1759)
- *Jun. 2009*, **Waxman-Markey** (HR 2454)
  - passed US House (219-212)
- *Nov. 2009*, **Kerry-Boxer** (S. 1733)
  - passed Senate Committee (no Republicans present)
- *Dec. 2009*, **Interagency Report**
  - Responding to request from Sen. Bayh and colleagues
- *May 2010*, **Kerry-Lieberman**
  - Discussion-draft made public

Leakage Prevention & Transition Assistance

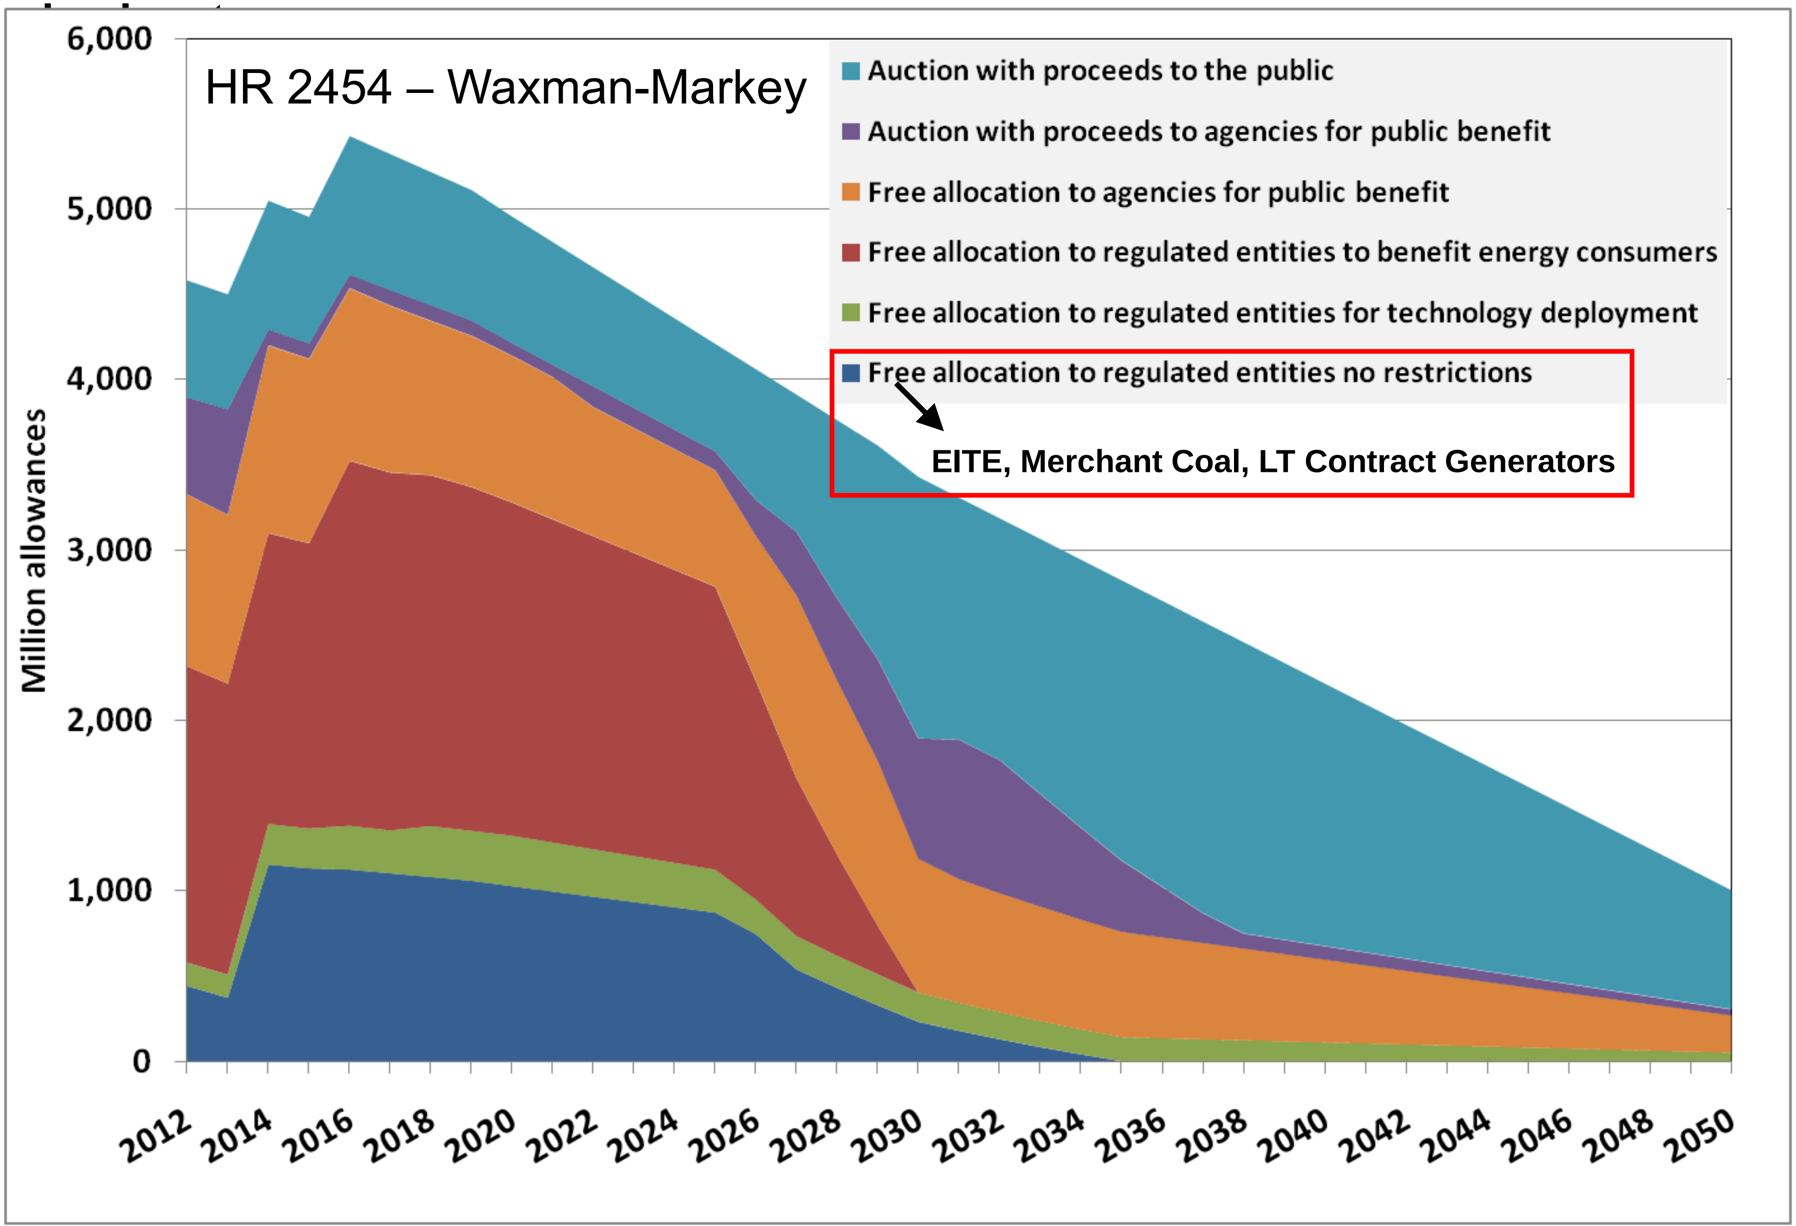
For *Energy-Intensive Trade Exposed* Industries:

- Allowance rebates for direct and indirect carbon costs
  - Up to 13.5% of the cap through 2025 (2% in 2012 & 2013)
  - Phased out by 2035 (w/ presidential discretion to persist)
- Border measures for EITEs in 2020

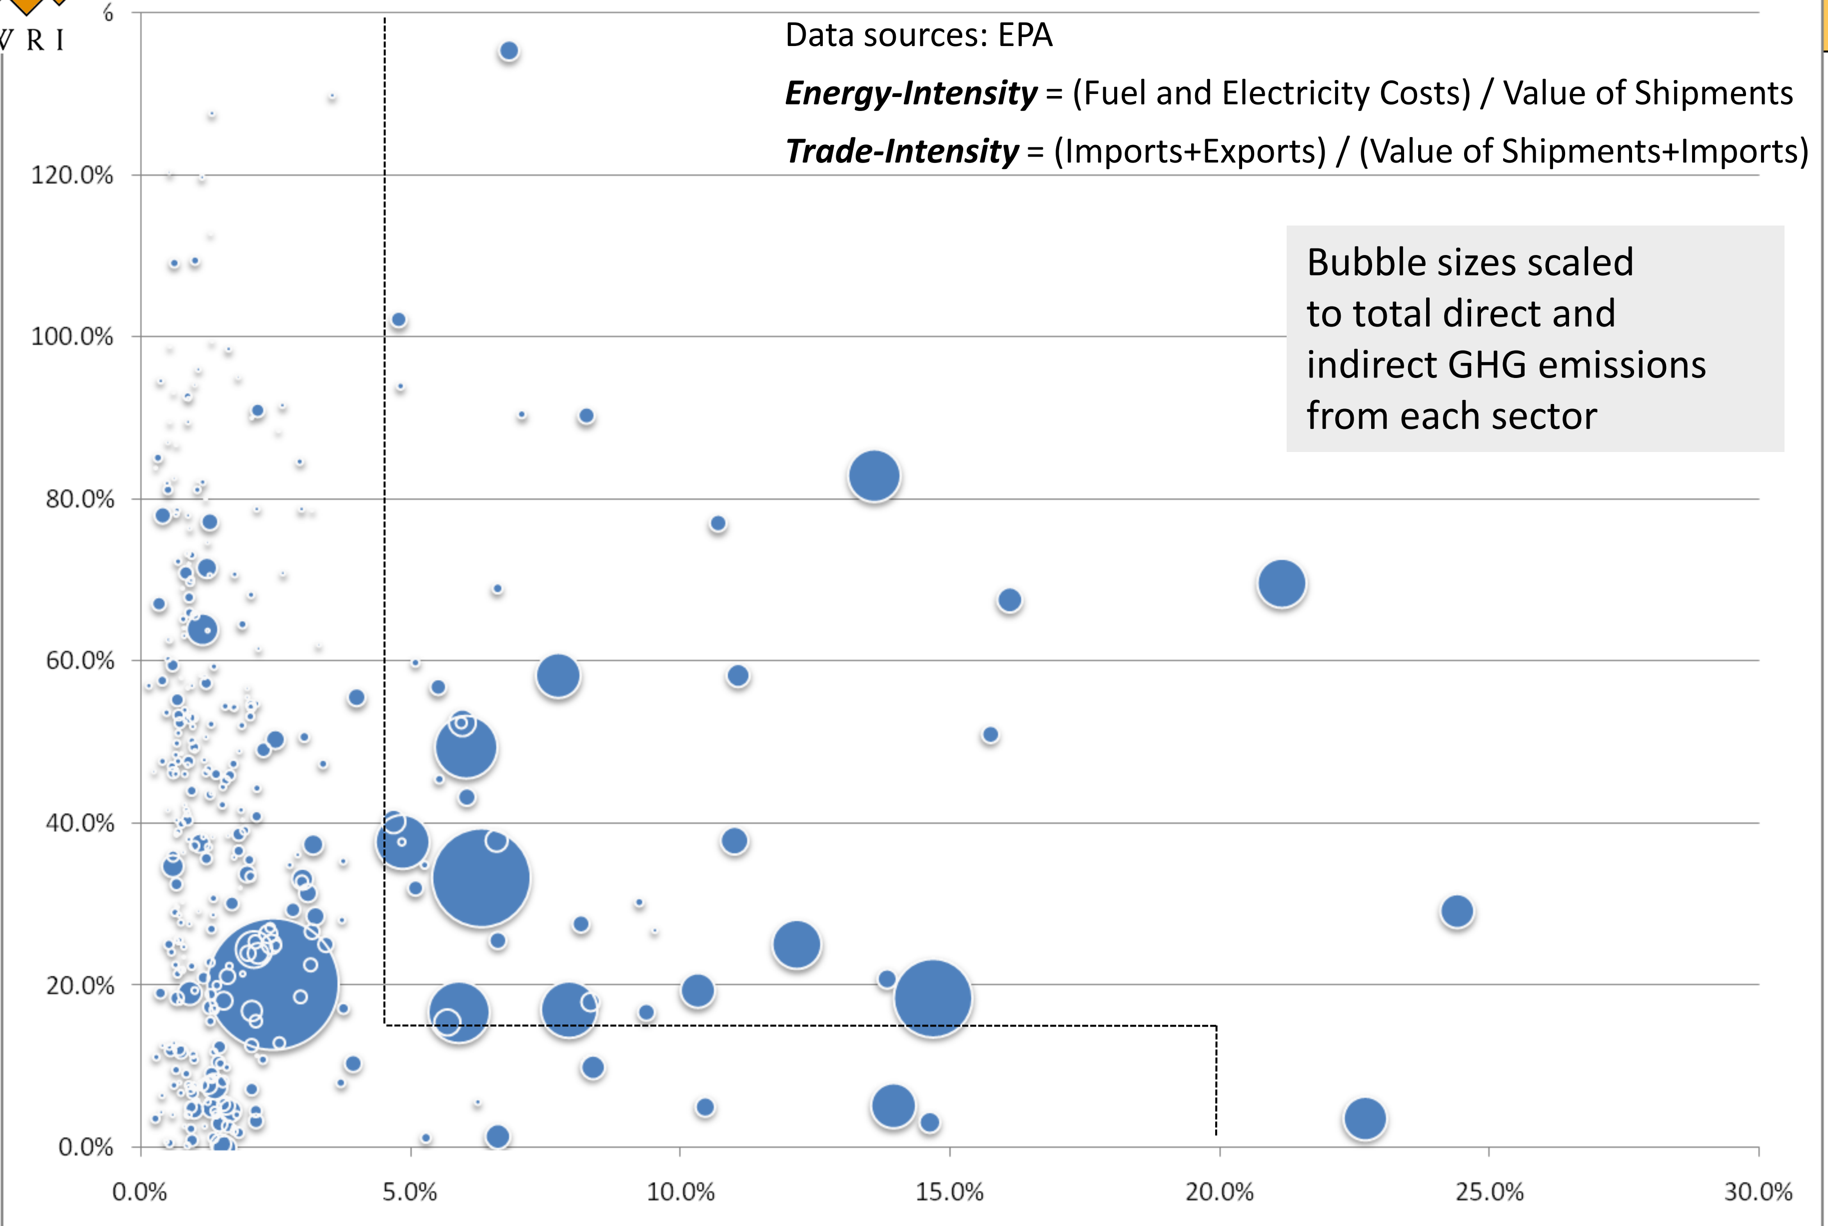
Other Assistance (through 2025, phased out by 2030):

- 40% of allowances to electric & nat. gas LDCs
  - "exclusively for the benefit of retail ratepayers"
  - >10% for industrial customers, including EITEs

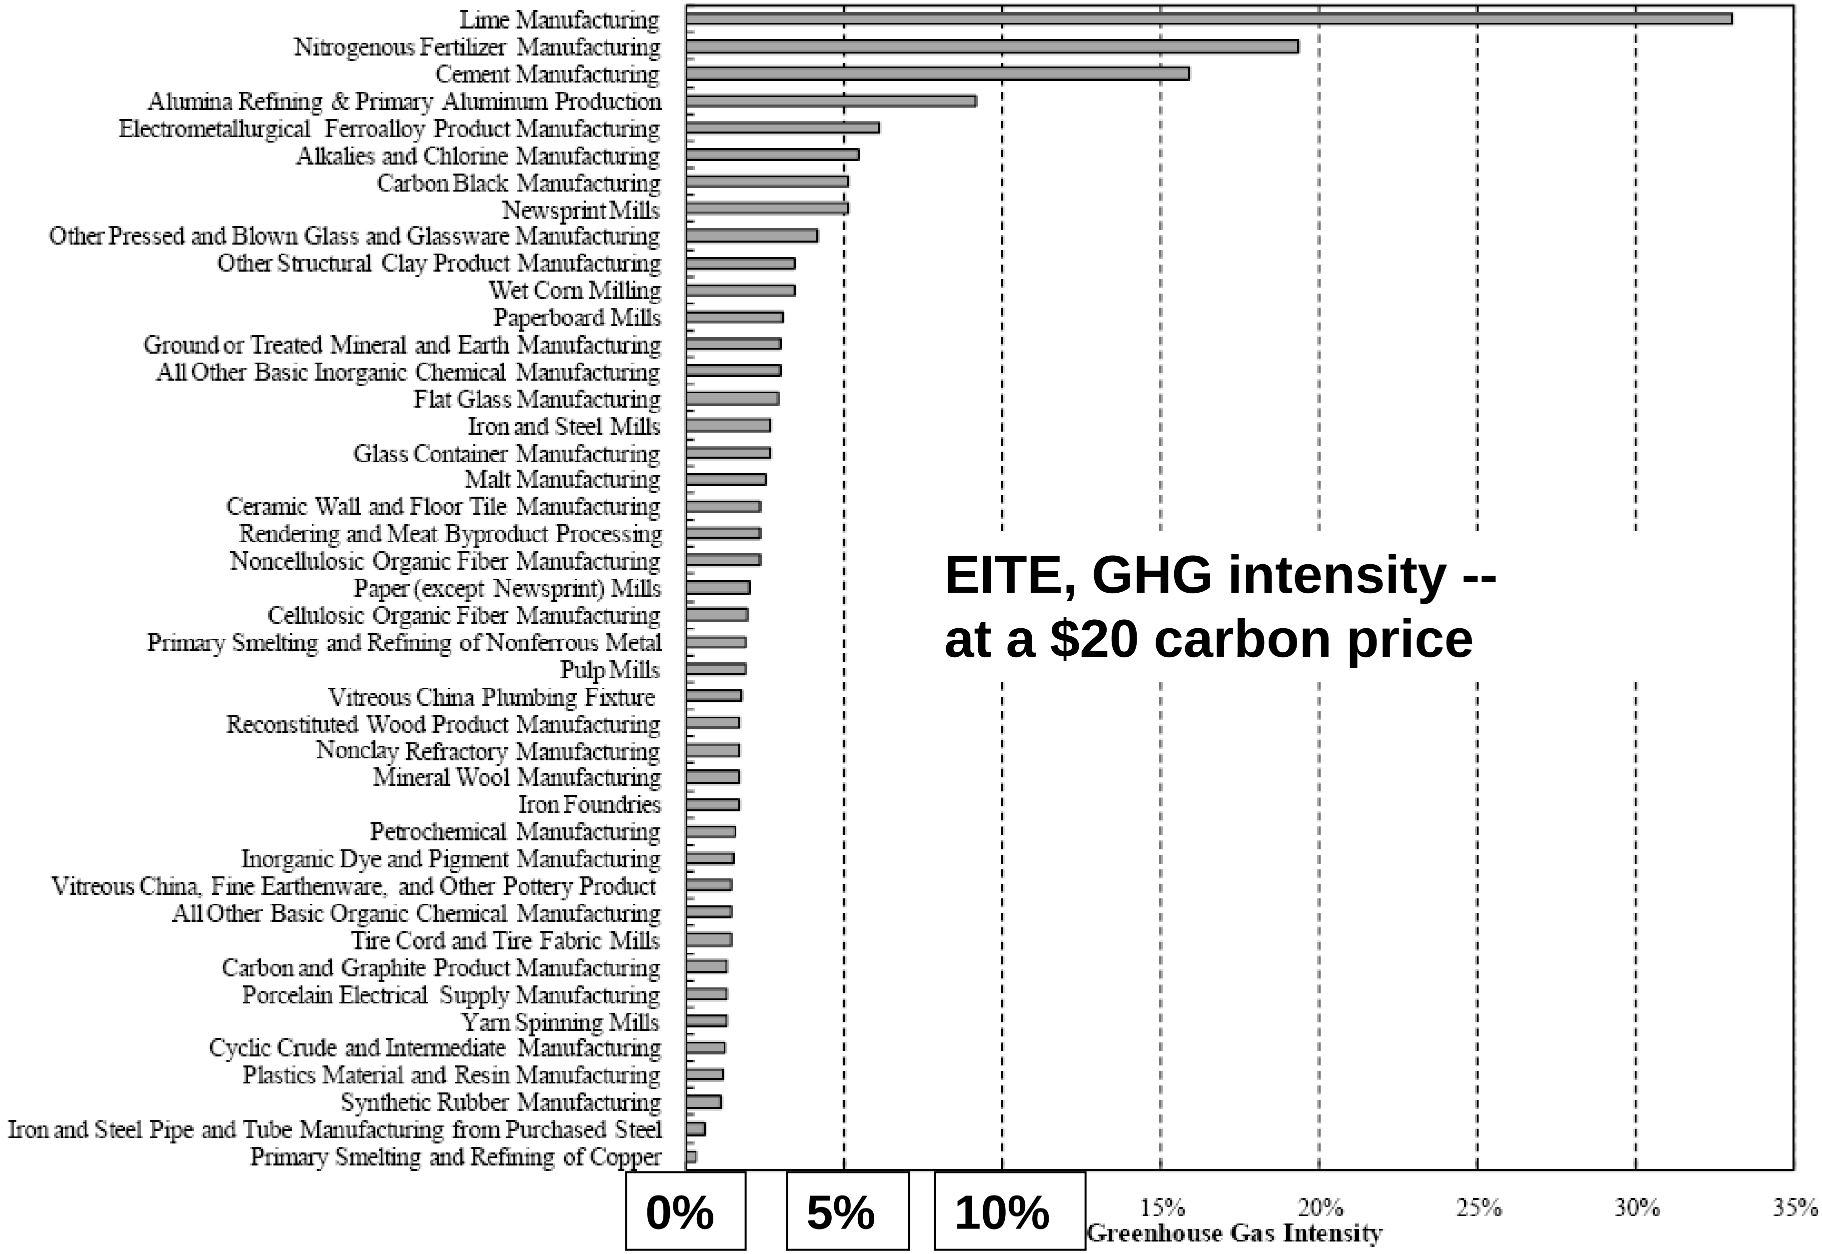
- Allowance value is targeted at public programs, consumer assistance and "transition assistance" for:



EITE Eligibility – Sectors by NAICS Code (6-digit level)



H.R. 2454's Greenhouse Gas Intensity Measure for the "Presumptively Eligible" Manufacturing Industries



Note: The H.R. 2454 greenhouse gas intensity measure is calculated by multiplying a sector's direct emissions and indirect emissions associated with electricity consumption by an allowance price of $20 per ton, and dividing by the sector's value of shipments.

Source: EPA analysis.

Which Costs Should be Compensated?

- Direct compliance costs
- Indirect compliance costs
  - Electricity
  - Purchased Steam

- Indirect, indirect

  (Costs of underlying climate policy)
  - Cost of utility investments in low carbon resources
  - Market dynamics that (may) cause fuel-switching and higher nat. gas prices

Output-Based Allocation Method and Level

- Allowances would be allocated to industry on a production *Output basis,* *based on:*
  - Each **facility's output** from 2 and 3 years prior

    and
  - 4-year **sector average,** updating benchmark
    - *The big (important) question is ability to pass-through costs (this assumes zero ability to pass-through)*
    - *HR 1759 included more stringent benchmark:*

      85% "allocation factor"

But how would the Benchmarks work?

- In HR 2454, sectors defined at 6-digit level of NAICS-code (won’t work for benchmarks)
- In Kerry Lieberman, issue is getting more attention
  - EPA is given discretion to define subsectors, accounting for products and intermediate products, CHP (not processes)
  - Coverage under cap is delayed until 2016
- Growing discussion of applying 80-20 rule

However… there has not yet been a lot of attention to this at the Federal Level

Finally, phase down

- Recognizing that a harmonized international policy offers the best solution…
- At what point does domestic allowance allocation <u>phase down</u> or get replaced with an alternative policy mechanism?
  - Waxman-Markey (ACES)
    - Allowance pool reduces with the cap
    - Allocations reduced on a pro-rata basis, for any year in which demand exceeds supply
    - After 2025 (though 2035), allowances phase-down for all sectors, <u>unless exposure to leakage persists</u>

Final Comments

- There is growing consensus around output-based allocation to EITEs to address leakage from economy-wide climate policy
- There is a critical unmet need for better data and analysis on how to conduct proper benchmarking, in the US
- In DC, too much focus on eliminating *all costs* for industries, not enough attention to:
  - Policies to improve efficiency of manufacturing through financing capital investments
  - R&D, other transition assistance

Thank you!

James Bradbury

WRI

Overview of Current Efforts in Industrial GHG Benchmarking

Michael Lazarus

Stockholm Environment Institute – US, Seattle

WA Ecology/WCI Symposium on Understanding the Value of Benchmarking, May 19, 2010, Seattle, WA

STOCKHOLM ENVIRONMENT INSTITUTE

Industry is a major source of greenhouse gas emissions

- One fifth of global GHG emissions
  - Fossil fuel combustion and process emissions
  - Over one quarter when electricity considered
- Also one fifth of Washington state GHG emissions
- Over a fifth of global emissions reduction potential (McKinsey)

A handful of sectors account for large majority of industrial GHG emissions

- Iron & steel
- Nonferrous metals (aluminum)
- Chemicals and fertilizers
- Petroleum refining
- Minerals (including cement and glass)
- Pulp and paper

… represent 85% of industrial energy use and most process GHG emissions (IPCC, 2007)

Energy and emissions intensive sectors

- Energy (carbon) costs represent a greater fraction of production cost and product value
- Many are subject to international competition, and
- Manufacture products that could be instrumental in a transition to low-carbon economy

Most energy and emissions intensive sectors are present in WA state

Sector	Contribution to WA Emissions	Major facilities in WA state (>25ktCO2e/yr)
Aluminum	High	Alcoa, Kaiser
Cement	High	Ash Grove, Lafarge
Chemical	Low	Solvay, Emerald Kalama
Food Processing	Medium	Many
Glass	Low	Cardinal, St. Gobain
Oil refineries	High	Several
Pulp and Paper	High	Many
Steel	Low	Nucor, Jorgenson

STOCKHOLM ENVIRONMENT INSTITUTE

The impetus for industry GHG benchmarking in WA state

- Executive Order 09-05 directs the Department of Ecology to develop greenhouse gas benchmarks
  - By industry for industry sectors that might be covered by federal or regional cap-and-trade program
  - To support use for allowance distribution and to recognize businesses that have made investments in emissions reduction
  - Based on best practices: highly efficient, low emitting facilities
  - For application as state-based emissions standards if needed to complement, or in absence of, federal program

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Ecology's process for moving forward

- Phase I (to June 2010): Benchmarking Issues and Options
  - White Paper and Symposium
- Phase II (July 2010 to June 2011): Development of Benchmarks for Some Sectors
- Focus on Washington State industries
- Engagement at regional and federal levels

SEI STOCKHOLM ENVIRONMENT INSTITUTE

What is a GHG Benchmark?

- GHG emissions per unit of output

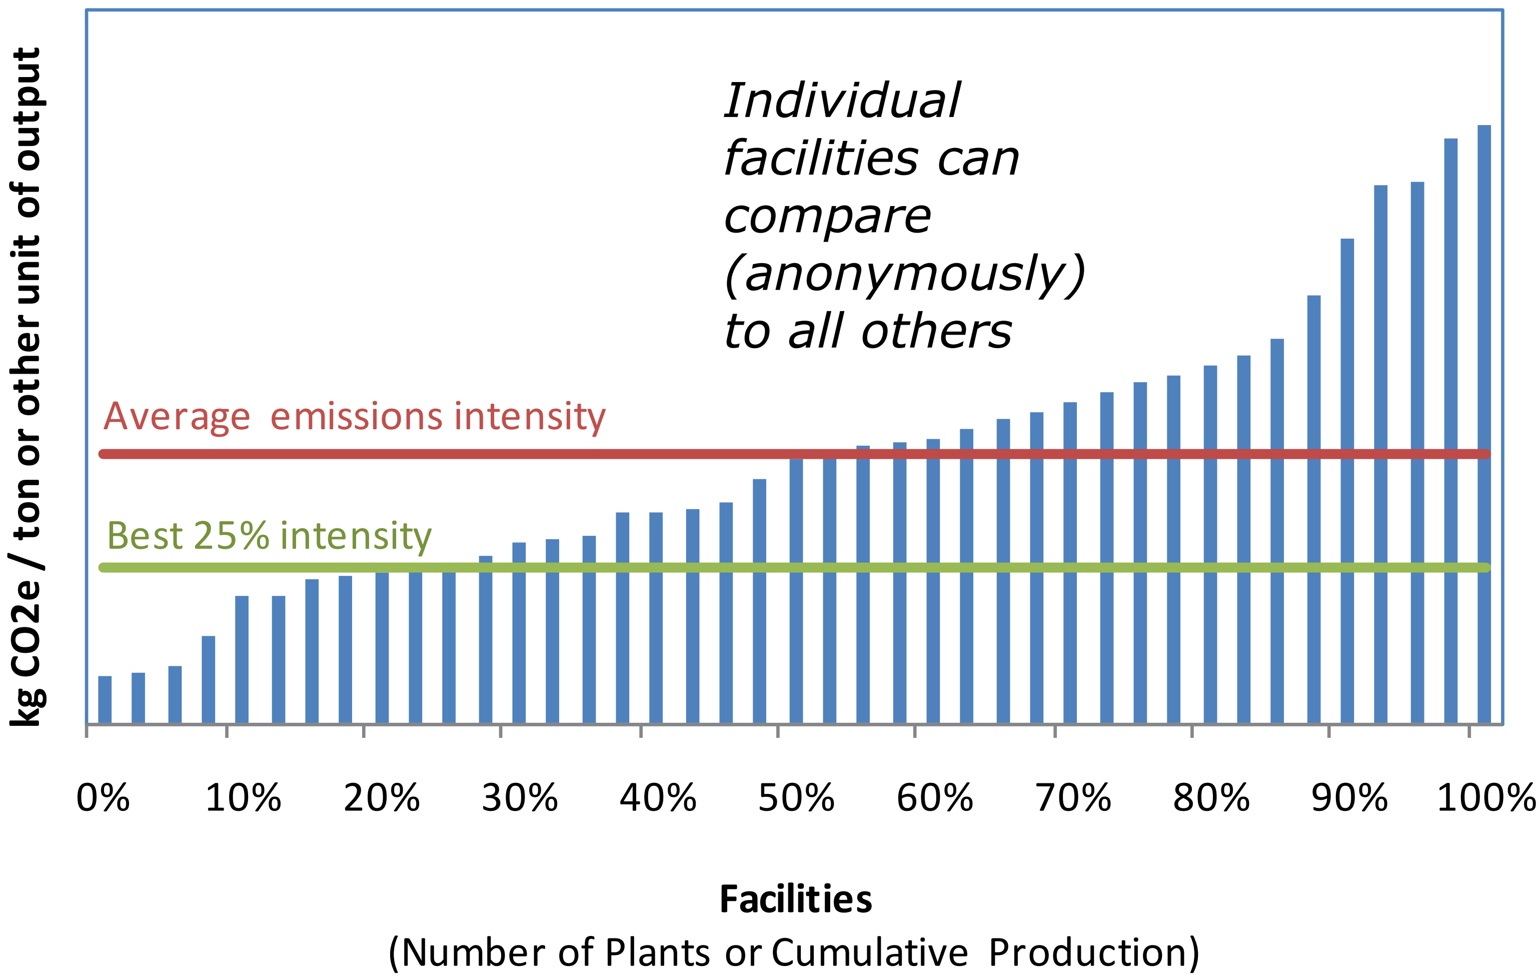
$$\text{Benchmark} = \frac{\text{Emissions}}{\text{Unit of Output}}$$

- Enables comparison across facilities against a common standard
- Used in a variety of industries and contexts worldwide

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Comparison among facilities requires data and (often) confidentiality agreements

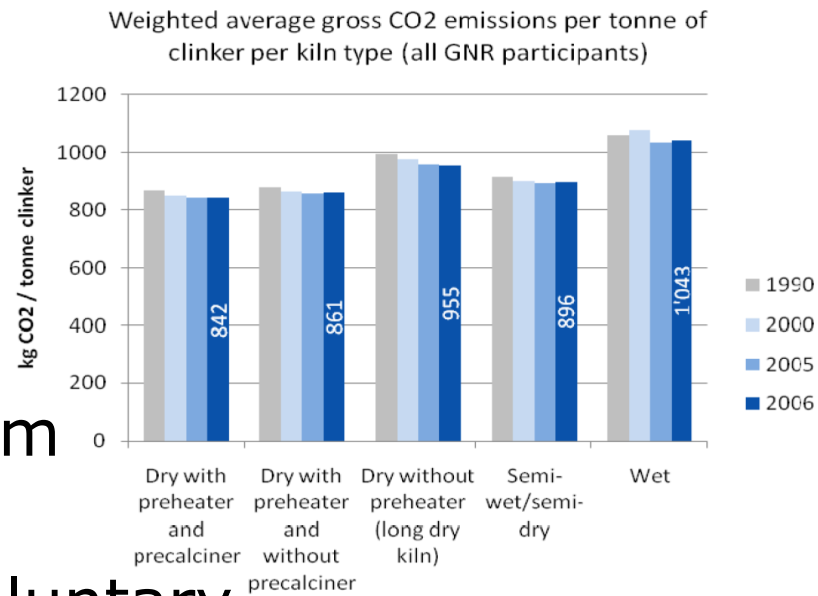
Hypothetical Benchmarking Curve



Voluntary industry and government efforts have relied on benchmarking

…to identify best practices and promote enhanced energy and emissions performance:

- US EPA's EnergyStar program
- Cement Sustainability Initiative
- International Aluminum Institute
- German and Dutch voluntary industry agreements



Source: Global data from Cement Sustainability Initiative, 2009. "Getting the Numbers Right".

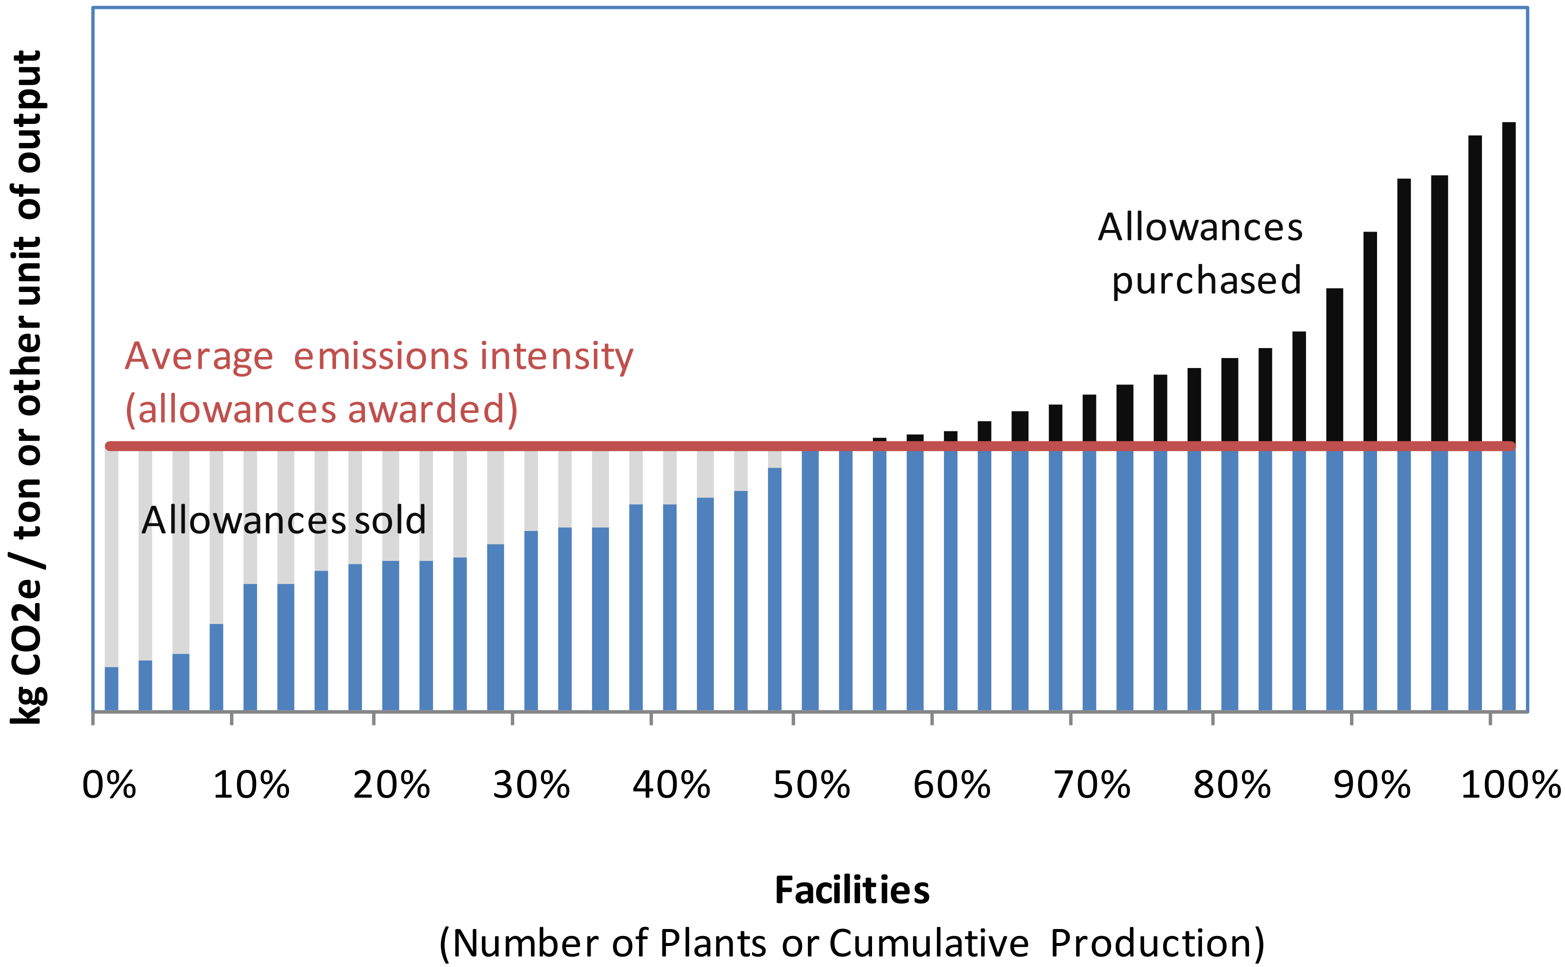
SEI STOCKHOLM ENVIRONMENT INSTITUTE

Cap-and-Trade programs may use benchmarks for allowance allocation

- Output-based rebates to emissions-intensive, trade-exposed industries can limit carbon leakage and maintain competitiveness of domestic industries…
  - Proposed US legislation (Kerry-Lieberman, Waxman-Markey)
  - European Union Emission Trading System (EU ETS)
  - Australian Carbon Pollution Reduction Scheme

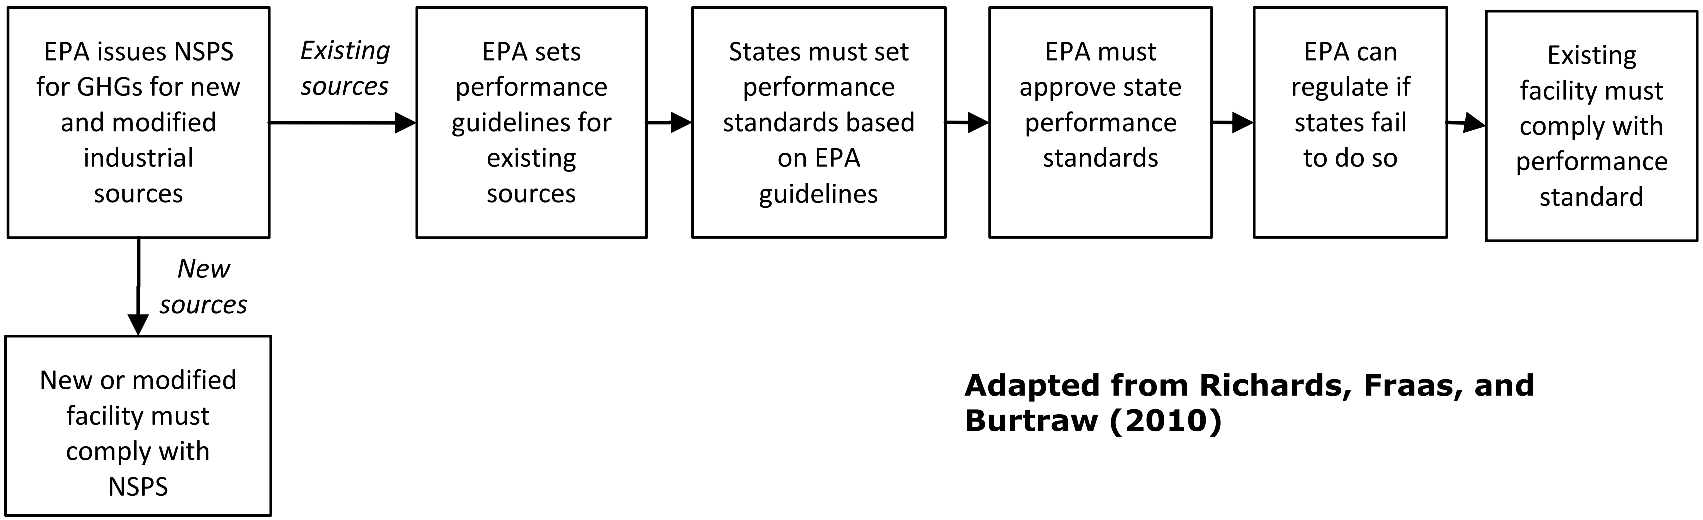
SEI STOCKHOLM ENVIRONMENT INSTITUTE

Waxman-Markey/Kerry-Lieberman bills use US average emission intensity as benchmark for allocation



Regulatory emissions performance standards can employ benchmarks

- Large stationary sources under the Clean Air Act:



Adapted from Richards, Fraas, and Burtraw (2010)

- WA already has a GHG performance standard (benchmark) for new power projects (ESSB 6001)
  - 1100 lbs CO2e/MWh for baseload generation or long-term contracts
  - And output-based performance standards for other pollutants

STOCKHOLM ENVIRONMENT INSTITUTE

Development of benchmarks poses several challenges

- **Ambition** – average, best available, top percentile?
- **Scope and boundaries** – direct only or total, including indirect?

$$\textbf{Benchmark} = \frac{\textbf{Emissions}}{\textbf{Unit of Output}}$$

- **Data** sources
- **Choice of unit and level of aggregation**: Sector, product, activity

All facets influenced by benchmark application

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Specific issues GHG benchmarking must address

- **Combined heat and power**, or use of waste gases (paper and pulp, steel, and others)
- **Feedstock quality and quantity**: Use and quality of recovered/recycled feedstock (glass, aluminum, steel)
- **Facilities that produce multiple products** (paper or steel mills)
- **Integrated vs. non-integrated facilities** (paper and pulp and steel)
- **Alternative definitions of the final product** (e.g. cement or clinker)

SEI STOCKHOLM ENVIRONMENT INSTITUTE

Other key points

- Benchmarks should be based on facility performance at regional, national or international levels
  - WA state has leading industries in energy and environmental performance
- Benchmark design will depend upon the policy application

Questions to consider

- What are the benefits and challenges of developing and applying benchmarks?
- What approaches to benchmark development and use seem the most promising for managing GHG emissions?
- What would make a Phase II effort on benchmarking (July 2010-June 2011) most useful from your perspective?

Using Benchmarks to Develop Regulatory Performance Standards

Judi Greenwald

Vice President for Innovative Solutions

Pew Center on Global Climate Change

SYMPOSIUM ON UNDERSTANDING THE VALUE OF BENCHMARKING

May 19, 2010

PEW CENTER ON Global CLIMATE CHANGE

Presentation Overview

- Setting Performance Standards Under the Clean Air Act and Other Environmental Statutes
- Role of Performance Standards as Benchmarks in Allowance Allocation under the U.S. Acid Rain Program
- Potential Application of CAA performance standards to GHGs

Setting Performance Standards Under the Clean Air Act and Other Environmental Statutes

(See Handout)

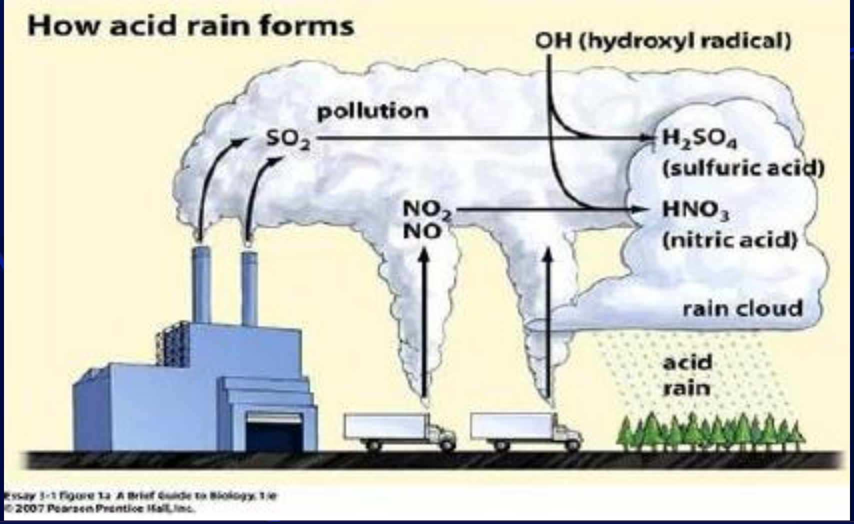
Setting Performance Standards: CAA

- Clean Air Act has several different technology-based, performance standard setting provisions
  - All are emission limits based on a technology
  - All consider feasibility, costs, co-benefits, etc.
  - All have some role for benchmarking
  - But different definitions, processes, and considerations
  - Alphabet soup: NSPS (BDT), NSR-PSD (BACT), NSR-NA (LAER), NAAQS SIP (RACT), Air Toxics (MACT and GACT)
  - MACT example

Other Environmental Statutes

- Clean Water Act: NPDES conventional (BCT); NPDES toxic and nonconventional (BAT); NPDES new sources (NSPS)
- RCRA LDR (BDAT)

Role of Performance Standards as Benchmarks in Allowance Allocation under the U.S. Acid Rain Program



PEW CENTER ON Global CLIMATE CHANGE

Key Allocation Formula Decisions

- ***Input* vs. output**
- Updating vs. ***fixed***
- ***Fuel-specific* vs. fuel-neutral benchmarks**
- Formula structure: Heat input x an emission rate for several classes of sources, plus some special cases

Some Specifics

- Heat input baseline: average of 1985-87; some adjustments possible for shutdowns or outages
- Emission rate varied by source category
  - .6 - 1.2, and 2.5 lbs/mmBtu were touchstones
- Bonus allowances for cleaner sources
- Alternative formula for cleaner states

What *were* we thinking?

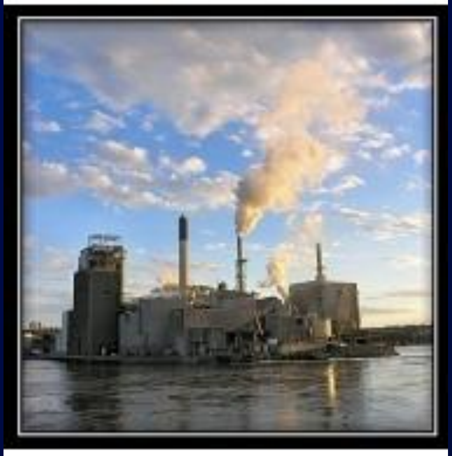
NSPS was frame of reference, touchstone or benchmark

- 1971: 1.2 lbs/mmBtu
- 1977/79: % reduction requirement; 0.6 to 1.2 lbs/mmBtu

Potential Application of CAA Performance Standards to GHGs

Challenges of Applying New Source Review to GHGs

- Timing
- Applicability
- What is BACT for GHGs?
- Role of states
- Innovation
- Energy Efficiency

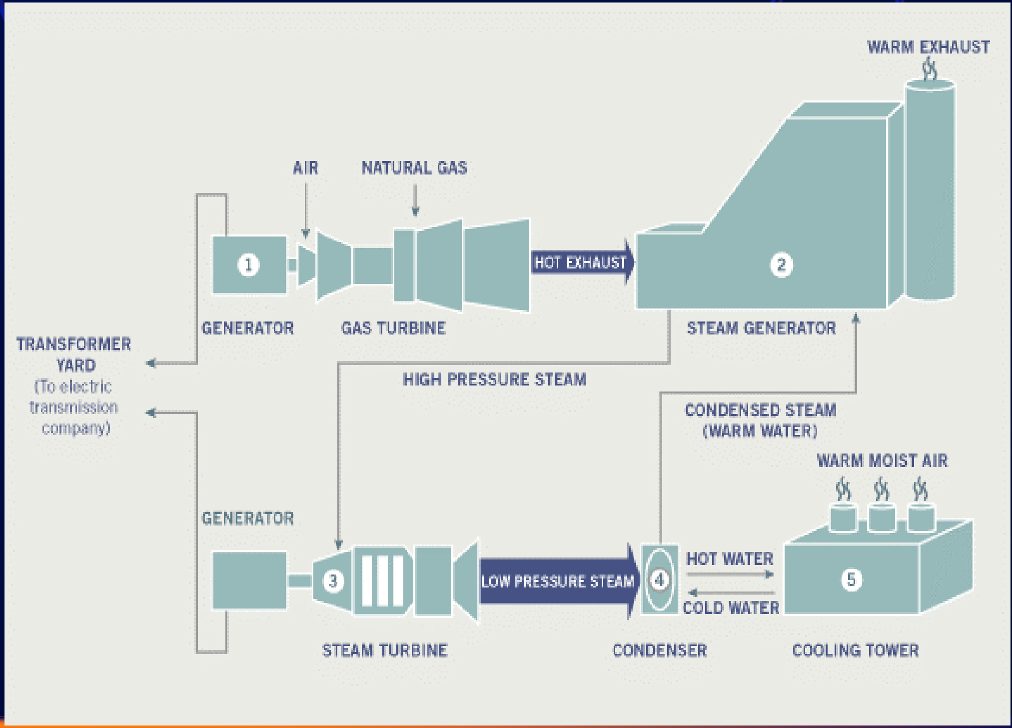


EPA Rising to the Challenge

- Timing
- Applicability
- Tailoring
- RACT/BACT/LAER Clearinghouse (benchmarking tool)
- Clean Air Act Advisory Committee Climate Change Work Group
  - Innovation
  - Energy Efficiency

Example: Russell City

- Bay Area Air Quality Management District and Calpine agreed to GHG BACT review and voluntary GHG limit as test case
- 612 MW natural gas fired combined cycle power plant in Hayward, CA
- Reviewed available technologies; concluded that high-efficiency power generation technology is the only available and feasible control technology
- BACT review resulted in slightly higher efficiency than originally proposed (56.45 vs. 55.8% efficiency)
- Tried to do an output based standard but wound up doing an input based standard plus an efficiency standard because GHGs per unit of output was too variable
- Covered all GHGs
- Also set BACT for fire pump and circuit breakers



Comparable Projects for Benchmarking

Facility	CEC Application Date	Facility Size (MW)	Thermal Efficiency (LHV)
Colusa Generation Station	11/6/2006	660	56%
Blythe Energy Project Phase II	2/19/2002	520	55-58% (est.)
Lodi Energy Center	9/10/2008	255	55.6%
CPV Vaca Station Power Plant	11/18/2008	660	55%
Victorville 2 Hybrid Power Project	2/28/2007	563	52.7% (w/ duct burn)
Avenal Energy Power Plant[44]	2/21/2008	600	50.5%
Palomar Energy Project	8/2003	550	55.3% (w/o duct firing) 54.2% (w/ duct firing)
SMUD Consumnes Phase I	9/13/2001	500	55.1%

Lessons from Russell City

- Can do GHG BACT like BACT for traditional air pollution, including benchmarking
- Modest impact on industry; modest impact on the environment
- Significant impact on permitting costs for first one; later ones should be more modest

New Source Performance Standards

- How to define source categories
- What is BDT for GHGs for new sources?
- What is cost-effective?
- How to drive innovation
- How to drive energy efficiency

?

Setting New Source Performance Standards

Section 111 defines NSPS as the “degree of emission limitation achievable through…the best system of emission reduction…taking into account the cost of achieving such reduction and any non-air quality health and environmental impact and energy requirements…adequately demonstrated” = Best Demonstrated Technology (BDT)

Applicability:

- Source category/stationary source category = industrial segment covered by standard
- Stationary source/affected facility = emission units subject to standard (affected facility means a discrete emitting unit, can be piece of equipment or whole plant)

EPA sets standards but states typically granted implementation, enforcement authority

NSPS: How is BDT Determined?

- "Degree of emission limitation" = maximum quantity of pollutant that may be emitted; meant to provide flexibility, but may be few practical means of achieving this

- EPA considers costs, but is not required to conduct a true CBA
  - Considers economic costs to the industry and ability to pass costs along to consumers without affecting demand
  - Incremental "cost-effectiveness" approach (costs of achieving incremental additional reductions under different controls)

- BDT may not be lowest emission standard achievable if it creates negative environmental/health consequences

NSPS: How is BDT Determined?

- Does not require commercial demonstration
  - EPA can rely on pilot projects, those in other industries or countries
  - Must be achievable under wide range of operating conditions
  - Can't be theoretical, but can result from technology forcing (projection based on existing technology, within reason)
- May be specific technologies based on their ability to meet a particular emissions benchmark
- Innovative technology waivers: for new sources with undemonstrated technology; intended to encourage innovation and reductions beyond NSPS, but it has been rarely used, if ever.

Control of existing sources under 111(d)

- EPA may issue guidelines to states for control of existing sources
  - NSPS must exist for source category; pollutant is not a criteria pollutant
  - To date, usually specialized sources that emit discrete types of pollutants
- Guidelines include information contained in NSPS:
  - Known/suspected health or welfare concerns
  - Control systems that reflect BDT
  - Information on costs
  - Time necessary for design, installation, and start-up of control systems
- States required to implement guidelines
  - States submit plan within 9 months, based on guidelines
  - If pollutant threatens public health, state standards must be ≥ guidelines, unless on a case-by-case basis the state shows controls are unreasonable

Section 111(d) issues

- How to define source categories
- What is BDT for GHGs for existing sources?
- What is cost-effective?
- How to drive innovation
- How to drive energy efficiency
- Is trading allowed?

PEW CENTER ON Global CLIMATE CHANGE

The EPA has issued Section 111(d) guidelines for:

- sulfuric acid mist from sulfuric acid plants
- fluoride emissions from phosphate fertilizer plants
- total reduced sulfur (TRS) emissions from kraft pulp mills
- fluoride emissions from primary aluminum plants
- municipal waste combustion (MSW) emissions from solid waste incinerators (NOx trading is allowed)
- nonmethane organic emissions from landfills, hospital/medical infectious waste incinerators
- others

Some Takeaways

- Setting performance standards under the Clean Air Act and other environmental statutes utilizes benchmarking and provides some useful models.
- Performance standards played a role as benchmarks in allowance allocation under the U.S. acid rain program.
- Potential application of CAA performance standards to GHGs poses some special challenges; 111(d) may be applied to GHGs.

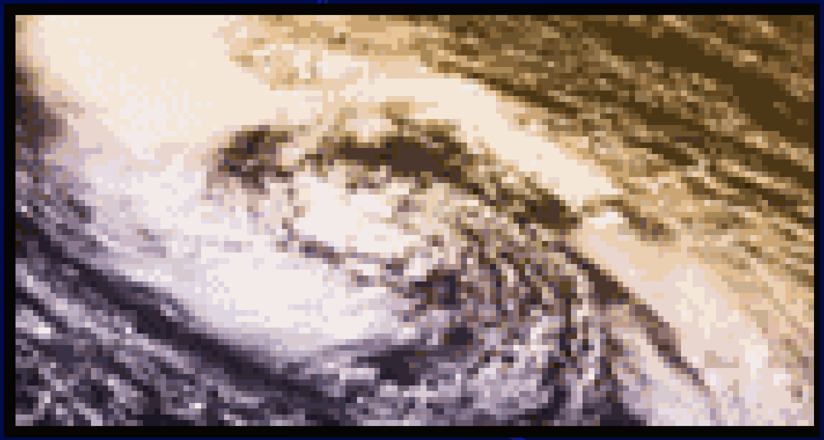
www.pewclimate.org



Technology-Based Standards Under Different Federal Environmental Statutes

Statute	Technology Standard-setting Provision	Decision Rule	Comments
Clean Air Act	New Source Performance Standards (NSPS) (for new sources)	Best Demonstrated Technology (BDT)	Degree of emission limitation achievable through the application of the best system which (taking into account cost and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated. Technology may not be one that is purely theoretical but it can be a result of technology forcing. The EPA may make a projection based on existing technology, though that projection is subject to the restraints of reasonableness and cannot be based on crystal ball inquiry. Can do work practice standards if performance standard infeasible. Creates a floor for New Source Review.
Clean Air Act	Innovative Technology Waivers	Designed to allow testing of control systems that might prove to achieve greater reductions than the NSPS.	Not used very often or successfully.
Clean Air Act	111(d) ("NSPS" for existing sources)	Similar criteria to NSPS	EPA establishes emission guidelines for existing sources which must be implemented by states. Only applies to a limited set of sources (non-criteria, non-hazardous)

Statute	Technology Standard-setting Provision	Decision Rule	Comments
Clean Air Act	New Source Review (NAAQS[1] attainment areas)	Best Available Control Technology (BACT)	--Case by case review --Maximum degree of reduction achievable taking into account energy, environmental and economic impacts and other costs --EPA recommended top-down process for BACT determination: Step 1: Identify available pollution control options Step 2: Eliminate technically infeasible options Step 3: Rank remaining control technologies by control effectiveness Step 4: Evaluate the most effective controls (considering energy, environmental, and economic impacts) and document the results. Step 5: Make the BACT selection.
Clean Air Act	New Source Review (NAAQS non-attainment areas)	Lowest Available Emission Rate (LAER)	The most stringent emission limitation which is contained in the implementation plan of any State for such class or category of source, unless the owner or operator of the proposed source demonstrates that such limitations are not achievable; or the most stringent emission limitation which is achieved in practice by such class or category of source. Similar analysis to BACT, except no consideration of economic, energy or environmental factors.
Clean Air Act	State Implementation Plans (SIPs) for existing sources to meet NAAQS	Reasonably Available Control Technology (RACT) and Reasonably Available Control Measures (RACM)	Lowest emission limitation that a particular source is capable of meeting by the application of control technology that is reasonably available considering technological and economic feasibility.
Clean Air Act	RACT/BACT/LAER Clearinghouse	Database of state air permitting decisions	Essentially a benchmarking tool for state agencies and permit applicants

[1] National Ambient Air Quality Standards

Statute	Technology Standard-setting Provision	Decision Rule	Comments
Clean Air Act	Air Toxics Emission Standards for major sources	Maximally Available Control Technology (MACT)	Maximum degree of reductions and emissions deemed achievable for the source category or subcategory that, taking into consideration the cost of achieving the reduction, any non-air-quality health and environmental impacts and energy requirements, is achievable for new or existing sources. MACT floor for new sources is the emission control that is achieved in practice by the best controlled similar source. MACT floor for existing sources is the average emission limitation achieved by the best performing 12 percent of the existing sources; or if fewer than 30 sources, the best performing 5 sources. EPA says 94^{th} percentile (others say 88^{th}).
Clean Air Act	Air Toxics Emission Standards for some area sources	Generally Available Control Technology (GACT)	Agency has broad discretion. No floor analysis or minimum control requirement.
Clean Air Act	Vehicle and engine standards		Mostly federal, but CA allowed to continue to be laboratory. Generally Congress set specific limits for light duty vehicles but allowed for suspension if technology not available. More flexibility for heavy duty engines: the greatest degree of emission reduction achievable from available technology giving appropriate consideration to cost, energy and safety factors; manufacturers may bank and trade emission credits. The EPA generally follows international standards for aircraft emissions.
Clean Air Act	Fuel standards		EPA can regulate based on (1) public health impacts or (2) impacts on pollution control equipment. Under (1) can only consider health and other means of achieving standard. Under (2) must do cost-benefit analysis. Also Congress specified many rules.

Statute	Technology Standard-setting Provision	Decision Rule	Comments
Clean Water Act (CWA)	National Pollutant Discharge Elimination System (NPDES) permit (including both technology-based effluent standards and water quality-based standards)	Best practicable control technology currently available (BPT)	The first level of technology-based standards established by the CWA to control pollutants discharged to U.S. waters. This standard is used for conventional, toxic, and nonconventional pollutants and is applied to existing dischargers. BPT limit guidelines are generally set using the average of the best existing performance by plants within an industrial category or subcategory. EPA must conduct a cost-benefit analysis in setting BPT standards. All regulated industries have a BPT standard, and then industries may also have BAT and/or BCT standards set (see below).
Clean Water Act	National Pollutant Discharge Elimination System (NPDES) permit (including both technology-based effluent standards and water quality-based standards)[2]	Best conventional pollutant control technology (BCT)	Technology-based standard for conventional pollutants only and applicable to existing dischargers. Rather than a standard cost-benefit analysis, BCT is established using a two-part "cost reasonableness" test which compares the cost for an industry to reduce its discharges with the cost to a publicly owned treatment works (POTW) for similar levels of reduction. The second test examines the cost-effectiveness of additional treatment beyond the best practicable control technology (BPT; see above). EPA must find limits which are reasonable under both tests before establishing them as BCT. Generally, BCT represents the best existing treatment technologies that are economically achievable within an industrial category.

[2] Effluent limitations serve as the primary mechanism in NPDES permits for controlling discharges of pollutants. When developing effluent limitations for an NPDES permit, permit writers must consider limits based on both the technology available to control the pollutants (i.e., technology-based effluent limits) and limits that are protective of the water quality standards of the receiving water (i.e., water quality-based effluent limits).

The intent of technology-based effluent limits in NPDES permits is to require a minimum level of treatment of pollutants for point source discharges based on available treatment technologies, while allowing the discharger to use any available control technique to meet the limits. For industrial (and other non-municipal) facilities, technology-based effluent limits are derived by using national effluent limitations guidelines and standards established by EPA, and/or using best professional judgment (BPJ) on a case-by-case basis in the absence of national guidelines and standards.

Statute	Technology Standard-setting Provision	Decision Rule	Comments
Clean Water Act	National Pollutant Discharge Elimination System (NPDES) permit	Best available technology economically achievable (BAT)	Technology-based standard for toxic and nonconventional pollutants and applicable to existing dischargers; established as the most appropriate means available for controlling the direct discharge of toxic and nonconventional pollutants. BAT effluent limitations guidelines generally represent the best existing performance of treatment technologies that are economically achievable within an industrial category. EPA must consider costs in setting BAT, but does not have to weigh them against the benefits of effluent reduction.
Clean Water Act	National Pollutant Discharge Elimination System (NPDES) permit	New source performance standards (NSPS)	Technology-based standard for conventional pollutants and applicable to new sources. Standards consider that the new source facility has an opportunity to design operations to more effectively control pollutant discharges.
Resource Recovery and Conservation Act (RCRA) – Hazardous and Solid Waste Amendments (HSWA)	Land Disposal Restriction (LDR) treatment standards	Best Demonstrated Available Technologies (BDAT)	Technology-based treatment standards for hazardous waste. BDAT can be expressed either as a performance standard (based on a maximum allowable concentration of particular wastes) or as a specific technology or practice. These standards are determined through a process that involves dividing wastes into similar groups; assessing technologies based on availability, performance, and quality; and testing to determine the "best" technologies.

Executive Summary

This whitepaper is a product of the Three-Regions collaborative process. The Three-Regions process includes member jurisdictions of the three sub-national greenhouse gas cap-and-trade initiatives in North America: the Midwestern Greenhouse Gas Reduction Accord (Midwestern Accord), the Northeastern and Mid-Atlantic Regional Greenhouse Gas Initiative (RGGI), and the Western Climate Initiative (WCI). It represents a consensus among the three regional programs on key offset policy design and implementation components that are necessary to ensure high quality offsets in a regulatory greenhouse gas cap-and-trade program.

Offsets provide a compliance flexibility mechanism that reduces the compliance cost of a cap-and-trade program, since more and varied emissions reduction opportunities may be used to meet a compliance obligation. Lower emissions abatement costs result in lower impacts on consumers, which allows for the pursuit of more aggressive emissions reduction targets. Examples of offset projects provided for in a number of programs include projects that capture and destroy methane from landfills, projects that avoid methane emissions from agricultural manure management, and afforestation and forestry management projects. Since offsets, if designed and implemented properly, maintain the integrity of the emissions cap while providing compliance flexibility, use of offsets avoids the implementation of flexibility mechanisms that undermine the emissions cap, such as a safety valve or price cap.

To be equivalent to an emissions reduction achieved at a regulated emissions source, an offset project, and the emissions reductions or removals achieved by the project, must be real, additional, verifiable, enforceable, and permanent.

Implementing a high-quality offset program also requires transparency, credible verification, and a degree of administrative flexibility over time. This includes clear and transparent project documentation requirements, high quality independent verification to support regulatory review, and regular program review and adjustment.

The three regional cap-and-trade initiatives have either implemented or intend to implement the offset component of their program through a standardized approach, to the extent possible. This approach, as outlined in this whitepaper, provides multiple benefits that improve both offset quality and program efficiency, compared to a project-by-project approach. These benefits include increased program transparency, a more objective project review process, reduced project transaction costs, reduced financial risk for project developers, a reduction in market uncertainty, and a more streamlined project regulatory review process.

This document discusses key offset quality concepts and presents the consensus of the three regional cap-and-trade programs on the following core offset quality criteria.

Real

For a greenhouse gas offset to be “real,” an offset compliance unit must represent one ton of CO_2-equivalent (CO_2e) greenhouse gas emissions reduction or removal (carbon sequestration) that results from an identified emissions reduction activity (i.e., a clearly identified action or decision). Offset project emissions reductions or removals must not be an artifact of incomplete or inaccurate accounting. Therefore, a project emissions or carbon sequestration baseline and project emissions reductions or removals must be quantified using accurate quantification methodologies and conservative assumptions where appropriate to account for measurement uncertainty. Quantification methodologies must appropriately account for all relevant greenhouse gas emissions sources and sinks and identified project leakage.

Additional

A greenhouse gas offset results from an emissions reduction or removal caused by a project specifically intended to compensate for emissions occurring elsewhere. A greenhouse gas emissions reduction or removal project is considered additional if the offset project activity would not have occurred in the absence of the offset program.[1] Because awarded offset compliance units allow a regulated entity to emit more than it otherwise would have been able to, the underlying offset project only provides a true emissions reduction benefit if the project would not have occurred absent the offset program—i.e., it is “additional” to activities that would have otherwise occurred in the absence of the offset program.

Verifiable

Offset projects and offset project emissions reductions or removals must be verifiable. Verification is necessary to ensure that an offset project is eligible and has met all program requirements and that the offset compliance units awarded are based on emissions reductions or removals that have actually occurred and been properly measured. As used here, the concept of verification applies to both evaluation of project eligibility (sometimes referred to as validation) and verification of periodic monitoring reports of greenhouse gas emissions reductions or removals achieved by a project (commonly referred to as verification).

[1] By extension, this also means that emission reductions, avoidance, or sequestration achieved by an offset project result in a lower level of net greenhouse gas emissions or atmospheric concentrations than would occur in the absence of the offset project.

Permanent
Greenhouse gas emissions reductions or removals achieved by offset projects must be permanent. Offset project emissions reductions or removals are considered permanent if they are not reversible or, if reductions or removals are reversible, certain programmatic requirements are met to ensure the permanence of the reductions or removals.

Enforceable
An offset is enforceable if the offset program has sufficient regulatory authority and enforcement mechanisms to compel compliance with its program requirements. To ensure that offsets are enforceable, any party submitting an offset project for regulatory review and that may receive an award of offset compliance units must already be subject to the jurisdiction of the appropriate regulatory agency or must voluntarily submit itself to the jurisdiction of the regulatory agency. The regulatory agency should also maintain authority related to the offset compliance unit itself, as it represents a limited authorization to emit a CO_2e ton of greenhouse gas issued by the regulatory agency.

I. Introduction

This whitepaper is a product of the Three-Regions collaborative process. The Three-Regions process includes member jurisdictions of the three sub-national greenhouse gas cap-and-trade initiatives in North America: the Midwest Greenhouse Gas Reduction Accord (Midwestern Accord), the Northeastern and Mid-Atlantic Regional Greenhouse Gas Initiative (RGGI), and the Western Climate Initiative (WCI). The Three-Regions process is a forum for each of the programs to share information related to the design and implementation of each of the regional cap-and-trade programs and to discuss issues related to potential future linking of the programs.

This whitepaper represents a consensus among the three regional programs on key offset policy design and implementation components that are necessary to ensure high-quality offsets in a regulatory greenhouse gas cap-and-trade program.

The whitepaper is intended to serve as both an internal policy document for use among the programs and as a public policy document to inform the development of comprehensive climate policy in North America. As an internal document, the whitepaper articulates key quality requirements for offsets and offset programs to facilitate potential future linking of regional cap-and-trade programs. Future linking of programs could include coordination of offset programs and offset reciprocity among programs, which would require that each program maintain minimum offset quality requirements and standards. As an external document, the whitepaper communicates common underlying offset quality concepts that are incorporated into the design and implementation of each of the regional cap-and-trade programs to inform the design and implementation of national cap-and-trade programs in the U.S. and Canada.

A. Introduction to offsets and the importance of offset quality

In a greenhouse gas cap-and-trade program, a greenhouse gas (GHG) offset ("offset") is a project-based greenhouse gas emissions reduction or removal that occurs outside the capped emissions sector or sectors regulated by the cap-and-trade program.[2] For each CO_2-equivalent (CO_2e) ton of greenhouse gas emissions reduction or carbon sequestration achieved by an offset project, the project is awarded an offset credit or allowance (a "compliance unit") that can be used by an emissions source in a capped sector to emit a CO_2e ton of greenhouse gas. Conceptually, an offset is used to allow a regulated emissions source to emit an additional ton of greenhouse gas in exchange for a ton of

[2] "Capped sector" as used in this whitepaper refers to the specific category or categories of emissions sources regulated through a cap-and-trade program (e.g., electricity generation facilities above a certain size threshold or industrial facilities above a certain annual emissions threshold). Capped sector may also refer to activities that indirectly reduce or increase emissions at a regulated source (e.g., electric end-use).

greenhouse gas emissions reduction or removal achieved outside of the capped sector(s) by an offset project activity (Figure 1). The regulated emissions source is allowed to emit more in exchange for achievement of an emissions reduction elsewhere.

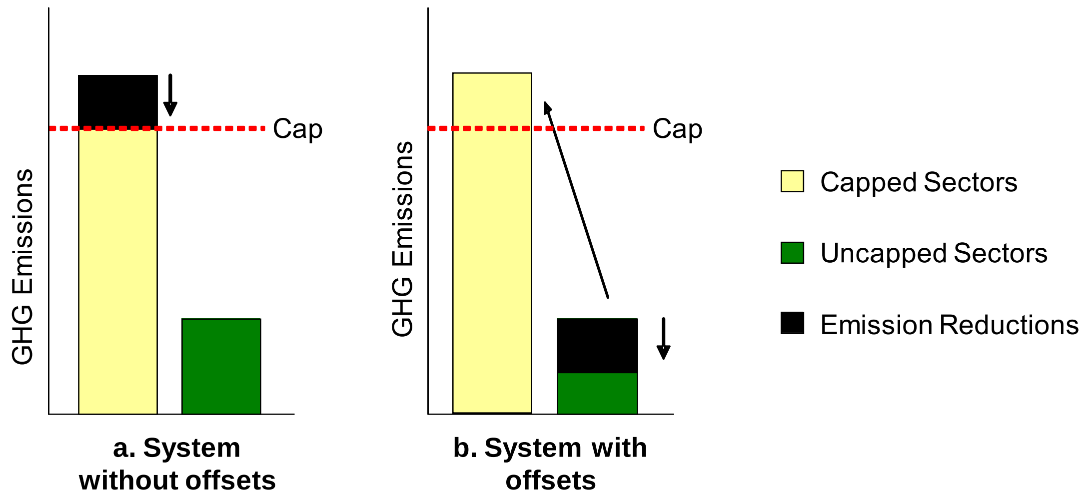

Figure 1. The Role of Offsets in Cap-and-Trade Programs[3]

Offsets provide a compliance flexibility mechanism that reduces the compliance cost of a cap-and-trade program, since more and varied emissions reduction opportunities may be used to meet a compliance obligation. Lower emissions abatement costs result in lower impacts on consumers, which allows for the pursuit of more aggressive emissions reduction targets. Since offsets, if designed and implemented properly, maintain the integrity of the emissions cap (the called for emissions reductions under the program) while providing compliance flexibility, use of offsets avoids the implementation of flexibility mechanisms that reduce the emissions reduction benefits achieved by the program, such as a safety valve or price cap.

Offsets result in the issuance of more compliance units in addition to the established emissions budget for a cap-and-trade program (the finite number of compliance units issued represents the emissions cap for regulated emissions sources). In order to maintain the integrity of the emissions cap, any offset compliance units that are issued must represent emissions reductions achieved outside capped sectors *as a result of the cap-and-trade program*. The premise is that rather than investing in more costly emissions abatement opportunities at regulated emissions sources, the owners or operators of a source (or a third party) are investing in lower-cost emissions abatement opportunities outside of the capped sectors.

[3] World Resources Institute, 2010

This basic premise means that the compliance obligation imposed by the cap-and-trade program is what drives investment in emissions reduction projects outside the capped sectors in order to generate offset compliance units.[4] Thus, there is a one-to-one relationship between emissions reductions achieved outside the capped sectors through an offset project and additional emissions permitted within the capped sectors. Net emissions to the atmosphere do not exceed the level of the established emissions cap because offsets represent equivalent emissions reductions or removals achieved elsewhere as a result of the cap-and-trade program. Absent this one-to-one relationship—the exchange of an emissions reduction elsewhere for an expansion of the emissions cap for regulated emissions sources—net emissions would exceed the level of the established emissions cap and the integrity of the emissions cap would be undermined. Simply put, the cap-and-trade program would not reduce the emissions it claims to.

B. Implications of offset quality

To maintain cap integrity, emissions reductions achieved through an offset should be functionally equivalent to emissions reductions achieved by a regulated emissions source. This has important implications for the quality requirements that an offset project must meet. In particular, emissions reductions or removals achieved through an offset project activity must meet functionally comparable standards to emissions reductions achieved by a regulated emissions source. An offset project must:

- be evaluated and verified (it must be eligible under the cap-and-trade program and implemented as claimed);
- achieve emissions reductions or removals that are properly quantified, monitored, and verified (as is required for regulated emissions sources); and
- achieve emissions reductions or removals that are permanent and enforceable (as is the case by default for regulated emissions sources).

In short, to be equivalent to an emissions reduction achieved at a regulated emissions source, an offset project, and the emissions reductions or removals achieved by the project, must be real, verifiable, permanent, and enforceable.

Perhaps most importantly, an offset project must occur *as a result of the offset component of the cap-and-trade program*, because more emissions from regulated emissions sources are being allowed in exchange for offset emissions reductions. This means that the offset project must be additional—it would not have happened anyway in the absence of the economic incentive created by the

[4] While this premise is straightforward, operationalizing this concept in order to evaluate offset project additionality is complex and requires workable, rigorous mechanisms, as discussed later in the whitepaper.

compliance obligation required by the cap-and-trade-program.[5] As discussed above, the concept of an offset rests on "exchanging" emissions reductions or removals that occur outside the capped sector(s) for allowing additional emissions from a regulated emissions source (Figure 1). In practice, this means that the compliance obligation of a cap-and-trade program is driving investment in emissions reduction opportunities outside the capped sector, in exchange for offset compliance units that can be used by a regulated emissions source for compliance. If an offset project that is awarded offset compliance units would have occurred anyway in the absence of the incentive provided by the offset component of the cap-and-trade program, then the award of offset compliance units would result in a net increase in atmospheric levels of greenhouse gases relative to those that would be achieved through the cap-and-trade program emissions cap (Figure 2). This outcome would undermine the cap-and-trade program's established emissions limitation and reduce the actual environmental benefits achieved by the program.

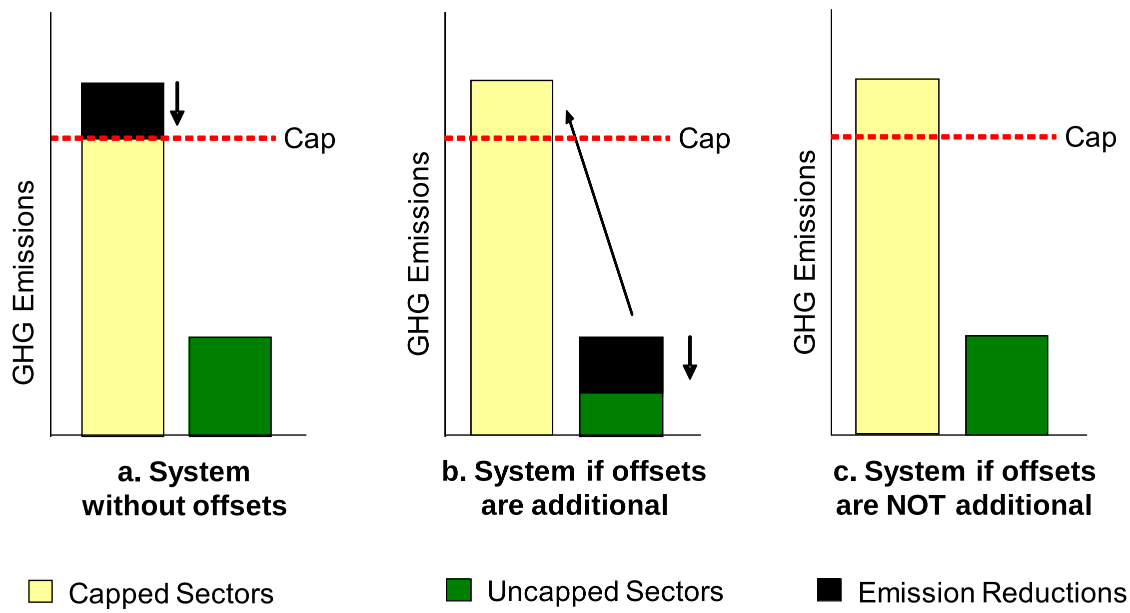

Figure 2. Impacts of Additional vs. Non-Additional Offsets on Emissions.[6]

In the absence of offsets (A), imposing a cap-and-trade program will result in emissions reductions in the capped sectors. Offsets provide regulated emissions sources with additional flexibility and allow them to meet a portion of their emissions obligations through reductions in an uncapped sector or sectors. When offsets are additional, the emissions reductions of the cap-and-trade program are preserved (B). However, if offset projects are not additional, and would have occurred in the absence of the program, then cap-and-trade program emissions benefits are

[5] Methods for operationalizing this concept and the complexities of evaluating offset project additionality are discussed in detail in Section II of the whitepaper.
[6] Bianco, Nicholas, "Stacking Payments for Ecosystem Services," WRI Fact Sheet, November 2009, World Resources Institute. Available at : http://pdf.wri.org/factsheets/factsheet_stacking_payments_for_ecosystem_services.pdf

lost (C), because the cap-and-trade program has not resulted in emissions reductions (either within the capped sector or through offsets).

To operationalize the additionality concept, assurance should be provided that an offset project was unlikely to occur absent the revenue stream provided by offset compliance units awarded through the offset component of the cap-and-trade program. Typically, this is done by evaluating an offset project in comparison to a “business-as-usual” baseline scenario that represents expected typical market activity that would have occurred in the absence of the project. To be eligible, the offset project must represent activity that is “in addition to” this expected typical market activity. This may involve a project-by-project assessment of financial data or market barriers, or the implementation of standardized criteria that represent activity that is significantly above standard market practice. Both types of evaluation strive to assure that the project would not have been implemented but for the anticipated revenue provided by the award of offset compliance units for project emissions reductions or removals.

The key offset quality criteria—real, additional, verifiable, permanent, and enforceable—are discussed in detail in the next section.

II. Key Offset Quality Criteria

This section provides an overview of the core attributes that ensure greenhouse gas emissions offsets are delivering their stated environmental benefits. These attributes are typically defined as real, additional, verifiable, permanent, and enforceable. The definitions and criteria presented here represent the consensus of the three regional greenhouse gas cap-and-trade programs, the Midwestern Accord, RGGI, and WCI.

Real

For a greenhouse gas offset to be real, an offset compliance unit must represent one ton of CO_2e greenhouse gas emissions reduction or removal (carbon sequestration) that results from an identified emissions reduction activity (i.e., a clearly identified action or decision). Offset project emissions reductions or removals must not be an artifact of incomplete or inaccurate accounting. Therefore, a project emissions or carbon sequestration baseline and project emissions reductions or removals must be quantified using accurate quantification methodologies and conservative assumptions where appropriate to account for measurement uncertainty. Quantification methodologies must appropriately account for all relevant greenhouse gas emissions sources and sinks and identified project leakage.[7] This includes adjusting project emissions

[7] Leakage occurs when greenhouse gas emissions or removals change outside the project boundary due to the implementation of the project. These changes in greenhouse gas emissions or removals may occur for a variety of reasons, including the shifting of emitting activities to other facilities or due to market forces indirectly impacted by the implementation of an offset project.

reductions or removals that are the basis for the award of offset compliance units to adequately account for leakage risk.

If offset compliance units are awarded in excess of the emissions reduction or carbon removal benefits that actually result from the offset project, then the integrity of the cap-and-trade program emissions cap will be compromised. This will result if the emissions reductions or removals claimed by a project are not in fact caused by the project, or if the emissions reductions or removals claimed do not actually occur. Projects may also be awarded excess offset compliance units if methodologies are employed that over-estimate the emissions reductions or removals achieved by the project. This can be avoided by employing conservative assumptions whenever there are uncertainties in quantifying emissions reductions or removals.

Meeting these goals also requires that an offset project and the offset compliance units awarded for the project be recorded in a transparent registry. This ensures that offset compliance units are only awarded once for each CO_2e ton of emissions reductions or removals occurring due to an offset project.

Additional

A greenhouse gas offset results from an emissions reduction or removal caused by a project specifically intended to compensate for emissions occurring elsewhere. A greenhouse gas emissions reduction or removal project is considered additional if the offset project activity (or activities) would not have occurred in the absence of the offset program.[8] Because awarded offset compliance units allow a regulated emissions source to emit more than it otherwise would have been able to, the underlying offset project only provides a true emissions reduction benefit if the project would not have occurred absent the offset program—i.e., it is “additional” to activities that would have otherwise occurred in the absence of the offset program.

While the concept of additionality is relatively straightforward, evaluating the additionality of an individual offset project can be complex. In practice, an offset project is considered additional if the project involves activities beyond standard market practice and the project is being implemented in response to economic incentives provided through the offset program (anticipated award of offset compliance units that have a market value). This does not necessarily preclude an offset project activity from receiving other economic incentives or providing other marketable ecosystem services or other economic products and services, provided it can be demonstrated that the offset program, alone or in combination with other incentives, is necessary to drive the implementation of the offset project (Figure 3).

[8] By extension, this also means that emission reductions, avoidance, or sequestration achieved by an offset project result in a lower level of net greenhouse gas emissions or atmospheric concentrations than would occur in the absence of the offset project.

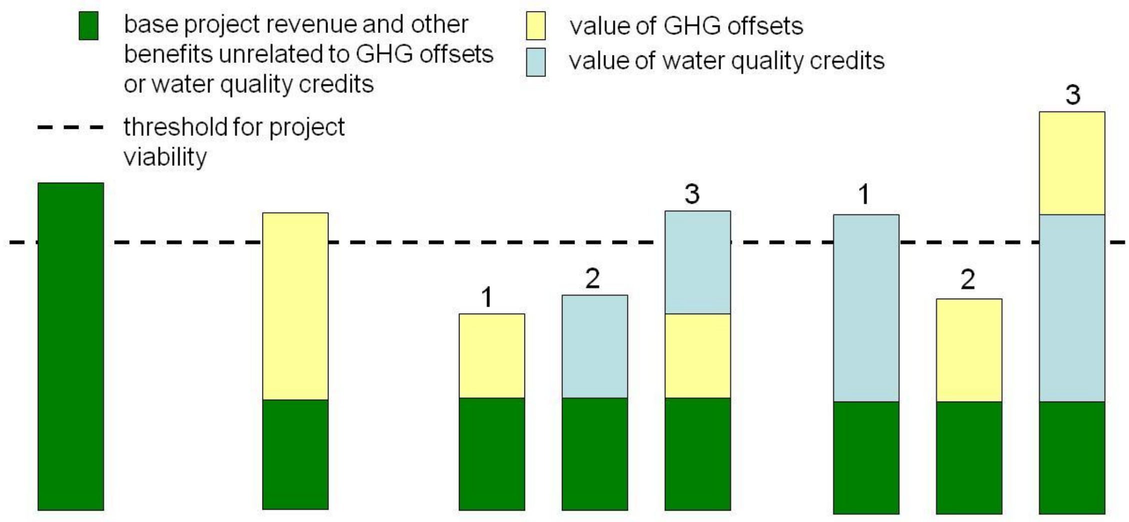

Figure 3. Additionality Evaluation, Considering Stacking of Multiple Project Incentives[9]

As shown in Figure 3a, some types of projects may be commonplace because they save the developer money or generate considerable revenue even without receiving offset compliance units ("GHG offsets"). Such projects are not additional. Figure 3b depicts a scenario where a project will not move forward without a carbon payment in the form of tradable offset compliance units. This project would be considered additional, and would be eligible for the award of offset compliance units. A project should be eligible for stacking of multiple project incentives if multiple incentives are necessary to drive project development. This scenario is depicted in Figure 3c, where neither offset compliance units (3c1) nor water quality credits (3c2) alone are sufficient to drive project development. However, when combined these two payments are sufficient to drive project development (3c3). However, if water quality credits alone are sufficient to drive project development without the need for carbon incentives in the form of offset compliance units (3d1), then offset compliance units do not drive project development, and therefore the project should not be eligible for stacking of multiple incentives under a cap-and-trade program.

An offset project should be evaluated to ensure that the project is not required by any local, state/provincial, or federal law, regulation, or administrative or judicial order. If a project or activity is required by regulation, law, or administrative or judicial order it is assumed to be implemented to achieve compliance with the law, and not to generate offset compliance units. Therefore, awarding offset compliance units for an offset project that involves mandated activities would

[9] Adapted from Bianco, Nicholas, "Stacking Payments for Ecosystem Services," WRI Fact Sheet, November 2009, World Resources Institute. Available at : http://pdf.wri.org/factsheets/factsheet_stacking_payments_for_ecosystem_services.pdf

undermine the emissions limitation of the cap-and-trade program. This concept is commonly referred to as “regulatory additionality”.

In addition to ensuring that a project is additional to regulation, the offset project activities must be shown to exceed a business-as-usual or “without-project” baseline scenario. The business-as-usual baseline scenario represents the expected activity that would occur in the absence of the offset program incentive.[10] Offset projects should only be awarded offset compliance units for greenhouse gas emissions reductions or removals if the project represents activities that exceed the activities under an approved business-as-usual baseline scenario.

Verifiable

Offset projects and offset project emissions reductions or removals must be verifiable. Verification is necessary to ensure that an offset project is eligible and has met all program requirements and that the offset compliance units awarded are based on emissions reductions or removals that have actually occurred and been properly measured. As used here, the concept of verification applies to both evaluation of project eligibility (sometimes referred to as validation) and verification of periodic monitoring reports of greenhouse gas emissions reductions or removals achieved by a project (commonly referred to as verification).

Prior to verification of project emissions reductions or removals, an offset project must be validated. Project validation confirms that the offset project either has been or will be implemented and that the project meets all program eligibility and other requirements. Typically, validation also includes a review of the adequacy of the project monitoring and reporting plan.

Emissions reductions or sequestration achieved through an offset project typically accrue over a multi-year period of time, which requires ongoing monitoring. As a result, robust monitoring and verification plans should be in place to ensure that project activities are monitored and project emissions reductions or removals are appropriately measured and recorded over time. Emissions reductions or removals should have occurred and been verified before the award of offset compliance units (sometimes referred to as *ex post* crediting). An emissions reduction or removal and the related offset compliance unit that is awarded can be verified if it results from a project for which the project activities and emissions reductions or removals can be readily monitored and quantified with reasonable precision and certainty, and the completeness and validity of project data underlying project assertions can be independently substantiated.

[10] This means that the proposed project activity could itself be considered to occur under a baseline scenario, and therefore would be non-additional. When considered as part of a “without project” scenario, this means that a valid claim could not be made that the project would not have occurred absent the incentive provided by offset compliance units; the without project scenario and project scenario would effectively be the same, and the project would be non-additional.

This requires that a given project's emissions reductions or removals are well documented and transparent, such that an objective ex-post review by a qualified verifier can be conducted.

Permanent
Greenhouse gas emissions reductions or removals achieved by offset projects must be permanent. Offset project emissions reductions or removals are considered permanent if they are not reversible or, if reductions or removals are reversible, certain programmatic requirements are met to ensure the permanence of the reductions or removals.

Offset project emissions reductions or removals should be comparable to emissions reductions by emissions sources regulated under the cap-and-trade program. Emissions reduced from a regulated emissions source during a specified period of time are permanent by default, since the absence of emissions during that past compliance period cannot be reversed. If the emissions reductions or removals provided by an offset project are not permanent, then the emissions limitation of the cap-and-trade program can be compromised if reversals occur.

For some offset project types, ensuring permanence is straightforward. For example, methane captured and destroyed through oxidation cannot reform into methane. As a result, the emissions reductions are permanent because they cannot be reversed. However, other offset project types face a risk of reversal. Specifically, the sequestration of carbon dioxide through biological means inherently bears the risk of reversal, as carbon can be released through a variety of causes, including fire, insect infestation, natural decay, and human caused reversals such as unsustainable harvesting. Therefore, if projects that sequester carbon through biological means are to be awarded offset compliance units, it is critical that programmatic safeguards be established to minimize the risk of reversal and that mechanisms be established to address and account for any reversals that may occur.

Enforceable
An offset compliance unit must be enforceable. An offset is enforceable if the offset program has sufficient regulatory authority and enforcement mechanisms to compel compliance with its program requirements. To ensure that offsets are enforceable, any party submitting an offset project for regulatory review and that may receive an award of offset compliance units must already be subject to the jurisdiction of the appropriate regulatory agency or must voluntarily submit itself to the jurisdiction of the regulatory agency. The regulatory agency should also maintain authority related to the offset compliance unit itself, as it represents a limited authorization to emit a CO_2e ton of greenhouse gas issued by the regulatory agency.

Offset compliance units must only be awarded after the project proponent demonstrates compliance with offset program requirements and protocols to the satisfaction of the issuing authority.

In the event of demonstrated non-compliance with any offset program requirement, enforcement measures may include: 1) mandated on-site changes to a project to bring it into compliance with program requirements; 2) administrative fines or penalties; 3) cancellation of awarded offset compliance units; and 4) mandated procurement and submittal to the regulatory agency of offset compliance units from the market to make up for awarded offset compliance units related to an offset project that is non-compliant with program requirements.

Failure to provide for the enforceability of offsets creates the potential for fraud and risks compromising the integrity of the cap-and-trade program emissions limitation. It could also undermine the establishment of a liquid offset market by creating potential uncertainty related to the market value of offset compliance units, both for regulated emissions sources using offsets for compliance and other market purchasers of offset compliance units.

III. Key Process Requirements Critical to Offset Quality

Implementing a high-quality offset program requires transparency and high-quality verification. Key process requirements that impact offset quality are discussed below.

A. Project documentation

Offset projects typically involve documentation of complex activities in diverse applications and locations. As a result, project documentation should be transparent and understandable, and readily accessible by the public. Transparency is key to assuring program integrity and maintaining public and market confidence in offset emissions reductions and removals, and by extension the market value of offset compliance units.

An offset program should have a secure yet transparent tracking system for offset projects and the award of offset compliance units (a project registry or tracking system). The offset tracking system and program regulatory requirements and administrative protocols should include measures to ensure against double counting of project emissions reductions and removals and double award of offset compliance units, and to assure that offset compliance units are properly assigned. At a minimum, offset project proponents should be required to attest that they hold the rights to project emissions reductions or removals, or have been assigned such rights, and also disclose any reporting related to a project to another voluntary or mandatory greenhouse gas reduction program.

B. High-quality independent verification to support regulatory review

High-quality, independent verification is critical to support regulatory agency review of offset projects and emissions reductions or removals achieved by offset projects.[11] Verification should be conducted by an independent party that does not have any financial interest or other interest in an offset project, or a relationship with an offset project developer or other party involved in an offset project that could cause a conflict of interest, which would undermine the objectivity of the verifier.

Verification should be conducted for both the evaluation of offset project eligibility and review of project monitoring reports that quantify periodic project emissions reductions or removals. In addition to evaluation of project eligibility, project validation should include a review of the project's monitoring and verification plan that will be used to monitor, quantify, and verify project emissions reductions or removals.

Project validation should include an on-site, or equivalent, review to ensure that projects will be or have been implemented as claimed and in accordance with program requirements. Verification of project monitoring reports of project emissions reductions or removals should also involve on-site review, or an equivalent review if appropriate for a specific offset project category. For example, in certain instances remote sensing technology may be adequate to demonstrate that a project is being implemented as claimed. Determinations about the appropriateness of various alternatives to on-site review should be based on well accepted methodologies.

The quality of verification services provided is dependent on the quality of the verifiers that provide such services. As a result, one of the keys to high-quality verification is the implementation of a robust verifier accreditation process. The focus of this process is three-fold: 1) to assure that verifiers have proper qualifications to provide verification services for specific types of offset projects; 2) to ensure that verification services are provided competently and ethically; and 3) to ensure that verifiers do not have any conflicts of interest with regard to offset projects for which they are providing verification services.

A verifier accreditation process should involve an initial assessment of prospective verifiers, including verifier competence and organizational protocols used to evaluate potential conflicts of interest. Verifier accreditation should also

[11] Verification as used here refers to both evaluation of project eligibility (sometimes referred to as validation) and verification of periodic monitoring reports of greenhouse gas emissions reductions or removals achieved by a project (commonly referred to as verification).

include ongoing requirements for maintenance of accreditation status, such as conflict of interest disclosure, and periodic evaluation of verifier performance.

C. Program review and adjustment

Regular review and adjustment of offset program requirements will allow an offset program to respond to changes in science, technology, regulations, market conditions, or other relevant factors. For example, global warming potentials may change and improved monitoring protocols may become available. There may also be changes in regulations or market dynamics that could affect project additionality. Regular review and adjustment of program requirements will help ensure that offsets are of high quality. Program revisions should be performed in a transparent manner to ensure public confidence in the offset program.

The need to revise program requirements over time should be balanced with the need to provide project developers with sufficient regulatory certainty to enable project development. This balance can be achieved by tying project approval to crediting periods of an appropriate length. Under this approach, projects would apply for offset program approval using the most current program requirements. If a project is qualified for the award of offset compliance units, then it is eligible for the award of offset compliance units throughout the approved crediting period, pursuant to the program requirements in effect at the time of project approval. During the crediting period, the regulatory agency may revise offset program requirements to accommodate changes in science, regulations, market conditions, or other relevant factors. New program requirements would be applied to all new projects submitted for approval. However, new program requirements would not retroactively be applied to an already approved offset project during its original crediting period.

IV. Importance of Standardized Implementation Approach

The three regional cap-and-trade initiatives have either implemented or intend to implement the offset component of their program through a standardized approach. This approach, as outlined below, provides multiple benefits that improve both offset quality and program efficiency, compared to a project-by-project approach. These benefits include increased program transparency, a more objective project review process, reduced project transaction costs, reduced financial risk for project developers, a reduction in market uncertainty, and a more streamlined project regulatory review process.

A. Introduction

As used here, a standardized approach to offset implementation sets program requirements up-front. This requires the relevant regulatory agency to develop a single set of program requirements for each offset project type (i.e., standardized for a category of projects). These requirements include mechanisms for evaluating project additionality, such as performance standards or benchmarks, and specified quantification, monitoring, reporting, and verification requirements. Standardized requirements need to address the five primary offset quality criteria discussed in Section II (real, additional, verifiable, permanent, and enforceable). For certain categories of offsets, standardized requirements may also address project permanence and project emissions leakage.

A standardized approach is distinct from a project-by-project approach. A project-by-project approach specifies certain process requirements for the evaluation of offset projects, but specific requirements are not set for project additionality, emissions quantification, monitoring, reporting, and verification. A project-by-project approach involves an offset project proponent proposing a customized set of evaluation criteria and other requirements for an individual offset project, including: (A) additionality evaluation process; and (B) quantification, monitoring, reporting, and verification criteria. The set of evaluation criteria and other project requirements proposed by the project proponent is then evaluated by the regulatory agency for sufficiency.

B. Examples of project-by-project and standardized approaches

Additionality

Project-by-project approach to evaluating additionality
The most notable program implementing the project-by-project approach is the Clean Development Mechanism (CDM). For example, the CDM specifies *process* requirements for evaluating project additionality, but does not specify additionality requirements for a category or type of project. The CDM evaluates project additionality through a process that typically involves the following:

- Identification of alternatives to the project
- Barriers analysis (market barriers, technology barriers, or financial barriers)
- Common practice analysis
- Investment analysis (project-by-project analysis, such as internal rate of return (IRR) or net present value (NPV)) with and without the projected revenue stream provided by the CDM offset compliance units; a determination is made as to whether the project, without offset revenue, is less financially attractive than other market options.

The overall goal is to provide reasonable assurance that the offset project would not have been implemented in the absence of the offset program. This process requires the creation by the project proponent of a project-specific baseline scenario of activities that are likely to occur in the absence of the offset project. A key component of this process is the evaluation of financial additionality – essentially an evaluation of the intent of the project developer, and whether the offset project would have been implemented absent the anticipated revenue stream from the market of value of offset compliance units awarded for the project.

Project-by-project evaluation of financial additionality requires a project-specific counterfactual assessment, which is by definition problematic. In particular, the outcome of a project-by-project evaluation of financial additionality is highly dependent on the selection by the project proponent of a project-specific business-as-usual scenario and other assumptions for threshold investment decision criteria, such as a project's benchmark internal rate of return or net present value required by the project developer to move forward with project implementation. These investment decision thresholds can vary significantly among individual investors. The project-specific nature of individual investment decisions makes it difficult for the regulatory agency to sufficiently evaluate project proponent assumptions.

Standardized approach to evaluating additionality
In contrast to the project-by-project approach, a standardized approach specifies a set of additionality criteria for a category of project types. The program administrator designs and specifies these criteria to provide reasonable assurance that an offset project eligible under a project category would not have been implemented absent the anticipated revenue stream from the market of value of offset compliance units awarded for the project. This is done by setting specific additionality requirements that provide reasonable assurance that an individual offset project significantly exceeds standard market practice. In practice, this typically involves conducting a market evaluation to develop and specify benchmarks and performance standards for a category of projects[12] that are used as proxies to infer the financial additionality of individual projects[13]:

- A benchmark is a qualitative eligibility criterion for a category of projects that ensures that a project is unlikely to occur under standard market practice. A benchmark could include a technology or practice standard and could also be a qualitative market evaluation criterion; for example, a criterion that addresses the stacking of multiple project incentives based on typical project economics for a category of projects, considering other available non-carbon economic incentives.

- A performance standard is a quantitative eligibility criterion that establishes a metric for determining if categories of projects are unlikely to occur under

[12] It should be noted that this process is more straightforward than a project-by-project analysis of financial additionality, as it involves evaluating actual market practices and project economics in a defined market, based on projects that have already occurred and evidenced trends, rather than a counterfactual assessment of future alternative project-level investments. It also reduces transaction costs for project proponents, as they do not need to conduct such an analysis to support the development of project-specific evaluation assumptions.
[13] If a project exceeds standard market practice, it is assumed to be financially additional and is assumed to be implemented in response to the financial incentive provided through the receipt of offset compliance units that have a market value.

standard market practice. The criterion is usually established in relation to the performance level achieved through standard market practice for the category of activities eligible under a certain offset category. Projects that meet or surpass the standard qualify as additional. Examples of performance standards include:

- Emission rate
- Energy efficiency criteria
- Market penetration rate

Quantification

There are many ways to determine the amount of greenhouse gas emissions reduced or sequestered by a given project. A project-by-project approach allows project proponents to propose their own quantification methods. This has lead to the development of methodologies that are highly tailored to specific projects, and thus not easily applied to a broad number of projects in a single category. This has increased the administrative burden of protocol and project review.[14] This problem can be avoided if quantification methods are initially standardized. Standardized quantification methodologies specify the quantification protocols that must be applied to a particular project type (e.g., anaerobic digesters).

Permanence

When a project type bears some risk of having its emissions benefits reversed, then administrative measures are necessary to ensure the permanence of the offset project emissions reductions or removals that are the basis for the award of offset compliance units. The purpose of these measures is to ensure that if an offset compliance unit is issued for an emissions reduction or removal that could be reversed, safeguards are in place to ensure that the integrity of the cap-and-trade program emissions cap is maintained, even if a reversal occurs. There are a number of potential approaches for addressing permanence, including: buyer liability for reversals, seller liability for reversals, insurance requirements, creation of project buffer pools or offset compliance unit reserves, discounting of project emissions reductions or removals used as the basis for awarding offset compliance units, and conservation easements, among others. A number of these approaches may be used individually or together to address potential project reversals.

Under a project-by-project approach to permanence, offset project proponents could propose which permanence mechanisms to employ, leading to the potential for considerable variation from project to project. Requiring regulatory agencies to evaluate the adequacy of the specifics of each proposed methodology would be labor intensive. Allowing for the adoption of a multitude of

[14] As a result, the CDM, which is administered through a project-by-project approach, has begun to develop consolidated methodologies that can be used for a wide range of project types.

approaches to address permanence could also introduce considerable uncertainty into the marketplace, thereby reducing the liquidity of the offset market.

A standardized approach specifies requirements for addressing permanence for a category of offset projects. Standardizing the approach to addressing project permanence provides more certainty to project developers, maximizes offset market liquidity, and reduces the administrative burden of implementing the program.

Monitoring and Reporting

A project-by-project approach to monitoring and reporting allows a project proponent to propose a monitoring and reporting plan for a specific offset project. The regulatory agency must then review the monitoring and reporting plan for sufficiency. A standardized approach specifies requirements for project monitoring and reporting for a category of offset projects. Standardizing the process for monitoring and reporting simplifies the verification process, and makes it easier to detect inconsistencies and errors.

Verification

Under a project-by-project approach to verification, the project proponent and independent verifier specify the verification protocol for an individual offset project and the required contents of verification reports, including the appropriate level of assurance to be provided. The regulatory agency must then evaluate the sufficiency of the proposed verification process. A standardized approach specifies verification requirements for a category of offset projects, which may include the required contents of verification reports and the minimum level of assurance that must be provided.

Providing standardized requirements for independent verifiers outlining what is expected of them during project review and the implications of failing to adequately review project details will help ensure that verified projects meet established regulatory standards. Moreover, ensuring that all non-governmental verifiers are accredited to a single standard of professional expertise and requirements ensures that professionals are trained in greenhouse gas emissions and carbon sequestration accounting and offset project verification, and are conducting objective verification activities with accuracy and competence.

C. Value of standardization in ensuring offset quality

The primary value of a standardized approach is that it sets program criteria up-front, through a regulatory process that provides for full technical, market, and policy evaluation, including full public participation. This approach increases program transparency and reduces the potential for the application of subjective project review criteria. However, a standardized approach can require more administrative resources during program design, but should reduce administrative resources required over the life of the program. It can also be difficult to establish standardized project evaluation criteria that are applicable across a wide range of regions and markets, which may require customizing standards for a respective region or regional market. Certain types of offset projects may not be amenable to a standardized approach if market data is lacking for development of additionality benchmarks and performance standards or quantification and monitoring protocols are not well developed.

The alternative is a case-law type approach, where program requirements evolve over time as project proponents submit proposed evaluation criteria and quantification, monitoring, and verification requirements for individual offset projects. This approach limits public participation by creating an administratively resource-intensive process that requires active ongoing participation from all affected stakeholders, some of which may lack the organizational capacity to fully participate in such a process. It also creates pressure to expedite technical and policy review in order to bring more offset projects to market.

If implemented properly, based on a robust market analysis, a standardized process avoids certain pitfalls of a project-by-project approach. In particular, the outcome of a project-by-project evaluation of financial additionality is highly dependent on the selection by the project proponent of project-specific business-as-usual scenarios and other assumptions for threshold investment decision criteria, such as a project's benchmark internal rate of return or net present value. These investment decision thresholds can vary significantly among individual investors. As a result, the evaluation criteria and key assumptions proposed by a project developer to evaluate project additionality must be validated by the relevant regulatory agency in order for the process to work as intended. To work properly, this could require significant additional market research, for which data might not be available, and would significantly slow the evaluation process. The end result is a potential for subjective evaluation results, an administrative overload that slows the project approval process, and pressure to expedite the regulatory agency review process without fully validating the project proponent's project evaluation criteria and other proposed project requirements.

A standardized process, in contrast, limits project eligibility to certain categories of projects for which sufficient market data is available and for which robust quantification, monitoring, and verification protocols already exist or can be readily developed. The market analysis is conducted up-front to develop standardized additionality criteria that can be applied to a group of like projects. If properly implemented, this ensures that the market analysis is objective and thorough.

A standardized process increases program transparency by allowing all parties to fully understand program requirements up-front. This reduces uncertainty for the project developer and decreases financial risk and market uncertainty. It also decreases project transaction costs by avoiding the need for project developers to develop their own complex project evaluation process and evaluation criteria. The complexity and potential subjectivity of the project review process is reduced, which should also reduce the time required to complete the regulatory review of a project.

D. Issues that need to be taken into account when using a standardized approach

A key offset quality issue that must be addressed when implementing a standardized approach is the need to update program requirements over time. For example, a standardized approach sets additionality requirements up-front, through regulation or other process, based on a market evaluation. However, while program requirements are specified up-front, program requirements should not be static. Since market conditions change over time, a program needs to build in a process for periodic market evaluation and the modification of program additionality requirements over time if warranted. Program administrators may also want to consider fine tuning standardized additionality criteria based on a project-specific evaluation of a subset of projects submitted for review under the program, in order to validate standardized program requirements.

Program administrators should also recognize that even with standardization of requirements, a number of project-specific assessments still need to be conducted. How these assessments are to be conducted may be specified in rule or protocol (i.e., standardized), but the project-specific evaluations still need to be conducted. An example is the determination of a project-specific emissions or sequestration baseline and monitoring and reporting of project performance and emissions reductions or removals.

For example, a standardized approach to evaluating additionality may employ default standards (referred to in pending U.S. federal legislation as “standardized activity baselines”), such as emissions performance standards, to determine project eligibility. When determining how many offset compliance units should be awarded for a project, it is important to consider not only such default values, but also project-specific baseline emissions (or carbon sequestration). Offset compliance units awarded should be calculated as the difference between project emissions reductions and either the standardized default emissions performance standard, or the project’s own emissions baseline, whichever produces a lower value.[15] If emissions reductions are credited directly against a standardized

[15] An example of the distinction between a baseline scenario that uses an emissions performance standard (a standardized activity baseline) and a project-specific emissions baseline is provided by the RGGI offset requirements for electricity-sector SF_6 offset projects. In RGGI, electricity transmission and distribution entities must meet an entity-wide SF_6 emissions performance

baseline scenario that is emissions-based, this could lead to over crediting of offset compliance units if the actual project emissions baseline differs from the default emissions baseline.
