(2) After such time as [jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, the carbon dioxide emissions from the combustion of those fuels may be excluded from calculation of GHG emissions for determining whether the 10,000 metric tons CO2e per year emission threshold in paragraph (a)(1) of this section has been met.

(ii) The exceptions in paragraphs (b)(2)(i) of this section shall not apply in determining whether a facility is subject to the reporting requirements of 40 C.F.R. Part 98.

(3) For miscellaneous uses of carbonate, calculate the annual CO2 emissions in metric tons using the procedures specified in subpart U of this part.

(4) Sum the emissions estimates from paragraphs (b)(1), (b)(2), and (b)(3) of this section for each GHG and calculate metric tons of CO2e using Equation A– 1 of this section.

$$CO_2e = \sum_{i=1}^{n} GHG_i \times GWP_i \qquad \text{(Eq. A-1)}$$

Where:

CO2e = Carbon dioxide equivalent, metric tons/year.

GHGi = Mass emissions of each greenhouse gas listed in Table A–1 of this subpart, metric tons/year.

GWPi = Global warming potential for each greenhouse gas from Table A–1 of this subpart.

n = The number of greenhouse gases emitted.

(5) For purpose of determining if an emission threshold has been exceeded, include in the emissions calculation any CO2 that is captured for transfer off site.

(c) To calculate GHG emissions for comparison to the ~~25,000~~10,000 metric ton CO2e/year emission threshold for stationary fuel combustion under paragraph (a)(3) of this section, calculate CO2, CH4, and N2O emissions from each stationary fuel combustion unit by following the methods specified in paragraph (b)(2) of this section. Then, convert the emissions of each GHG to metric tons CO2e per year using Equation A–1 of this section, and sum the emissions for all units at the facility.

(d) To calculate GHG quantities for comparison to the 25,000 metric ton CO_2 per year threshold for importers and exporters of coal-to-liquid products under paragraph (a)(4)(i) of this section, calculate the mass in metric tons per year of CO_2 that would result from the complete combustion or oxidation of the quantity of coal-to-liquid products that are imported during the reporting year and that are exported during the reporting year. Calculate the emissions using the methodology specified in subpart LL of this part.

(e) To calculate GHG quantities for comparison to the 25,000 metric ton CO_2e per year threshold for importers and exporters of petroleum products under paragraph (a)(4)(ii) of this section, calculate the mass in metric tons per year of CO_2 that would result from the complete combustion or oxidation of the volume of petroleum products and natural gas liquids that are imported during the reporting year and that are exported during the reporting year. Calculate the emissions using the methodology specified in subpart MM of this part.

(f) To calculate GHG quantities for comparison to the 25,000 metric ton CO_2e per year threshold under paragraph (a)(4) of this section for importers and exporters of industrial greenhouse gases and for importers and exporters of CO_2, the owner or operator shall calculate the mass in metric tons per year of CO_2e imports and exports as described in paragraphs (f)(1) through (f)(3) of this section.

(1) Calculate the mass in metric tons per year of CO_2, N_2O, and each fluorinated GHG that is imported and the mass in metric tons per year of CO_2, N_2O, and each fluorinated GHG that is exported during the year. Include only those gases listed in Table A–1 of this subpart.

(2) Convert the mass of each imported and each GHG exported from paragraph (f)(1) of this section to metric tons of CO_2e using Equation A–1 of this section.

(3) Sum the total annual metric tons of CO_2e in paragraph (f)(2) of this section for all imported GHGs. Sum the total annual metric tons of CO_2e in paragraph (f)(2) of this section for all exported GHGs.

(g) If a capacity or generation reporting threshold in paragraph (a)(1) of this section applies, the owner or operator shall review the appropriate records and perform any necessary calculations to determine whether the threshold has been exceeded.

(h) An owner or operator of a facility or supplier that does not meet the applicability requirements of paragraph (a) of this section is not subject to this rule. Such owner or operator would become subject to the rule and reporting requirements § 98.3(b)(3), if a facility or supplier exceeds the applicability requirements of paragraph (a) of this section at a later time. Thus, the owner or operator should reevaluate the applicability to this part (including the revising of any relevant emissions calculations or other calculations) whenever there is any change that could cause a facility or supplier to meet the applicability requirements of paragraph (a) of this section. Such changes include but are not limited to process modifications, increases in operating hours, increases in production, changes in fuel or raw material use, addition of equipment, and facility expansion.

(i) Except as provided in this paragraph, once a facility or supplier is subject to the requirements of this part, the owner or operator must continue for each year thereafter to comply with all requirements of this part, including the requirement to submit annual GHG reports, even if the facility or supplier does not meet the applicability requirements in paragraph (a) of this section in a future year.[7]

(1) [Reserved] ~~If reported emissions are less than 25,000 metric tons CO2e per year for five consecutive years, then the owner or operator may discontinue complying with this part provided that the owner or operator submits a notification to the Administrator that announces the cessation of reporting and explains the reasons for the reduction in emissions. The notification shall be submitted no later than March 31 of the year immediately following the fifth consecutive year of emissions less than 25,000 tons CO2e per year. The owner or operator must maintain the corresponding records required under § 98.3(g) for each of the five consecutive years and retain such records for three years following the year that reporting was discontinued. The owner or operator must resume reporting if annual emissions in any future calendar year increase to 25,000 metric tons CO2e per year or more.~~

(2) If the operations of a facility change such that emissions fall below ~~reported emissions are less than 15,000~~ 10,000 metric tons CO2e per year ~~for three consecutive years~~, then the following reporting requirements shall apply:

(i) If, prior to the emission reduction, the facility was required to report under both this Article and 40 C.F.R. Part 98, then the owner or operator shall continue to submit emission reports until reported emissions are below 10,000 metric tons CO_2e per year for a

[7] As modified, section 98.2(i) of this Article covers only the circumstances under which a facility may cease reporting to the jurisdiction under this Article. There are circumstances under which a facility might be eligible to cease reporting to EPA but must continue to report to the jurisdiction. To determine whether these circumstances apply, the owner or operator should consult 40 C.F.R. § 98.2(i).

minimum of three consecutive years. If reported emissions are less than 10,000 metric tons CO_2 per year for three consecutive years then the owner or operator may discontinue complying with this ~~part~~ Article provided that the owner or operator submits a notification to the Administrator that announces the cessation of reporting and explains the reasons for the reduction in emissions. The notification shall be submitted no later than March 31 of the year immediately following the third consecutive year of emissions less than ~~15,000~~10,000 tons CO2e per year. The owner or operator must maintain the corresponding records required under § 98.3(g) for each of the three consecutive years and retain such records for three years following the year that reporting was discontinued. The owner or operator must resume reporting if annual emissions in any future calendar year increase to ~~25,000~~10,000 metric tons CO2e per year or more.

(ii) If prior to the emission reduction, the facility was required to report under this Article but was not required to report under 40 C.F.R. Part 98, then in lieu of submitting a report under this Article the owner or operator shall submit to [jurisdiction] a signed statement certifying that emissions were less than 10,000 metric tons CO2e during the prior year. After certifying that emissions are below 10,000 metric tons CO2e per year for three consecutive years under this paragraph, the owner or operator shall be exempted from further reporting until CO2e emissions again exceed 10,000 metric tons in any future calendar year.

(3) If the operations of a facility or supplier are changed such that all applicable GHG-emitting processes and operations listed in paragraphs (a)(1) through (a)(4) of this section cease to operate, then the owner or operator is exempt from reporting in the years following the year in which cessation of such operations occurs, provided that the owner or operator submits a notification to the Administrator that announces the cessation of reporting and certifies to the closure of all GHG emitting processes and operations. This paragraph (i)(~~2~~3) does not apply to seasonal or other temporary cessation of operations. This paragraph (i)(3) does not apply to facilities with municipal solid waste landfills or industrial waste landfills, or to underground coal mines. The owner or operator must resume reporting for any future

calendar year during which any of the GHG-emitting processes or operations resume operation.[8]

(j) Table A–2 of this subpart provides a conversion table for some of the common units of measure used in part 98.

§ 98.3 What are the general monitoring, reporting, recordkeeping and verification requirements of this part?

The owner or operator of a facility or supplier that is subject to the requirements of this part must submit GHG reports to the Administrator, as specified in this section.

(a) General. Except as provided in paragraph (d) of this section, follow the procedures for emission calculation, monitoring, quality assurance, missing data, recordkeeping, and reporting that are specified in each relevant subpart of this part.

(b) Schedule. The annual GHG report must be submitted no later than March 31 of each calendar year for GHG emissions in the previous calendar year. As an example, for a facility that is subject to the rule in calendar year 2010, the first report must be submitted on March 31, 2011.

(1) [Reserved]

(2) For a new facility or supplier that begins operation on or after January 1, 2010 and becomes subject to the rule in the year that it becomes operational, report emissions beginning with the first operating month and ending on December 31 of that year. Each subsequent annual report must cover emissions for the calendar year, beginning on January 1 and ending on December 31.

(3) For any facility or supplier that becomes subject to this rule because of a physical or operational change that is made after January 1, 2010, report emissions for the first calendar year in which the change occurs, beginning with the first month of the change and ending on December 31 of that year. For a facility or supplier that becomes subject to this rule solely because of an increase in hours of operation or level of production, the first month of the change is the month in which the increased hours of operation or level of production, if maintained for the remainder of the year, would cause the facility or supplier to exceed the applicable threshold. Each subsequent annual report must cover emissions for the calendar year, beginning on January 1 and ending on December 31.

[8] This provision may require modification to meet the needs of the cap-and-trade program.

(c) Content of the annual report. Except as provided in paragraph (d) of this section, each annual GHG report shall contain the following information:

(1) Facility name or supplier name (as appropriate) and physical street address including the city, state, and zip code.

(2) Year and months covered by the report.

(3) Date of submittal.

(4) For facilities, report annual emissions of CO_2, CH_4, N_2O, and each fluorinated GHG (as defined in § 98.6) as follows:

(i) Annual emissions (excluding biogenic CO_2) aggregated for all GHG from all applicable source categories listed in Tables A-3 and Table A-4 of this subpart and expressed in metric tons of CO_2e calculated using Equation A-1 of this subpart.

(ii) Annual emissions of biogenic CO_2 aggregated for all applicable source categories in listed in Tables A-3 and Table A-4 of this subpart.

(iii) Annual emissions from each applicable source category listed in Tables A-3 and Table A-4 of this subpart, expressed in metric tons of each GHG listed in paragraphs (c)(4)(iii)(A) through (c)(4)(iii)(E) of this section.

(A) Biogenic CO_2.

(B) CO_2 (excluding biogenic CO_2).

(C) CH_4.

(D) N_2O.

(E) Each fluorinated GHG (including those not listed in Table A–1 of this subpart).

(iv) Emissions and other data for individual units. processes, activities, and operations as specified in the ‘‘Data reporting requirements’’ section of each applicable subpart of this part.

(5) For suppliers, report annual quantities of CO_2, CH_4, N_2O, and each fluorinated GHG (as defined in § 98.6) that would be emitted from combustion or use of the products supplied, imported, and exported during the year. Calculate and report quantities at the following levels:

(i) Total quantity of GHG aggregated for all GHG from all applicable supply categories in subparts KK through PP of this part and expressed in metric tons of CO_2e calculated using Equation A–1 of this subpart.

(ii) Quantity of each GHG from each applicable supply category in subparts KK through PP of this part, expressed in metric tons of each GHG. For fluorinated GHG, report emissions of all fluorinated GHG, including those not listed in Table A–1 of this subpart.

(iii) Any other data specified in the ‘‘Data reporting requirements’’ section of each applicable subpart of this part.

(6) A written explanation, as required under § 98.3(e), if you change emission calculation methodologies during the reporting period.

(7) A brief description of each “best available monitoring method” used according to paragraph (d) of this section, the parameter measured using the method, and the time period during which the “best available monitoring method” was used, if applicable.

(8) Each data element for which a missing data procedure was used according to the procedures of an applicable subpart and the total number of hours in the year that a missing data procedure was used for each data element.

(9) A signed and dated certification statement provided by the designated representative of the owner or operator, according to the requirements of § 98.4(e)(1).

(d) Special provisions for reporting year 2010.

(1) Best available monitoring methods. During January 1, 2010 through March 31, 2010, owners or operators may use best available monitoring methods for any parameter (e.g., fuel use, daily carbon content of feedstock by process line) that cannot reasonably be measured according to the monitoring and QA/QC requirements of a relevant subpart. The owner or operator must use the calculation methodologies and equations in the ‘‘Calculating GHG Emissions’’ sections of each relevant subpart, but may use the best available monitoring method for any parameter for which it is not reasonably feasible to acquire, install, and operate a required piece of monitoring equipment by January 1, 2010. Starting no later than April 1, 2010, the owner or operator must discontinue using best available methods and begin following all applicable monitoring and QA/QC requirements of this part, except as provided in paragraphs (d)(2) and (d)(3) of this section. Best available monitoring methods means any of the following methods specified in this paragraph:

(i) Monitoring methods currently used by the facility that do not meet the specifications of an relevant subpart.

(ii) Supplier data.

(iii) Engineering calculations.

(iv) Other company records.

(2) Requests for extension of the use of best available monitoring methods. The owner or operator may submit a request to the Administrator to use one or more best available monitoring methods beyond March 31, 2010.

(i) Timing of request. The extension request must be submitted to EPA no later than 30 days after the effective date of the GHG reporting rule.

(ii) Content of request. Requests must contain the following information:

(A) A list of specific item of monitoring instrumentation for which the request is being made and the locations where each piece of monitoring instrumentation will be installed.

(B) Identification of the specific rule requirements (by rule subpart, section, and paragraph numbers) for which the instrumentation is needed.

(C) A description of the reasons why the needed equipment could not be obtained and installed before April 1, 2010.

(D) If the reason for the extension is that the equipment cannot be purchased and delivered by April 1, 2010, include supporting documentation such as the date the monitoring equipment was ordered, investigation of alternative suppliers and the dates by which alternative vendors promised delivery, backorder notices or unexpected delays, descriptions of actions taken to expedite delivery, and the current expected date of delivery.

(E) If the reason for the extension is that the equipment cannot be installed without a process unit shutdown, include supporting documentation demonstrating that it is not practicable to isolate the equipment and install the monitoring instrument without a full process unit shutdown. Include the date of the most recent process unit shutdown, the frequency of shutdowns for this process unit, and the date of the next planned shutdown during which the monitoring equipment can be installed. If there has been a shutdown or if there is a planned process unit shutdown between promulgation of this part and April 1, 2010, include a justification of why the equipment could not be obtained and installed during that shutdown.

(F) A description of the specific actions the facility will take to obtain and install the equipment as soon as reasonably feasible and the expected date by which the equipment will be installed and operating.

(iii) Approval criteria. To obtain approval, the owner or operator must demonstrate to the Administrator's satisfaction that it is not reasonably feasible to acquire, install, and operate a required piece of monitoring equipment by April 1, 2010. The use of best available methods will not be approved beyond December 31, 2010.

(3) Abbreviated emissions report for facilities containing only general stationary fuel combustion sources. In lieu of the report required by paragraph (c) of this section, the owner or operator of an existing facility that is in operation on January 1, 2010 and that meets the conditions of § 98.2 (a)(3) may submit an abbreviated GHG report for the facility for GHGs emitted in 2010. The abbreviated report must be submitted by March 31, 2011. An owner or operator that submits an abbreviated report must submit a full GHG report according to the requirements of paragraph (c) of this section beginning in calendar year 2011. The abbreviated facility report must include the following information:

(i) Facility name and physical street address including the city, state and zip code.

(ii) The year and months covered by the report.

(iii) Date of submittal.

(iv) Total facility GHG emissions aggregated for all stationary fuel combustion units calculated according to any method specified in § 98.33(a) and expressed in metric tons of CO2, CH4, N2O, and CO2e.

(v) Any facility operating data or process information used for the GHG emission calculations.

(vi) A signed and dated certification statement provided by the designated representative of the owner or operator, according to the requirements of paragraph (e)(1) of this section.

(e) Emission calculations. In preparing the GHG report, you must use the calculation methodologies specified in the relevant subparts, except as specified in paragraph (d) of this section. For each source category, you must use the same calculation methodology throughout a reporting period unless you provide a written explanation of why a change in methodology was required.

(f) Verification. Owner or operators subject to the verification requirements of WCI.8 shall obtain verification services and submit a verification statement meeting the requirements of WCI.8, if applicable.~~To verify the completeness and accuracy of reported GHG emissions, the Administrator may review the certification statements described in paragraphs (c)(8) and (d)(3)(vi) of this section and any other credible evidence, in conjunction with a comprehensive review of the GHG reports and periodic audits of selected reporting facilities. Nothing in this section prohibits the Administrator from using additional information to verify the completeness and accuracy of the reports.~~

(g) Recordkeeping. An owner or operator that is required to report GHGs under this part must keep records as specified in this paragraph. Retain all required records for at least ~~3~~ 7 years. The records shall be kept in an electronic or hard-copy format (as appropriate) and recorded in a form that is suitable for expeditious inspection and review. Upon request by the Administrator, the records required under this section must be made available to EPA within 20 days after the request. Records may be retained off site if the records are readily available for expeditious inspection and review. For records that are electronically generated or maintained, the equipment or software necessary to read the records shall be made available, or, if requested by EPA, electronic records shall be converted to paper documents. You must retain the following records, in addition to those records prescribed in each applicable subpart of this part:

(1) A list of all units, operations, processes, and activities for which GHG emission were calculated.

(2) The data used to calculate the GHG emissions for each unit, operation, process, and activity, categorized by fuel or material type. These data include but are not limited to the following information in this paragraph (g)(2):

(i) The GHG emissions calculations and methods used.

(ii) Analytical results for the development of site-specific emissions factors.

(iii) The results of all required analyses for high heat value, carbon content, and other required fuel or feedstock parameters.

(iv) Any facility operating data or process information used for the GHG emission calculations.

(3) The annual GHG reports.

(4) Missing data computations. For each missing data event, also retain a record of the duration of the event, actions taken to restore malfunctioning monitoring equipment, the cause of the event, and the actions taken to prevent or minimize occurrence in the future.

(5) For sources subject to reporting under 40 C.F.R. Part 98, ~~A~~ a written GHG Monitoring Plan.[9]

(i) At a minimum, the GHG Monitoring Plan shall include the elements listed in this paragraph (g)(5)(i).

(A) Identification of positions of responsibility (i.e., job titles) for collection of the emissions data.

(B) Explanation of the processes and methods used to collect the necessary data for the GHG calculations.

(C) Description of the procedures and methods that are used for quality assurance, maintenance, and repair of all continuous monitoring systems, flow meters, and other instrumentation used to provide data for the GHGs reported under this part.

(ii) The GHG Monitoring Plan may rely on references to existing corporate documents (e.g., standard operating procedures, quality assurance programs under appendix F to 40 CFR part 60 or appendix B to 40 CFR part 75, and other documents) provided that the elements required by paragraph (g)(5)(i) of this section are easily recognizable.

(iii) The owner or operator shall revise the GHG Monitoring Plan as needed to reflect changes in production processes, monitoring instrumentation, and quality assurance procedures; or to improve procedures for the maintenance and repair of monitoring systems to reduce the frequency of monitoring equipment downtime.

(iv) Upon request by the Administrator, the owner or operator shall make all information that is collected in conformance with the GHG Monitoring Plan available for review during an audit within 20 days after the request. Electronic storage of the information in the plan is permissible, provided that the information can be made available in hard copy upon request during an audit.

[9] WCI jurisdictions may elect to require a GHG Monitoring Plan from all sources. This provision is optional for Canadian jurisdictions.

(6) The results of all required certification and quality assurance tests of continuous monitoring systems, fuel flow meters, and other instrumentation used to provide data for the GHGs reported under this part.

(7) Maintenance records for all continuous monitoring systems, flow meters, and other instrumentation used to provide data for the GHGs reported under this part.

(h) Annual GHG report revisions.

(1) The owner or operator of a facility subject to reporting under both this Article and 40 C.F.R. Part 98 shall submit a revised report within 45 days of discovering or being notified by EPA of errors in an annual GHG report. The revised report must correct all identified errors. The owner or operator shall retain documentation for ~~3~~ 7 years to support any revisions made to an annual GHG report.

(2) The owner or operator of a facility subject to reporting under this Article but not 40 C.F.R. Part 98 shall submit a revised report within 30 days of finding that a report contains an error, or accumulation of errors, greater than 5 percent of the total CO_2e emissions reported. To the extent possible, the revised report must correct all identified errors. A revised report will be accepted only if approved by [jurisdiction]. The owner or operator shall retain documentation for 7 years to support any revisions made to an annual GHG report.

(i) Calibration accuracy requirements. The owner or operator of a facility or supplier that is subject to the requirements of this part must meet the calibration accuracy requirements of this paragraph (i).

(1) Except as provided in paragraphs (i)(4) through (i)(6) of this section, flow meters and other devices (e.g., belt scales) that measure data used to calculate GHG emissions shall be calibrated using the procedures specified in this paragraph and each relevant subpart of this part. All measurement devices must be calibrated according to the manufacturer's recommended procedures, an appropriate industry consensus standard, or a method specified in a relevant subpart of this part. All measurement devices shall be calibrated to an accuracy of 5 percent. For facilities and suppliers that are subject to this part on January 1, 2010, the initial calibration shall be conducted by April 1, 2010. For facilities and suppliers that become subject to this part after April 1, 2010, the initial calibration shall be conducted by the date

that data collection is required to begin. Subsequent calibrations shall be performed at the frequency specified in each applicable subpart.[10]

(2) For flow meters, perform all calibrations at measurement points that are representative of normal operation of the meter. Except for the orifice, nozzle, and venturi flow meters described in paragraph (i)(3) of this section, calculate the calibration error at each measurement point using Equation A–2 of this section. The terms ‘‘R’’ and ‘‘A’’ in Equation A–2 must be expressed in consistent units of measure (e.g., gallons/minute, ft 3/min). The calibration error at each measurement point shall not exceed 5.0 percent of the reference value.

$$CE = \frac{R - A}{R} \times 100 \qquad \text{(Eq. A-2)}$$

Where:

CE = Calibration error (%)

R = Reference value

A = Flow meter response to the reference value

(3) For orifice, nozzle, and venturi flow meters, the initial quality assurance consists of in-situ calibration of the differential pressure (delta-P), total pressure, and temperature transmitters. Calibrate each transmitter at a zero point and at least one upscale point. Fixed reference points, such as the freezing point of water, may be used for temperature transmitter calibrations. Calculate the calibration error of each transmitter at each measurement point, using Equation A–3 of this subpart. The terms ‘‘R’’, ‘‘A’’, and ‘‘FS’’ in Equation A–3 of this subpart must be in consistent units of measure (e.g., milliamperes, inches of water, psi, degrees). For each transmitter, the CE value at each measurement point shall not exceed 2.0 percent of full-scale. Alternatively, the results are acceptable if the sum of the calculated CE values for the three transmitters at each calibration level (i.e., at the zero level and at each upscale level) does not exceed 5.0 percent.

[10] Canadian jurisdictions may grant an exemption for the combustion of solid biomass or biomass fuels determined to be carbon neutral.

$$CE = \frac{R - A}{FS} \times 100 \qquad \text{(Eq. A-3)}$$

Where:

CE = Calibration error (%)

R = Reference value

A = Transmitter response to the reference value

FS = Full-scale value of the transmitter

(4) Fuel billing meters are exempted from the calibration requirements of this section, provided that the fuel supplier and any unit combusting the fuel do not have any common owners and are not owned by subsidiaries or affiliates of the same company.

(5) For a flow meter or other measurement device that has been previously calibrated in accordance with this part, an initial calibration is not required by the date specified in paragraph (i)(1) of this section if, as of the date required for the initial calibration, the previous calibration is still active (i.e., the device is not yet due for recalibration because the time interval between successive calibrations, as required by this part, has not elapsed).

(6) For units and processes that operate continuously with infrequent outages, it may not be possible to meet the April 1, 2010 deadline for the initial calibration of a flow meter or other measurement device without removing the device from service and shipping it to a remote location, thereby disrupting normal process operation. In such cases, the owner or operator may postpone the initial calibration until the next scheduled maintenance outage, and may similarly postpone the subsequent recalibrations. Such postponements shall be documented in the monitoring plan that is required under § 98.3(g)(5) and submitted before December 31, 2011 to the [jurisdiction] for approval.

(j) Where a rule in this Article requires sampling of a parameter on a more frequent basis than the corresponding rule in 40 C.F.R. Part 98, the following shall apply unless in conflict with any other provision in 40 C.F.R. Part 98:

(1) The samples must be spaced apart as evenly as possible over time, taking into account the operating schedule of the relevant unit or facility.

(2) You must calculate and report a weighted average of the values derived from the samples by using the following formula:

$$V_E = \frac{\sum_{j=1}^{n} (V_j \times M_j)}{\sum_{j=1}^{n} M_j}$$

Where:

V_E = The value of the parameter to be reported under 40 C.F.R. Part 98 for period E.

j = Each period during period E for which a sample is required by [jurisdiction] under the applicable rule in this Article.

n = The number of periods j in period E.

Vj = The value of the sample for period j.

Mj = The mass of the sampled material processed or otherwise used by the relevant unit or facility in period j.

(3) You must keep records of the date and result for each sample and mass measurement used in the equation in subsection (2) and of the calculation of each weighted average included in your report.

(k)Where this Article specifies a choice between use of a fuel-based or mass balance-based calculation or use of a continuous emissions monitoring system (CEMS) to calculate CO2 emissions, the operator shall make this choice and continue to use the method chosen for all future emissions data reports, unless the use of the alternative calculation method is approved in advance by [the jurisdiction].[11]

(l) The owner or operator may elect to designate as de minimis one or more sources or pollutants that collectively emit no more than 3 percent of the facility's total CO2e emissions, but not to exceed 20,000 metric tons CO2e. Where this Article otherwise requires the use of a more stringent method for monitoring and reporting emissions than the method required by 40

[11] Approval may be granted by rule or by other general authorization. A case-by-case approval process may not be required.

C.F.R. Part 98, the owner or operator may elect to use any other method allowed under 40 C.F.R. Part 98 for the sources or pollutants designated as de minimis.[12]

(m) Notwithstanding the missing data procedures specified in this Article, the failure to conduct monitoring in accordance with this Article shall constitute a violation.

§ 98.4 Authorization and responsibilities of the designated representative.[13]

(a) General. Except as provided under paragraph (f) of this section, each facility, and each supplier, that is subject to this part, shall have one and only one designated representative, who shall be responsible for certifying, signing, and submitting GHG emissions reports and any other submissions for such facility and supplier respectively to the Administrator under this part. If the facility is required under any other part of title 40 of the Code of Federal Regulations to submit to the Administrator any other emission report that is subject to any requirement in 40 CFR part 75, the same individual shall be the designated representative responsible for certifying, signing, and submitting the GHG emissions reports and all such other emissions reports under this part.

(b) Authorization of a designated representative. The designated representative of the facility or supplier shall be an individual selected by an agreement binding on the owners and operators of such facility or supplier and shall act in accordance with the certification statement in paragraph (i)(4)(iv) of this section.

(c) Responsibility of the designated representative. Upon receipt by the Administrator of a complete certificate of representation under this section for a facility or supplier, the designated representative identified in such certificate of representation shall represent and, by his or her representations, actions, inactions, or submissions, legally bind each owner and operator of such facility or supplier in all matters pertaining to this part, notwithstanding any agreement between the designated representative and such owners and operators. The owners and operators shall be bound by any decision or order issued to the designated representative by the Administrator or a court.

(d) Timing. No GHG emissions report or other submissions under this part for a facility or supplier will be accepted until the Administrator has received a complete certificate of

---

[12] Canadian jurisdictions may include de minimis provisions consistent with WCI.2(d).

[13] In Canadian jurisdictions, the responsibilities specified in this section will ordinarily fall on the "operator's representative" as defined in Canadian law.

representation under this section for a designated representative of the facility or supplier. Such certificate of representation shall be submitted at least 60 days before the deadline for submission of the facility's or supplier's initial emission report under this part.

(e) Certification of the GHG emissions report. Each GHG emission report and any other submission under this part for a facility or supplier shall be certified, signed, and submitted by the designated representative or any alternate designated representative of the facility or supplier in accordance with this section and § 3.10 of this chapter.

(1) Each such submission shall include the following certification statement signed by the designated representative or any alternate designated representative: ''I am authorized to make this submission on behalf of the owners and operators of the facility or supplier, as applicable, for which the submission is made. I certify under penalty of law that I have personally examined, and am familiar with, the statements and information submitted in this document and all its attachments. Based on my inquiry of those individuals with primary responsibility for obtaining the information, I certify that the statements and information are to the best of my knowledge and belief true, accurate, and complete. I am aware that there are significant penalties for submitting false statements and information or omitting required statements and information, including the possibility of fine or imprisonment.''

(2) The Administrator will accept a GHG emission report or other submission for a facility or supplier under this part only if the submission is certified, signed, and submitted in accordance with this section.

(f) Alternate designated representative. A certificate of representation under this section for a facility or supplier may designate one alternate designated representative, who shall be an individual selected by an agreement binding on the owners and operators, and may act on behalf of the designated representative, of such facility or supplier. The agreement by which the alternate designated representative is selected shall include a procedure for authorizing the alternate designated representative to act in lieu of the designated representative.

(1) Upon receipt by the Administrator of a complete certificate of representation under this section for a facility or supplier identifying an alternate designated representative.

(i) The alternate designated representative may act on behalf of the designated representative for such facility or supplier.

(ii) Any representation, action, inaction, or submission by the alternate designated representative shall be deemed to be a representation, action, inaction, or submission by the designated representative.

(2) Except in this section, whenever the term ‘‘designated representative’’ is used in this part, the term shall be construed to include the designated representative or any alternate designated representative.

(g) Changing a designated representative or alternate designated representative. The designated representative or alternate designated representative identified in a complete certificate of representation under this section for a facility or supplier received by the Administrator may be changed at any time upon receipt by the Administrator of another later signed, complete certificate of representation under this section for the facility or supplier. Notwithstanding any such change, all representations, actions, inactions, and submissions by the previous designated representative or the previous alternate designated representative of the facility or supplier before the time and date when the Administrator receives such later signed certificate of representation shall be binding on the new designated representative and the owners and operators of the facility or supplier.

(h) Changes in owners and operators. In the event an owner or operator of the facility or supplier is not included in the list of owners and operators in the certificate of representation under this section for the facility or supplier, such owner or operator shall be deemed to be subject to and bound by the certificate of representation, the representations, actions, inactions, and submissions of the designated representative and any alternate designated representative of the facility or supplier, as if the owner or operator were included in such list. Within 90 days after any change in the owners and operators of the facility or supplier (including the addition of a new owner or operator), the designated representative or any alternate designated representative shall submit a certificate of representation that is complete under this section except that such list shall be amended to reflect the change. If the designated representative or alternate designated representative determines at any time that an owner or operator of the facility or supplier is not included in such list and such exclusion is not the result of a change in the owners and operators, the designated representative or any alternate designated representative shall submit, within 90 days of making such determination, a certificate of representation that is complete under this section except that such list shall be amended to include such owner or operator.

(i) Certificate of representation. A certificate of representation shall be complete if it includes the following elements in a format prescribed by the Administrator in accordance with this section:

(1) Identification of the facility or supplier for which the certificate of representation is submitted.

(2) The name, address, e-mail address (if any), telephone number, and facsimile transmission number (if any) of the designated representative and any alternate designated representative.

(3) A list of the owners and operators of the facility or supplier identified in paragraph (i)(1) of this section, provided that, if the list includes the operators of the facility or supplier and the owners with control of the facility or supplier, the failure to include any other owners shall not make the certificate of representation incomplete.

(4) The following certification statements by the designated representative and any alternate designated representative:

(i) ‘‘I certify that I was selected as the designated representative or alternate designated representative, as applicable, by an agreement binding on the owners and operators of the facility or supplier, as applicable.’’

(ii) ‘‘I certify that I have all the necessary authority to carry out my duties and responsibilities under 40 CFR part 98 on behalf of the owners and operators of the facility or supplier, as applicable, and that each such owner and operator shall be fully bound by my representations, actions, inactions, or submissions.’’

(iii) ‘‘I certify that the owners and operators of the facility or supplier, as applicable, shall be bound by any order issued to me by the Administrator or a court regarding the facility or supplier.’’

(iv) ‘‘If there are multiple owners and operators of the facility or supplier, as applicable, I certify that I have given a written notice of my selection as the ‘designated representative’ or ‘alternate designated representative’, as applicable, and of the agreement by which I was selected to each owner and operator of the facility or supplier.’’

(5) The signature of the designated representative and any alternate designated representative and the dates signed.

(j) Documents of agreement. Unless otherwise required by the Administrator, documents of agreement referred to in the certificate of representation shall not be submitted to the Administrator. The Administrator shall not be under any obligation to review or evaluate the sufficiency of such documents, if submitted.

(k) Binding nature of the certificate of representation. Once a complete certificate of representation under this section for a facility or supplier has been received, the Administrator will rely on the certificate of representation unless and until a later signed, complete certificate of representation under this section for the facility or supplier is received by the Administrator.

(l) Objections Concerning a Designated Representative

(1) Except as provided in paragraph (g) of this section, no objection or other communication submitted to the Administrator concerning the authorization, or any representation, action, inaction, or submission, of the designated representative or alternate designated representative shall affect any representation, action, inaction, or submission of the designated representative or alternate designated representative, or the finality of any decision or order by the Administrator under this part.

(2) The Administrator will not adjudicate any private legal dispute concerning the authorization or any representation, action, inaction, or submission of any designated representative or alternate designated representative.

(m) Delegation by designated representative and alternate designated representative.

(1) A designated representative or an alternate designated representative may delegate his or her own authority, to one or more individuals, to submit an electronic submission to the Administrator provided for or required under this part, except for a submission under this paragraph.

(2) In order to delegate his or her own authority, to one or more individuals, to submit an electronic submission to the Administrator in accordance with paragraph (m)(1) of this section, the designated representative or alternate designated representative must submit electronically to the Administrator a notice of delegation, in a format prescribed by the Administrator, that includes the following elements:

(i) The name, address, e-mail address (if any), telephone number, and facsimile transmission number (if any) of such designated representative or alternate designated representative.

(ii) The name, address, e-mail address, telephone number, and facsimile transmission number (if any) of each such individual (referred to as an ‘‘agent’’).

(iii) For each such individual, a list of the type or types of electronic submissions under paragraph (m)(1) of this section for which authority is delegated to him or her.

(iv) For each type of electronic submission listed in accordance with paragraph (m)(2)(iii) of this section, the facility or supplier for which the electronic submission may be made.

(v) The following certification statements by such designated representative or alternate designated representative:

(A) ‘‘I agree that any electronic submission to the Administrator that is by an agent identified in this notice of delegation and of a type listed, and for a facility or supplier designated, for such agent in this notice of delegation and that is made when I am a designated representative or alternate designated representative, as applicable, and before this notice of delegation is superseded by another notice of delegation under § 98.4(m)(3) shall be deemed to be an electronic submission certified, signed, and submitted by me.’’

(B) ‘‘Until this notice of delegation is superseded by a later signed notice of delegation under § 98.4(m)(3), I agree to maintain an e-mail account and to notify the Administrator immediately of any change in my e-mail address unless all delegation of authority by me under § 98.4(m) is terminated.’’

(vi) The signature of such designated representative or alternate designated representative and the date signed.

(3) A notice of delegation submitted in accordance with paragraph (m)(2) of this section shall be effective, with regard to the designated representative or alternate designated representative identified in such notice, upon receipt of such notice by the Administrator and until receipt by the Administrator of another such notice that was signed later by such designated representative or alternate designated representative, as applicable. The later

signed notice of delegation may replace any previously identified agent, add a new agent, or eliminate entirely any delegation of authority.

(4) Any electronic submission covered by the certification in paragraph (m)(2)(iv)(A) of this section and made in accordance with a notice of delegation effective under paragraph (m)(3) of this section shall be deemed to be an electronic submission certified, signed, and submitted by the designated representative or alternate designated representative submitting such notice of delegation.

§ 98.5 How is the report submitted?

Each GHG report and certificate of representation for a facility or supplier must be submitted electronically in accordance with the requirements of § 98.4 and in a format specified by the Administrator.

Subpart C—General Stationary Combustion

§98.30 Definition of the source category.

(a) Stationary fuel combustion sources are devices that combust solid, liquid, or gaseous fuel, generally for the purposes of producing electricity, generating steam, or providing useful heat or energy for industrial, commercial, or institutional use, or reducing the volume of waste by removing combustible matter. Stationary fuel combustion sources include, but are not limited to, boilers, simple and combined-cycle combustion turbines, engines, incinerators, and process heaters.

(b) This source category does not include:

(1) Portable equipment, as defined in §98.6.

(2) Emergency generators and emergency equipment, as defined in §98.6.

(3) Irrigation pumps at agricultural operations.

(4) Flares, unless otherwise required by provisions of another subpart of 40 CFR part 98 to use methodologies in this subpart.

(5) Electricity generating units that are subject to subpart D of this part.

(c) For a unit that combusts hazardous waste (as defined in 40 CFR 261.3), reporting of GHG emissions is not required unless either of the following conditions apply:

(1) Continuous emission monitors (CEMS) are used to quantify CO_2 mass emissions.

(2) Any fuel listed in Table C-1 of this subpart is also combusted in the unit. In this case, report GHG emissions from combustion of all fuels listed in Table C-1 of this subpart.

§98.31 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains one or more stationary fuel combustion sources and the facility meets the applicability requirements of either §§98.2(a)(1), 98.2(a)(2), or 98.2(a)(3).

§98.32 GHGs to report.

(a) You must report CO_2, CH_4, and N_2O mass emissions from each stationary fuel combustion unit.

(b) [Reporting only] Units that generate electricity either for sale or for use onsite must also report fugitive HFC emissions from cooling units by following the requirements of §98.33(f).

§98.33 Calculating GHG emissions.

You must calculate CO_2 emissions according to paragraph (a) of this section, and calculate CH_4 and N_2O emissions according to paragraph (c) of this section.

Subpart C—General Stationary Combustion

(a) CO_2 emissions from fuel combustion. Calculate CO_2 emissions by using one of the four calculation methodologies in this paragraph (a) subject to the conditions, requirements, and restrictions set forth in paragraph (b) of this section. If you co-fire biomass fuels with fossil fuels, report CO_2 emissions from the combustion of biomass separately using the methods in paragraph (e) of this section.

(1) Tier 1 Calculation Methodology. Calculate the annual CO_2 mass emissions for each type of fuel by using Equation C-1 of this section.

$$CO_2 = 1x\,10^{-3} * Fuel * HHV * EF \qquad \text{(Eq. C-1)}$$

Where:

CO_2 = Annual CO_2 mass emissions for the specific fuel type (metric tons).

Fuel = Mass or volume of fuel combusted per year, from company records as defined in §98.6 (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).

HHV = Default high heat value of the fuel, from Table C-1 of this subpart (mmBtu per mass or mmBtu per volume, as applicable).

EF = Fuel-specific default CO_2 emission factor, from Table C-1 of this subpart (kg CO_2/mmBtu).

1×10^{-3} =
Conversion factor from kilograms to metric tons.

(2) Tier 2 Calculation Methodology. Calculate the annual CO_2 mass emissions for each type of fuel by using either Equation C2a or C2c of this section, as appropriate.

(i) Equation C-2a of this section applies to any type of fuel listed in Table C-1 of the subpart, except for municipal solid waste (MSW). For MSW combustion, use Equation C-2c of this section.

$$CO_2 = 1x10^{-3} * Fuel * HHV * EF \qquad \text{(Eq. C-2a)}$$

Where:

CO_2 = Annual CO_2 mass emissions for a specific fuel type (metric tons).

Fuel = Mass or volume of the fuel combusted during the year, from company records as defined in §98.6 (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).

HHV = Annual average high heat value of the fuel from all valid samples for the year (mmBtu per mass or volume). The average HHV shall be calculated according to the requirements of paragraph (a)(2)(ii) of this section.

EF = Fuel-specific default CO_2 emission factor, from Table C-1 of this subpart (kg CO_2/mmBtu).

1×10^{-3} = Conversion factor from kilograms to metric tons.

(ii) The minimum number of HHV samples for determining annual average HHV is specified (e.g., monthly, quarterly, semi-annually, or by lot) in §98.34. The method for computing the annual average HHV is a function of how frequently you perform or receive from the fuel supplier the results of fuel sampling for HHV. The method is specified in paragraph (a)(2)(ii)(A) or (a)(2)(ii)(B) of this section, as applicable.

(A) If the results of fuel sampling are received monthly or more frequently, then the annual average HHV shall be calculated using Equation C-2b of this section. If multiple HHV determinations are made in any month, average the values for the month arithmetically.

$$(HHV)_{annual} = \frac{\sum_{i=1}^{n} (HHV)_i * (Fuel)_i}{\sum_{i=1}^{n} (Fuel)_i} \qquad \text{(Eq. C-2b)}$$

Where:

$(HHV)_{annual}$	=	Weighted annual average high heat value of the fuel (mmBtu per mass or volume).
$(HHV)_i$	=	High heat value of the fuel, for month "i" (mmBtu per mass or volume).
$(Fuel)_i$	=	Mass or volume of the fuel combusted during month "i" (express mass in short tons for solid fuel, volume in standard cubic feet for gaseous fuel, and volume in gallons for liquid fuel).
n	=	Number of months in the year that fuel is burned in the unit.

(B) If the results of fuel sampling are received less frequently than monthly, then the annual average HHV shall be computed as the arithmetic average HHV for all values for the year (including valid samples and substitute data values under 98.35).

(iii) For units that combust municipal solid waste (MSW) and that produce steam, use Equation C-2c of this section. Equation C-2c of this section may also be used for any ~~other~~ solid biomass fuel listed in Table C-1 of this subpart provided that steam is generated by the unit.

$$CO_2 = 1 \times 10^{-3}\, Steam * B * EF \qquad \text{(Eq. C-2c)}$$

Where:

CO_2	=	Annual CO_2 mass emissions from MSW or solid fuel combustion (metric tons).
Steam	=	Total mass of steam generated by MSW or solid fuel combustion during the reporting year (lb steam).
B	=	Ratio of the boiler's maximum rated heat input capacity to its design rated steam output capacity (mmBtu/lb steam).
EF	=	Fuel-specific default CO_2 emission factor, from Table C-1 of this subpart (kg CO_2/mmBtu)[1].
1×10^{-3}	=	Conversion factor from kilograms to metric tons.

(3) Tier 3 Calculation Methodology. Calculate the annual CO_2 mass emissions for each fuel by using either Equation C3, C4, or C5 of this section, as appropriate.

(i) For a solid fuel, use Equation C-3 of this section.

[1] The ER required development of a site-specific emission factor for MSW. For harmonization with the MRR, this requirement was deleted. However, jurisdictions may allow or require testing to develop a site-specific emission factor as an alternative to the default emission factors in Table C-1.

$$CO_2 = \frac{44}{12} * \text{Fuel} * \text{CC} * 0.91 \qquad \text{(Eq. C-3)}$$

Where:

CO_2 = Annual CO_2 mass emissions from the combustion of the specific solid fuel (metric tons).

Fuel = Annual mass of the solid fuel combusted, from company records as defined in §98.6 (short tons).

CC = Annual average carbon content of the solid fuel (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.

44/12 = Ratio of molecular weights, CO_2 to carbon.

0.91 = Conversion factor from short tons to metric tons.

(ii) For a liquid fuel, use Equation C-4 of this section.

$$CO_2 = \frac{44}{12} * \text{Fuel} * \text{CC} * 0.001 \qquad \text{(Eq. C-4)}$$

Where:

CO_2 = Annual CO_2 mass emissions from the combustion of the specific liquid fuel (metric tons).

Fuel = Annual volume of the liquid fuel combusted (gallons). The volume of fuel combusted must be measured directly, using fuel flow meters calibrated according to §98.3(i). Fuel billing meters may be used for this purpose. Tank drop measurements may also be used.

CC = Annual average carbon content of the liquid fuel (kg C per gallon of fuel). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.

44/12 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to metric tons.

(iii) For a gaseous fuel, use Equation C-5 of this section.

$$CO_2 = \frac{44}{12} * Fuel * CC * \frac{MW}{MVC} * 0.001 \qquad \text{(Eq. C-5)}$$

Where:

CO_2	=	Annual CO_2 mass emissions from combustion of the specific gaseous fuel (metric tons).
Fuel	=	Annual volume of the gaseous fuel combusted (scf). The volume of fuel combusted must be measured directly, using fuel flow meters calibrated according to §98.3(i). Fuel billing meters may be used for this purpose.
CC	=	Annual average carbon content of the liquid fuel (kg C per gallon of fuel). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.
MW	=	Annual average molecular weight of the gaseous fuel (kg/kg-mole). The annual average carbon content shall be determined using the same procedures as specified for HHV in paragraph (a)(2)(ii) of this section.
MVC	=	Molar volume conversion factor (849.5 scf per kg-mole at standard conditions, as defined in §98.6).
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(iv) Fuel flow meters that measure mass flow rates may be used for liquid fuels, provided that the fuel density is used to convert the readings to volumetric flow rates. The density shall be measured at the same frequency as the carbon content, using ASTM D1298-99 (Reapproved 2005) "Standard Test Method for Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and

Liquid Petroleum Products by Hydrometer Method" (incorporated by reference, see §98.7).

(v) The following default density values may be used for fuel oil, in lieu of using the ASTM method in paragraph (a)(3)(iv) of this section: 6.8 lb/gal for No. 1 oil; 7.2 lb/gal for No. 2 oil; 8.1 lb/gal for No. 6 oil.

(4) Tier 4 Calculation Methodology. Calculate the annual CO_2 mass emissions from all fuels combusted in a unit, by using quality-assured data from continuous emission monitoring systems (CEMS).

(i) This methodology requires a CO_2 concentration monitor and a stack gas volumetric flow rate monitor, except as otherwise provided in paragraph (a)(4)(iv) of this section. Hourly measurements of CO_2 concentration and stack gas flow rate are converted to CO_2 mass emission rates in metric tons per hour.

(ii) When the CO_2 concentration is measured on a wet basis, Equation C-6 of this section is used to calculate the hourly CO_2 emission rates:

$$CO_2 = 5.18x10^{-7} * C_{CO2} * Q \qquad \text{(Eq. C-6)}$$

Where:

CO_2 = CO_2 mass emission rate (metric tons/hr).
C_{CO2} = Hourly average CO_2 concentration (% CO_2).

Q = Hourly average stack gas volumetric flow rate (scfh).

5.18×10^{-7} = Conversion factor (metric tons/scf/% CO_2).

(iii) If the CO_2 concentration is measured on a dry basis, a correction for the stack gas moisture content is required. You shall either continuously monitor the stack gas moisture content as described in §75.11(b)(2) of this chapter or, for certain types of fuel, use a default moisture percentage from §75.11(b)(1) of this chapter. For each unit operating hour, a moisture correction must be applied to Equation C-6 of this section as follows:

$$CO_2^* = CO_2\left(\frac{100 - \%H_2O}{100}\right) \qquad \text{(Eq. C-7)}$$

Where:

CO_2^* = Hourly CO_2 mass emission rate, corrected for moisture (metric tons/hr).

CO_2 = Hourly CO_2 mass emission rate from Equation C-6 of this section, uncorrected (metric tons/hr).

$\%H_2O$ = Hourly moisture percentage in the stack gas (measured or default value, as appropriate).

(iv) An oxygen (O_2) concentration monitor may be used in lieu of a CO_2 concentration monitor in a CEMS installed before January 1, 2012,[2] to determine the hourly CO_2 concentrations, in accordance with Equation F-14a or F-14b (as applicable) in appendix F to 40 CFR part 75, if the

[2] A jurisdiction may want to modify this date depending on the effective date of the jurisdiction's reporting regulations.

effluent gas stream monitored by the CEMS consists solely of combustion products (i.e., no process CO_2 emissions are mixed with the combustion products) and if only fuels that are listed in Table 1 in section 3.3.5 of appendix F to 40 CFR part 75 are combusted in the unit. If the O_2 monitoring option is selected, the F-factors used in Equations F-14a and F-14b shall be determined according to section 3.3.5 or section 3.3.6 of appendix F to 40 CFR part 75, as applicable. If Equation F-14b is used, the hourly moisture percentage in the stack gas shall be either a measured value in accordance with §75.11(b)(2) of this chapter, or, for certain types of fuel, a default moisture value from §75.11(b)(1) of this chapter. An operator without a CO_2 monitor who uses a CEMS and O_2 concentrations to calculate and report a unit's CO_2 emissions, and who regularly conducts a Relative Accuracy Test Audit (RATA) for the unit, must include in the RATA at least annually the monitoring of CO2 concentration and flow, and the calculation of CO_2 mass. The operator must retain these results and make them available to [the jurisdiction] upon request.[3]

(v) Each hourly CO_2 mass emission rate from Equation C-6 or C-7 of this section is multiplied by the operating

[3] The additional language is optional.

time to convert it from metric tons per hour to metric tons. The operating time is the fraction of the hour during which fuel is combusted (e.g., the unit operating time is 1.0 if the unit operates for the whole hour and is 0.5 if the unit operates for 30 minutes in the hour). For common stack configurations, the operating time is the fraction of the hour during which effluent gases flow through the common stack.

(vi) The hourly CO_2 mass emissions are then summed over each calendar quarter and the quarterly totals are summed to determine the annual CO_2 mass emissions.

(vii) If both biomass and fossil fuel are combusted during the year, determine and report the biogenic CO_2 mass emissions separately, as described in paragraph (e) of this section.

(5) Alternative methods for units with continuous monitoring systems. Units not subject to the Acid Rain Program that report data to EPA according to 40 CFR part 75 may use the alternative methods in this paragraph in lieu of using any of the four calculation methodology tiers.

(i) For a unit that combusts only natural gas and/or fuel oil, is not subject to the Acid Rain Program, monitors and reports heat input data year-round according to appendix D to 40 CFR part 75, but is not required by the applicable 40 CFR part 75 program to report CO_2 mass emissions data, calculate the annual CO_2 mass emissions for the purposes of this part as follows:

(A) Use the hourly heat input data from appendix D to 40 CFR part 75, together with Equation G-4 in appendix G to 40 CFR part 75 to determine the hourly CO_2 mass emission rates, in units of tons/hr;

(B) Use Equations F-12 and F-13 in appendix F to 40 CFR part 75 to calculate the quarterly and cumulative annual CO_2 mass emissions, respectively, in units of short tons; and

(C) Divide the cumulative annual CO_2 mass emissions value by 1.1 to convert it to metric tons.

(ii) For a unit that combusts only natural gas and/or fuel oil, is not subject to the Acid Rain Program, monitors and reports heat input data year-round according to 40 CFR 75.19 of this chapter but is not required by the applicable 40 CFR part 75 program to report CO_2 mass emissions data, calculate the annual CO_2 mass emissions for the purposes of this part as follows:

(A) Calculate the hourly CO_2 mass emissions, in units of short tons, using Equation LM-11 in 40 CFR 75.19(c)(4)(iii).

(B) Sum the hourly CO_2 mass emissions values over the entire reporting year to obtain the cumulative annual CO_2 mass emissions, in units of short tons.

(C) Divide the cumulative annual CO_2 mass emissions value by 1.1 to convert it to metric tons.

(iii) For a unit that is not subject to the Acid Rain Program, uses flow rate and CO_2 (or O_2) CEMS to report heat input data year-round according to 40 CFR part 75, but is not required by the applicable 40 CFR part 75 program to report CO_2 mass emissions data, calculate the annual CO_2 mass emissions as follows:

(A) Use Equation F-11 or F-2 (as applicable) in appendix F to 40 CFR part 75 to calculate the hourly CO_2 mass emission rates from the CEMS data. If an O_2 monitor is used, convert the hourly average O_2 readings to CO_2 using Equation F-14a or F-14b in appendix F to 40 CFR part 75 (as applicable), before applying Equation F-11 or F-2.

(B) Use Equations F-12 and F-13 in appendix F to 40 CFR part 75 to calculate the quarterly and cumulative annual CO_2 mass emissions, respectively, in units of short tons.

(C) Divide the cumulative annual CO_2 mass emissions value by 1.1 to convert it to metric tons.

(D) If both biomass and fossil fuel are combusted during the year, determine and report the biogenic CO_2 mass emissions separately, as described in paragraph (e) of this section.

(b) Use of the four tiers. Use of the four tiers of CO_2 emissions calculation methodologies described in paragraph (a) of this section is subject to the following conditions, requirements, and restrictions:

(1) The Tier 1 Calculation Methodology:

(i) May be used for any fuel listed in Table C-1 of this subpart that is combusted in a unit with a maximum rated heat input capacity of 250 mmBtu/hr or less at a facility that is not subject to verification, and may be used for any fuel listed in Table C-1a of this subpart that is combusted in a unit with a maximum rated heat input capacity of 250 mmBtu/hr or less at any facility.

(ii) May be used for MSW in a unit of any size that does not produce steam, if the use of Tier 4 is not required.

(iii) May be used for solid, gaseous, or liquid biomass fuels in a unit of any size provided that the fuel is listed in Table C-1 of this subpart and has been determined by [the jurisdiction] not to be subject to a compliance obligation under the cap-and-trade program.[4]

(iv) May not be used if you routinely perform fuel sampling and analysis for the fuel high heat value (HHV) or routinely receives the results of HHV sampling and analysis from the fuel supplier at the minimum frequency specified in §98.34(a), or at a greater frequency. In such cases, Tier 2 or higher shall be used.

(2) The Tier 2 Calculation Methodology:

(i) May be used for the combustion of any type of fuel in a unit with a maximum rated heat input capacity of 250 mmBtu/hr or less at any facility provided that the fuel is pipeline quality natural gas or is listed in ~~Table C-1~~ Table C-1a of this subpart.

(ii) May be used in a unit with a maximum rated heat input capacity greater than 250 mmBtu/hr for the combustion of pipeline quality natural gas and distillate fuel oil.

(iii) May be used for MSW or solid biomass fuel[5] in a unit of any size that produces steam, if Equation C-2c is employed and if the use of Tier 4 is not required.

---

[4] Under the WCI design recommendations, biomass determined to be carbon neutral may be excluded from the cap-and-trade program.

The added language in this paragraph is optional. A jurisdiction may choose to require a higher tier for any or all biomass fuels.

[5] Consistent with 98.33(a)(2)(iii).

(iv) May be used for the combustion of any fuel listed in Table C-1 at a facility that is not subject to verification or to 40 C.F.R. Part 98.

(3) The Tier 3 Calculation Methodology:

(i) May be used for a unit of any size that combusts any type of fuel listed in Table C-1 of this subpart (except for MSW), unless the use of Tier 4 is required.

(ii) Shall be used for the combustion of a fuel listed in Table C-1 of this subpart in a unit ~~with~~ that has a maximum rated heat input capacity greater than 250 mmBtu/hr or is located a a facility subject to verification ~~that combusts any type of fuel listed in Table C-1 of this subpart (except MSW)~~, unless either of the following conditions apply:

(A) The use of Tier 1 or 2 is permitted, as described in paragraphs (b)(1)~~(iii)~~ and (b)(2)~~(ii)~~ of this section.

(B) The use of Tier 4 is required.

(iii) Shall be used for a fuel not listed in Table C-1 of this subpart ~~if the fuel is combusted in a unit with a maximum rated heat input capacity greater than 250 mmBtu/hr~~ provided that ~~both of the following conditions apply:~~

~~(A)~~ The use of Tier 4 is not required.

~~(B) The fuel provides 10% or more of the annual heat input to the unit or, if §98.36(c)(3)applies, to a group of units served by common supply pipe.~~ [Reserved]

(4) The Tier 4 Calculation Methodology:

(i) May be used for a unit of any size, combusting any type of fuel.

(ii) Shall be used if the unit meets all six of the conditions specified in paragraphs (b)(4)(ii)(A) through (b)(4)(ii)(F) of this section:

(A) The unit has a maximum rated heat input capacity greater than 250 mmBtu/hr, or if the unit combusts municipal solid waste and has a maximum rated input capacity greater than 250 tons per day of MSW.

(B) The unit combusts solid fossil fuel or MSW, either as a primary or secondary fuel.

(C) The unit has operated for more than 1,000 hours in any calendar year since 2005.

(D) The unit has installed CEMS that are required either by an applicable Federal or State regulation or the unit's operating permit.

(E) The installed CEMS include a gas monitor of any kind or a stack gas volumetric flow rate monitor, or both and the monitors have been certified, either in accordance with the requirements of 40 CFR part 75, part 60 of this chapter, or an applicable State continuous monitoring program.

(F) The installed gas or stack gas volumetric flow rate monitors are required, either by an applicable Federal or State regulation or by the unit's operating permit, to undergo periodic quality assurance testing in accordance with either appendix B to 40 CFR part 75, appendix F to 40 CFR part 60, or an applicable State continuous monitoring program.

(iii) Shall be used for a unit with a maximum rated heat input capacity of 250 mmBtu/hr or less and for a unit that combusts municipal solid waste with a maximum rated input capacity of 250 tons of MSW per day or less, if the unit meets all of the following three conditions:

(A) The unit has both a stack gas volumetric flow rate monitor and a CO_2 concentration monitor.

(B) The unit meets the conditions specified in paragraphs (b)(4)(ii)(B) through (b)(4)(ii)(D) of this section.

(C) The CO_2 and stack gas volumetric flow rate monitors meet the conditions specified in paragraphs (b)(4)(ii)(E) and (b)(4)(ii)(F) of this section.

(5) The Tier 4 Calculation Methodology shall be used beginning on:

(i) January 1, 2010, for a unit that is required to report CO_2 mass emissions beginning on that date, if all of the monitors needed to measure CO_2 mass emissions have been installed and certified by that date.

(ii) January 1, 2011, for a unit that is required to report CO_2 mass emissions beginning on January 1, 2010, if all of the monitors needed to measure CO_2 mass emissions have not been installed and certified by January 1, 2010. In this case, you may use Tier 2 or Tier 3 to report GHG emissions for 2010.

(6) You may elect to use any applicable higher tier for one or more of the fuels combusted in a unit. For example, if a 100 mmBtu/hr unit combusts natural gas and distillate fuel oil, you may elect to use Tier 1 for natural gas and Tier 3 for the fuel oil, even though Tier 1 could have been used for both fuels. However, for units that use either the Tier 4 or the alternative calculation methodology specified in paragraph (a)(5) of this section, CO_2 emissions from the combustion of all fuels shall be based solely on CEMS measurements.

(c) Calculation of CH_4 and N_2O emissions from stationary combustion sources. You must calculate annual CH_4 and N_2O mass emissions only for units that are required to report CO_2 emissions using the calculation methodologies of this subpart and for only those fuels that are listed in Table C-2 of this subpart.

(1) Use Equation C-8 of this section to estimate CH_4 and N_2O emissions for any fuels for which you use the Tier 1 or Tier 3 calculation methodologies for CO_2. Use the same values for fuel combustion that you use for the Tier 1 or Tier 3 calculation.

$$CH_4 \ or \ N_2O = 1 \, x \, 10^{-3} * Fuel * HHV * EF \qquad \text{(Eq. C-8)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (metric tons).

Fuel = Mass or volume of the fuel combusted, either from company records or directly measured by a fuel flow meter, as applicable (mass or volume per year).

HHV = Default high heat value of the fuel from Table C-1 of this subpart (mmBtu per mass or volume).

EF = Fuel-specific default emission factor for CH_4 or N_2O, from Table C-2 of this subpart (kg CH_4 or N_2O per mmBtu).

1×10^{-3} = Conversion factor from kilograms to metric tons.

(2) Use Equation C-9a of this section to estimate CH_4 and N_2O emissions for any fuels for which you use the Tier 2 Equation C-2a of this section to estimate CO_2 emissions. Use the same values for fuel combustion and HHV that you use for the Tier 1 or Tier 3 calculation.

$$CH_4 \text{ or } N_2O = 1 \text{ x } 10^{-3} * HHV * EF * Fuel \qquad \text{(Eq. C-9a)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (metric tons).

Fuel = Mass or volume of the fuel combusted during the reporting year.

HHV = High heat value of the fuel, averaged for all valid measurements for the reporting year (mmBtu per mass or volume).

EF = Fuel-specific default emission factor for CH_4 or N_2O, from Table C-2 of this subpart (kg CH_4 or N_2O per mmBtu).

1 x 10^{-3} = Conversion factor from kilograms to metric tons.

(3) Use Equation C-9b of this section to estimate CH_4 and N_2O emissions for any fuels for which you use Equation C-2c of this section to calculate the CO_2 emissions. Use the same values for steam generation and the ratio "B" that you use for Equation C-2c.

$$CH_4 \text{ or } N_2O = 1 \text{ x } 10^{-3} \text{ Steam} * B * EF \qquad \text{(Eq. C-9b)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a solid fuel (metric tons).

Steam = Total mass of steam generated by solid fuel combustion during the reporting year (lb steam).

B = Ratio of the boiler's maximum rated heat input capacity to its design rated steam output (mmBtu/lb steam).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Table C-2 of this subpart (kg CH_4 or N_2O per mmBtu).

1×10^{-3} = Conversion factor from kilograms to metric tons.

(4) Use Equation C-10 of this section for units in the Acid Rain Program, units that monitor and report heat input on a year-round basis according to 40 CFR part 75, and units that use the Tier 4 Calculation Methodology.

$$CH_4 \text{ or } N_2O = 0.001 * (HI)_A * EF \qquad \text{(Eq. C-10)}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (metric tons).

$(HI)_A$ = Cumulative annual heat input from the fuel, derived from the electronic data reports required under §75.64 of this chapter or, for Tier 4 units, from the best available information as described in paragraph (c)(4)(ii) of this section(mmBtu).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Table C-2 of this section (kg CH_4 or N_2O per mmBtu).

0.001 = Conversion factor from kg to metric tons.

(i) If only one type of fuel listed in Table C-2 of this subpart is combusted during normal operation, substitute the cumulative annual heat input from combustion of the fuel into Equation C-10 of this section to calculate the annual CH_4 or N_2O emissions.

(ii) If more than one type of fuel listed in Table C-2 of this subpart is combusted during normal operation, use Equation C-10 of this section separately for each type of fuel. If flow rate and diluent gas monitors are used to measure the unit heat input, use the best available information (e.g., fuel feed rate measurements, fuel heating values, engineering analysis) to estimate the annual heat input from each type of fuel.

(5) When multiple fuels are combusted during the reporting year, sum the fuel-specific results from Equations C-8, C-9a, C-9b, or C-10 of this section (as applicable) to obtain the total annual CH_4 and N_2O emissions, in metric tons.

(6) The operator may elect to calculate CH_4 or N_2O emissions using source-specific emission factors derived from source tests conducted at least annually under the supervision of [jurisdiction]. Upon approval of a source test plan, the source test procedures in that plan shall be repeated in each future year to update the source specific emission factors annually.

(d) Calculation of CO_2 from sorbent.

(1) When a unit is a fluidized bed boiler, is equipped with a wet flue gas desulfurization system, or uses other acid gas emission controls with sorbent

injection, use Equation C-11 of this section to calculate the CO_2 emissions from the sorbent, if those CO_2 emissions are not monitored by CEMS:

$$CO_2 = 0.91 * S * R * \left(\frac{MW_{CO2}}{MW_S}\right) \qquad \text{(Eq. C-11)}$$

Where:

CO_2 = CO_2 emitted from sorbent for the reporting year (metric tons).

S = Limestone or other sorbent used in the reporting year, from company records (short tons).

R = 1.00, the calcium-to-sulfur stoichiometric ratio.

MW_{CO2} = Molecular weight of carbon dioxide (44).

MW_S = Molecular weight of sorbent (100 if calcium carbonate).

0.91 = Conversion factor from short tons to metric tons

(2) The annual CO_2 mass emissions for the unit shall be the sum of the CO_2 emissions from the combustion process and the CO_2 emissions from the sorbent.

(e) CO_2 emissions from combustion of biomass. Use the procedures of this paragraph (e) to estimate biogenic CO_2 emissions from units that combust a combination of biomass and fossil fuels. Reporting of CO_2 emissions from combustion of biomass is required only for those biomass fuels listed in Table C-1 of this section, unless emissions are measured using CEMS.

(1) If CEMS are not used to measure CO_2, use Equation C-1 or C-2c of this subpart to calculate the annual CO_2 mass emissions from the combustion of biomass (except MSW) for a unit of any size. Determine the mass of biomass combusted using one of the following procedures in this paragraph (e)(1), as appropriate.

(i) Use company records.

(ii) Follow the procedures in paragraph (e)(5) of this section.

(iii) For premixed fuels that contain biomass and fossil fuels (e.g., mixtures containing biodiesel), use best available information to determine the mass of biomass fuels and document the procedure used in the GHG Monitoring Plan required by §98.3(g)(5).

(2) If a CO_2 CEMS (or a surrogate O_2 monitor) and a stack gas flow rate monitor are used to determine the annual CO_2 mass emissions either according to 40 CFR part 75, the Tier 4 Calculation Methodology, or the alternative calculation methodology specified in paragraph (a)(5)(iii); and if both fossil fuel and biomass (except for MSW) are combusted in the unit during the reporting year, you may use the following procedure to determine the annual biogenic CO_2 mass emissions. If MSW or a fossil fuel/biomass mixture containing an undeterminable quantity

of fossil fuels is combusted in the unit, follow the procedures in paragraph (e)(3) of this section.

(i) For each operating hour, use Equation C-12 of this section to determine the volume of CO_2 emitted.

$$V_{CO2h} = \frac{(\%CO_2)_h}{100} * Q_h * t_h \qquad \text{(Eq. C-12)}$$

Where:

V_{CO2h} = Hourly volume of CO_2 emitted (scf).

$(\%CO_2)_h$ = Hourly average CO_2 concentration, measured by the CO_2 concentration monitor, or, if applicable, calculated from the hourly average O_2 concentration ($\%CO_2$).

Q_h = Hourly average stack gas volumetric flow rate, measured by the stack gas volumetric flow rate monitor (scfh).

t_h = Source operating time (decimal fraction of the hour during which the source combusts fuel, i.e., 1.0 for a full operating hour, 0.5 for 30 minutes of operation, etc.).

100 = Conversion factor from percent to a decimal fraction.

(ii) Sum all of the hourly V_{CO2h} values for the reporting year, to obtain V_{total}, the total annual volume of CO_2 emitted.

(iii) Calculate the annual volume of CO_2 emitted from fossil fuel combustion using Equation C-13 of this section. If two or more types of fossil fuel are combusted during the year, perform a separate calculation with Equation C-13 of this section for each fuel and sum the results.

$$V_{ff} = \frac{Fuel * F_c * HHV}{10^6} \qquad \text{(Eq. C-13)}$$

Where:

V_{ff} = Annual volume of CO_2 emitted from combustion of a particular fossil fuel (scf).

Fuel = Total quantity of the fossil fuel combusted in the reporting year, from company records, as defined in §98.6 (lb for solid fuel, gallons for liquid fuel, and scf for gaseous fuel).

F_c = Fuel-specific carbon based F-factor, either a default value from Table 1 in section 3.3.5 of appendix F to 40 CFR part 75 or a site-specific value determined under section 3.3.6 of appendix F to 40 CFR part 75 (scf CO_2/mmBtu).

HHV = High heat value of the fossil fuel, from fuel sampling and analysis (annual average value in Btu/lb for solid fuel, Btu/gal for liquid fuel and Btu/scf for gaseous fuel, sampled as specified (e.g., monthly, quarterly, semi-annually, or by lot) in §98.34(a)(2)). The average HHV shall be calculated according to the requirements of paragraph (a)(2)(ii) of this section.

10^6 = Conversion factor, Btu per mmBtu.

(iv) Subtract V_{ff} from V_{total} to obtain V_{bio}, the annual volume of CO_2 from the combustion of biomass. If a CEMS is being used to measure the combined combustion and process emissions from a unit that is subject to another subpart of part 98, then also subtract CO_2 process emissions from V_{total} to determine V_{bio}. The CO_2 process emissions must be calculated according to the requirements of the applicable subpart.

(v) Calculate the biogenic percentage of the annual CO_2 emissions,expressed as a decimal fraction, using Equation C-14 of this section:

$$\%\ Biogenic = \frac{V_{bio}}{V_{total}} \qquad \text{(Eq. C-14)}$$

(vi) Calculate the annual biogenic CO_2 mass emissions, in metric tons, by multiplying the results obtained from Equation C-14 of this section by the annual CO_2 mass emissions in metric tons, as determined:

(A) Under paragraph (a)(4)(vi) of this section, for units using the Tier 4 Calculation Methodology.

(B) Under paragraph (a)(5)(iii)(B) of this section, for units using the alternative calculation methodology specified in paragraph (a)(5)(iii).

(C) From the electronic data report required under §75.64 of this chapter, for units in the Acid Rain Program and other units using CEMS to monitor and report CO_2 mass emissions according to 40 CFR part 75. However, before calculating the annual biogenic CO_2 mass emissions, multiply the cumulative annual CO_2 mass emissions by 0.91 to convert from short tons to metric tons.

(3) For a unit that combusts MSW, the annual biogenic CO_2 emissions shall be calculated using the procedures in this paragraph (3).

(i) If the Tier 1 or Tier 2 Calculation Methodology is used to quantify CO_2 mass emissions:

(A) Use Equation C-1 or C-2c of this subpart, as appropriate, to calculate the annual CO_2 mass emissions from MSW combustion.

(B) Determine the relative proportions of biogenic and non-biogenic CO_2 emissions on a quarterly basis using the method specified in §98.34(d).

(C) Determine the annual biogenic CO_2 mass emissions from MSW combustion by multiplying the annual CO_2 mass emissions by the annual average biogenic decimal fraction obtained from §98.34(d).

(ii) If the unit uses Tier 4 to quantify CO_2 emissions:

(A) Follow the procedures in paragraphs (e)(2)(i) and (ii) of this section, to determine V_{total}.

(B) If any fossil fuel was combusted during the year, follow the procedures in paragraph (e)(2)(iii) of this section, to determine V_{ff}.

(C) Subtract V_{ff} from V_{total}, to obtain V_{MSW} , the annual volume of CO_2 emissions from MSW combustion.

(D) Determine the annual volume of biogenic CO_2 emissions (V_{bio}) from MSW combustion as follows. Multiply the annual volume of CO_2 emissions from MSW combustion (V_{MSW})

by the annual average biogenic decimal fraction obtained from ASTM D6866-08 and ASTM D7459-08.

(E) Calculate the biogenic percentage of the annual CO_2 emissions from the unit, using Equation C-14 of this section. For the purposes of this calculation, the term "V_{bio}" in the numerator of Equation C-14 of this section shall be the results of the calculation performed under paragraph (e)(3)(ii)(D) of this section.

(F) Calculate the annual biogenic CO_2 mass emissions according to paragraph (e)(2)(vi)(A) of this section.

(4) As an alternative to the procedures in paragraph (e)(2) of this section, use ASTM Methods D7459-08 and D6866-08 to determine the biogenic portion of the annual CO_2 emissions, as described in §98.34(e). If this option is selected, the results of each determination shall be expressed as a decimal fraction (e.g., 0.30, if 30 percent of the CO_2 is biogenic), and the values shall be averaged over the reporting year. The annual biogenic CO_2 mass emissions shall be calculated by multiplying the the total annual CO_2 mass emissions by the annual average biogenic fraction obtained from ASTM D6866-08 and ASTM D7459-08.

(5) If Equation C-1 of this section is selected to calculate the annual biogenic mass emissions for wood, wood waste, or other solid biomass-derived fuel, Equation C-15

of this section may be used to quantify biogenic fuel consumption, provided that all of the required input parameters are accurately quantified. Similar equations and calculation methodologies based on steam generation and boiler efficiency may be used, provided that they are documented in the GHG Monitoring Plan required by §98.3(g)(5).

$$(Fuel)_p = \frac{[H * S] - (HI)_{nb}}{2000\,(HHV)_{bio}\,(Eff)_{bio}} \quad \text{(Eq. C-15)}$$

Where:

$(Fuel)_p$	=	Quantity of biomass consumed during the measurement period "p" (tons/year or tons/month, as applicable).
H	=	Average enthalpy of the boiler steam for the measurement period (Btu/lb).
S	=	Total boiler steam production for the measurement period (lb/month or lb/year, as applicable).
$(HI)_{nb}$	=	Heat input from co-fired fossil fuels and non-biomass-derived fuels for the measurement period, based on company records of fuel usage and default or measured HHV values (Btu/month or Btu/year, as applicable).
$(HHV)_{bio}$	=	Default or measured high heat value of the biomass fuel (Btu/lb).
$(Eff)_{bio}$	=	Percent efficiency of biomass-to-energy conversion, expressed as a decimal fraction.
2000	=	Conversion factor (lb/ton).

(f) [Reporting only] Calculating fugitive HFC emissions from cooling units.[6] Operators of electricity generating facilities shall calculate fugitive HFC emissions for each HFC compound used in cooling units that support power generation or are used in heat transfers to cool stack gases using either the methodology in paragraph (f)(1) or (f)(2). The Operator is not required to report GHG emissions from air or water cooling systems or condensers that do not contain HFCs.

(1) Use Equation C-16 to calculate annual HFC emissions:

$$HFC = HFC_{inventory} + HFC_{purchases/acquisitions} - HFC_{sales/disbursements} + HFC_{\Delta capacity} \qquad \text{Eqn. C-16}$$

Where:

HFC = Annual fugitive HFC emission, metric tons;

$HFC_{inventory}$ = The difference between the quantity of HFC in storage at the beginning of the year and the quantity in storage at the end of the year. Stored HFC includes HFC contained in cylinders (such as 115-pound storage cylinders), gas carts, and other storage containers. It does not include HFC gas held in operating equipment. The change in inventory will be negative if the quantity of HFC in storage increases over the course of the year.

$HFC_{purchases/acquisitions}$ = The sum of all HFC acquired from other entities during the year either in storage containers or in equipment.

$HFC_{sales/disbursements}$ = The sum of all the HFC sold or otherwise transferred offsite to other entities during the year either in storage containers or in equipment.

[6] Taken from WCI.43(d).

$HFC_{\Delta capacity}$ = The net change in the total nameplate capacity (i.e. the full and proper charge) of the cooling equipment). The net change in capacity will be negative if the total nameplate capacity at the end of the year is less than the total nameplate capacity at the beginning of the year.

(2) Use service logs to document HFC usage and emissions from each cooling unit. Service logs should document all maintenance and service performed on the unit during the report year, including the quantity of HFCs added to or removed from the unit, and include a record at the beginning and end of each report year. The operator may use service log information along with the following simplified material balance equations to quantify fugitive HFCs from unit installation, servicing, and retirement, as applicable. The operator shall include the sum of HFC emissions from the applicable equations in the greenhouse gas emissions data report.

$$HFC_{Install} = R_{new} - C_{new}$$

$$HFC_{Service} = R_{recharge} - R_{Recover}$$

$$HFC_{Retire} = C_{retire} - R_{retire}$$

Where:

$HFC_{Install}$ = HFC emitted during initial charging/installation of the unit, kilograms;

$HFC_{Service}$ = HFC emitted during use and servicing of the unit for the report year, kilograms;

HFC_{Retire} = HFC emitted during the removal from service/retirement of the unit, kilograms;

R_{new} = HFC used to fill new unit (omit if unit was pre-charged by the manufacturer), kilograms;

C_{new} = Nameplate capacity of new unit (omit if unit was pre-charged by the manufacturer), kilograms;

$R_{recharge}$ = HFC used to recharge the unit during maintenance and service, kilograms;

$R_{recover}$ = HFC recovered from the unit during maintenance and service, kilograms;

C_{retire} = Nameplate capacity of the retired unit, kilograms; and

R_{retire} = HFC recovered from the retired unit, kilograms.

§98.34 Monitoring and QA/QC requirements.

The CO_2 mass emissions data for stationary fuel combustion sources shall be monitored as follows:

(a) For the Tier 2 Calculation Methodology:

(1) All fuel samples shall be taken at a location in the fuel handling system that provides a sample representative of the fuel combusted. The fuel sampling and analysis may be performed by either the owner or operator or the supplier of the fuel.

(2) The minimum required frequency of the HHV sampling and analysis for each type of fuel is specified in this paragraph. When the specified frequency is based on a specified time period (i.e., weekly, monthly, quarterly, or semiannually), fuel sampling and analysis is required only for those periods in which the unit operates.

(i) For natural gas, semiannual sampling and analysis is required (i.e., twice in a calendar year, with consecutive samples taken at least four months apart).

(ii) For coal and fuel oil, analysis of at least one representative sample from each fuel lot is required. For the purposes of this section, a fuel lot is defined as a shipment or delivery of a single fuel (e.g., ship load, barge load, group of trucks, group of railroad cars, etc.).

(iii) For liquid fuels other than fuel oil, for fossil fuel-derived gaseous fuels, and for biogas; sampling and analysis is required at least once per calendar quarter. To the extent practicable, consecutive quarterly samples shall be taken at least 30 days apart.

(iv) For solid fuels other than coal and MSW, weekly sampling is required to obtain composite samples, which are then analyzed monthly.

(3) If different types of fuel (e.g., different ranks of coal or different grades of fuel oil) are blended prior to combustion, use one of the following procedures in this paragraph.

(i) Use a weighted HHV value in the emission calculations, based on the relative proportions of each fuel in the blend.

(ii) Take a representative sample of the blend and analyze it for HHV.

(4) If, for a particular type of fuel, HHV sampling and analysis is performed more often than the minimum frequency specified in paragraphs (a)(2)of this section, the results of all valid fuel analyses shall be used in the GHG emission calculations.

(5) If, for a particular type of fuel, valid HHV values are obtained at less than the minimum frequency specifed in paragraphs (a)(2) of this section, appropriate substitute data values shall be used in the emissions calculations, in accordance with missing data procedures of §98.35.

(6) Use any applicable fuel sampling and analysis methods in this paragraph (a)(6) to determine the high heat values. Alternatively, for gaseous fuels, the HHV may be calculated using chromatographic analysis together with standard heating values of the fuel constituents, provided that the gas chromatograph is operated, maintained, and calibrated according to the manufacturer's instructions.

(i) ASTM D4809-06 Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (Precision Method) (incorporated by reference, see §98.7).

(ii) ASTM D240-02 (Reapproved 2007) Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (incorporated by reference, see §98.7).

(iii) ASTM D1826-94 (Reapproved 2003) Standard Test Method for Calorific (Heating) Value of Gases in Natural Gas Range by Continuous Recording Calorimeter (incorporated by reference, see §98.7).

(iv) ASTM D3588-98 (Reapproved 2003) Standard Practice for Calculating Heat Value, Compressibility Factor, and Relative Density of Gaseous Fuels (incorporated by reference, see §98.7).

(v) ASTM D4891-89 (Reapproved 2006) Standard Test Method for Heating Value of Gases in Natural Gas Range by Stoichiometric Combustion (incorporated by reference, see §98.7).

(vi) GPA Standard 2172–09 Calculation of Gross Heating Value, Relative Density, Compressibility and Theoretical Hydrocarbon Liquid Content for Natural Gas Mixtures for Custody Transfer (incorporated by reference, see §98.7).

(vii) GPA Standard 2261–00, Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography (incorporated by reference, see §98.7).

(viii) ASTM D5865-07a, Standard Test Method for Gross Calorific Value of Coal and Coke (incorporated by reference, see §98.7).

(b) For the Tier 3 Calculation Methodology:

(1) Calibrate each oil and gas flow meter according to §98.3(i) and the provisions of paragraph (b).

(i) Perform calibrations using any of the test methods and procedures in this paragraph (b)(1)(i):

(A) An applicable flow meter test method listed in paragraphs (b)(4)(i) through (b)(4)(viii) of this section.

(B) The calibration procedures specified by the flow meter manufacturer.

(C) An industry-accepted or industry standard calibration practice.

(ii) In addition to the initial calibration required by §98.3(i), recalibrate each fuel flow meter (except for qualifying billing meters under paragraph (b)(1)(iii) of this section) either annually, at the minimum frequency specified by the manufacturer, or at the interval specified by the industry consensus standard practice used.

(iii) Fuel billing meters are exempted from the initial and ongoing calibration requirements of this paragraph, provided that the fuel supplier and the unit combusting the fuel do not have any common owners and are not owned by subsidiaries or affiliates of the same company.

(iv) For the initial calibration of an orifice, nozzle, or venturi meter; in-situ calibration of the transmitters is sufficient. A primary element inspection (PEI) shall be performed at least once every three years.

(v) For the continuously-operating units and processes described in §98.3(i)(6), the required flow meter recalibrations and, if necessary, the PEIs may be postponed until the next scheduled maintenance outage.

(vi) If a mixture of fuels is transported by a common pipe (e.g., still gas and supplementary natural gas), you must either separately meter each of the fuels prior to mixing using flow meters calibrated according to §98.3(i), or use flow meters calibrated according to §98.3(i) to measure the mixed fuel at the common pipe and to separately meter an appropriate subset of the fuels prior to mixing. If the latter option is chosen, quantify the fuels that are not measured prior to mixing by subtracting out the fuels measured prior to mixing from the fuel measured at the common pipe.

(2) Oil tank drop measurements (if used to determine liquid fuel use volume) shall be performed according to any an appropriate method published by a consensus-based standards organization (e.g., the American Petroleum Institute).

(3) The carbon content and, if applicable, molecular weight of the fuels shall be determined according to the procedures in paragraph (b)(3).

(i) All fuel samples shall be taken at a location in the fuel handling system that provides a sample representative of the fuel combusted. The fuel sampling and analysis may be performed by either the owner or operator or by the supplier of the fuel.

(ii) At a minimum, fuel samples shall be collected at the frequency specified in this paragraph. When sampling is required at a specified time interval (e.g., weekly, monthly, quarterly, or semiannually), fuel sampling and analysis is required for only those specified periods in which the unit operates.

(A) For natural gas, semiannual sampling and analysis is required (i.e., twice in a calendar year, with consecutive samples taken at least four months apart).

(B) For coal and fuel oil, analysis of at least one representative sample from each fuel lot is required. For the purposes of this section, a fuel lot is defined as a shipment or delivery of a single fuel (e.g., ship load, barge load, group of trucks, group of railroad cars, etc.).

(C) For other liquid fuels other than fuel oil, for fossil fuel-derived gaseous fuels, and for biogas; sampling and analysis is required at least once per calendar quarter. To the extent practicable, consecutive quarterly samples shall be taken at least 30 days apart.

(D) For solid fuels other than coal, weekly sampling is required to obtain composite samples, which are then analyzed monthly.

(E) For gaseous fuels other than natural gas and biogas (e.g., refinery gas), daily sampling and analysis to determine the carbon content and molecular weight of the fuel is required if the necessary equipment is in place to make these measurements. Otherwise, weekly sampling and analysis shall be performed. The equipment necessary to perform daily sampling and analysis of carbon content and molecular weight for refinery fuel gas must be installed no later than January 1, 2012.

(iii) If, for a particular type of fuel, sampling and analysis for carbon content and molecular weight is performed more often than the minimum frequency specified in paragraph (b)(3) of this section, the results of all valid fuel analyses shall be used in the GHG emission calculations.

(iv) If, for a particular type of fuel, sampling and analysis for carbon content and molecular weight is performed at less than the minimum frequency specifed in paragraph (b)(3) of this section, appropriate substitute data values shall be used in the emissions calculations, in accordance with the missing data procedures of §98.35.

(v) The procedures of paragraphs (a)(3) of this section apply to carbon content and molecular weight determinations.

(4) Use any applicable standard method from the following list to quality assure the data from each fuel flow meter.

(i) AGA Report No. 3, Orifice Metering of Natural Gas and Other Related Hydrocarbon Fluids, Part 1: General Equations and Uncertainty Guidelines (1990) and Part 2: Specification and Installation Requirements (2000)(incorporated by reference, see §98.7).

(ii) AGA Transmission Measurement Committee Report No. 7, Measurement of Gas by Turbine Meters (2006) (incorporated by reference, see §98.7).

(iii) ASME MFC-3M-2004 Measurement of Fluid Flow in Pipes Using Orifice, Nozzle, and Venturi (incorporated by reference, see §98.7).

(iv) ASME MFC-4M-1986 (Reaffirmed 1997), Measurement of Gas Flow by Turbine Meters (incorporated by reference, see §98.7).

(v) ASME MFC-5M-1985 (Reaffirmed 1994), Measurement of Liquid Flow in Closed Conduits Using Transit-Time Ultrasonic Flowmeters (incorporated by reference, see §98.7).

(vi) ASME MFC-6M-1998 Measurement of Fluid Flow in Pipes Using Vortex Flowmeters (incorporated by reference, see §98.7).

(vii) ASME MFC–7M–1987 (Reaffirmed 1992), Measurement of Gas Flow by Means of Critical Flow Venturi Nozzles (incorporated by reference, see §98.7).

(viii) ASME MFC–9M–1988 (Reaffirmed 2001), Measurement of Liquid Flow in Closed Conduits by Weighing Method (incorporated by reference, see §98.7).

(5) Use any applicable methods from the following list to determine the carbon content and molecular weight (for gaseous fuel) of the fuel. Alternatively, the results of chromatographic analysis of the fuel may be used, provided that the gas chromatograph is operated, maintained, and calibrated according to the manufacturer's instructions.

(i) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see §98.7).

(ii) ASTM D1946-90 (Reapproved 2006) Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see §98.7).

(iii) ASTM D2502-04 (Reapproved 2002) Standard Test Method for Estimation of Molecular Weight (Relative Molecular Mass) of Petroleum Oils from Viscosity Measurements (incorporated by reference, see §98.7).

(iv) ASTM D2503-92 (Reapproved 2007) Standard Test Method for Relative Molecular Mass (Relative Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure (incorporated by reference, see §98.7).

(v) ASTM D3238-95 (Reapproved 2005) Standard Test Method for Calculation of Carbon Distribution and Structural Group Analysis of Petroleum Oils by the n-d-M Method (incorporated by reference, see §98.7).

(vi) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, see §98.7).

(vii) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7).

(c) For the Tier 4 Calculation Methodology, the CO_2 and flow rate monitors must be certified prior to the applicable deadline specified in §98.33(b)(5).

(1) For initial certification, you may use any one of the following three procedures in this paragraph.

(i) §75.20(c)(2) and (4) and appendix A to 40 CFR part 75.

(ii) The calibration drift test and relative accuracy test audit (RATA) procedures of Performance Specification 3 in appendix B to part 60 (for the CO_2 concentration monitor) and Performance Specification 6 in appendix B to part 60 (for the continuous emission rate monitoring system (CERMS)).

(iii) The provisions of an applicable State continuous monitoring program.

(2) If an O_2 concentration monitor is used to determine CO_2 concentrations, the applicable provisions of 40 CFR part 75, 40 CFR part 60, or an applicable State continuous monitoring program shall be followed for initial certification and on-going quality assurance, and all required RATAs of the monitor shall be done on a percent CO_2 basis.

(3) For ongoing quality assurance, follow the applicable procedures in either appendix B to 40 CFR part 75, appendix F to 40 CFR part 60, or an applicable State continuous monitoring program. If appendix F to 40 CFR part 60 is selected for on-going quality assurance, perform daily calibration drift assessments for both the CO_2 monitor (or surrogate O_2 monitor) and the flow rate monitor, conduct cylinder gas audits of the CO_2 concentration monitor in three of the four quarters of each year (except for non-

operating quarters), and perform annual RATAs of the CO_2 concentration monitor and the CERMS.

(4) For the purposes of this part, the stack gas volumetric flow rate monitor RATAs required by appendix B to 40 CFR part 75 and the annual RATAs of the CERMS required by appendix F to 40 CFR part 60 need only be done at one operating level, representing normal load or normal process operating conditions, both for initial certification and for ongoing quality assurance.

(5) If, for any source operating hour, quality assured data are not obtained with a CO_2 monitor (or surrogate O_2 monitor), flow rate monitor, or (if applicable) moisture monitor, use appropriate substitute data values in accordance with the missing data provisions of §98.35.

(d) When municipal solid waste (MSW) is combusted in a unit, determine the biogenic portion of the CO_2 emissions from MSW combustion using ASTM D6866-08 Standard Test Methods for Determining the Biobased Content of Solid, Liquid, and Gaseous Samples Using Radiocarbon Analysis (incorporated by reference, see §98.7) and ASTM D7459-08 Standard Practice for Collection of Integrated Samples for the Speciation of Biomass (Biogenic) and Fossil-Derived Carbon Dioxide Emitted from Stationary Emissions Sources (incorporated by reference, see §98.7). Perform the ASTM

D7459-08 sampling and the ASTM D6866-08 analysis at least once in every calendar quarter in which MSW is combusted in the unit. Collect each gas sample during normal unit operating conditions while MSW is the only fuel being combusted for at least 24 consecutive hours or for as long as is necessary to obtain a sample large enough to meet the specifications of ASTM D6866-08. Separate CO_2 emissions into the biogenic and non-biogenic fraction using the average proportion of biogenic emissions of all samples analyzed during the reporting year. Express the results as a decimal fraction (e.g., 0.30, if 30 percent of the CO_2 from MSW combustion is biogenic). If there is a common fuel source of MSW that feeds multiple units at the facility, performing the testing at only one of the units is sufficient.

(e) For units that use CEMS to measure the total CO_2 mass emissions and combust a combination of biogenic fuels (other than MSW) with a fossil fuel, ASTM D6866-08 and ASTM D7459-08 may be used to determine the biogenic portion of the CO_2 emissions. Perform the ASTM D7459-08 sampling and the ASTM D6866-08 analysis at least once in every calendar quarter in which biogenic and non-biogenic fuels are co-fired in the unit. The relative proportions of the biogenic and non-biogenic fuels during the sampling shall be representative of the average fuel blend for a typical operating year. Collect each gas sample using ASTM D7459-08 during normal unit operation for at least 24 consecutive hours or for as long as is necessary to obtain a sample large enough to meet the specifications of ASTM D6866-08.

(f) Whenever company records are used in the calculation of CO_2 emissions, the records required under §98.3(g) shall include both the company records and an explanation of how those records are used to estimate the following parameters:

(1) Fuel consumption, when the Tier 1 and Tier 2 Calculation Methodologies are used.

(2) Fuel consumption, when solid fuel is combusted and the Tier 3 Calculation Methodology is used.

(3) Fossil fuel consumption when §98.33(e) applies to a unit that uses CEMS to quantify CO_2 emissions and that combusts both fossil and biomass fuels.

(4) Sorbent usage, when §98.33(d) applies.

(5) Quantity of steam generated by a unit when §98.33(a)(2) applies.

(6) Biogenic fuel consumption under §98.33(e)(5).

(g) As part of the GHG Monitoring Plan required under §98.3(g)(5), you must document the procedures used to ensure the accuracy of the estimates of fuel usage, sorbent usage, steam production, and boiler efficiency (as applicable) in paragraph (f) of this section, including but not limited to calibration of weighing equipment, fuel flow meters, steam flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices shall also be recorded, and the technical basis for these estimates shall be provided.

§98.35 Procedures for estimating missing data.

Required in U.S. jurisdictions only. Canadian jurisdictions may impose data substitution procedures that differ from the following.

Whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For all units subject to the requirements of the Acid Rain Program, and all other stationary combustion units subject to the requirements of this part that monitor and report emissions and heat input data in accordance with 40 CFR part 75, the missing data substitution procedures in 40 CFR part 75 shall be followed for CO_2 concentration, stack gas flow rate, fuel flow rate, high heating value, and fuel carbon content.

(b) For units that use the Tier 1, Tier 2, Tier 3, and Tier 4 Calculation Methodologies, perform missing data substitution as follows for each parameter:

(1) For each missing value of the high heating value, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the "after" value has not been obtained by the time that the GHG emissions report is due, you may use the "before" value for missing data substitution or the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production, operating hours). If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(2) For missing records of CO_2 concentration, stack gas flow rate, percent moisture, fuel usage, and sorbent usage, the substitute data value shall be the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production,

operating hours, etc.). You must document and retain records of the procedures used for all such estimates.

§98.36 Data reporting requirements.

Canadian jurisdictions may allow or require aggregation of emissions data up to the facility level.

(a) In addition to the facility-level information required under §98.3, the annual GHG emissions report shall contain the unit-level or process-level emissions data in paragraphs (b) through (d) of this section (as applicable) and the emissions verification data in paragraph (e) of this section.

(b) Units that use the four tiers. You shall report the following information for stationary combustion units that use the Tier 1, Tier 2, Tier 3, or Tier 4 methodology in §98.33(a) to calculate CO_2 emissions, except as otherwise provided in paragraphs (c) and (d) of this section:

(1) The unit ID number.

(2) A code representing the type of unit.

(3) Maximum rated heat input capacity of the unit, in mmBtu/hr for boilers and process heaters only and relevant units of measure for other combustion sources.

(4) Each type of fuel combusted in the unit during the report year.

(5) The tier used to calculate the CO_2 emissions for each type of fuel combusted (i.e., Tier 1, 2, 3, or 4).

(6) For a unit that uses Tiers 1, 2, and 3; the CO_2, CH_4, and N_2O emissions for each type of fuel combusted, expressed in metric tons of each gas and in metric tons of CO_2e.

(7) For a unit that uses Tier 4:

(i) For units that burn fossil fuels only, the annual CO_2 emissions for all fuels combined. Reporting CO_2 emissions by type of fuel is not required.

(ii) For units that burn both fossil fuels and biomass, the annual CO_2 emissions from combustion of all fossil fuels combined and the annual CO_2 emissions from combustion of all biomass fuels combined. Reporting CO_2 emissions by type of fuel is not required.

(iii) Annual CH_4 and N_2O emissions for each type of fuel combusted expressed in metric tons of each gas and in metric tons of CO_2e.

(8) Annual CO_2 emissions from sorbent (if calculated using Equation C-11 of this subpart), expressed in metric tons.

(9) Annual GHG emissions from all fossil fuels burned in the unit (i.e., the sum of the CO_2 , CH_4, and N_2O emissions), expressed in metric tons of CO_2e.

(10) Customer meter number for units that combust natural gas.

(11) For units that generate electricity, nameplate generating capacity (MW) and net power generated (MWh) during the reporting year.

(12) For each cogeneration unit, indicate whether topping or bottoming cycle and provide useful thermal output as applicable, in mmBtu. Where steam or heat is acquired from another facility for the generation of electricity, report the provider and amount of acquired steam or heat in mmBtu. Where supplemental firing has been applied to support electricity generation or industrial output, report this purpose and fuel consumption by fuel type using the following units:[7]

(i) For gases, report in units of million standard cubic feet.
(ii) For liquids, report in units of gallons.
(iii) For non-biomass solids, report in units of short tons.
(iv) For biomass-derived solid fuels, report in units of bone dry short tons.

(c) Reporting alternatives for units using the four Tiers. You may use any of the applicable reporting alternatives of this paragraph to simplify the unit-level reporting required under paragraph (b) of this section:

[7] Taken from WCI.42(b).

Subpart C—General Stationary Combustion

(1) Aggregation of units. If a facility contains two or more units (e.g., boilers or combustion turbines), each of which has a maximum rated heat input capacity of 250 mmBtu/hr or less, you may report the combined GHG emissions for the group of units in lieu of reporting GHG emissions from the individual units, provided that the use of Tier 4 is not required or elected for any of the units and the units use the same tier for any common fuels combusted. If this option is selected, the following information shall be reported instead of the information in paragraph (b) of this section:

(i) Group ID number, beginning with the prefix "GP".

(ii) An identification number for each unit in the group.

(iii) Cumulative maximum rated heat input capacity of the group (mmBtu/hr).

(iv) The highest maximum rated heat input capacity of any unit in the group (mmBtu/hr).

(v) Each type of fuel combusted in the group of units during the reporting year.

(vi) Annual CO_2, CH_4, and N_2O mass emissions aggregated for each type of fuel combusted in the group of units during the year, expressed in metric tons of each gas and in metric tons of CO_2e. If any of the units burn both fossil fuels and biomass, report also the annual CO_2 emissions from combustion of all fossil fuels combined and annual CO_2 emissions from combustion of all biomass fuels combined, expressed in metric tons.

(vii) The tier used to calculate the CO_2 mass emissions for each type of fuel combusted in the units (i.e., Tier 1, Tier 2, or Tier 3).

(viii) The calculated CO_2 mass emissions (if any) from sorbent.

(ix) Annual GHG emissions from all fossil fuels burned in the group (i.e., the sum of the CO_2 , CH_4, and N_2O emissions), expressed in metric tons of CO2e.

(2) Monitored common stack or duct configurations. When the flue gases from two or more stationary combustion units at a facility are discharged through a common stack or duct before exiting to the atmosphere and if CEMS are used to continuously monitor CO_2 mass emissions at the common stack or duct according to the Tier 4 Calculation Methodology, you may report the combined emissions from the units sharing the common stack or duct, in lieu of separately reporting the GHG emissions from the individual units. The following information shall be reported instead of the information in paragraph (b) of this section:

(i) Common stack or duct identification number, beginning with the prefix "CS".

(ii) Identification numbers of the units sharing the common stack or duct.

(iii) Maximum rated heat input capacity of each unit sharing the common stack or duct (mmBtu/hr).

(iv) Each type of fuel combusted in the units during the year.

(v) The methodology used to calculate the CO_2 mass emissions, i.e., Tier 4.

(vi) If the any of the units burn both fossil fuels and biomass, annual CO_2 mass emissions, annual CO_2 emissions from combustion of fossil fuels, and annual CO_2 emissions from combustion of biomass measured at the common stack or duct, expressed in metric tons.

(vii) The annual CH_4 and N_2O emissions from the units sharing the common stack or duct, expressed in metric tons of each gas and in metric tons of CO_2e.

(viii) Annual GHG emissions from all fossil fuels burned in the group (i.e., the sum of the CO_2 , CH_4, and N_2O emissions), expressed in metric tons of CO2e.

(3) <u>Common pipe configurations</u>. When two or more liquid-fired or gaseous-fired stationary combustion units at a facility combust the same type of fuel and the fuel is

fed to the individual units through a common supply line or pipe, you may report the combined emissions from the units served by the common supply line, in lieu of separately reporting the GHG emissions from the individual units, provided that the total amount of fuel combusted by the units is accurately measured at the common pipe or supply line using a fuel flow meter that is calibrated in accordance with §98.34(a). If a portion of the fuel measured at the common pipe is diverted to a chemical or industrial process where it is used but not combusted, you may subtract the diverted fuel from the fuel measured at the common pipe prior to performing the GHG emissions calculations, provided that the amount of fuel diverted is also measured with a calibrated flow meter per §98.3(i). If the common pipe option is selected, the applicable tier shall be used based on the maximum rated heat input capacity of the largest unit served by the common pipe configuration. The following information shall be reported instead of the information in paragraph (b) of this section:

(i) Common pipe identification number, beginning with the prefix “CP”.

(ii) The identification numbers of the units served by the common pipe.

(iii) Maximum rated heat input capacity of each unit served by the common pipe (mmBtu/hr).

(iv) The fuels combusted in the units during the reporting year.

(v) The methodology used to calculate the CO_2 mass emissions (i.e., Tier 1, Tier 2, or Tier 3).

(vi) If the any of the units burns both fossil fuels and biomass, the annual CO_2 mass emissions from combustion of all fossil fuels and annual CO_2 emissions from combustion of all biomass fuels from the units served by the common pipe, expressed in metric tons.

(vii) Annual CH_4 and N_2O emissions from the units served by the common pipe, expressed in metric tons of each gas and in metric tons of CO_2e.

(viii) Annual GHG emissions from all fossil fuels burned in units served by the common pipe (i.e., the sum of the CO_2, CH_4, and N_2O emissions), expressed in metric tons of CO_2e.

(d) Units subject to 40 CFR part 75.

(1) For stationary combustion units that are either subject to the Acid Rain Program or not in the Acid Rain Program but monitor and report CO_2 mass emissions year-round according to 40 CFR part 75, you shall report the following unit-level information:

(i) Unit or stack identification numbers. Use exact same unit, common stack, or multiple stack identification numbers that represent the monitored locations (e.g., 1, 2, CS001, MS1A, etc.) that are reported under §75.64 of this chapter.

(ii) Annual CO_2, CH_4, and N_2O emissions at each monitored location, expressed in metric tons of CO_2e.

(iii) Identification of the Part 75 methodology used to determine the CO_2 mass emissions.

(iv) Annual fuel consumption, if not reported under 40 CFR part 75.

(A) For gases, report in units of thousands of standard cubic feet.

(B) For liquids, report in units of gallons.

(C) For non-biomass solids, report in units of short tons.

(D) For biomass solid fuels, report in units of bone dry short tons or bone dry metric tons.

(v) Average carbon content of each fuel, if used to compute CO_2 emissions but not reported under 40 CFR part 75.

(vi) Average high heating value of each fuel, if used to compute CO_2 emissions but not reported under 40 CFR part 75.

(vii) For units that burn both fossil fuels and biomass, the annual CO2 emissions from combustion of all fossil fuels combined and the annual CO2 emissions from combustion of all biomass fuels combined. Reporting CO2 emissions by type of fuel is not required.

(viii) For units that generate electricity, nameplate generating capacity (MW) and net power generated (MWh) during the reporting year.

(ix) For each cogeneration unit, indicate whether topping or bottoming cycle and provide useful thermal output as applicable, in mmBtu. Where steam or heat is acquired from another facility for the generation of electricity, report the provider and amount of acquired steam or heat in mmBtu. Where supplemental firing has been applied to support electricity generation or industrial output, report this purpose and fuel consumption by fuel type using the units in WCI.42(b).

(2) For units that use the alternative CO_2 mass emissions calculation methods for units with continuous monitoring systems provided in §98.33(a)(5), you shall report the following unit-level information:

(i) Unit, stack, or pipe ID numbers. Use exact same unit, common stack, or multiple stack identification numbers that represent the monitored locations (e.g., 1, 2, CS001, MS1A, etc.) that are reported under §75.64 of this chapter.

(ii) For units that use the alternative methods specified in §98.33(a)(5)(i) and (ii) to monitor and report heat input data year-round according to appendix D to 40 CFR part 75 or 40 CFR 75.19:

(A) Each type of fuel combusted in the unit during the reporting year.

(B) The methodology used to calculate the CO_2 mass emissions for each fuel type.

(C) A code or flag to indicate whether heat input is calculated according to appendix D to 40 CFR part 75 or 40 CFR 75.19.

(D) Annual CO_2, CH_4, and N_2O emissions at each monitored location, across all fuel types, expressed in metric tons of CO_2e.

(iii) For units with continuous monitoring systems that use the alternative method for units with continuous monitoring systems in §98.33(a)(5)(iii) to monitor heat input year-round according to 40 CFR part 75:

(A) Fuel combusted during the reporting year.

(B) Methodology used to calculate the CO_2 mass emissions.

(C) A code or flag to indicate that the heat input data is derived from CEMS measurements.

(D) The total annual CO_2, CH_4, and N_2O emissions at each monitored location, expressed in metric tons of CO_2e.

(iv) The information required in paragraphs (d)(1)(iv) through (d)(1)(ix) of this section, as applicable.

(e) Verification data. You must keep on file, in a format suitable for inspection and auditing, sufficient data to verify the reported GHG emissions. This data and information must, where indicated in this paragraph (e), be included in the annual GHG emissions report.

(1) The applicable verification data specified in this paragraph (e) are not required to be kept on file or reported for units that meet any one of the three following conditions:

(i) Are subject to the Acid Rain Program.

(ii) Use the alternative methods for units with continuous monitoring systems provided in §98.33(a)(5).

(iii) Are not in the Acid Rain Program, but are required monitor and report CO_2 mass emissions and heat input data year-round, in accordance with 40 CFR part 75.

(2) For stationary combustion sources using the Tier 1, Tier 2, Tier 3, and Tier 4 Calculation Methodologies in

Subpart C—General Stationary Combustion

§98.33(a) to quantify CO_2 emissions, the following additional information shall be kept on file and included in the GHG emissions report, where indicated:

(i) For the Tier 1 Calculation Methodology, report the total quantity of each type of fuel combusted in the unit or group of aggregated units (as applicable) during the reporting year, in short tons for solid fuels, gallons for liquid fuels and standard cubic feet for gaseous fuels.

(ii) For the Tier 2 Calculation Methodology, report:

(A) The total quantity of each type of fuel combusted in the unit or group of aggregated units (as applicable) during each month of the reporting year. Express the quantity of each fuel combusted during the measurement period in short tons for solid fuels, gallons for liquid fuels, and scf for gaseous fuels.

(B) The frequency of the HHV determinations (e.g., once a month, once per fuel lot).

(C) The high heat values used in the CO_2 emissions calculations for each type of fuel combusted, in mmBtu per short ton for solid fuels, mmBtu per gallon for liquid fuels, and mmBtu per scf for gaseous fuels. Specify the date on which each fuel sample was taken. Indicate whether each HHV is a measured value of a substitute data value.

(D) If Equation C-2c of this subpart is used to calculate CO_2 mass emissions, report the total quantity (i.e., pounds) of steam produced from MSW or solid fuel combustion during the year, and the ratio of the maximum rate heat input capacity to the design rated steam output capacity of the unit, in mmBtu per lb of steam.

(iii) For the Tier 2 Calculation Methodology, keep records of the methods used to determine the HHV for each type of fuel combusted and the date on which each fuel sample was taken.

(iv) For the Tier 3 Calculation Methodology, report:

(A) The quantity of each type of fuel combusted in the unit or group of units (as applicable) during the year, in short tons for solid fuels, gallons for liquid fuels, and scf for gaseous fuels.

(B) The frequency of carbon content and, if applicable, molecular weight determinations for each type of fuel for the reporting year (e.g., daily, weekly, monthly, semiannually, once per fuel lot).

(C) The carbon content and, if applicable, gas molecular weight values used in the emission calculations (including both valid and substitute data values). Report all measured values if the fuel is sampled monthly or less frequently. Otherwise, for daily and weekly sampling, report monthly average values determined using the calculation procedures in Equation C-2b for each variable. Express carbon content as a decimal fraction for solid fuels, kg C per gallon for liquid fuels, and kg C per kg of fuel for gaseous fuels. Express the gas molecular weights in units of kg per kg-mole.

(D) The total number of valid carbon content determinations and, if applicable, molecular weight determinations made during the reporting year, for each fuel type.

(E) The number of substitute data values used for carbon content and, if applicable, molecular weight used in the annual GHG emissions calculations.

(v) For the Tier 3 Calculation Methodology, keep records of the following:

(A) For liquid and gaseous fuel combustion, the dates and results of the initial calibrations and periodic recalibrations of the required fuel flow meters.

(B) For fuel oil combustion, the method from §98.34(b) used to make tank drop measurements (if applicable).

(C) The methods used to determine the carbon content for each type of fuel combusted.

(D) The methods used to calibrate the fuel flow meters).

(vi) For the Tier 4 Calculation Methodology, report:

(A) The total number of source operating hours in the reporting year.

(B) The cumulative CO_2 mass emissions in each quarter of the reporting year, i.e., the sum of the hourly values calculated from Equation C-6 or C-7 of this subpart (as applicable), in metric tons.

(C) For CO_2 concentration, stack gas flow rate, and (if applicable) stack gas moisture content, the percentage of source operating hours in which a substitute data value of each parameter was used in the emissions calculations.

(vii) For the Tier 4 Calculation Methodology, keep records of:

(A) Whether the CEMS certification and quality assurance procedures of 40 CFR part 75, 40 CFR part 60, or an applicable State continuous monitoring program were used.

(B) The dates and results of the initial certification tests of the CEMS.

(C) The dates and results of the major quality assurance tests performed on the CEMS during the reporting year, i.e., linearity checks, cylinder gas audits, and relative accuracy test audits (RATAs).

(viii) If CO_2 emissions that are generated from acid gas scrubbing with sorbent injection are not captured using CEMS, report:

(A) The total amount of sorbent used during the report year, in short tons.

(B) The molecular weight of the sorbent.

(C) The ratio ("R") in Equation C-11 of this subpart.

(ix) For units that combust both fossil fuel and biomass, when CEMS are used to quantify the annual CO_2 emissions and biogenic CO_2 is determined according to §98.33(e)(2), you shall report the following additional information, as applicable:

(A) The annual volume of CO_2 emitted from the combustion of all fuels, i.e., V_{total}, in scf.

(B) The annual volume of CO_2 emitted from the combustion of fossil fuels, i.e., V_{ff}, in scf. If more than one type of fossil fuel was combusted, report the combustion volume of CO_2 for each fuel separately as well as the total.

(C) The annual volume of CO_2 emitted from the combustion of biomass, i.e., V_{bio}, in scf.

(D) The carbon-based F-factor used in Equation C-13 of this subpart, for each type of fossil fuel combusted, in scf CO_2 per mmBtu.

(E) The annual average HHV value used in Equation C-13 of this subpart, for each type of fossil fuel combusted, in Btu/lb, Btu/gal, or Btu/scf, as appropriate.

(F) The total quantity of each type of fossil fuel combusted during the reporting year, in lb, gallons, or scf, as appropriate.

(G) Annual biogenic CO_2 mass emissions, in metric tons.

(x) When ASTM methods D7459-08 and D6866-08 are used to determine the biogenic portion of the annual CO_2 emissions from MSW combustion, report:

(A) The results of each quarterly sample analysis, expressed as a decimal fraction (e.g., if the biogenic fraction of the CO_2 emissions from MSW combustion is 30 percent, report 0.30).

(B) Annual combined biomass and fossil fuel CO_2 emissions from MSW combustion, in metric tons of CO_2e.

(C) The quantities V_{ff}, V_{total}, and V_{MSW} from §98.33(e)(4)(ii), if CEMS are used to measure CO_2 emissions.

(D) The annual volume of biogenic CO_2 emissions from MSW combustion, in metric tons.

(xi) When ASTM methods D7459-08 and D6866-08 are used to determine the biogenic portion of the annual CO_2 emissions from a unit that co-fires biogenic (other than MSW) and non-biogenic fuels, you shall report the results of each quarterly sample analysis, expressed as a decimal fraction (e.g., if the biogenic fraction of the CO_2 emissions is 30 percent, report 0.30).

(3) Within ~~30~~20 days of receipt of a written request from the Administrator, you shall submit explanations of the following:

(i) An explanation of how company records are used to quantify fuel consumption, if the Tier 1 or Tier 2 Calculation Methodology is used to calculate CO_2 emissions.

(ii) An explanation of how company records are used to quantify fuel consumption, if solid fuel is combusted and the Tier 3 Calculation Methodology is used to calculate CO_2 emissions.

(iii) An explanation of how sorbent usage is quantified.

(iv) An explanation of how company records are used to quantify fossil fuel consumption in units that uses CEMS to quantify CO_2 emissions and combusts both fossil fuel and biomass.

(v) An explanation of how company records are used to measure steam production, when it is used to calculate CO_2 mass emissions under §98.33(a)(2)(iii) or to quantify solid fuel usage under §98.33(c)(3).

(4) Within ~~30~~20 days of receipt of a written request from the Administrator, you shall submit the verification data and information described in paragraphs (e)(2)(iii), (e)(2)(v), and (e)(2)(vii) of this section.

§98.37 Records That Must be Retained.

In addition to the requirements of §98.3(g), you must retain the applicable records specified in §§98.34(f) and (g), 98.35(b), and 98.36(e).

§98.38 Definitions.

Except as specified in this section, all~~All~~ terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

"Bottoming cycle plant" means a cogeneration plant in which the energy input to the system is first applied to a useful thermal energy application or process, and at least some of the reject heat emerging from the application or process is then used for electricity production.

"Cogeneration unit" means a stationary fuel combustion device which simultaneously generates electrical and thermal energy that is (i) used by the operator of the facility where the cogeneration unit is located; or (ii) transferred to another facility for use by that facility.

"Cogeneration system" means individual cogeneration components including the prime mover (heat engine), generator, heat recovery, and electrical interconnection, configured into an integrated system that provides sequential generation of multiple forms of useful energy (usually electrical and thermal), at least one form of which the facility consumes on-site or makes available to other users for an end-use other than electricity generation.

"Pipeline quality natural gas" means natural gas having a high heat value greater than 970 Btu/scf and equal to or less than 1,100 Btu/scf, and which is at least ninety percent methane by volume and less than five percent carbon dioxide by volume.

"Topping cycle plant" means a cogeneration plant in which the energy input to the plant is first used to produce electricity, and at least some of the reject heat from the electricity production process is then used to provide useful thermal output.

Canadian jurisdictions will substitute tables that contain Canada-specific emission factors for Tables C-1 and C-2 below:

Table C-1 of Subpart C—Default CO_2 Emission Factors and High Heat Values for Various Types of Fuel

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Coal and Coke	**mmBtu/short ton**	**kg CO_2 /mmBtu**
Anthracite	25.09	103.54
Bituminous	24.93	93.40
Subbituminous	17.25	97.02
Lignite	14.21	96.36
Coke	24.80	102.04
Mixed (Commercial sector)	21.39	95.26
Mixed (Industrial coking)	26.28	93.65
Mixed (Industrial sector)	22.35	93.91
Mixed (Electric Power sector)	19.73	94.38
Natural Gas	**mmBtu/scf**	**kg CO_2 /mmBtu**
Pipeline (Weighted U.S. Average)	1.028×10^{-3}	53.02
Petroleum Products	**mmBtu/gallon**	**kg CO_2 /mmBtu**
Distillate Fuel Oil No. 1	0.139	73.25
Distillate Fuel Oil No. 2	0.138	73.96
Distillate Fuel Oil No. 4	0.146	75.04
Residual Fuel Oil No. 5	0.140	72.93
Residual Fuel Oil No. 6	0.150	75.10
Still Gas	0.143	66.72
Kerosene	0.135	75.20
Liquefied petroleum gases (LPG)	0.092	62.98
Propane	0.091	61.46
Propylene	0.091	65.95
Ethane	0.096	62.64
Ethylene	0.100	67.43
Isobutane	0.097	64.91
Isobutylene	0.103	67.74
Butane	0.101	65.15
Butylene	0.103	67.73
Naphtha (<401 deg F)	0.125	68.02
Natural Gasoline	0.110	66.83
Other Oil (>401 deg F)	0.139	76.22
Pentanes Plus	0.110	70.02
Petrochemical Feedstocks	0.129	70.97
Petroleum Coke	0.143	102.41
Special Naphtha	0.125	72.34
Unfinished Oils	0.139	74.49
Heavy Gas Oils	0.148	74.92
Lubricants	0.144	74.27
Motor Gasoline	0.125	70.22
Aviation Gasoline	0.120	69.25

Subpart C—General Stationary Combustion

Table C-1 of Subpart C—Default CO_2 Emission Factors and High Heat Values for Various Types of Fuel

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Kerosene-Type Jet Fuel	0.135	72.22
Asphalt and Road Oil	0.158	75.36
Crude Oil	0.138	74.49
Fossil Fuel-derived Fuels (Solid)	**mmBtu/short ton**	**kg CO_2 /mmBtu**
Municipal Solid Waste[1]	9.95	90.7
Tires	26.87	85.97
Fossil Fuel-derived Fuels (Gaseous)	**mmBtu/scf**	**kg CO_2 /mmBtu**
Blast Furnace Gas	0.092×10^{-3}	274.32
Coke Oven Gas	0.599×10^{-3}	46.85
Biomass Fuels - Solid	**mmBtu/short Ton**	**kg CO_2 /mmBtu**
Wood and Wood Residuals	15.38	93.80
Agricultural Byproducts	8.25	118.17
Peat	8.00	111.84
Solid Byproducts	25.83	105.51
Biomass Fuels - Gaseous	**mmBtu/scf**	**kg CO_2 /mmBtu**
Biogas (Captured methane)	0.841×10^{-3}	52.07
Biomass Fuels - Liquid	**mmBtu/gallon**	**kg CO_2 /mmBtu**
Ethanol (100%)	0.084	68.44
Biodiesel (100%)	0.128	73.84
Rendered Animal Fat	0.125	71.06
Vegetable Oil	0.120	81.55

[1]Allowed only for units that do not generate steam and use Tier 1.

Table C-1a of Subpart C—Fuels for which Tier 1 or Tier 2 Calculation Methodologies May Be Used

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Petroleum Products	**mmBtu/gallon**	**kg CO_2 /mmBtu**
Distillate Fuel Oil No. 1	0.139	73.25
Distillate Fuel Oil No. 2	0.138	73.96
Distillate Fuel Oil No. 4	0.146	75.04
Kerosene	0.135	75.20
Liquefied petroleum gases (LPG)[8]	0.092	62.98
Propane	0.091	61.46
Propylene	0.091	65.95
Ethane	0.096	62.64
Ethylene	0.100	67.43
Isobutane	0.097	64.91
Isobutylene	0.103	67.74
Butane	0.101	65.15
Butylene	0.103	67.73

[8] Commercially sold as "propane", including grades such as HD5.

Table C-1a of Subpart C—Fuels for which Tier 1 or Tier 2 Calculation Methodologies May Be Used

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Natural Gasoline	0.110	66.83
Motor Gasoline	0.125	70.22
Aviation Gasoline	0.120	69.25
Kerosene-Type Jet Fuel	0.135	72.22

Table C-2 of Subpart C—Default CH_4 and N_2O Emission Factors for Various Types of Fuel.

Fuel Type	Default CH_4 Emission Factor (kg CH_4 /mmBtu)	Default N_2O Emission Factor (kg N_2O/mmBtu)
Coal and Coke (All fuel types in Table C-1)	1.1×10^{-2}	1.6×10^{-03}
Natural Gas	1.0×10^{-03}	1.0×10^{-04}
Petroleum (All fuel types in Table C-1)	3.0×10^{-03}	6.0×10^{-04}
Municipal Solid Waste	3.2×10^{-02}	4.2×10^{-03}
Tires	3.2×10^{-02}	4.2×10^{-03}
Blast Furnace Gas	2.2 x 10-05	1.0×10^{-04}
Coke Oven Gas	4.8 x 10-04	1.0×10^{-04}
Biomass Fuels - Solid (All fuel types in Table C-1)	3.2×10^{-02}	4.2×10^{-03}
Biogas	3.2×10^{-03}	6.3×10^{-04}
Biomass Fuels – Liquid (All fuel types in Table C-1)	1.1×10^{-03}	1.1×10^{-04}

Note: Those employing this table are assumed to fall under the IPCC definitions of the "Energy Industry" or "Manufacturing Industries and Construction". In all fuels except for coal the values for these two categories are identical. For coal combustion, those who fall within the IPCC "Energy Industry" category may employ a value of 1 g of CH_4/MMBtu.

[1]Allowed only for units that do not generate steam and use Tier 1.

Table C-2 of Subpart C—Default CH_4 and N_2O Emission Factors for Various Types of Fuel.

Fuel Type	Default CH_4 Emission Factor (kg CH_4 /mmBtu)	Default N_2O Emission Factor (kg N_2O/mmBtu)
Coal and Coke (All fuel types in Table C-1)	1.1×10^{-2}	1.6×10^{-03}
Natural Gas	1.0×10^{-03}	1.0×10^{-04}
Petroleum (All fuel types in Table C-1)	3.0×10^{-03}	6.0×10^{-04}
Municipal Solid Waste	3.2×10^{-02}	4.2×10^{-03}
Tires	3.2×10^{-02}	4.2×10^{-03}
Blast Furnace Gas	2.2×10^{-05}	1.0×10^{-04}
Coke Oven Gas	4.8×10^{-04}	1.0×10^{-04}

Fuel Type	Default CH_4 Emission Factor (kg CH_4 /mmBtu)	Default N_2O Emission Factor (kg N_2O/mmBtu)
Biomass Fuels - Solid (All fuel types in Table C-1)	3.2×10^{-02}	4.2×10^{-03}
Biogas	3.2×10^{-03}	6.3×10^{-04}
Biomass Fuels – Liquid (All fuel types in Table C-1)	1.1×10^{-03}	1.1×10^{-04}

Note: Those employing this table are assumed to fall under the IPCC definitions of the "Energy Industry" or "Manufacturing Industries and Construction". In all fuels except for coal the values for these two categories are identical. For coal combustion, those who fall within the IPCC "Energy Industry" category may employ a value of 1 g of CH_4/MMBtu.

Subpart D—Electricity Generation

§98.40 Definition of the source category.

(a) The electricity generation source category comprises electricity generating units that are subject to the requirements of the Acid Rain Program and any other electricity generating units that are required to monitor and report to EPA CO_2 emissions year-round according to 40 CFR part 75.

(b) This source category does not include portable equipment, emergency equipment, or emergency generators, as defined in §98.6.[1]

§98.41 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains one or more electricity generating units and the facility meets the requirements of §98.2(a)(1).

§98.42 GHGs to report[2].

(a) For each electricity generating unit that is subject to the requirements of the Acid Rain Program or is otherwise required to monitor and report to EPA CO_2 emissions year-round according to 40 CFR part 75, you must

[1] Retain for U.S. rules. Canadians will decide whether or not to retain for their jurisdictions.

[2] Reporting of fugitive CO2 by geothermal facilities is in the ERMRs but not in the MRR. Flag for Partners decision on whether or not to retain reporting by geothermal facilities. If geothermal is retained, it may be clearer to publish the requirement as a separate WCI subpart rather than be included in MRR subpart D.

report under this subpart the annual mass emissions of CO_2, N_2O, and CH_4 by following the requirements of this subpart.

(b) For each electricity generating unit that is not subject to the Acid Rain Program or otherwise required to monitor and report to EPA CO_2 emissions year-round according to 40 CFR part 75, you must report under subpart C of this part (General Stationary Fuel Combustion Sources) the emissions of CO_2, CH_4, and N_2O by following the requirements of subpart C.

(c) For each stationary fuel combustion unit that does not generate electricity, you must report under subpart C of this part (General Stationary Fuel Combustion Sources) the emissions of CO_2, CH_4, and N_2O by following the requirements of subpart C of this part.

§98.43 Calculating GHG emissions.

Continue to monitor and report CO_2 mass emissions as required under §75.13 or section 2.3 of apppendix G to 40 CFR part 75, and §75.64. Calculate CO_2, CH_4, and N_2O emissions as follows:

(a) Convert the cumulative annual CO_2 mass emissions reported in the fourth quarter electronic data report required under §75.64 from units of short tons to metric tons. To convert tons to metric tons, divide by 1.1023.

(b) Calculate and report annual CH_4 and N_2O mass emissions under this subpart by following the applicable method specified in §98.33(c).

§98.44 Monitoring and QA/QC requirements

Follow the applicable quality assurance procedures for CO_2 emissions in appendices B, D, and G to 40 CFR part 75.

§98.45 Procedures for estimating missing data.

Follow the applicable missing data substitution procedures in 40 CFR part 75 for CO_2 concentration, stack gas flow rate, fuel flow rate, high heating value, and fuel carbon content.

§98.46 Data reporting requirements.

The annual report shall comply with the data reporting requirements specified in §98.36(d~~b~~)[3] and, if applicable, §98.36(c)(2) or (c)(3).

§98.47 Records that must be retained.

You shall comply with the recordkeeping requirements of §§98.3(g) and 98.37.

§98.48 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

[3] This corrects an error in the MRR that EPA is in the process of correcting.

Subpart F—Aluminum Production

§98.60 Definition of the source category.

(a) A primary aluminum production facility manufactures primary aluminum using the Hall-Héroult manufacturing process. The primary aluminum manufacturing process comprises the following operations:

(1) Electrolysis in prebake and Søderberg cells.

(2) Anode baking for prebake cells.

(b) This source category does not include experimental cells or research and development process units.

§98.61 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains an aluminum production process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.62 GHGs to report.

You must report:

(a) Perfluoromethane (CF_4), and perfluoroethane (C_2F_6) emissions from anode effects in all prebake and Søderberg electolysis cells.

(b) CO_2 emissions from anode consumption during electrolysis in all prebake and Søderberg electolysis cells.

(c) CO_2 emissions from on-site anode baking.

(d) You must report under subpart C of this part (General Stationary Fuel Combustion Sources) the emissions of CO_2, N_2O, and CH_4 emissions from each stationary fuel combustion unit by following the requirements of subpart C.

§98.63 Calculating GHG emissions.

(a) The annual value for PFC emissions shall be estimated from the sum of monthly values using Equation F-1 of this section:

$$E_{PFC} = \sum_{m=1}^{m=12} E_m \qquad \text{(Eq. F-1)}$$

Where:

E_{PFC} = Annual PFC emissions from aluminum production (metric tons PFC).

E_m = PFC emissions from aluminum production for the month “m” (metric tons PFC).

(b) Use Equation F-2 of this section to estimate CF_4 emissions from anode effect duration or Equation F-3 of this section to estimate CF_4 emissions from overvoltage, and use Equation F-4 of this section to estimate C_2F_6 emissions from anode effects from each prebake and Søderberg electolysis cell.

$$E_{CF4} = S_{CF4} \times AEM \times MP \times 0.001 \qquad \text{(Eq. F-2)}$$

Where:

E_{CF4} = Monthly CF_4 emissions from aluminum production (metric tons CF_4).

S_{CF4} = The slope coefficient ((kg CF_4/metric ton Al)/(AE-Mins/cell-day)).

AEM = The anode effect minutes per cell-day (AE-Mins/cell-day).

MP = Metal production (metric tons Al), where AEM and MP are calculated monthly.

$$E_{CF4} = EF_{CF4} \times MP \times 0.001 \qquad \text{(Eq. F-3)}$$

Where:

E_{CF4} = Monthly CF_4 emissions from aluminum production (metric tons CF_4).

EF_{CF4} = The overvoltage emission factor (kg CF_4/metric ton Al).

MP = Metal production (metric tons Al), where MP is calculated monthly.

$$E_{C2F6} = E_{CF4} \times F_{C2F6/CF4} \times 0.001 \qquad \text{(Eq. F-4)}$$

Where:

E_{C2F6} = Monthly C_2F_6 emissions from aluminum production (metric tons C_2F_6).

E_{CF4} = CF_4 emissions from aluminum production(kg CF_4).

$F_{C2F6/CF4}$ = The weight fraction of C_2F_6/CF_4 (kg C_2F_6/kg CF_4).

0.001 = Conversion factor from kg to metric tons, where E_{CF4} is calculated monthly.

(c) You must calculate and report the annual process CO_2 emissions from anode consumption during electrolysis and anode baking of prebake cells using either the procedures in paragraph (d) of this section or the procedures in paragraphs (e) and (f) of this section.

(d) Calculate and report under this subpart the process CO_2 emissions by operating and maintaining CEMS according to the Tier 4 Calculation Methodology in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(e) Use the following procedures to calculate CO_2 emissions from anode consumption during electrolysis:

(1) For Prebake cells: you must calculate CO_2 emissions from anode consumption using Equation F-5 of this section:[1]

$$E_{CO2} = NAC \times MP \times ([100 - S_a - Ash_a] / 100) \times (44/12) \quad \text{(Eq. F-5)}$$

Where:

E_{CO2}	=	Annual CO_2 emissions from prebaked anode consumption (metric tons CO_2).
NAC	=	Net annual prebaked anode consumption per metric ton Al (metric tons C/metric tons Al).
MP	=	Annual metal production (metric tons Al).
S_a	=	Sulfur content in baked anode (percent weight).
Ash_a	=	Ash content in baked anode(percent weight).
44/12	=	Ratio of molecular weights, CO_2 to carbon.

(2) For Søderberg cells you must calculate CO_2 emissions using Equation F-6 of this section:[2]

$$E_{CO2} = (PC \times MP - [CSM \times MP] / 1000 - BC / 100 \times PC \times MP \times [S_p + Ash_p + H_p] / 100 - [100 - BC] / 100 \times PC \times MP \times [S_c + Ash_c] / 100 - MP \times CD) \times (44/12) \quad \text{(Eq. F-6)}$$

Where:

E_{CO2}	=	Annual CO_2 emissions from paste consumption (metric ton CO_2).
PC	=	Annual paste consumption (metric ton/metric ton Al).
MP	=	Annual metal production (metric ton Al).

---

[1]The WCI equivalents for equations F-5, F-6 and F-8 in the existing ERs for aluminum production include a deduction for impurities in the baked anode, pitch and packing coke respectively. Allowing such a deduction, however, would be inconsistent with harmonization, since it would require reporting different amounts for these processes to EPA and the WCI. WCI solicits stakeholder input on the significance of this omission.

[2]WCI discussed removing the factor for carbon removed as skimmed dust (CD) since it is not included in the WCI methodology. It has been retained to assure harmonization.

CSM = Annual emissions of cyclohexane soluble matter (kg/metric ton Al).

BC = Binder content of paste (percent weight).

S_p = Sulfur content of pitch (percent weight).

Ash_p = Ash content of pitch (percent weight).

H_p = Hydrogen content of pitch (percent weight).

S_c = Sulfur content in calcined coke (percent weight).

Ash_c = Ash content in calcined coke (percent weight).

CD = Carbon in skimmed dust from Søderberg cells (metric ton C/metric ton Al).

44/12 = Ratio of molecular weights, CO_2 to carbon.

(e) Use the following procedures to calculate CO_2 emissions from anode baking of prebake cells:

(1) Use Equation F-7 of this section to calculate emissions from pitch volatiles combustion.

$$E_{CO2PV} = (GA - H_w - BA - WT) \times (44/12) \qquad \text{(Eq. F-7)}$$

Where:

E_{CO2PV} = Annual CO_2 emissions from pitch volatiles combustion (metric tons CO_2).

GA = Initial weight of green anodes (metric tons).

H_w = Annual hydrogen content in green anodes (metric tons).

BA = Annual baked anode production (metric tons).

WT = Annual waste tar collected (metric tons).

44/12 = Ratio of molecular weights, CO_2 to carbon.

(2) Use Equation F-8 of this section to calculate emissions from bake furnace packing material.

$$E_{CO2PC} = PCC \times BA \times ([100 - S_{pc} - Ash_{pc}] / 100) \times (44/12) \qquad \text{(Eq. F-8)}$$

Where:

E_{CO2PC} = Annual CO_2 emissions from bake furnace packing material (metric tons CO_2).

PCC = Annual packing coke consumption (metric tons/metric ton baked anode).

BA = Annual baked anode production (metric tons).
S_{pc} = Sulfur content in packing coke (percent weight).
Ash_{pc} = Ash content in packing coke (percent weight).
44/12 = Ratio of molecular weights, CO_2 to carbon.

(f) If process CO_2 emissions from anode consumption during electrolysis or anode baking of prebake cells are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part (General Stationary Fuel Combustion Sources), then the calculation methodology in paragraphs (d) and (e) of this section shall not be used to calculate those process emissions. The owner or operation shall report under this subpart the combined stack emissions according to the Tier 4 Calculation Methodology in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

§98.64 Monitoring and QA/QC requirements.

(a) Effective one year after publication of the rule for smelters with no prior measurement or effective three years after publication for facilities with historic measurements, the smelter-specific slope coefficients used in Equations F-2, F-3, and F-4 of this subpart must be measured in accordance with the recommendations of the

Subpart F—Aluminum Production

EPA/IAI Protocol for Measurement of Tetrafluoromethane (CF_4) and Hexafluoroethane (C_2F_6) Emissions from Primary Aluminum Production (2008), except the minimum frequency of measurement shall be every ~~10 years~~ 36 months ~~unless~~ and when a change occurs in the control algorithm that affects the mix of types of anode effects or the nature of the anode effect termination routine or when changes occur in the distribution or duration of anode effects (i.e., when the percentage of manual kills changes or if the number of anode effects decreases and results in a fewer number of longer anode effects) or for Rio Tinto Alcan control technology (i.e., when the algorithm for bridge movements and anode effect overvoltage accounting changes). Facilities which operate at less than 0.2 anode effect minutes per cell day or operate with less than 1.4mV anode effect overvoltage ~~can~~ must use ~~either~~ smelter-specific slope coefficients ~~or the technology specific default values in Table F-1 of this subpart~~.

(b) The minimum frequency of the measurement and analysis is ~~annually except as follows: Monthly – anode effect minutes per cell day (or anode effect overvoltage and current efficiency), production~~monthly.

(c) Sources ~~may~~ must use ~~either~~ smelter-specific values from annual measurements of parameters needed to complete the equations in §98.63 (e.g., sulfur, ash, and hydrogen contents)~~ or the default values shown in Table F-2 of this subpart~~.

§98.65 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required sample measurement is not taken), a substitute data value for the missing parameter shall be used in the calculations, according to the following requirements:

(a) Where anode or paste consumption data are missing, CO_2 emissions can be estimated from aluminum production using Tier 1 method per Equation F-8 of this section.

$$ECO_2 = EF_p \times MP_p + EF_s \times MP_s \qquad \text{(Eq. F-8)}$$

Where:

ECO_2 = CO_2 emissions from anode and/or paste consumption, metric tons CO_2.

EF_p = Prebake technology specific emission factor (1.6 metric tons CO_2/metric ton aluminum produced).

MP_p = Metal production from prebake process (metric tons Al).

EF_s = Søderberg technology specific emission factor (1.7 metric tons CO_2/metric ton Al produced).

MP_s = Metal production from Søderberg process (metric tons Al).

(b) For other parameters, use the average of the two most recent data points after the missing data.

§98.66 Data reporting requirements.

In addition to the information required by §98.3(c), you must report the following information at the facility level:

(a) Annual aluminum production in metric tons.

(b) Type of smelter technology used.

(c) The following PFC-specific information on an annual basis:

(1) Perfluoromethane emissions and perfluoroethane emissions from anode effects in all prebake and all Søderberg electolysis cells combined.

(2) Anode effect minutes per cell-day (AE-mins/cell-day), anode effect frequency (AE/cell-day), anode effect duration (minutes). (Or anode effect overvoltage factor ((kg CF_4/metric ton Al)/(mV/cell day)), potline overvoltage (mV/cell day), current efficiency (%).)

(3) Smelter-specific slope coefficients (or overvoltage emission factors) and the last date when the smelter-specific-slope coefficients (or overvoltage emission factors) were measured.

(d) Method used to measure the frequency and duration of anode effects (or overvoltage).

(e) The following CO_2-specific information for prebake cells:

(1) Annual anode consumption.

(2) Annual CO_2 emissions from the smelter.

(f) The following CO_2-specific information for Søderberg cells:

(1) Annual paste consumption.

(2) Annual CO_2 emissions from the smelter.

(g) Smelter-specific inputs to the CO_2 process equations (e.g., levels of sulfur and ash) that were used in the calculation, on an annual basis.

(h) Exact data elements required will vary depending on smelter technology (e.g., point-feed prebake or Søderberg) and process control technology (e.g., Pechiney or other).

§98.67 Records that must be retained.

In addition to the information required by §98.3(g), you must retain the following records:

(a) Monthly aluminum production in metric tons.

(b) Type of smelter technology used.

(c) The following PFC-specific information on a monthly basis:

Subpart F—Aluminum Production

(1) Perfluoromethane and perfluoroethane emissions from anode effects in prebake and Søderberg electolysis cells.

(2) Anode effect minutes per cell-day (AE-mins/cell-day), anode effect frequency (AE/cell-day), anode effect duration (minutes). (Or anode effect overvoltage factor ((kg CF_4/metric ton Al)/(mV/cell day)), potline overvoltage (mV/cell day), current efficiency (%).))

(3) Smelter-specific slope coefficients and the last date when the smelter-specific-slope coefficients were measured.

(d) Method used to measure the frequency and duration of anode effects (or to measure anode effect overvoltage and current efficiency).

(e) The following CO_2-specific information for prebake cells:

(1) Annual anode consumption.

(2) Annual CO_2 emissions from the smelter.

(f) The following CO_2-specific information for Søderberg cells:

(1) Annual paste consumption.

(2) Annual CO_2 emissions from the smelter.

(g) Smelter-specific inputs to the CO_2 process equations (e.g., levels of sulfur and ash) that were used in the calculation, on an annual basis.

(h) Exact data elements required will vary depending on smelter technology (e.g., point-feed prebake or Søderberg) and process control technology (e.g., Pechiney or other).

§98.68 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Table F-1 of Subpart F—Slope and Overvoltage Coefficients for the Calculation of PFC Emissions from Aluminum Production

Technology	**CF_4 Slope Coefficient [(kg CF_4/metric ton Al)/(AE-Mins/cell-day)]**	**CF_4 Overvoltage Coefficient [(kg CF_4/metric ton Al)/(mV)]**	**Weight Fraction C_2F_6/CF_4 [(kg C_2F_6/kg CF_4)]**
CWPB	0.143	1.16	0.121
SWPB	0.272	3.65	0.252
VSS	0.092	NA	0.053
HSS	0.099	NA	0.085

Table F-2 of Subpart F—Default Data Sources for Parameters Used for CO_2 Emissions

CO_2 Emissions from Prebake Cells (CWPB and SWPB)	
Parameter	Data Source
MP: metal production (metric tons Al)	Individual facility records
NAC: net annual prebaked anode consumption per metric ton Al (metric tons C/metric tons Al)	Individual facility records
S_a: sulfur content in baked	2.0

anode (percent weight)	
Ash_a: ash content in baked anode(percent weight)	0.4
CO_2 Emissions from Søderberg Cells (VSS and HSS)	
Parameter	Data Source
MP: metal production (metric tons Al)	Individual facility records
PC: annual paste consumption (metric ton/metric ton Al)	Individual facility records
CSM: annual emissions of cyclohexane soluble matter (kg/metric ton Al)	HSS: 4.0 VSS: 0.5
BC: binder content of paste (percent weight)	Dry Paste: 24 Wet Paste: 27
S_p: sulfur content of pitch (percent weight)	0.6
Ash_p: ash content of pitch (percent weight)	0.2
H_p: hydrogen content of pitch (percent weight)	3.3
S_c: sulfur content in calcined coke (percent weight)	1.9
Ash_c: ash content in calcined coke (percent weight)	0.2
CD: carbon in skimmed dust from Søderberg cells (metric ton C/metric ton Al)	0.01
CO_2 Emissions from Pitch Volatiles Combustion (VSS and HSS)	
Parameter	Data Source
GA: initial weight of green anodes (metric tons)	Individual facility records
H_w: annual hydrogen content in green anodes (metric tons)	0.005 × GA
BA: annual baked anode production (metric tons)	Individual facility records
WT: annual waste tar collected (metric tons) (a) Riedhammer furnaces (b) all other furnaces	(a) 0.005 × GA (b) insignificant
CO_2 Emissions from Bake Furnace Packing Materials (CWPB	

and SWPB)	
Parameter	Data Source
PCC: annual packing coke consumption (metric tons/metric ton baked anode)	0.015
BA: annual baked anode production (metric tons)	Individual facility records
S_{pc}: sulfur content in packing coke (percent weight)	2
Ash_{pc}: ash content in packing coke (percent weight)	2.5

Subpart N—Glass Production

§98.140 Definition of the source category.

(a) A glass manufacturing facility manufactures flat glass, container glass, pressed and blown glass, or wool fiberglass by melting a mixture of raw materials to produce molten glass and form the molten glass into sheets, containers, fibers, or other shapes. A glass manufacturing facility uses one or more continuous or batch glass melting furnaces to produce glass.[1]

(b) A glass melting furnace that is an experimental furnace or a research and development process unit is not subject to this subpart.

§98.141 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a glass production process and the facility meets the requirements of either §98.2(a)(1) or (2).

§98.142 GHGs to report.

You must report:

(a) CO_2 process emissions from each continuous or batch glass melting furnace.

[1]EPA's definition of a glass manufacturing facility is limited to only continuous glass melting furnaces. WCI has requested that batch furnaces be included as well. Expanded definition included in §98.140(a). All references in Subpart N to "continuous glass melting furnace" have been changed to "continuous or batch glass melting furnace" or "continuous and batch glass melting furnace", depending upon the specific text.

(b) CO_2 combustion emissions from each continuous or batch glass melting furnace.

(c) CH_4 and N_2O combustion emissions from each continuous or batch glass melting furnace. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(d) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit other than continuous or batch glass melting furnaces. You must report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

§98.143 Calculating GHG emissions.

You must calculate and report the annual process CO_2 emissions from each continuous or batch glass melting furnace using the procedure in paragraphs (a) and (b) of this section.

(a) For each continuous or batch glass melting furnace that meets the conditions specified in §98.33(b)(4)(ii) or (iii), you must calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(b) For each continuous or batch glass melting furnace that is not subject to the requirements in paragraph (a) of this section, calculate and report the process and combustion CO_2 emissions from the glass melting furnace by using either the procedure in paragraph (b)(1) of this section or the procedure in paragraphs (b)(2) through (b)(7) of this section, except as specified in paragraph (c) of this section.

(1) Calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(2) Calculate and report the process and combustion CO_2 emissions separately using the procedures specified in paragraphs (b)(2)(i) through (b)(2)(vi) of this section.

(i) For each carbonate-based raw material charged to the furnace, obtain from the supplier of the raw material the carbonate-based mineral mass fraction.

(ii) Determine the quantity of each carbonate-based raw material charged to the furnace.

(iii) Apply the appropriate emission factor for each carbonate-based raw material charged to the furnace, as shown in Table N-1 to this subpart.

(iv) Use Equation N-1 of this section to calculate process mass emissions of CO_2 for each furnace:

$$E_{CO2} = \sum_{i=1}^{n} MF_i \bullet (M_i \bullet \frac{2000}{2205}) \bullet EF_i \bullet F_i \qquad \text{(Eq. N-1)}$$

Where:

E_{CO2}	=	Process emissions of CO_2 from the furnace (metric tons).
n	=	Number of carbonate-based raw materials charged to furnace.
MF_i	=	Annual average mass fraction of carbonate-based mineral i in carbonate-based raw material i (percentage, expressed as a decimal).
M_i	=	Annual amount of carbonate-based raw material i charged to furnace (tons).
2000/2205	=	Conversion factor to convert tons to metric tons.
EF_i	=	Emission factor for carbonate-based raw material i (metric ton CO_2 per metric ton carbonate-based raw material as shown in Table N-1 to this subpart).
F_i	=	Fraction of calcination achieved for carbonate-based raw material i, assumed to be equal to 1.0 (percentage, expressed as a decimal).

(v) You must calculate the total process CO_2 emissions from continuous and batch glass melting furnaces at the facility using Equation N-2 of this section:

$$CO_2 = \sum_{i=1}^{k} E_{CO_2 i} \qquad \text{(Eq. N-2)}$$

Where:

CO_2 = Annual process CO_2 emissions from glass manufacturing facility (metric tons).

E_{CO2i} = Annual CO_2 emissions from glass melting furnace i (metric tons).

k = Number of continuous and batch glass melting furnaces.

(vi) Calculate and report under subpart C of this part (General Stationary Fuel Combustion Sources) the combustion CO_2 emissions in the glass furnace according to the applicable requirements in subpart C.

(c) As an alternative to data provided by the raw material supplier, a value of 1.0 can be used for the mass fraction (MF_i) of carbonate-based mineral i in Equation N-1 of this section.

§98.144 Monitoring and QA/QC requirements.

(a) You must measure annual amounts of carbonate-based raw materials charged to each continuous or batch glass melting furnace from monthly measurements using plant instruments used for accounting purposes, such as calibrated scales or weigh hoppers. Total annual mass charged to glass melting furnaces at the facility shall be compared to records of raw material purchases for the year.

(b) You must measure carbonate-based mineral mass fractions at least annually to verify the mass fraction data provided by the supplier of the raw material; such measurements shall be based on sampling and chemical analysis conducted by a certified laboratory using ASTM D3682-01 (Reapproved 2006) Standard Test Method for Major and Minor Elements in Combustion Residues from Coal Utilization Processes (incorporated by reference, see §98.7).

(c) You must determine the annual average mass fraction for the carbonate-based mineral in each carbonate-based raw material by calculating an arithmetic average of the monthly data obtained from raw material suppliers or sampling and chemical analysis.

(d) You must determine on an annual basis the calcination fraction for each carbonate consumed based on sampling and chemical analysis using an industry consensus standard. This chemical analysis must be conducted using an x-ray fluorescence test or other enhanced testing method published by an industry consensus standards organization (e.g., ASTM, ASME, API, etc.).

§98.145 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., carbonate raw materials consumed, etc.). If the monitoring and quality assurance procedures in §98.144 cannot be followed and data is missing, you must use the most appropriate of the missing data procedures in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such missing value estimates.

(a) For missing data on the monthly amounts of carbonate-based raw materials charged to any continuous or batch glass melting furnace use the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes, such as purchase records.

(b) For missing data on the mass fractions of carbonate-based minerals in the carbonate-based raw materials assume that the mass fraction of each carbonate based mineral is 1.0.

§98.146 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information specified in paragraphs (a) and (b) of this section, as applicable.

Subpart N—Glass Production

(a) If a CEMS is used to measure CO_2 emissions, then you must report under this subpart the relevant information required under §98.37 for the Tier 4 Calculation Methodology and the following information specified in paragraphs (a)(1) and (a)(2) of this section:

(1) Annual quantity of each carbonate-based raw material charged to each continuous or batch glass melting furnace and for all furnaces combined (tons).

(2) Annual quantity of glass produced (tons).

(b) If a CEMS is not used to determine CO_2 emissions from continuous or batch glass melting furnaces, and process CO_2 emissions are calculated according to the procedures specified in §98.143(b), then you must report the following information as specified in paragraphs (b)(1) through (b)(9) of this section:

(1) Annual process emissions of CO_2 (metric tons) for each continuous or batch glass melting furnace and for all furnaces combined.

(2) Annual quantity of each carbonate-based raw material charged (tons) to each continuous or batch glass melting furnace and for all furnaces combined.

(3) Annual quantity of glass produced (tons) from each continuous or batch glass melting furnace and from all furnaces combined.

(4) Carbonate-based mineral mass fraction (percentage, expressed as a decimal) for each carbonate-based raw material charged to a continuous or batch glass melting furnace.

(5) Results of all tests used to verify the carbonate-based mineral mass fraction for each carbonate-based raw material charged to a continuous or batch glass melting furnace, as specified in paragraphs (b)(5)(i) through (b)(5)(iii) of this section.

(i) Date of test.

(ii) Method(s) and any variations used in the analyses.

(iii) Mass fraction of each sample analyzed.

(6) The fraction of calcination achieved for each carbonate-based raw material, if a value other than 1.0 is used to calculate process mass emissions of CO_2.

(7) Method used to determine fraction of calcination (percentage, expressed as a decimal).

(8) Total number of continuous or batch glass melting furnaces.

(9) The number of times in the reporting year that missing data procedures were followed to measure monthly quantities of carbonate-based raw materials any continuous

or batch glass melting furnace or mass fraction of the carbonate-based minerals (months).

§98.147 Records that must be retained.

In addition to the information required by §98.3(g), you must retain the records listed in paragraphs (a), (b), and (c) of this section.

(a) If a CEMS is used to measure emissions, then you must retain the records required under §98.37 for the Tier 4 Calculation Methodology and the following information specified in paragraphs (a)(1) and (a)(2) of this section:

(1) Monthly glass production rate for each continuous or batch glass melting furnace (tons).

(2) Monthly amount of each carbonate-based raw material charged to each continuous or batch glass melting furnace (tons).

(b) If process CO_2 emissions are calculated according to the procedures specified in §98.143(b), you must retain the records in paragraphs (b)(1) through (b)(5) of this section.

(1) Monthly glass production rate for each continuous or batch glass melting furnace (metric tons).

(2) Monthly amount of each carbonate-based raw material charged to each continuous or batch glass melting furnace (metric tons).

(3) Data on carbonate-based mineral mass fractions provided by the raw material supplier for all raw materials consumed annually and included in calculating process emissions in Equation N-1 of this subpart.

(4) Results of all tests used to verify the carbonate-based mineral mass fraction for each carbonate-based raw material charged to a continuous or batch glass melting furnace, including the data specified in paragraphs (b)(4)(i) through (b)(4)(v) of this section.

(i) Date of test.

(ii) Method(s), and any variations of the methods, used in the analyses.

(iii) Mass fraction of each sample analyzed.

(iv) Relevant calibration data for the instrument(s) used in the analyses.

(v) Name and address of laboratory that conducted the tests.

(5) The fraction of calcination achieved for each carbonate-based raw material (percentage, expressed as a decimal), if a value other than 1.0 is used to calculate process mass emissions of CO_2.

(c) All other documentation used to support the reported GHG emissions.

§98.148 Definitions.

Subpart N—Glass Production

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Table N-1 of Subpart N—CO_2 Emission Factors for Carbonate-Based Raw Materials

Carbonate-Based Raw Material – Mineral	CO_2 Emission Factor[a]
Limestone – $CaCO_3$	0.440
Dolomite – $CaMg(CO_3)_2$	0.477
Sodium carbonate/soda ash – Na_2CO_3	0.415

[a] Emission factors in units of metric tons of CO_2 emitted per metric ton of carbonate-based raw material charged to the furnace.

Subpart P—Hydrogen Production

§98.160 Definition of the source category.

(a) A hydrogen production source category consists of facilities that produce hydrogen gas for use onsite or sold as a product to other entities.

(b) This source category comprises process units that produce hydrogen by reforming, gasification, oxidation, reaction, or other transformations of feedstocks.

(c) This source category includes merchant hydrogen production facilities located within a petroleum refinery if they are not owned by, or under the direct control of, the refinery owner and operator.

§98.161 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a hydrogen production process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.162 GHGs to report.

You must report:

(a) CO_2 process emissions from each hydrogen production process unit.

(b) CO_2, CH_4 and N_2O combustion emissions from each hydrogen production process unit. You must calculate and report these combustion emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(c) CO_2, CH_4, and N_2O emissions from each stationary combustion unit other than hydrogen production process units. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(d) For CO_2 collected and transferred off site, you must follow the requirements of subpart PP of this part.

§98.163 Calculating GHG emissions.

You must calculate and report the annual process CO_2 emissions from each hydrogen production process unit using the procedures specified in either paragraph (a) or (b) of this section.

(a) Continuous Emissions Montoring Systems (CEMS). Calculate and report under this subpart the process CO_2 emissions by operating and maintaining CEMS according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(b) Fuel and feedstock material balance approach. Calculate and report process CO_2 emissions as the sum of the annual emissions associated with each fuel and feedstock used for hydrogen production by following paragraphs (b)(1) through (b)(3) of this section.

(1) Gaseous fuel and feedstock. You must calculate the annual CO_2 process emissions from gaseous fuel and feedstock according to Equation P-1 of this section:

$$CO_2 = \left(\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n * \frac{MW}{MVC}\right) * 0.001 \quad \text{(Eq. P-1)}$$

Where:

CO_2	=	Annual CO_2 process emissions arising from fuel and feedstock consumption (metric tons/yr).
$Fdstk_n$	=	Volume of the gaseous fuel and feedstock used in month n(scf (at standard conditions of 68 °F and atmospheric pressure) of fuel and feedstock).
CC_n	=	Weighted ~~A~~average carbon content of the gaseous fuel and feedstock, from the results of one or more analyses for month n for natural gas or from daily analysis for gasseous feedstocks other than natural gas(kg carbon per kg of fuel and feedstock).
MW	=	Molecular weight of the gaseous fuel and feedstock (kg/kg-mole).
MVC	=	Molar volume conversion factor (849.5 scf per kg-mole at standard conditions).
k	=	Months in the year.
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to metric tons.

(2) Liquid fuel and feedstock. You must calculate the annual CO_2 process emissions from liquid fuel and feedstock according to Equation P-2 of this section:

$$CO_2 = (\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n) * 0.001 \qquad \text{(Eq. P-2)}$$

Where:

CO_2 = Annual CO_2 emissions arising from fuel and feedstock consumption (metric tons/yr).

$Fdstk_n$ = Volume of the liquid fuel and feedstock used in month n (gallons of fuel and feedstock).

CC_n = Weighted a~~A~~verage carbon content of the liquid fuel and feedstock, from the results of daily ~~one or more~~ sampling~~analyses~~ for month n (kg carbon per gallon of fuel and feedstock). Daily liquid samples may be combined to generate a monthly composite sample for carbon analysis.

k = Months in the year.

44/12 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to metric tons.

(3) Solid fuel and feedstock. You must calculate the annual CO_2 process emissions from solid fuel and feedstock according to Equation P-3 of this section:

$$CO_2 = \sum_{n=1}^{k} \frac{44}{12} * (Fdstk_n * CC_n) * 0.001 \qquad \text{(Eq.P-3)}$$

Where:

CO_2 = Annual CO_2 emissions from fuel and feedstock consumption in metric tons per year (metric tons/yr).

$Fdstk_n$ = Mass of solid fuel and feedstock used in month n (kg of fuel and feedstock).

CC_n = Weighted ~~A~~average carbon content of the solid fuel and feedstock, from the results of daily~~one or more~~ sampling~~analyses~~ for month n (kg carbon per kg of fuel and feedstock). Daily solid samples may be combined to generate a monthly composite sample for carbon analysis.

k = Months in the year.

44/12 = Ratio of molecular weights, CO_2 to carbon.
0.001 = Conversion factor from kg to metric tons.

(c) If GHG emissions from a hydrogen production process unit are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part (General Stationary Fuel Combustion Sources), then the calculation methodology in paragraph (b) of this section shall not be used to calculate process emissions. The owner or operator shall report under this subpart the combined stack emissions according to the Tier 4 Calculation Methodology in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

§98.164 Monitoring and QA/QC requirements.

The GHG emissions data for hydrogen production process units must be quality-assured as specified in paragraphs (a) or (b) of this section, as appropriate for each process unit:

(a) If a CEMS is used to measure GHG emissions, then the facility must comply with the monitoring and QA/QC procedures specified in §98.34(c).

(b) If a CEMS is not used to measure GHG emissions, then you must:

(1) Calibrate all oil and gas flow meters (except for gas billing meters), solids weighing equipment, and oil tank drop measurements (if used to determine liquid fuel and feedstock use volume) according to the calibration accuracy requirements in §98.3(i) of this part .

(2) Determine the carbon content and the molecular weight monthly ~~annually~~ for ~~of standard gaseous hydrocarbon fuels and feedstocks having consistent composition (e.g.,~~ natural gas~~)~~. For other gaseous fuels and feedstocks (e.g., biogas, refinery gas, or process gas), daily ~~weekly~~ sampling and analysis is required to determine the carbon content and molecular weight of the fuel and feedstock.

(3) Determine the carbon content of fuel oil, naphtha, and other liquid fuels and feedstocks at least ~~monthly~~daily~~,~~. ~~except annually for standard liquid hydrocarbon fuels and feedstocks having consistent composition, or upon delivery for liquid fuels delivered by bulk transport (e.g., by truck or rail).~~ Daily weighted liquid samples may be combined to generate a monthly composite sample for carbon analysis.

(4) Determine the carbon content of coal, coke, and other solid fuels and feedstocks at least ~~monthly,~~daily

~~except annually for standard solid hydrocarbon fuels and feedstocks having consistent composition, or upon delivery for solid fuels delivered by bulk transport (e.g., by truck or rail)~~. Daily weighted solid samples may be combined to generate a monthly composite sample for carbon analysis.

(5) You must use the following applicable methods to determine the carbon content for all fuels and feedstocks, and molecular weight of gaseous fuels and feedstocks.

(i) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see §98.7).

(ii) ASTM D1946-90 (Reapproved 2006), Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see §98.7).

(iii) ASTM D2013-07 Standard Practice of Preparing Coal Samples for Analysis (incorporated by reference, see §98.7).

(iv) ASTM D2234/D2234M-07 Standard Practice for Collection of a Gross Sample of Coal (incorporated by reference, see §98.7).

(v) ASTM D2597-94 (Reapproved 2004) Standard Test Method for Analysis of Demethanized Hydrocarbon Liquid Mixtures Containing Nitrogen and Carbon Dioxide by Gas Chromatography (incorporated by reference, see §98.7).

(vi) ASTM D3176-89 (Reapproved 2002), Standard Practice for Ultimate Analysis of Coal and Coke (incorporated by reference, see §98.7).

(vii) ASTM D3238-95 (Reapproved 2005), Standard Test Method for Calculation of Carbon Distribution and Structural Group Analysis of Petroleum Oils by the n-d-M Method (incorporated by reference, see §98.7).

(viii) ASTM D4057-06 Standard Practice for Manual Sampling of Petroleum and Petroleum Products (incorporated by reference, see §98.7).

(ix) ASTM D4177-95 (Reapproved 2005) Standard Practice for Automatic Sampling of Petroleum and Petroleum Products (incorporated by reference, see §98.7).

(x) ASTM D5291-02 (Reapproved 2007), Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, see §98.7).

(xi) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7).

(xii) ASTM D6609-08 Standard Guide for Part-Stream Sampling of Coal (incorporated by reference, see §98.7).

(xiii) ASTM D6883-04 Standard Practice for Manual Sampling of Stationary Coal from Railroad Cars, Barges, Trucks, or Stockpiles (incorporated by reference, see §98.7).

(xiv) ASTM D7430-08ae1 Standard Practice for Mechanical Sampling of Coal (incorporated by reference, see §98.7).

(xv) ASTM UOP539-97 Refinery Gas Analysis by Gas Chromatography (incorporated by reference, see §98.7).

(xvi) GPA 2261–00 Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography (incorporated by reference, see §98.7).

(xvii) ISO 3170: Petroleum Liquids -- Manual sampling – Third Edition (incorporated by reference, see §98.7).

(xviii) ISO 3171: Petroleum Liquids -- Automatic pipeline sampling – Second Edition (incorporated by reference, see §98.7).

(c) For units using the calculation methodologies described in this section, the records required under §98.3(g) must include both the company records and a detailed explanation of how company records are used to estimate the following:

(1) Fuel and feedstock consumption, when solid fuel and feedstock is combusted and a CEMS is not used to measure GHG emissions.

(2) Fossil fuel consumption, when, pursuant to §98.33(e), the owner or operator of a unit that uses CEMS to quantify CO_2 emissions and that combusts both fossil and biogenic fuels separately reports the biogenic portion of the total annual CO_2 emissions.

(3) Sorbent usage, if the methodology in §98.33(d) is used to calculate CO_2 emissions from sorbent.

(d) The owner or operator must document the procedures used to ensure the accuracy of the estimates of fuel and feedstock usage and sorbent usage (as applicable) in paragraph (b) of this section, including, but not limited to, calibration of weighing equipment, fuel and feedstock flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices must also be recorded, and the technical basis for these estimates must be provided.

<u>§98.165 Procedures for estimating missing data.</u>

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation), a substitute data value for the missing parameter must be used in the calculations as specified in paragraphs (a), (b), and (c) of this section:

(a) For each missing value of the monthly fuel and feedstock consumption, the substitute data value must be the best available estimate of the fuel and feedstock consumption, based on all available process data (e.g., hydrogen production, electrical load, and operating hours). You must document and keep records of the procedures used for all such estimates.

(b) For each missing value of the carbon content or molecular weight of the fuel and feedstock, the substitute data value must be the arithmetic average of the quality-assured values of carbon contents or molecular weight of the fuel and feedstock immediately preceding and immediately following the missing data incident. If no quality-assured data on carbon contents or molecular weight of the fuel and feedstock are available prior to the missing data incident, the substitute data value must be the first quality-assured value for carbon contents or molecular weight of the fuel and feedstock obtained after the missing data period. You must document and keep records of the procedures used for all such estimates.

(c) For missing CEMS data, you must use the missing data procedures in §98.35.

§98.166 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information specified in paragraphs (a) or (b) of this section, as appropriate:

(a) If a CEMS is used to measure CO_2 emissions, then you must report the relevant information required under §98.36 for the Tier 4 Calculation Methodology and the following information in this paragraph (a):

(1) Unit identification number and annual CO_2 process emissions.

(2) Annual quantity of hydrogen produced (metric tons) for each process unit and for all units combined.

(3) Annual quantity of ammonia produced (metric tons), if applicable, for each process unit and for all units combined.

(b) If a CEMS is not used to measure CO_2 emissions, then you must report the following information for each hydrogen production process unit:

(1) Unit identification number and annual CO_2 process emissions (2) Monthly consumption of each fuel and feedstock used for hydrogen production and its type (scf of

gaseous fuels and feedstocks, gallons of liquid fuels and feedstocks, kg of solid fuels and feedstocks).

(3) Annual quantity of hydrogen produced (metric tons).

(4) Annual quantity of ammonia produced, if applicable (metric tons).

(5) Monthly or daily analyses of carbon content for each fuel and feedstock used in hydrogen production (kg carbon/kg of gaseous and solid fuels and feedstocks, (kg carbon per gallon of liquid fuels and feedstocks).

(6) Monthly or daily analyses of the molecular weight of gaseous fuels and feedstocks (kg/kg-mole) used, if any.~~.~~

(7) Amount of carbon in unconverted feedstock for which GHG emissions are calculated and reported by your facility using other calculation methods provided in this regulation. For example, carbon in waste diverted to a fuel system or flare, where the CO_2 and CH_4 emissions are calculated and reported using other methods provided in this regulation. (metric tons CO_2e/year).

(c) Quarterly quantity of CO_2 collected and transferred off site in either gas, liquid, or solid forms (kg), following the requirements of subpart PP of this part.

(d) Annual quantity of carbon other than CO_2 collected and transferred off site in either gas, liquid, or solid forms (kg carbon).

§98.167 Records that must be retained.

In addition to the information required by §98.3(g), you must retain the records specified in paragraphs (a) through (b) of this section for each hydrogen production facility.

(a) If a CEMS is used to measure CO_2 emissions, then you must retain under this subpart the records required for the Tier 4 Calculation Methodology in §98.37.

(b) If a CEMS is not used to measure CO_2 emissions, then you must retain records of all analyses and calculations conducted as listed in §§98.166(b), (c), and (d).

§98.168 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Subpart Y—Petroleum Refineries

§98.250 Definition of Source Category.

(a) A petroleum refinery is any facility engaged in producing gasoline, gasoline blending stocks, naphtha, kerosene, distillate fuel oils, residual fuel oils, lubricants, or asphalt (bitumen) through distillation of petroleum or through redistillation, cracking, or reforming of unfinished petroleum derivatives, except as provided in paragraph (b) of this section.

(b) For the purposes of this subpart, facilities that distill only pipeline transmix (off-spec material created when different specification products mix during pipeline transportation) are not petroleum refineries, regardless of the products produced.

(c) This source category consists of the following sources at petroleum refineries: catalytic cracking units; fluid coking units; delayed coking units; catalytic reforming units; coke calcining units; asphalt blowing operations; blowdown systems; storage tanks; process equipment components (compressors, pumps, valves, pressure relief devices, flanges, and connectors) in gas service; marine vessel, barge, tanker truck, and similar loading operations; flares; sulfur recovery plants; and non-merchant hydrogen plants (i.e., hydrogen plants that are owned or under the direct control of the refinery owner and operator).

Subpart Y—Petroleum Refineries

§98.251 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a petroleum refineries process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.252 GHGs to report.

You must report:

(a) CO_2, CH_4, and N_2O combustion emissions from stationary combustion units and from each flare. Calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C, except for CO_2 emissions from combustion of refinery fuel gas. For CO_2 emissions from combustion of fuel gas, use either equation C-5 in subpart C of this part or the Tier 4 methodology in subpart C of this part. You may aggregate units, monitor common stacks, or monitor common (fuel) pipes as provided in §98.36(c) when calculating and reporting emissions from stationary combustion units.

(b) CO_2, CH_4, and N_2O coke burn-off emissions from each catalytic cracking unit, fluid coking unit, and catalytic reforming unit under this subpart.

(c) CO_2 emissions from sour gas sent off site for sulfur recovery operations under this subpart. You must follow the calculation methodologies from §98.253(f)and the monitoring and

QA/QC methods, missing data procedures, reporting requirements, and recordkeeping requirements of this subpart.

(d) CO_2 process emissions from each on-site sulfur recovery plant under this subpart.

(e) CO_2, CH_4, and N_2O emissions from each coke calcining unit under this subpart.

(f) CO_2 and CH_4 emissions from asphalt blowing operations under this subpart.

(g) CH_4 emissions from equipment leaks, storage tanks, loading operations, delayed coking units, and uncontrolled blowdown systems under this subpart.

(h) CO_2, CH_4, and N_2O emissions from each process vent not specifically included in paragraphs (a) through (g) of this section under this subpart.

(i) CO_2 and CH_4 emissions from non-merchant hydrogen production under this subpart. You must follow the calculation methodologies, monitoring and QA/QC methods, missing data procedures, reporting requirements, and recordkeeping requirements of subpart P of this part.

§98.253 Calculating GHG emissions.

(a) Calculate GHG emissions required to be reported in §98.252(b) through (i) using the applicable methods in paragraphs (b) through (n) of this section.

(b) For flares, calculate GHG emissions according to the requirements in paragraphs (b)(1) through (b)(3) of this section.

(1) Calculate the CO_2 emissions according to the applicable requirements in paragraphs (b)(1)(i) through (b)(1)(iii) of this section.

(i) Flow measurement. If you have a continuous flow monitor on the flare, you must use the measured flow rates when the monitor is operational and the flow rate is within the calibrated range of the measurement device to calculate the flare gas flow. If you do not have a continuous flow monitor on the flare and for periods when the monitor is not operational or the flow rate is outside the calibrated range of the measurement device, you must use engineering calculations, company records, or similar estimates of volumetric flare gas flow.

(ii) Heat value or carbon content measurement. If you have a continuous higher heating value monitor or gas composition monitor on the flare or if you monitor these parameters at least weekly, you must use the measured heat value or carbon content value in calculating the CO_2 emissions from the flare using the applicable methods in paragraphs (b)(1)(ii)(A) and (b)(1)(ii)(B).

(A) If you monitor gas composition, calculate the CO_2 emissions from the flare using Equation Y-1 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation Y-1 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[\frac{44}{12} \times (Flare)_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right) \qquad \text{(Eq.Y-1)}$$

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
n	=	Number of measurement periods. The minimum value for n is 52 (for weekly measurements); the maximum value for n is 366 (for daily measurements during a leap year).
p	=	Measurement period index.
44	=	Molecular weight of CO_2 (kg/kg-mole).
12	=	Atomic weight of C (kg/kg-mole).
$(Flare)_p$	=	Volume of flare gas combusted during measurement period (standard cubic feet per period, scf/period). If a mass flow meter is used, measure flare gas flow rate in kg/period and replace the term "$(MW)_p$/MVC" with "1".
$(MW)_p$	=	Average molecular weight of the flare gas combusted during measurement period (kg/kg-mole). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.
MVC	=	Molar volume conversion factor (849.5 scf/kg-mole).
$(CC)_p$	=	Average carbon content of the flare gas combusted during measurement period (kg C per kg flare gas). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.

(B) If you monitor heat content but do not monitor gas composition, calculate the CO_2 emissions from the flare using Equation Y-2 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation Y-2 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \sum_{p=1}^{n} \left[(Flare)_p \times (HHV)_p \times EmF \right] \qquad \text{(Eq.Y-2)}$$

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
n	=	Number of measurement periods. The minimum value for n is 52 (for weekly measurements); the maximum value for n is 366 (for daily measurements during a leap year).
p	=	Measurement period index.
$(Flare)_p$	=	Volume of flare gas combusted during measurement period (million (MM) scf/period). If a mass flow meter is used, you must also measure molecular weight and convert the mass flow to a volumetric flow as follows: Flare[MMscf] = 0.000001 × Flare[kg] × MVC/$(MW)_p$, where MVC is the molar volume conversion factor (849.5 scf/kg-mole) and $(MW)_p$ is the average molecular weight of the flare gas combusted during measurement period (kg/kg-mole).
$(HHV)_p$	=	Higher heating value for the flare gas combusted during measurement period (British thermal units per scf, Btu/scf = MMBtu/MMscf). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.
EmF	=	Default CO_2 emission factor of 60 kilograms CO_2/MMBtu (HHV basis).

(iii) Alternative Method for Startup, Shutdown, and Malfunctions~~to heat value or carbon content measurements~~. For startup, shutdown, and malfunctions during which you were unable to measure the parameters required by Equations Y-1 and Y-2 of this section, ~~If you do not measure the~~ you must ~~higher heating value or carbon content of the flare gas at least weekly,~~ determine the quantity of gas discharged to the flare separately for each ~~periods of routine flare operation and for periods of~~ start-up, shutdown, or malfunction, and calculate the CO_2 emissions as specified in paragraphs (b)(1)(iii)(A) ~~through~~ and (b)(1)(iii)(C) of this section.

(A) For periods of start-up, shutdown, or malfunction, use engineering calculations and process knowledge to estimate the carbon content of the flared gas for each start-up, shutdown, or malfunction event. ~~exceeding 500,000 scf/day.~~

(B) ~~For periods of normal operation, use the average heating value measured for the fuel gas for the heating value of the flare gas. If heating value is not measured, the heating value may be estimated from historic data or engineering calculations.~~

Reserved.

(C) Calculate the CO_2 emissions using Equation Y-3 of this section.

$$\cancel{CO_2 = 0.98 \times 0.001 \times \left(Flare_{Norm} \times HHV \times EmF + \sum_{p=1}^{n} \left[\frac{44}{12} \times (Flare_{SSM})_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right)}$$ ~~(Eq.Y-3)~~

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[\frac{44}{12} \times (Flare_{SSM})_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right)$$ (Eq.Y-3)[1]

Where:

CO_2	=	Annual CO_2 emissions for a specific fuel type (metric tons/year).
0.98	=	Assumed combustion efficiency of a flare.
0.001	=	Unit conversion factor (metric tons per kilogram, mt/kg).
~~$Flare_{Norm}$~~	~~=~~	~~Annual volume of flare gas combusted during normal operations from company records, (million (MM) standard cubic feet per year, MMscf/year).~~
~~HHV~~	~~=~~	~~Higher heating value for fuel gas or flare gas from company records (British thermal units per scf, Btu/scf = MMBtu/MMscf).~~
~~EmF~~	~~=~~	~~Default CO_2 emission factor for flare gas of 60 kilograms CO_2/MMBtu (HHV basis).~~
n	=	Number of start-up, shutdown, and malfunction events during the reporting year exceeding 500,000 scf/day.
p	=	Start-up, shutdown, and malfunction event index.
44	=	Molecular weight of CO_2 (kg/kg-mole).
12	=	Atomic weight of C (kg/kg-mole).
$(Flare_{SSM})_p$	=	Volume of flare gas combusted during indexed start-up, shutdown, or malfunction event from engineering calculations, (scf/event).
$(MW)_p$	=	Average molecular weight of the flare gas, from the analysis results or engineering calculations for the event (kg/kg-mole).
MVC	=	Molar volume conversion factor (849.5 scf/kg-mole).

[1] Equation Y-3 was revised to delete the factors used to calculate CO_2 emissions during normal operation of the flare. For normal operation of flares, ERMR proposes that CO_2 emissions be calcualted using either Equation Y-1 or Y-2.

$(CC)_p$ = Average carbon content of the flare gas, from analysis results or engineering calculations for the event (kg C per kg flare gas).

(2) Calculate CH_4 using Equation Y-4 of this section.

$$CH_4 = \left(CO_2 \times \frac{EmF_{CH4}}{EmF}\right) + CO_2 \times \frac{0.02}{0.98} \times \frac{16}{44} \times f_{CH4} \qquad \text{(Eq. Y-4)}$$

Where:

CH_4	=	Annual methane emissions from flared gas (metric tons CH_4/year).
CO_2	=	Emission rate of CO_2 from flared gas calculated in paragraph (b)(1) of this section (metric tons/year).
EmF_{CH4}	=	Default CH_4 emission factor for "PetroleumProducts" from Table C-2 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CH_4/MMBtu).
EmF	=	Default CO_2 emission factor for flare gas of 60 kg CO_2/MMBtu (HHV basis).
0.02/0.98	=	correction factor for flare combustion efficiency.
16/44	=	correction factor ratio of the molecular weight of CH_4 to CO_2
f_{CH4}	=	Weight fraction of carbon in the flare gas prior to combustion that is contributed by methane from measurement values or engineering calculations (kg C in methane in flare gas/kg C in flare gas); default is 0.4.

(3) Calculate N_2O emissions using Equation Y-5 of this section.

$$N_2O = \left(CO_2 \times \frac{EmF_{N2O}}{EmF}\right) \qquad \text{(Eq. Y-5)}$$

Where:

N_2O = Annual nitrous oxide emissions from flared gas (metric tons N_2O/year).

CO_2 = Emission rate of CO_2 from flared gas calculated in paragraph (b)(1) of this section (metric tons/year).

EmF_{N2O} = Default N_2O emission factor for "PetroleumProducts" from Table C-2 of subpart C of this part (General Stationary Fuel Combustion Sources)(kg N_2O/MMBtu).

EmF = Default CO_2 emission factor for flare gas of 60 kg CO_2/MMBtu (HHV basis).

(c) For catalytic cracking units and traditional fluid coking units, calculate the GHG emissions using the applicable methods described in paragraphs (c)(1) through (c)(5) of this section.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part (General Stationary Fuel Combustion Sources), you must calculate and report CO_2 emissions as provided in paragraphs (c)(1)(i) and (c)(1)(ii) of this section. Other catalytic cracking units and traditional fluid coking units must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part (General Stationary Combustion Souces), or follow the requirements of paragraphs (c)(2) or (3) of this section.

(i) Calculate CO_2 emissions by following the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(ii) If a CO boiler or other post-combustion device is used, you must also calculate the CO_2 emissions from the fuel fired to the CO boiler or post-combustion device using the applicable methods for stationary combustion units in subpart C of this part. Calculate the process emissions from the catalytic cracking unit or fluid coking unit as the difference in the CO_2 CEMS emissions and the calculated combustion emissions associated with the CO boiler.

(2) For catalytic cracking units and fluid coking units ~~with rated capacities greater than 10,000 barrels per stream day (bbls/sd)~~ that do not use a continuous CO_2 CEMS for the final exhaust stack, you must continuously or no less frequently than hourly monitor the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels and calculate the CO_2 emissions according to the requirements of paragraphs (c)(2)(i) through (c)(2)(iii) of this section:

(i) Calculate the CO_2 emissions from each catalytic cracking unit and fluid coking unit using Equation Y-6 of this section.

$$CO_2 = \sum_{p=1}^{n}\left[(Q_r)_p \times \frac{(\%CO_2 + \%CO)_p}{100\%} \times \frac{44}{MVC} \times 0.001\right] \qquad \text{(Eq. Y-6)}$$

Where:

CO_2 = Annual CO_2 mass emissions (metric tons/year).

Q_r = Volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels (dry standard cubic feet per hour, dscfh).

$\%CO_2$ = Hourly average percent CO_2 concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis).

$\%CO$ = Hourly average percent CO concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis). When there is no post-combustion device, assume %CO to be zero.

44 = Molecular weight of CO_2 (kg/kg-mole).

MVC = Molar volume conversion factor (849.5 scf/kg-mole).

0.001 = Conversion factor (metric ton/kg).

n = Number of hours in calendar year.

(ii) Either continuously monitor the volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels or calculate the volumetric flow rate of this exhaust gas stream using Equation Y-7 of this section.

$$Q_r = \frac{\left(79 * Q_a + (100 - \%O_{oxy}) * Q_{oxy}\right)}{100 - \%CO_2 - \%CO - \%O_2} \qquad \text{(Eq. Y-7)}$$

Where:

Q_r = Volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels (dscfh).

Q_a = Volumetric flow rate of air to the fluid catalytic cracking unit regenerator or fluid coking unit burner, as determined from control room instrumentation (dscfh).

Q_{oxy} = Volumetric flow rate of oxygen enriched air to the fluid catalytic cracking unit regenerator or fluid coking unit burner as determined from control room instrumentation (dscfh).

$\%O_2$	=	Hourly average percent oxygen concentration in exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis).
$\%O_{oxy}$	=	O_2 concentration in oxygen enriched gas stream inlet to the fluid catalytic cracking unit regenerator or fluid coking unit burner based on oxygen purity specifications of the oxygen supply used for enrichment (percent by volume – dry basis).
$\%CO_2$	=	Hourly average percent CO_2 concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis).
$\%CO$	=	Hourly average percent CO concentration in the exhaust gas stream from the fluid catalytic cracking unit regenerator or fluid coking unit burner (percent by volume – dry basis). When no auxiliary fuel is burned and a continuous CO monitor is not required under 40 CFR part 63 subpart UUU, assume %CO to be zero.

(iii) If you have a CO boiler that uses auxiliary fuels or combusts materials other than catalytic cracking unit or fluid coking unit exhaust gas, you must determine the CO_2 emissions resulting from the combustion of these fuels or other materials following the requirements in subpart C and report those emissions by following the requirements of subpart C of this part.

(3) ~~For catalytic cracking units and fluid coking units with rated capacities of 10,000 barrels per stream day (bbls/sd) or less that do not use a continuous CO_2 CEMS for the final exhaust stack, comply with the requirements in paragraphs (c)(3)(i) of this section or paragraphs (c)(3)(ii) and (c)(3)(iii) of this section, as applicable.~~

Reserved.

~~(i) If you continuously or no less frequently than daily monitor the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels, you must calculate the CO_2 emissions according to the requirements of paragraphs (c)(2)(i) through (c)(2)(iii) of this section, except that daily averages are allowed and the summation can be performed on a daily basis.~~

~~(ii) If you do not monitor at least daily the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels, calculate the CO_2 emissions from each catalytic cracking unit and fluid coking unit using Equation Y-8 of this section.~~

$$\cancel{CO_2 = Q_{unit} \times (CBF \times 0.001) \times CC \times \frac{44}{12}} \qquad \text{(Eq. Y-8)}$$

~~Where:~~

~~CO_2 = Annual CO_2 mass emissions (metric tons/year).~~

~~Q_{unit} = Annual throughput of unit from company records (barrels (bbls) per year, bbl/yr).~~

~~CBF = Coke burn-off factor from engineering calculations (kg coke per barrel of feed); default for catalytic cracking units = 7.3; default for fluid coking units = 11.~~

~~0.001 = Conversion factor (metric ton/kg).~~

~~CC = Carbon content of coke based on measurement or engineering estimate (kg C per kg coke); default = 0.94.~~

~~44/12 = Ratio of molecular weight of~~ ~~CO_2~~ ~~to C (kg~~ ~~CO_2~~ ~~per kg C).~~

~~(iii) If you have a CO boiler that uses auxiliary fuels or combusts materials other than catalytic cracking unit or fluid coking unit exhaust gas, you must determine the~~ ~~CO_2~~ ~~emissions resulting from the combustion of these fuels or other materials following the requirements in subpart C of this part (General Stationary Fuel Combustion Sources) and report those emissions by following the requirements of subpart C of this part.~~

(4) Calculate CH_4 emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation Y-9 of this section.

$$CH_4 = \left(CO_2 * \frac{EmF_2}{EmF_1} \right) \quad \text{(Eq. Y-9)}$$

Where:

CH_4 = Annual methane emissions from coke burn-off (metric tons CH_4/year).

CO_2 = Emission rate of CO_2 from coke burn-off calculated in paragraphs (c)(1), (c)(2), (e)(1), (e)(2), (g)(1), or (g)(2) of this section, as applicable (metric tons/year).

EmF_1 = Default CO_2 emission factor for petroleum coke from Table C-1 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CO_2/MMBtu).

EmF_2 = Default CH_4 emission factor for "PetroleumProducts" from Table C-2 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CH_4/MMBtu).

(5) Calculate N_2O emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation Y-10 of this section.

$$N_2O = \left(CO_2 * \frac{EmF_3}{EmF_1} \right) \qquad \text{(Eq. Y-10)}$$

Where:

N_2O = Annual nitrous oxide emissions from coke burn-off (mt N_2O/year).

CO_2 = Emission rate of CO_2 from coke burn-off calculated in paragraphs (c)(1), (c)(2), (e)(1), (e)(2), (g)(1), or (g)(2) of this section, as applicable (metric tons/year).

EmF_1 = Default CO_2 emission factor for petroleum coke from Table C-1 of subpart C of this part (General Stationary Fuel Combustion Sources) (kg CO_2/MMBtu).

EmF_3 = Default N_2O emission factor for ”PetroleumProducts” from Table C-2 of subpart C of this part (kg N_2O/MMBtu).

(d) For fluid coking units that use the flexicoking design, the GHG emissions from the resulting use of the low value fuel gas must be accounted for only once. Typically, these emissions will be accounted for using the methods described in subpart C of this part (General Stationary Fuel Combustion Sources). Alternatively, you may use the methods in paragraph (c) of this section provided that you do not otherwise account for the subsequent combustion of this low value fuel gas.

(e) For catalytic reforming units, calculate the CO_2 emissions using the applicable methods described in paragraphs (e)(1) through (e)(3) of this section and calculate the CH_4 and N_2O emissions using the methods described in paragraphs (c)(4) and (c)(5) of this section, respectively.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part (General Stationary Fuel Combustion Sources), you must calculate CO_2 emissions as provided in paragraphs (c)(1)(i) and (c)(1)(ii) of this section. Other catalytic reforming units must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part, or follow the requirements of paragraph (e)(2) or (e)(3) of this section.

(2) If you continuously or no less frequently than daily monitor the O_2, CO_2, and (if necessary) CO concentrations in the exhaust stack from the catalytic reforming unit catalyst regenerator prior to the combustion of other fossil fuels, you must calculate the CO_2 emissions according to the requirements of paragraphs (c)(2)(i) through (c)(2)(iii) of this section.

(3) Calculate CO_2 emissions from the catalytic reforming unit catalyst regenerator using Equation Y-11 of this section.

$$CO_2 = \sum_{1}^{n} \left[\left(CB_Q\right)_n \times CC \times \frac{44}{12} \times 0.001 \right] \qquad \text{(Eq. Y-11)}$$

Where:

CO_2	=	Annual CO_2 emissions (metric tons/year).
CB_Q	=	Coke burn-off quantity per regeneration cycle from engineering estimates (kg coke/cycle).
n	=	Number of regeneration cycles in the calendar year.
CC	=	Carbon content of coke based on measurement or engineering estimate (kg C per kg coke); default = 0.94.
44/12	=	Ratio of molecular weight of CO_2 to C (kg CO_2 per kg C).
0.001	=	Conversion factor (metric ton/kg).

(f) For on-site sulfur recovery plants, calculate and report CO_2 process emissions from sulfur recovery plants according to the requirements in paragraphs (f)(1) through (f)(5) of this section. Combustion emissions from the sulfur recovery plant (e.g., from fuel combustion in the Claus burner or the tail gas treatment incinerator) must be reported under subpart C of this part (General Stationary Fuel Combustion Sources). For the purposes of this subpart, the sour gas stream for which monitoring is required according to paragraphs (f)(2) through (f)(5) of this section is not considered a fuel.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part, you must calculate CO_2 emissions under this subpart by following the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources). You must monitor fuel use in the Claus burner, tail gas incinerator, or other

combustion sources that discharge via the final exhaust stack from the sulfur recovery plant and calculate the combustion emissions from the fuel use according to subpart C of this part. Calculate the process emissions from the sulfur recovery plant as the difference in the CO_2 CEMS emissions and the calculated combustion emissions associated with the sulfur recovery plant final exhaust stack. Other sulfur recovery plants must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C, or follow the requirements of paragraphs (f)(2) through (f)(5) of this section.

(2) Flow measurement. If you have a continuous flow monitor on the sour gas feed to the sulfur recovery plant, you must use the measured flow rates when the monitor is operational to calculate the sour gas flow rate. If you do not have a continuous flow monitor on the sour gas feed to the sulfur recovery plant, you must use engineering calculations, company records, or similar estimates of volumetric sour gas flow.

(3) Carbon content. If you have a continuous gas composition monitor capable of measuring carbon content on the sour gas feed to the sulfur recovery plant or if you monitor gas composition for carbon content on a routine basis, you must use the measured carbon content value. Alternatively, you may develop a site-specific carbon content factor using limited

measurement data or engineering estimates or use the default factor of 0.20.

(4) Calculate the CO_2 emissions from each sulfur recovery plant using Equation Y-12 of this section.

$$CO_2 = F_{SG} * \frac{44}{MVC} * MF_C * 0.001 \quad \text{(Eq. Y-12)}$$

Where:

CO_2 = Annual CO_2 emissions (metric tons/year).

F_{SG} = Volumetric flow rate of sour gas feed (including sour water stripper gas) to the sulfur recovery plant (scf/year).

44 = Molecular weight of CO_2 (kg/kg-mole).

MVC = Molar volume conversion factor (849.5 scf/kg-mole).

MF_C = Mole fraction of carbon in the sour gas to the sulfur recovery plant (kg-mole C/kg-mole gas); default = 0.20.

0.001 = Conversion factor, kg to metric tons

(5) If tail gas is recycled to the front of the sulfur recovery plant and the recycled flow rate and carbon content is included in the measured data under paragraphs (f)(2) and (f)(3) of this section, respectively, then the annual CO_2 emissions calculated in paragraph (f)(4) of this section must be corrected to avoid double counting these emissions. You may use engineering estimates to perform this correction or assume that the corrected CO_2 emissions are 95 percent of the uncorrected value calculated using Equation Y-12 of this section.

(g) For coke calcining units, calculate GHG emissions according to the applicable provisions in paragraphs (g)(1) through (g)(3) of this section.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to subpart C of this part, you must calculate and report CO_2 emissions under this subpart by following the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources). You must monitor fuel use in the coke calcining unit that discharges via the final exhaust stack from the coke calcining unit and calculate the combustion emissions from the fuel use according to subpart C of this part. Calculate the process emissions from the coke calcining unit as the difference in the CO_2 CEMS emissions and the calculated combustion emissions associated with the coke calcining unit final exhaust stack. Other coke calcining units must either install a CEMS that complies with the Tier 4 Calculation Methodology in subpart C of this part, or follow the requirements of paragraph (g)(2) of this section.

(2) Calculate the CO_2 emissions from the coke calcining unit using Equation Y-13 of this section.

$$CO_2 = \frac{44}{12} * \left(M_{in} * CC_{GC} - \left(M_{out} + M_{dust}\right) * CC_{MPC}\right) \qquad \text{(Eq. Y-13)}$$

Where:

CO_2	=	Annual CO_2 emissions (metric tons/year).
M_{in}	=	Annual mass of green coke fed to the coke calcining unit from facility records (metric tons/year).
CC_{GC}	=	Average mass fraction carbon content of green coke from facility measurement data (metric ton carbon/metric ton green coke).
M_{out}	=	Annual mass of marketable petroleum coke produced by the coke calcining unit from facility records (metric tons petroleum coke/year).
M_{dust}	=	Annual mass of petroleum coke dust collected in the dust collection system of the coke calcining unit from facility records (metric ton petroleum coke dust/year)
CC_{MPC}	=	Average mass fraction carbon content of marketable petroleum coke produced by the coke calcining unit from facility measurement data (metric ton carbon/metric ton petroleum coke).
44	=	Molecular weight of CO_2 (kg/kg-mole).
12	=	Atomic weight of C (kg/kg-mole).

(3) For all coke calcining units, use the CO_2 emissions from the coke calcining unit calculated in paragraphs (g)(1) or (g)(2), as applicable, and calculate CH_4 using the methods described in paragraph (c)(4) of this section and N_2O emissions using the methods described in paragraph (c)(5) of this section.

(h) [Reporting only.] For asphalt blowing operations, calculate GHG emissions according to the requirements in paragraph (j) of this section or according to the applicable provisions in paragraphs (h)(1) and (h)(2) of this section.

(1) For uncontrolled asphalt blowing operations or asphalt blowing operations controlled by vapor scrubbing, calculate CO_2

and CH_4 emissions using Equations Y-14 and Y-15 of this section, respectively.

$$CO_2 = \left(Q_{AB} \times EF_{AB.CO2}\right) \qquad \text{(Eq. Y-14)}$$

Where:

CO_2 = Annual CO_2 emissions from uncontrolled asphalt blowing (metric tons CO_2/year).

Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).

$EF_{AB,CO2}$ = Emission factor for CO_2 from uncontrolled asphalt blowing from facility-specific test data (metric tons CO_2/MMbbl asphalt blown); default = 1,100.

$$CH_4 = \left(Q_{AB} \times EF_{AB,CH4}\right) \qquad \text{(Eq. Y-15)}$$

Where:

CH_4 = Annual methane emissions from uncontrolled asphalt blowing (metric tons CH_4/year).

Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).

$EF_{AB,CH4}$ = Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (metric tons CH_4/MMbbl asphalt blown); default = 580.

(2) For asphalt blowing operations controlled by thermal oxidizer or flare, calculate CO_2 and CH_4 emissions using Equations Y-16 and Y-17 of this section, respectively, provided these emissions are not already included in the flare emissions calculated in paragraph (b) of this section or in the stationary combustion unit emissions required under subpart C of this part (General Stationary Fuel Combustion Sources).

$$CO_2 = 0.98 \times \left(Q_{AB} \times CEF_{AB} \times \frac{44}{12}\right) \qquad \text{(Eq. Y-16)}$$

Where:

CO_2	=	Annual CO_2 emissions from controlled asphalt blowing (metric tons CO_2/year).
0.98	=	Assumed combustion efficiency of thermal oxidizer or flare.
Q_{AB}	=	Quantity of asphalt blown (MMbbl/year).
CEF_{AB}	=	Carbon emission factor from asphalt blowing from facility-specific test data (metric tons C/MMbbl asphalt blown); default = 2,750.
44	=	Molecular weight of CO_2 (kg/kg-mole).
12	=	Atomic weight of C (kg/kg-mole).

$$CH_4 = 0.02 \times \left(Q_{AB} \times EF_{AB,CH4}\right) \quad \text{(Eq. Y-17)}$$

Where:

CH_4	=	Annual methane emissions from controlled asphalt blowing (metric tons CH_4/year).
0.02	=	Fraction of methane uncombusted in thermal oxidizer or flare based on assumed 98% combustion efficiency.
Q_{AB}	=	Quantity of asphalt blown (million barrels per year, MMbbl/year).
$EF_{AB,CH4}$	=	Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (metric tons CH_4/MMbbl asphalt blown); default = 580.

(i) For delayed coking units, calculate the CH_4 emissions from the depressurization of the coking unit vessel (i.e., the "coke drum") to atmosphere using either of the methods provided in paragraphs (i)(1) or (i)(2), provided no water or steam is added to the vessel once it is vented to the atmosphere. You must use the method in paragraph (i)(1) of this section if you add water or steam to the vessel after it is vented to the atmosphere.

(1) Use the process vent method in paragraph (j) of this section and also calculate the CH_4 emissions from the subsequent opening of the vessel for coke cutting operations using Equation Y-18 of this section. If you have coke drums or vessels of different dimensions, use Equation Y-18 for each set of coke drums or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

$$CH_4 = \left(N \times H \times \frac{(P_{CV} + 14.7)}{14.7} \times f_{void} \times \frac{\pi \times D^2}{4} \times \frac{16}{MVC} \times MF_{CH4} \times 0.001 \right) \quad \text{(Eq. Y-18)}$$

Where:

CH_4 = Annual methane emissions from the delayed coking unit vessel opening (metric ton/year).

N = Cumulative number of vessel openings for all delayed coking unit vessels of the same dimensions during the year.

H = Height of coking unit vessel (feet).

P_{CV} = Gauge pressure of the coking vessel when opened to the atmosphere prior to coke cutting or, if the alternative method provided in paragraph (i)(2) of this section is used, gauge pressure of the coking vessel when depressurization gases are first routed to the atmosphere (pounds per square inch gauge, psig)

14.7 = Assumed atmospheric pressure (pounds per square inch, psi)

f_{void} = Volumetric void fraction of coking vessel prior to steaming based on engineering calculations (cf gas/cf of vessel)~~; default = 0.6~~.

D = Diameter of coking unit vessel (feet).

16 = Molecular weight of CH_4 (kg/kg-mole).

MVC = Molar volume conversion factor (849.5 scf/ kg-mole).

MF_{CH4} = Average ~~M~~mole fraction of methane in coking vessel gas based on the analysis of at least two samples per year, collected at least four months a part (kg-mole CH_4/kg-mole gas, wet basis)~~; default value is 0.01~~.

0.001 = Conversion factor (metric ton/kg).

(2) Calculate the CH_4 emissions from the depressurization vent and subsequent opening of the vessel for coke cutting operations using Equation Y-18 of this section and the pressure of the coking vessel when the depressurization gases are first routed to the atmosphere. If you have coke drums or vessels of different dimensions, use Equation Y-18 for each set of coke drums or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

(j) For each process vent not covered in paragraphs (a) through (i) of this section that can be reasonably expected to contain greater than 2 percent by volume CO_2 or greater than 0.5 percent by volume of CH_4 or greater than 0.01 percent by volume (100 parts per million) of N_2O, calculate GHG emissions using the Equation Y-19 of this section. You must use Equation Y-19 of this section for catalytic reforming unit depressurization and purge vents when methane is used as the purge gas or if you elected this method as an alternative to the methods in paragraphs (h)(1) or (h)(2) of this section.

$$E_x = \sum_{p=1}^{N}\left((VR)_p \times (MF_x)_p \times \frac{MW_x}{MVC} \times (VT)_p \times 0.001\right) \qquad \text{(Eq. Y-19)}$$

Where:

E_x	=	Annual emissions of each GHG from process vent (metric ton/yr).
N	=	Number of venting events per year.
P	=	Index of venting events.
$(VR)_p$	=	Average volumetric flow rate of process gas during the event (scf per hour).
$(MF_x)_p$	=	Mole fraction of GHG x in process vent during the event (kg-mol of GHG x/kg-mol vent gas).
MW_x	=	Molecular weight of GHG x (kg/kg-mole); use 44 for CO_2 or N_2O and 16 for CH_4.
MVC	=	Molar volume conversion factor (849.5 scf/kg-mole).
$(VT)_p$	=	Venting time for the event, (hours).
0.001	=	Conversion factor (metric ton/kg)

(k) For uncontrolled blowdown systems, you must ~~either~~ use the methods for process vents in paragraph (j) of this section. ~~or calculate CH_4 emissions using Equation Y-20 of this section. Blowdown systems where the uncondensed gas stream is routed to a flare or similar control device is considered to be controlled and is not required to estimate emissions under this paragraph (k).~~

$$\cancel{CH_4 = \left(Q_{Ref} \times EF_{BD} \times \frac{16}{MVC} \times 0.001 \right)} \qquad \text{~~(Eq. Y-20)~~}$$

~~Where:~~

~~CH_4~~	~~=~~	~~Methane emission rate from blowdown systems (mt CH_4/year).~~
~~Q_{Ref}~~	~~=~~	~~Quantity of crude oil plus the quantity of intermediate products received from off site that are processed at the facility (MMbbl/year).~~
~~EF_{BD}~~	~~=~~	~~Methane emission factor for uncontrolled blown systems (scf CH_4/MMbbl); default is 137,000.~~
~~16~~	~~=~~	~~Molecular weight of CH_4 (kg/kg-mole).~~

~~MVC = Molar volume conversion factor (849.5 scf/kg-mole).~~
~~0.001 = Conversion factor (metric ton/kg).~~

(l) [Reporting only.] For equipment leaks, calculate CH_4 emissions using the method specified in either paragraph (l)(1) or (l)(2) of this section.

(1) Use process-specific methane composition data (from measurement data or process knowledge) and any of the emission estimation procedures provided in the Protocol for Equipment Leak Emissions Estimates (EPA-453/R-95-017, NTIS PB96-175401).

(2) Use Equation Y-21 of this section.

$$CH_4 = \left(0.4 \times N_{CD} + 0.2 \times N_{PU1} + 0.1 \times N_{PU2} + 4.3 \times N_{H2} + 6 \times N_{FGS}\right) \quad \text{(Eq. Y-21)}$$

Where:

CH_4 = Annual methane emissions from equipment leaks (metric tons/year)

N_{CD} = Number of atmospheric crude oil distillation columns at the facility.

N_{PU1} = Cumulative number of catalytic cracking units, coking units (delayed or fluid), hydrocracking, and full-range distillation columns (including depropanizer and debutanizer distillation columns) at the facility.

N_{PU2} = Cumulative number of hydrotreating/hydrorefining units, catalytic reforming units, and visbreaking units at the facility.

N_{H2} = Total number of hydrogen plants at the facility.

N_{FGS} = Total number of fuel gas systems at the facility.

(m) [Reporting only.] For storage tanks, except as provided in paragraph (m)(3) of this section, calculate CH_4 emissions using the applicable methods in paragraphs (m)(1) and (m)(2) of this section.

(1) For storage tanks other than those processing unstabilized crude oil, you must either calculate CH_4 emissions from storage tanks that have a vapor-phase methane concentration of 0.5 volume percent or more using tank-specific methane composition data (from measurement data or product knowledge) and the AP-42 emission estimation methods provided in Section 7.1 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources", including TANKS Model (Version 4.09D) or similar programs, or estimate CH_4 emissions from storage tanks using Equation Y-22 of this section.

$$CH_4 = \left(0.1 \times Q_{Ref}\right) \quad \text{(Eq. Y-22)}$$

Where:

CH_4 = Annual methane emissions from storage tanks (metric tons/year).

0.1 = Default emission factor for storage tanks (metric ton CH_4/MMbbl).

Q_{Ref} = Quantity of crude oil plus the quantity of intermediate products received from off site that are processed at the facility (MMbbl/year).

(2) For storage tanks that process unstabilized crude oil, calculate CH_4 emissions from the storage of unstabilized crude oil using either tank-specific methane composition data (from measurement data or product knowledge) and direct measurement of the gas generation rate or by using Equation Y-23 of this section.

$$CH_4 = (995{,}000 \times Q_{un} \times \Delta P) \times MF_{CH4} \times \frac{16}{MVC} \times 0.001 \qquad \text{(Eq. Y-23)}$$

Where:

CH_4	=	Annual methane emissions from storage tanks (metric tons/year).
Q_{un}	=	Quantity of unstabilized crude oil received at the facility (MMbbl/year).
ΔP	=	Pressure differential from the previous storage pressure to atmospheric pressure (pounds per square inch, psi).
MF_{CH4}	=	Mole fraction of CH_4 in vent gas from the unstabilized crude oil storage tank from facility measurements (kg-mole CH_4/kg-mole gas); use 0.27 as a default if measurement data are not available.
995,000	=	Correlation Equation factor (scf gas per MMbbl per psi)
16	=	Molecular weight of CH_4 (kg/kg-mole).
MVC	=	Molar volume conversion factor (849.5 scf/kg-mole).
0.001	=	Conversion factor (metric ton/kg).

(3) You do not need to calculate CH_4 emissions from storage tanks that meet any of the following descriptions:

(i) Units permanently attached to conveyances such as trucks, trailers, rail cars, barges, or ships;

(ii) Pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere;

(iii) Bottoms receivers or sumps;

(iv) Vessels storing wastewater; or

(v) Reactor vessels associated with a manufacturing process unit.

(n) [Reporting only.] For crude oil, intermediate, or product loading operations for which the equilibrium vapor-phase concentration of methane is 0.5 volume percent or more, calculate CH_4 emissions from loading operations using product-specific, vapor-phase methane composition data (from measurement data or process knowledge) and the emission estimation procedures provided in Section 5.2 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources." For loading operations in which the equilibrium vapor-phase concentration of methane is less than 0.5 volume percent, you may assume zero methane emissions.

§98.254 Monitoring and QA/QC requirements.

(a) Fuel flow meters, gas composition monitors, and heating value monitors associated with stationary combustion sources must follow the monitoring and QA/QC requirements in §98.34.

(b) All flow meters, gas composition monitors, and heating value monitors that are used to provide data for the GHG emissions calculations in this subpart for sources other than stationary combustion sources shall be calibrated according to the procedures in the applicable methods specified in paragraphs (c) through (e) of this section, the procedures specified by the manufacturer, or §§98.3(i). Recalibrate each flow meter either biennially (every two years) or at the minimum frequency specified by the manufacturer. Recalibrate each gas composition monitor and heating value monitor either annually or at the minimum frequency specified by the manufacturer.

(c) For flare or sour gas flow meters, operate and maintain the flow meter using any of the following methods, a method published by a consensus-based standards organization (e.g., ASTM, API, etc.) or follow the procedures specified by the flow meter manufacturer. Flow meters must have a rated accuracy of ±5 percent or lower.

(1) ASME MFC–3M–2004 Measurement of Fluid Flow in Pipes Using Orifice, Nozzle, and Venturi (incorporated by reference, see §98.7).

(2) ASME MFC–4M–1986 (Reaffirmed 1997) Measurement of Gas Flow by Turbine Meters (incorporated by reference, see §98.7).

(3) ASME MFC–6M–1998 Measurement of Fluid Flow in Pipes Using Vortex Flowmeters (incorporated by reference, see §98.7).

(4) ASME MFC–7M–1987 (Reaffirmed 1992) Measurement of Gas Flow by Means of Critical Flow Venturi Nozzles (incorporated by reference, see §98.7).

(5) ASME MFC-11M-2006 Measurement of Fluid Flow by Means of Coriolis Mass Flowmeters (incorporated by reference, see §98.7).

(6) ASME MFC-14M-2003 Measurement of Fluid Flow Using Small Bore Precision Orifice Meters (incorporated by reference, see §98.7).

(7) ASME MFC-18M-2001 Measurement of Fluid Flow Using Variable Area Meters (incorporated by reference, see §98.7).

(8) AGA Report No. 11 Measurement of Natural Gas by Coriolis Meter (2003) (incorporated by reference, see §98.7).

(d) Determine flare gas composition using any of the following methods.

(1) Method 18 at 40 CFR part 60, appendix A-6.

(2) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see §98.7).

(3) ASTM D1946-90 (Reapproved 2006) Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see §98.7).

(4) GPA 2261–00 Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography (incorporated by reference, see §98.7).

(5) UOP539-97 Refinery Gas Analysis by Gas Chromatography (incorporated by reference, see §98.7).

(e) Determine flare gas higher heating value using any of the following methods.

(1) ASTM D4809-06 Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (Precision Method) (incorporated by reference, see §98.7).

(2) ASTM D240-02 (Reapproved 2007) Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (incorporated by reference, see §98.7).

(3) ASTM D1826-94 (Reapproved 2003) Standard Test Method for Calorific (Heating) Value of Gases in Natural Gas Range by Continuous Recording Calorimeter (incorporated by reference, see §98.7).

(4) ASTM D3588-98 (Reapproved 2003) Standard Practice for Calculating Heat Value, Compressibility Factor, and Relative Density of Gaseous Fuels (incorporated by reference, see §98.7).

(5) ASTM D4891-89 (Reapproved 2006) Standard Test Method for Heating Value of Gases in Natural Gas Range by Stoichiometric Combustion (incorporated by reference, see §98.7).

(f) For exhaust gas flow meters used to comply with the requirements in §98.253(c)(2)(ii), install, operate, calibrate, and maintain exhaust gas flow meter according to the requirements in 40 CFR 63.1572(c) or according to the following requirements.

(1) Locate the flow meter(s) and other necessary equipment such as straightening vanes in a position that provides representative flow; reduce swirling flow or abnormal velocity distributions due to upstream and downstream disturbances.

(2) Use a flow rate meter with an accuracy within ±5 percent.

(3) Use a continuous monitoring system capable of correcting for the temperature, pressure, and moisture content to output flow in dry standard cubic feet (standard conditions as defined in §98.6).

(4) Install, operate, and maintain each continuous monitoring system according to the manufacturer's specifications and requirements.

(g) For exhaust gas CO_2/CO/O_2 composition monitors used to comply with the requirements in §98.253(c)(2), install, operate, calibrate, and maintain exhaust gas composition monitors according to the the requirements in 40 CFR 60.105a(b)(2) or 40 CFR 63.1572(a) or according to the manufacturer's specifications and requirements.

(h) Determine the mass of petroleum coke as required by Equation Y-13 of this subpart using mass measurement equipment meeting the requirements for commercial weighing equipment as described in Specifications, Tolerances, and Other Technical Requirements For Weighing and Measuring Devices, NIST Handbook 44 (2009) (incorporated by reference, see §98.7). Calibrate the measurement device according to the procedures specified by the method, the procedures specified by the manufacturer, or

§98.3(i). Recalibrate either biennially or at the minimum frequency specified by the manufacturer.

(i) Determine the carbon content of petroleum coke as required by Equation Y-13 of this subpart using any one of the following methods. Calibrate the measurement device according to procedures specified by the method or procedures specified by the measurement device manufacturer.

(1) ASTM D3176-89 (Reapproved 2002) Standard Practice for Ultimate Analysis of Coal and Coke (incorporated by reference, see §98.7).

(2) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, see §98.7).

(3) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7).

(j) Determine the quantity of petroleum process streams using company records. These quantities include the quantity of asphalt blown, quantity of crude oil plus the quantity of intermediate products received from off site, and the quantity of unstabilized crude oil received at the facility.

(k) The owner or operator shall document the procedures used to ensure the accuracy of the estimates of fuel usage, gas composition, and heating value including but not limited to calibration of weighing equipment, fuel flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices shall also be recorded, and the technical basis for these estimates shall be provided.

(l) All CO_2 CEMS and flow rate monitors used for direct measurement of GHG emissions must comply with the QA procedures in §98.34(c).

(m) For purposes of §98.34(b)(3)(ii)(E), the equipment necessary to take daily measurements of carbon content and molecular weight shall be in place for refinery fuel gas, and daily sampling and analysis shall therefore be required, by no later than January 1, 2012.

§98.255 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., concentrations, flow rates, fuel heating values, carbon content values). Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For stationary combustion sources, use the missing data procedures in subpart C of this part.

(b) For each missing value of the heat content, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the “after” value is not obtained by the end of the reporting year, you may use the “before” value for the missing data substitution. If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(c) For missing CO_2, CO, O_2, CH_4, or N_2O concentrations, gas flow rate, and percent moisture, the substitute data values shall be the best available estimate(s) of the parameter(s), based on all available process data (e.g., processing rates, operating hours, etc.). The owner or operator shall document and keep records of the procedures used for all such estimates.

(d) For hydrogen plants, use the missing data procedures in subpart P of this part.

§98.256 Data reporting requirements.

In addition to the reporting requirements of §98.3(c), you must report the information specified in paragraphs (a) through (q) of this section.

Subpart Y—Petroleum Refineries

(a) For combustion sources, follow the data reporting requirements under subpart C of this part (General Stationary Fuel Combustion Sources).

(b) For hydrogen plants, follow the data reporting requirements under subpart P of this part (Hydrogen Production).

(c) [RESERVED].

(d) [RESERVED].

(e) For flares, owners and operators shall report:

(1) The flare ID number (if applicable).

(2) A description of the type of flare (steam assisted, air-assisted).

(3) A description of the flare service (general facility flare, unit flare, emergency only or back-up flare).

(4) The calculated CO_2, CH_4, and N_2O annual emissions for each flare, expressed in metric tons of each pollutant emitted.

(5) A description of the method used to calculate the CO_2 emissions for each flare (e.g., reference section and equation number).

(6) If you use Equation Y-1 of this subpart, the annual volume of flare gas combusted (in scf/year) and the annual average molecular weight (in kg/kg-mole) and carbon content of the flare gas (in kg carbon per kg flare gas).

(7) If you use Equation Y-2 of this subpart, the annual volume of flare gas combusted (in million (MM) scf/year) and the

annual average higher heating value of the flare gas (in MMBtu per MMscf).

(8) If you use Equation Y-3 of this subpart, ~~the annual volume of flare gas combusted (in MMscf/year) during normal operations, the annual average higher heating value of the flare gas (in MMBtu/MMscf),~~ the number of SSM events, and ~~exceeding 500,000 scf/day, and~~ the volume of gas flared (in scf/event) and the average molecular weight (in kg/kg-mole) and carbon content of the flare gas (in kg carbon per kg flare) for each SSM event ~~over 500,000 scf/day~~.

(9) The fraction of carbon in the flare gas contributed by methane used in Equation Y-4 of this subpart and the basis for its value.

(f) For catalytic cracking units, traditional fluid coking units, and catalytic reforming units, owners and operators shall report:

(1) The unit ID number (if applicable).

(2) A description of the type of unit (fluid catalytic cracking unit, thermal catalytic cracking unit, traditional fluid coking unit, or catalytic reforming unit).

(3) Maximum rated throughput of the unit, in bbl/stream day.

(4) The calculated CO_2, CH_4, and N_2O annual emissions for each unit, expressed in metric tons of each pollutant emitted.

(5) A description of the method used to calculate the CO_2 emissions for each unit (e.g., reference section and equation number).

(6) If you use a CEMS, the relevant information required under §98.36(e)(2)(vi) for the Tier 4 Calculation Methodology, the CO_2 annual emissions as measured by the CEMS (unadjusted to remove CO_2 combustion emissions associated with a CO boiler, if present) and the process CO_2 emissions as calculated according to §98.253(c)(1)(ii). Report the CO_2 annual emissions associated with fuel combustion under subpart C of this part (General Stationary Fuel Combustion Sources).

(7) If you use Equation Y-6 of this subpart, the annual average exhaust gas flow rate, $\%CO_2$, and %CO.

(8) If you use Equation Y-7 of this subpart, the annual average flow rate of inlet air and oxygen-enriched air, $\%O_2$, $\%O_{oxy}$, $\%CO_2$, and %CO.

(9) ~~If you use Equation Y-8 of this subpart, the coke burn-off factor, annual throughput of unit, and the average carbon content of coke and the basis for the value.~~

Reserved.

(10) ~~Indicate whether you use a measured value, a unit-specific emission factor, or a default emission factor for CH_4 emissions. If you use a unit-specific emission factor for CH_4, report the units of measure for the unit-specific factor, the~~

~~activity data for calculating emissions (e.g., if the emission factor is based on coke burn-off rate, the annual quantity of coke burned), and the basis for the factor.~~

Reserved.

(11) Indicate whether you use a measured value, a unit-specific emission factor, or a default emission factor for N_2O emissions. If you use a unit-specific emission factor for N_2O, report the units of measure for the unit-specific factor, the activity data for calculating emissions (e.g., if the emission factor is based on coke burn-off rate, the annual quantity of coke burned), and the basis for the factor.

(12) If you use Equation Y-11 of this subpart, the number of regeneration cycles during the reporting year, the average coke burn-off quantity per cycle, and the average carbon content of the coke.

(g) For fluid coking unit of the flexicoking type, the owner or operator shall report:

(1) The unit ID number (if applicable).

(2) A description of the type of unit.

(3) Maximum rated throughput of the unit, in bbl/stream day.

(4) Indicate whether the GHG emissions from the low heat value gas are accounted for in subpart C of this part or §98.253(c).

(5) If the GHG emissions for the low heat value gas are calculated at the flexicoking unit, also report the calculated annual CO_2, CH_4, and N_2O emissions for each unit, expressed in metric tons of each pollutant emitted, and the applicable equation input parameters specified in paragraphs (f)(7) through (f)(11) of this section.

(h) For sulfur recovery plants and for emissions from sour gas sent off-site for sulfur recovery, the owner and operator shall report:

(1) The plant ID number (if applicable).

(2) Maximum rated throughput of each independent sulfur recovery plant, in metric tons sulfur produced/stream day.

(3) The calculated CO_2 annual emissions for each sulfur recovery plant, expressed in metric tons. The calculated annual CO_2 emissions from sour gas sent off-site for sulfur recovery, expressed in metric tons.

(4) If you use Equation Y-12 of this subpart, the annual volumetric flow to the sulfur recovery plant (in scf/year) and the annual average mole fraction of carbon in the sour gas (in kg-mole C/kg-mole gas).

(5) If you recycle tail gas to the front of the sulfur recovery plant, indicate whether the recycled flow rate and carbon content are included in the measured data under §98.253(f)(2) and (3). Indicate whether a correction for CO_2

emissions in the tail gas was used in Equation Y-12. If so, then report the value of the correction, the annual volume of recycled tail gas (in scf/year) and the annual average mole fraction of carbon in the tail gas (in kg-mole C/kg-mole gas). Indicate whether you used the default (95%) or a unit specific correction, and if used, report the approach used.

(6) If you use a CEMS, the relevant information required under §98.36(e)(2)(vi) for the Tier 4 Calculation Methodology, the CO_2 annual emissions as measured by the CEMS and the annual process CO_2 emissions calculated according to §98.253(f)(1). Report the CO_2 annual emissions associated with fuel combustion subpart C of this part (General Stationary Fuel Combustion Sources).

(i) For coke calcining units, the owner and operator shall report:

(1) The unit ID number (if applicable).

(2) Maximum rated throughput of the unit, in metric tons coke calcined/stream day.

(3) The calculated CO_2, CH_4, and N_2O annual emissions for each unit, expressed in metric tons of each pollutant emitted.

(4) A description of the method used to calculate the CO_2 emissions for each unit (e.g., reference section and equation number).

(5) If you use Equation Y-13 of this subpart, annual mass and carbon content of green coke fed to the unit, the annual mass and carbon content of marketable coke produced, and the annual mass of coke dust collected in dust collection systems.

(6) If you use a CEMS, the relevant information required under §98.36(e)(2)(vi) for the Tier 4 Calculation Methodology, the CO_2 annual emissions as measured by the CEMS and the annual process CO_2 emissions calculated according to §98.253(g)(1). Report the CO_2 annual emissions associated with fuel combustion under subpart C of this part (General Stationary Fuel Combustion Sources).

(7) Indicate whether you use a measured value, a unit-specific emission factor or a default for CH_4 emissions. If you use a unit-specific emission factor for CH_4, the unit-specific emission factor for CH_4, the units of measure for the unit-specific factor, the activity data for calculating emissions (e.g., if the emission factor is based on coke burn-off rate, the annual quantity of coke burned), and the basis for the factor.

(8) If you use a site-specific emission factor in Equation Y-10 of this subpart, the site-specific emission factor and the basis of the factor.

(j) For asphalt blowing operations, the owner or operator shall report:

(1) The unit ID number (if applicable).

(2) The quantity of asphalt blown (in Million bbl) at the facility in the reporting year.

(3) The type of control device used to reduce methane (and other organic) emissions from the unit.

(4) The calculated annual CO_2 and CH_4 emissions for each unit, expressed in metric tons of each pollutant emitted.

(5) If you use Equation Y-14 of this subpart, the CO_2 emission factor used and the basis for the value.

(6) If you use Equation Y-15 of this subpart, the CH_4 emission factor used and the basis for the value.

(7) If you use Equation Y-16 of this subpart, the carbon emission factor used and the basis for the value.

(8) If you use Equation Y-17 of this subpart, the CH_4 emission factor used and the basis for the value.

(k) For delayed coking units, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for all delayed coking units at the facility.

(2) A description of the method used to calculate the CH_4 emissions for each unit (e.g., reference section and equation number).

(3) The total number of delayed coking units at the facility, the total number of delayed coking drums at the facility, and for each coke drum or vessel: the dimensions, the typical gauge pressure of the coking drum when first vented to the atmosphere, typical void fraction, the typical drum outage (i.e. the unfilled distance from the top of the drum, in feet), and annual number of coke-cutting cycles.

(4) For each set of coking drums that are the same dimensions: the number of coking drums in the set, the height and diameter of the coke drums (in feet), the cumulative number of vessel openings for all delayed coking drums in the set, the typical venting pressure (in psig), void fraction (in cf gas/cf of vessel), and the mole fraction of methane in coking gas (in kg-mole CF_4/kg-mole gas, wet basis).

(5) The basis for the volumetric void fraction of the coke vessel prior to steaming and the basis for the mole fraction of methane in the coking gas.

(l) For process vents subject to §98.253(j), the owner or operator shall report:

(1) The vent ID number (if applicable).

(2) The unit or operation associated with the emissions.

(3) The type of control device used to reduce methane (and other organic) emissions from the unit, if applicable.

(4) The calculated annual CO_2, CH_4, and N_2O emissions for each vent, expressed in metric tons of each pollutant emitted.

(5) The annual volumetric flow discharged to the atmosphere (in scf), mole fraction of each GHG above the concentration threshold, and for intermittent vents, the number of venting events and the cumulative venting time.

(m) For uncontrolled blowdown systems, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for uncontrolled blowdown systems.

(2) ~~The total quantity (in Million bbl) of crude oil plus the quantity of intermediate products received from off-site that are processed at the facility in the reporting year.~~The information required for process vents in paragraph (l) of this section.

(3) ~~The methane emission factor used for uncontrolled blowdown systems and the basis for the value.~~

Reserved.

(n) For equipment leaks, the owner or operator shall report:

(1) The cumulative CH_4 emissions (in metric tons of each pollutant emitted) for all equipment leak sources.

(2) The method used to calculate the reported equipment leak emissions.

(3) The number of each type of emission source listed in Equation Y-21 of this subpart at the facility.

(o) For storage tanks, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for all storage tanks, except for those used to process unstabilized crude oil.

(2) The method used to calculate the reported storage tank emissions for storage tanks other than those processing unstabilized crude (AP-42, TANKS 4.09D, Equation Y-22 of this subpart, other).

(3) The total quantity (in MMbbl) of crude oil plus the quantity of intermediate products received from off-site that are processed at the facility in the reporting year.

(4) The cumulative CH_4 emissions (in metric tons of each pollutant emitted) for storage tanks used to process unstabilized crude oil.

(5) The method used to calculate the reported storage tank emissions for storage tanks processing unstabilized crude oil.

(6) The quantity of unstabilized crude oil received during the calendar year (in MMbbl), the average pressure differential (in psi), and the mole fraction of CH_4 in vent gas from the unstabilized crude oil storage tank, and the basis for the mole fraction.

(7) The tank-specific methane composition data and the gas generation rate data, if you did not use Equation Y-23.

(p) For loading operations, the owner or operator shall report:

(1) The cumulative annual CH_4 emissions (in metric tons of each pollutant emitted) for loading operations.

(2) The quantity and types of materials loaded by vessel type (barge, tanker, marine vessel, etc.) that have an equilibrium vapor-phase concentration of methane of 0.5 volume percent or greater, and the type of vessels in which the material is loaded.

(3) The type of control system used to reduce emissions from the loading of material with an equilibrium vapor-phase concentration of methane of 0.5 volume percent or greater, if any (submerged loading, vapor balancing, etc.).

(q) Name of each method listed in §98.254 or a description of manufacturer's recommended method used to determine a measured parameter.

§98.257 Records that must be retained.

(a) In addition to the records required by §98.3(g), you must retain the records of all parameters monitored under §98.255.

(b) For each process vent for which the concentration of CO_2, N_2O and CH_4 are determined to be below the thresholds in

§98.253(j), the owner or operator shall maintain records of the method used to determine the CO_2, N_2O, and CH_4 concentration and all supporting documentation necessary to demonstrate the thresholds in §98.253(j) are not exceeded during the reporting year.

§98.258 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Subpart AA—Pulp and Paper Manufacturing

§98.270 Definition of Source Category.

(a) The pulp and paper manufacturing source category consists of facilities that produce market pulp (i.e., stand-alone pulp facilities), manufacture pulp and paper (i.e., integrated facilities), produce paper products from purchased pulp, produce secondary fiber from recycled paper, convert paper into paperboard products (e.g., containers), or operate coating and laminating processes.

(b) The emission units for which GHG emissions must be reported are listed in paragraphs (b)(1) through (b)(5) of this section:

(1) Chemical recovery furnaces at kraft and soda mills (including recovery furnaces that burn spent pulping liquor produced by both the kraft and semichemical process).

(2) Chemical recovery combustion units at sulfite facilities.

(3) Chemical recovery combustion units at stand-alone semichemical facilities.

(4) Pulp mill lime kilns at kraft and soda facilities.

(5) Systems for adding makeup chemicals ($CaCO_3$, Na_2CO_3) in the chemical recovery areas of chemical pulp mills.

Subpart AA—Pulp and Paper Manufacturing

§98.271 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a pulp and paper manufacturing process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.272 GHGs to report.

You must report the emissions listed in paragraphs (a) through (f) of this section:[1]

(a) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each kraft or soda chemical recovery furnace.

(b) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each sulfite chemical recovery combustion unit.

(c) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each stand-alone semichemical chemical recovery combustion unit.

(d) CO_2, biogenic CO_2, CH_4, and N_2O emissions from each kraft or soda pulp mill lime kiln.

(e) CO_2 emissions from addition of makeup chemicals ($CaCO_3$, Na_2CO_3) in the chemical recovery areas of chemical pulp mills.

(f) CO_2, CH_4, and N_2O combustion emissions from each stationary combustion unit. You must calculate and report these emissions under subpart C of this part (General

[1] WCI ERs previously included methodologies for calculating CH_4 and N_2O emissions from wastewater treatment plants at this source category. Coverage of these facilities will now be left to the discretion of the jurisdiction.

Stationary Fuel Combustion Sources) by following the requirements of subpart C.

§98.273 Calculating GHG emissions.

(a) For each chemical recovery furnace located at a kraft or soda facility, you must determine CO_2, biogenic CO_2, CH_4, and N_2O emissions using the procedures in paragraphs (a)(1) through (a)(3) of this section. CH_4 and N_2O emissions must be calculated as the sum of emissions from combustion of fossil fuels and combustion of biomass in spent liquor solids.

(1) Calculate fossil fuel-based CO_2 emissions from direct measurement of fossil fuels consumed and the methodology for stationary combustion sources specified by §98.33(a) (as modified by this Article) for the appropriate fuel type ~~default emissions factors according to the Tier 1 methodology for stationary combustion sources in §98.33(a)(1)~~.[2]

(2) Calculate fossil fuel-based CH_4 and N_2O emissions from direct measurement of fossil fuels consumed, default HHV, and default emissions factors and convert to metric tons of CO_2 equivalent according to the methodology for stationary combustion sources in §98.33(c).

[2] Although Subpart C generally allows the use of higher tiers, even when a lower tier is specified for a particular unit or fuel, section 98.273 could be read as *requiring* the use of Tier 1. WCI is seeking clarification of the correct interpretation of section 98.273 in order to assure that the proposed changes are consistent with harmonization.

(3) Calculate biogenic CO_2 emissions and emissions of CH_4 and N_2O from biomass using measured quantities of spent liquor solids fired, site-specific HHV, and default or site-specific emissions factors[3], according to Equation AA-1 of this section:

$$CO_2, CH_4, or\ N_2O\ from\ biomass = (0.907.18) * \text{Solids} * \text{HHV} * \text{EF} \quad \text{(Eq.AA-1)}$$

Where:

CO_2, CH_4, or N_2O, from Biomass	=	Biogenic CO_2 emissions or emissions of CH_4 or N_2O from spent liquor solids combustion (metric tons per year).
Solids	=	Mass of spent liquor solids combusted (short tons per year) determined according to §98.274(b).
HHV	=	Annual high heat value of the spent liquor solids (mmBtu per kilogram) determined according to 98.274(b).
EF	=	Default emission factor for CO_2, CH_4, or N_2O, from Table AA-1 of this subpart (kg CO_2, CH_4, or N_2O per mmBtu).
0.90718	=	Conversion factor from short tons to metric tons.

(b) For each chemical recovery combustion unit located at a sulfite or stand-alone semichemical facility, you must determine CO_2, CH_4, and N_2O emissions using the procedures in paragraphs (b)(1) through (b)(4) of this section:

(1) Calculate fossil CO_2 emissions from fossil fuels from direct measurement of fossil fuels consumed and the

methodology for stationary combustion sources specified by §98.33(a) (as modified by this Article) for the appropriate fuel type ~~default emissions factors according to the Tier 1 Calculation Methodology for stationary combustion sources in §98.33(a)(1)~~.

(2) Calculate CH_4 and N_2O emissions from fossil fuels from direct measurement of fossil fuels consumed, default HHV, and default emissions factors and convert to metric tons of CO_2 equivalent according to the methodology for stationary combustion sources in §98.33(c).

(3) Calculate biogenic CO_2 emissions using measured quantities of spent liquor solids fired and the carbon content of the spent liquor solids, according to Equation AA-2 of this section:

$$Biogenic\ CO_2 = \frac{44}{12} * \mathrm{Solids} * \mathrm{CC} * (0.90718) \qquad \text{(Eq. AA-2)}$$

Where:

Biogenic CO_2	=	Annual CO_2 mass emissions for spent liquor solids combustion (metric tons per year).
Solids	=	Mass of the spent liquor solids combusted (short tons per year) determined according to §98.274(b).
CC	=	Annual carbon content of the spent liquor solids, determined according to §98.274(b) (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.90718	=	Conversion from short tons to metric tons

(4) Calculate CH_4 and N_2O emissions from biomass using Equation AA-1 of this section and the default CH_4 and N_2O emissions factors for kraft facilities in Table AA-1 of this subpart and convert the CH_4 or N_2O emissions to metric tons of CO_2 equivalent by multiplying each annual CH_4 and N_2O emissions total by the appropriate global warming potential (GWP) factor from Table A-1 of subpart A of this part.

(c) For each pulp mill lime kiln located at a kraft or soda facility, you must determine CO_2, CH_4, and N_2O emissions using the procedures in paragraphs (c)(1) through (c)(3) of this section:

(1) Calculate CO_2 emissions from fossil fuels from direct measurement of fossil fuels consumed and the methodology for stationary combustion sources specified by §98.33(a) (as modified by this Article) for the appropriate fuel type. ~~and default HHV and default emissions factors, according to the Tier 1 Calculation Methodology for stationary combustion sources in §98.33(a)(1); use the default HHV listed in Table C-1 of subpart C and~~ Where the applicable method specified by § 98.33(a) allows the use of a default emission factor, use the default CO_2 emissions factors listed in Table AA-2 of this subpart.

(2) Calculate CH_4 and N_2O emissions from fossil fuel from direct measurement of fossil fuels consumed, default HHV, and default emissions factors and convert to metric tons of CO_2 equivalent according to the methodology for stationary combustion sources in §98.33(c); use the default HHV listed in Table C-1 of subpart C and the default CH_4 and N_2O emissions factors listed in Table AA-2 of this subpart.

(3) Biogenic CO_2 emissions from conversion of $CaCO_3$ to CaO are included in the biogenic CO_2 estimates calculated for the chemical recovery furnace in paragraph (a)(3) of this section.

(d) For makeup chemical use, you must calculate CO_2 emissions by using direct or indirect measurement of the quantity of chemicals added and ratios of the molecular weights of CO_2 and the makeup chemicals, according to Equation AA-3 of this section:

$$CO_2 = \left[M_{(CaCO_3)} * \frac{44}{100} + M_{(Na_2CO_3)} \frac{44}{105.99} \right] * 1000\, kg / metric\, ton \quad \text{(Eq. AA-3)}$$

Where:

CO_2	=	CO_2 mass emissions from makeup chemicals (kilograms/yr).
M ($CaCO_3$)	=	Make-up quantity of $CaCO_3$ used for the reporting year (metric tons per year).
M ($NaCO_3$)	=	Make-up quantity of Na_2CO_3 used for the reporting year (metric tons per year).
44	=	Molecular weight of CO_2.
100	=	Molecular weight of $CaCO_3$.
105.99	=	Molecular weight of Na_2CO_3.

§98.274 Monitoring and QA/QC requirements.

(a) Each facility subject to this subpart must quality assure the GHG emissions data according to the applicable requirements in §98.34. All QA/QC data must be available for inspection upon request.

(b) Fuel properties needed to perform the calculations in Equations AA-1 and AA-2 of this subpart must be determined according to paragraphs (b)(1) through (b)(3) of this section.

(1) High heat values of black liquor must be determined no less than annually using T684 om–06 Gross Heating Value of Black Liquor, TAPPI (incorporated by reference, see §98.7). If measurements are performed more frequently than annually, then the high heat value used in Equation AA-1 of this subpart must be based on the average of the representative measurements made during the year.

(2) The annual mass of spent liquor solids must be determined using either of the methods specified in paragraph (b)(2)(i) or (b)(2)(ii).

(i) Measure the mass of spent liquor solids annually (or more frequently) using T-650 om–05 Solids Content of Black Liquor, TAPPI (incorporated by reference in §98.7). If measurements are performed more frequently than annually, then the mass of spent liquor solids used in

Equation AA-1 of this subpart must be based on the average of the representative measurements made during the year.

(ii) Determine the annual mass of spent liquor solids based on records of measurements made with an online measurement system that determines the mass of spent liquor solids fired in a chemical recovery furnace or chemical recovery combustion unit.

(3) Carbon analyses for spent pulping liquor must be determined no less than annually using ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see §98.7). If measurements using ASTM D5373-08 are performed more frequently than annually, then the spent pulping liquor carbon content used in Equation AA-2 of this subpart must be based on the average of the representative measurements made during the year.

(c) Each facility must keep records that include a detailed explanation of how company records of measurements are used to estimate GHG emissions. The owner or operator must also document the procedures used to ensure the accuracy of the measurements of fuel, spent liquor solids, and makeup chemical usage, including, but not limited to calibration of weighing equipment, fuel flow meters, and other measurement devices. The estimated accuracy of measurements made with these devices must be recorded and the technical basis for these estimates must be provided. The procedures used to convert spent pulping liquor flow rates to units of mass (i.e., spent liquor solids firing rates) also must be documented.

(d) Records must be made available upon request for verification of the calculations and measurements.

§98.275 Procedures for estimating missing data.

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required sample is not taken), a substitute data value for the missing parameter shall be used in the calculations, according to the requirements of paragraphs (a) through (c) of this section:

(a) There are no missing data procedures for measurements of heat content and carbon content of spent pulping liquor. A re-test must be performed if the data from any annual measurements are determined to be invalid.

(b) For missing measurements of the mass of spent liquor solids or spent pulping liquor flow rates, use the lesser value of either the maximum mass or fuel flow rate for the combustion unit, or the maximum mass or flow rate that the fuel meter can measure.

(c) For the use of makeup chemicals (carbonates), the substitute data value shall be the best available estimate of makeup chemical consumption, based on available data (e.g., past accounting records, production rates). The owner or operator shall document and keep records of the procedures used for all such estimates.

§98.276 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information in paragraphs (a) through (K) of this section as applicable:

(a) Annual emissions of CO_2, biogenic CO_2, CH_4, biogenic CH_4 N_2O, and biogenic N_2O (metric tons per year).

(b) Annual quantities fossil fuels by type used in chemical recovery furnaces and chemical recovery combustion units in short tons for solid fuels, gallons for liquid fuels and scf for gaseous fuels.

(c) Annual mass of the spent liquor solids combusted (short tons per year), and basis for determining the annual mass of the spent liquor solids combusted (whether based on T650 om-05 Solids Content of Black Liquor, TAPPI (incorporated by reference, see §98.7) or an online measurement system).

(d) The high heat value (HHV) of the spent liquor solids used in Equation AA-1 of this subpart (mmBtu per kilogram).

(e) The default emission factor for CO_2, CH_4, or N_2O, used in Equation AA-1 of this subpart (kg CO_2, CH_4, or N_2O per mmBtu).

(f) The carbon content (CC) of the spent liquor solids, used in Equation AA-2 of this subpart (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).

(g) Annual quantities of fossil fuels by type used in pulp mill lime kilns in short tons for solid fuels, gallons for liquid fuels and scf for gaseous fuels.

(h) Make-up quantity of $CaCO_3$ used for the reporting year (metric tons per year) used in Equation AA-3 of this subpart.

(i) Make-up quantity of Na_2CO_3 used for the reporting year (metric tons per year) used in Equation AA-3 of this subpart.

(j) Annual steam purchases(pounds of steam per year).

(k) Annual production of pulp and/or paper products produced (metric tons).

§98.277 Records that must be retained.

Subpart AA—Pulp and Paper Manufacturing

In addition to the information required by §98.3(g), you must retain the records in paragraphs (a) through (f) of this section.

(a) GHG emission estimates (including separate estimates of biogenic CO_2) for each emissions source listed under §98.270(b).

(b) Annual analyses of spent pulping liquor HHV for each chemical recovery furnace at kraft and soda facilities.

(c) Annual analyses of spent pulping liquor carbon content for each chemical recovery combustion unit at a sulfite or semichemical pulp facility.

(d) Annual quantity of spent liquor solids combusted in each chemical recovery furnace and chemical recovery combustion unit, and the basis for detemining the annual quantity of the spent liquor solids combusted (whether based on T650 om–05 Solids Content of Black Liquor, TAPPI (incorporated by reference, see §98.7) or an online measurement system). If an online measurement system is used, you must retain records of the calaulations used to determine the annual quantity of spent liquor solids combusted from the continuous measurements.

(e) Annual steam purchases.

(f) Annual quantities of makeup chemicals used.

Subpart AA—Pulp and Paper Manufacturing

§98.278 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.

Table AA-1 of Subpart AA—Kraft Pulping Liquor Emissions Factors for Biomass-Based CO_2, CH_4, and N_2O.

Wood Furnish	Biomass-Based Emissions Factors (kg/mmBtu HHV)		
	CO_2[a]	**CH_4**	**N_2O**
North American Softwood	94.4	0.030	0.005
North American Hardwood	93.7		
Bagasse	95.5		
Bamboo	93.7		
Straw	95.1		

[a] Includes emissions from both the recovery furnace and pulp mill lime kiln.

Table AA-2 of Subpart AA—Kraft Lime Kiln and Calciner Emissions Factors for Fossil Fuel-Based CO_2, CH_4, and N_2O

Fuel	Fossil Fuel-Based Emissions Factors (kg/mmBtu HHV)					
	Kraft Lime Kilns			Kraft Calciners		
	CO_2	**CH_4**	**N_2O**	**CO_2**	**CH_4**	**N_2O**
Residual Oil	76.7	0.0027	0	76.7	0.0027	0.0003
Distillate Oil	73.5			73.5		0.0004
Natural Gas	56.0			56.0		0.0001
Biogas	0			0		0.0001

Subpart CC—Soda Ash Manufacturing

§98.290 Definition of the source category.

A soda ash manufacturing facility is any facility with a manufacturing line that produces soda ash by one of the methods in paragraphs (a) through (c) of this section:

(a) Calcining trona.

(b) Calcining sodium sesquicarbonate.

(c) Using a liquid alkaline feedstock process that directly produces CO_2.

In the context of the soda ash manufacturing sector, "calcining" means the thermal/chemical conversion of the bicarbonate fraction of the feedstock to sodium carbonate.

§98.291 Reporting threshold.

You must report GHG emissions under this subpart if your facility contains a soda ash manufacturing process and the facility meets the requirements of either §98.2(a)(1) or (a)(2).

§98.292 GHGs to report.

You must report:

(a) CO_2 process emissions from each soda ash manufacturing line combined.[1]

(b) CO_2 combustion emissions from each soda ash manufacturing line.

---

[1]Clarification – if CO_2 generated during calcination is recycled to carbonation towers, these calculated process emissions will be adjusted by the measured quantity of recycled CO_2 determined by the method identified in §98.293(d).

(c) CH_4 and N_2O combustion emissions from each soda ash manufacturing line. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

(d) CO_2, CH_4, and N_2O emissions from each stationary combustion unit other than soda ash manufacturing lines. You must calculate and report these emissions under subpart C of this part (General Stationary Fuel Combustion Sources) by following the requirements of subpart C.

§98.293 Calculating GHG emissions.

You must calculate and report the annual process CO_2 emissions from each soda ash manufacturing line using the procedures specified in paragraph (a) or (b) of this section.

(a) For each soda ash manufacturing line that meets the conditions specified in §98.33(b)(4)(ii) or (b)(4)(iii), you must calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(b) For each soda ash manufacturing line that is not subject to the requirements in paragraph (a) of this section, calculate and report the process CO_2 emissions from the soda ash manufacturing line by using the procedure in either paragraphs (b)(1), (b)(2), or (b)(3) of this section; and the combustion CO_2 emissions using the procedure in paragraph (b)(4) of this section.

(1) Calculate and report under this subpart the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Tier 4 Calculation Methodology specified in §98.33(a)(4) and all associated requirements for Tier 4 in subpart C of this part (General Stationary Fuel Combustion Sources).

(2) Use either Equation CC-1 or Equation CC-2 of this section to calculate annual CO_2 process emissions from each manufacturing line that calcines trona to produce soda ash:

$$E_k = \sum_{n=1}^{12} [(IC_T)_n * (T_t)_n] * \frac{2000}{2205} * \frac{0.097}{1} \quad \text{(Eq. CC-1)}$$

$$E_k = \sum_{n=1}^{12} [(IC_{sa})_n * (T_{sa})_n] * \frac{2000}{2205} * \frac{0.138}{1} \quad \text{(Eq. CC-2)}$$

Where:

E_k = Annual CO_2 process emissions from each manufacturing line, k (metric tons).

$(IC_T)_n$ = Inorganic carbon content (percent by weight, expressed as a decimal fraction) in trona input, from the carbon analysis results for

		month n. This represents the ratio of trona to trona ore.
$(IC_{sa})_n$	=	Inorganic carbon content(percent by weight, expressed as a decimal fraction) in soda ash output, from the carbon analysis results for month n. This represents the purity of the soda ash produced.
$(T_t)_n$	=	Mass of trona input in month n (tons).
$(T_{sa})_n$	=	Mass of soda ash output in month n (tons).
2000/2205	=	Conversion factor to convert tons to metric tons.
0.097/1	=	Ratio of ton of CO_2 emitted for each ton of trona.
0.138/1	=	Ratio of ton of CO_2 emitted for each ton of soda ash produced.

(3) Site-specific emission factor method. Use Equations CC-3, CC-4, and CC-5 of this section to determine annual CO_2 process emissions from manufacturing lines that use the liquid alkaline feedstock process to produce soda ash. You must conduct an annual performance test and measure CO_2 emissions and flow rates at all process vents from the mine water stripper/evaporator for each manufacturing line and calculate CO_2 emissions as described in paragraphs (b)(3)(i) through (b)(3)(iv) of this section.

(i) During the performance test, you must measure the process vent flow from each process vent during the test and calculate the average rate for the test period in metric tons per hour.

(ii) Using the test data, you must calculate the hourly CO_2 emission rate using Equation CC-3 of this section:

$$ER_{CO2} = [(C_{co2} * 10000) * 2.59x10^{-9} * 44] * (Q * 60) * 4.53x10^{-4} \quad \text{(Eq. CC-3)}$$

Where:

ER_{CO2}	=	CO_2 mass emission rate (metric tons/hour).
C_{CO2}	=	Hourly CO_2 concentration (percent CO_2) as determined by §98.294(c).
10000	=	Parts per million per percent
2.59×10^{-9}	=	Conversion factor (pounds-mole/dscf/ppm).
44	=	Pounds per pound-mole of carbon dioxide.
Q	=	Stack gas volumetric flow rate per minute (dscfm).
60	=	Minutes per hour
4.53×10^{-4}	=	Conversion factor (metric tons/pound)

(iii) Using the test data, you must calculate a CO_2 emission factor for the process using Equation CC-4 of this section:

$$EF_{CO2} = \frac{ER_{CO2}}{(V_t * 4.53x10^{-4})} \quad \text{(Eq. CC-4)}$$

Where:

EF_{CO2}	=	CO_2 emission factor (metric tons CO_2/metric ton of process vent flow from mine water stripper/evaporator).
ER_{CO2}	=	CO_2 mass emission rate (metric tons/hour).
V_t	=	Process vent flow rate from mine water stripper/evaporator during annual performance test (pounds/hour).
4.53×10^{-4}	=	Conversion factor (metric tons/pound)

(iv) You must calculate annual CO_2 process emissions from each manufacturing line using Equation CC-5 of this section:

$$E_k = EF_{CO2} * (V_a * 0.453) * H \qquad \text{(Eq. CC-5)}$$

Where:

E_k	=	Annual CO_2 process emissions for each manufacturing line, k (metric tons).
EF_{CO2}	=	CO_2 emission factor (metric tons CO_2/metric ton of process vent flow from mine water stripper/evaporator).
V_a	=	Annual process vent flow rate from mine water stripper/evaporator (thousand pounds/hour).
H	=	Annual operating hours for the each manufacturing line.
0.453	=	Conversion factor (metric tons/thousand pounds).

(4) Calculate and report under subpart C of this part (General Stationary Fuel Combustion Sources) the combustion CO_2, CH_4, and N_2O emissions in the soda ash manufacturing line according to the applicable requirements in subpart C.

§98.294 Monitoring and QA/QC requirements.

Section 98.293 provides ~~three~~ four different procedures for emission calculations. The appropriate paragraphs (a) through (~~c~~d) of this section should be used for the procedure chosen.[2]

[2]For plants that recycle CO_2 generated during calcination to carbonation towers, WCI requested that CEMS be installed in the recycle loop to measure the quantity of recycled CO_2. As a result, an additional method was added to §98.293(d). The resulting measurement of the quantity of recycled CO_2 was also added to §98.296(a)(5) and §98.296(b)(12).

Subpart CC—Soda Ash Manufacturing

(a) If you determine your emissions using §98.293(b)(2) (Equation CC-1 of this subpart) you must:

(1) Determine the monthly inorganic carbon content of the trona from a weekly composite analysis for each soda ash manufacturing line, using a modified version of ASTM E359-00(Reapproved 2005)e1, Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate) (incorporated by reference, see §98.7). ASTM E359-00(Reapproved 2005)e1 is designed to measure the total alkalinity in soda ash not in trona. The modified method of ASTM E359-00 adjusts the regular ASTM method to expresse the results in terms of trona. Although ASTM E359-00(Reapproved 2005)e1 uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of trona input produced by each soda ash manufacturing line on a monthly basis using belt scales or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of trona consumed.

(b) If you calculate CO_2 process emissions based on soda ash production (§98.293(b)(2)Equation CC-2 of this subpart), you must:

(1) Determine the inorganic carbon content of the soda ash (i.e., soda ash purity) using ASTM E359-

00(Reapproved 2005)e1 Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate) (incorporated by reference, see §98.7). Although ASTM E359-00(Reapproved 2005)e1 uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of soda ash produced by each soda ash manufacturing line on a monthly basis using belt scales, by weighing the soda ash at the truck or rail loadout points of your facility, or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of soda ash produced.

(c) If you calculate CO_2 emissions using the site-specific emission factor method in §98.293(b)(3), you must:

(1) Conduct an annual performance test that is based on representative performance (i.e., performance based on normal operating conditions) of the affected process.

(2) Sample the stack gas and conduct three emissions test runs of 1 hour each.

(3) Conduct the stack test using EPA Method 3A at 40 CFR part 60, appendix A-2 to measure the CO_2 concentration, Method 2, 2A, 2C, 2D, or 2F at 40 CFR part 60, appendix A-1 or Method 26 at 40 CFR part 60, appendix A-2 to determine the stack gas volumetric flow rate. All QA/QC procedures

specified in the reference test methods and any associated performance specifications apply. For each test, the facility must prepare an emission factor determination report that must include the items in paragraphs (c)(3)(i) through (c)(3)(iii) of this section.

(i) Analysis of samples, determination of emissions, and raw data.

(ii) All information and data used to derive the emissions factor(s).

(iii) You must determine the average process vent flow rate from the mine water stripper/evaporater during each test and document how it was determined.

(4) You must also determine the the annual vent flow rate from the mine water stripper/evaporater from monthly information using the same plant instruments or procedures used for accounting purposes (i.e., volumetric flow meter).

(d) If you recycle CO_2 generated during calcination to carbonation towers, then you must install a CEMS in the recycle loop and measure this quantity of CO_2.

§98.295 Procedures for estimating missing data.

For the emission calculation methodologies in §98.293(b)(2)and (b)(3), a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., inorganic carbon content values, etc.).

Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in the paragraphs (a) through (d) of this section. You must document and keep records of the procedures used for all such missing value estimates.

(a) For each missing value of the weekly composite of inorganic carbon content of either soda ash or trona, the substitute data value shall be the arithmetic average of the quality-assured values of inorganic carbon contents from the week immediately preceding and the week immediately following the missing data incident. If no quality-assured data on inorganic carbon contents are available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon contents obtained after the missing data period.

(b) For each missing value of either the monthly soda ash production or the trona consumption, the substitute data value shall shall be the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes.

(c) For each missing value collected during the performance test (hourly CO_2 concentration, stack gas volumetric flow rate, or average process vent flow from mine water stripper/evaporator during performance test), you must repeat the annual performance test following the calculation and monitoring and QA/QC requirements under §§98.293(b)(3) and 98.294(c).

(d) For each missing value of the monthly process vent flow rate from mine water stripper/evaporator, the subsititute data value shall be the best available estimate(s) of the parameter(s), based on all available process data or the lesser of the maximum capacity of the system or the maximum rate the meter can measure.

§98.296 Data reporting requirements.

In addition to the information required by §98.3(c), each annual report must contain the information specified in paragraphs (a) or (b) of this section, as appropriate for each soda ash manufacturing facility.

(a) If a CEMS is used to measure CO_2 emissions, then you must report under this subpart the relevant information required under §98.36 and the following information in this paragraph (a):

(1) Annual consumption of trona or liquid alkaline feedstock for each manufacturing line (metric tons).

(2) Annual production of soda ash for each manufacturing line (tons).

(3) Annual production capacity of soda ash for each manufacturing line (tons).

(4) Identification number of each manufacturing line.

(5) Annual quantity of generated CO_2 recycled to carbonation towers (tons), if applicable.

(b) If a CEMS is not used to measure CO_2 emissions, then you must report the information listed in this paragraph (b):

(1) Identification number of each manufacturing line.

(2) Annual process CO_2 emissions from each soda ash manufacturing line (metric tons).

(3) Annual production of soda ash (tons).

(4) Annual production capacity of soda ash for each manufacturing line (tons).

(5) Monthly consumption of trona or liquid alkaline feedstock for each manufacturing line (tons).

(6) Monthly production of soda ash for each manufacturing line (metric tons).

(7) Inorganic carbon content factor of trona or soda ash (depending on use of Equations CC-1 or CC-2 of this subpart) as measured by the applicable method in §98.294(b) or (c) for each month (percent by weight expressed as a decimal fraction).

(8) Whether CO_2 emissions for each manufacturing line were calculated using a trona input method as described in Equation CC-1 of this subpart, a soda ash output method as described in Equation CC-2 of this subpart, or a site-specific emission factor method as described in Equations CC-3 through CC-5 of this subpart.

(9) Number of manufacturing lines located used to produce soda ash.

(10) If you produce soda ash using the liquid alkaline feedstock process and use the site-specific emission factor method (§98.293(b)(3)) to estimate emissions then you must report the following relevant information:

(i) Stack gas volumetric flow rate per minute (dscfm)

(ii) Hourly CO_2 concentration (percent CO_2)

(iii) CO_2 emission factor (metric tons CO_2/metric tons of process vent flow from mine water stripper/evaporator).

(iv) CO_2 mass emission rate (metric tons/hour).

(v) Average process vent flow from mine water stripper/evaporater during performance test (pounds/hour).

(vi) Annual process vent flow rate from mine stripper/evaporator (thousand pounds/hour).

(vii) Annual operating hours for each manufacturing line used to produce soda ash using liquid alkaline feedstock (hours).

(11) Number of times missing data procedures were used and for which parameter as specified in this paragraph (b)(11):

(i) Trona or soda ash (number of months).

(ii) Inorganic carbon contents of trona or soda ash (weeks).

(iii) Process vent flow rate from mine water stripper/evaporator (number of months).

(iv) Stack gas volumetric flow rate during performance test(number of times).

(v) Hourly CO_2 concentration (number of times).

(vi) Average vent process vent flow rate from mine stripper/evaporator during performance test (number of times).

(12) Annual quantity of generated CO_2 recycled to carbonation towers (tons), if applicable.

§98.297 Records that must be retained.

In addition to the records required by §98.3(g), you must retain the records specified in paragraphs (a) and (b) of this section for each soda ash manufacturing line.

Subpart CC—Soda Ash Manufacturing

(a) If a CEMS is used to measure CO_2 emissions, then you must retain under this subpart the records required for the Tier 4 Calculation Methodology specified in subpart C of this part and the information listed in this paragraph (a):

(1) Monthly production of soda ash (tons)

(2) Monthly consumption of trona or liquid alkaline feedstock (tons)

(3) Annual operating hours (hours).

(b) If a CEMS is not used to measure emissions, then you must retain records for the information listed in this paragraph (b):

(1) Records of all analyses and calculations conducted for determining all reported data as listed in §98.296(b).

(2) If using Equation CC-1 or CC-2 of this subpart, weekly inorganic carbon content factor of trona or soda ash, depending on method chosen, as measured by the applicable method in §98.294(b)(percent by weight expressed as a decimal fraction).

(3) Annual operating hours for each manufacturing line used to produce soda ash (hours).

(4) You must document the procedures used to ensure the accuracy of the monthly trona consumption or soda ash

prodcution measurements including, but not limited to, calibration of weighing equipment and other measurement devices. The estimated accuracy of measurements made with these devices must also be recorded, and the technical basis for these estimates must be provided.

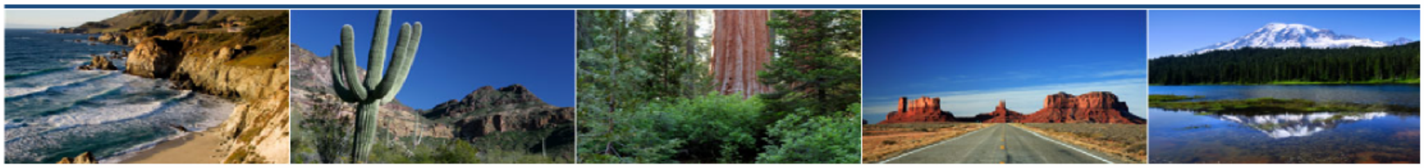
(5) If you produce soda ash using the liquid alkaline feedstock process and use the site-specific emission factor method to estimate emissions (§98.293(b)(3)) then you must also retain the following relevant information:

(i) Records of performance test results.

(ii) You must document the procedures used to ensure the accuracy of the annual average vent flow measurements including, but not limited to, calibration of flow rate meters and other measurement devices. The estimated accuracy of measurements made with these devices must also be recorded, and the technical basis for these estimates must be provided.

§98.298 Definitions.

All terms used in this subpart have the same meaning given in the Clean Air Act and subpart A of this part.



§WCI.8 REQUIREMENTS FOR VERIFICATION OF GREENHOUSE GAS EMISSIONS DATA REPORTS AND REQUIREMENTS APPLICABLE TO EMISSIONS DATA VERIFIERS (UPDATED FOR USE IN U.S. JURISDICTIONS TO CONFORM TO HARMONIZED ERS)

Note: The verification requirements laid out in this section strive for consistency with ISO 14064-3[1] requirements and set forth a high standard for verification that will ultimately support a WCI cap and trade program. Due to differences in rulemaking procedures between jurisdictions, Supplement 1 provides supplemental text that jurisdictions must incorporate into either the jurisdiction's prescriptive rule language, replacing more general procedural language in Section WCI.8, or into enforceable guidance documents. There are notes in WCI.8 that direct readers to appropriate text in Verification Supplement 1 when applicable.

It would be ideal for all jurisdictions to enforce the same requirements and have the same implementation processes for accreditation and verification to ensure that consistent accurate data exists throughout the WCI regional program. Reporters and verifiers with operations throughout the WCI region will benefit from a consistent approach and such an approach would facilitate administration of the verification requirements by a central body or designee.

(a) Applicability and Scope.

(1) Except as provided in WCI.8(a)(2) through (~~4~~5) owners or operators [Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices] are required to obtain annual verification for a facility that emits 25,000 metric tons CO_2e or more per year in combined emissions from one or more of the source categories listed in ~~WCI.1~~section 98.2 in any calendar year starting on or after 2010.

(2) When the operation of a facility, fuel supplier, or electricity importer subject to the requirements of this section is changed such that the operator has reported less than 25,000 metric tons of CO_2e emissions for a calendar year, the operator shall obtain verification of annual emissions reports for the lesser of three subsequent calendar years or for those years remaining in the current compliance period. If CO_2e emissions of a facility, fuel supplier, or electricity importer subject to the requirements of this section

[1] ISO (2006) ISO 14064-3: Greenhouse Gases-Part 3: Specification with guidance for the validation and verification of greenhouse gas assertions, March, 2006, International Organization for Standardization, Switzerland.

again exceed 25,000 metric tons in any calendar year the provisions of WCI.8(a)(1) apply.

(3) Carbon dioxide emissions from the combustion of biomass fuels shall be included in the determination regarding verification applicability, with the following exceptions:

(A) Until such time as [the jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, a maximum of 15,000 metric tons of carbon dioxide emissions from the combustion of pure solid biomass fuel may be excluded from calculation of GHG emissions for comparison to the 25,000 metric ton CO_2e per year verification threshold in paragraph (a) of this section.

(B) After such time as [the jurisdiction] has made a determination regarding the carbon neutrality of any biomass fuels, the carbon dioxide emissions from the combustion of those fuels may be excluded from calculation of GHG emissions for determining whether the 25,000 metric tons CO_2e per year verification threshold in paragraph (a)(1) of this section has been met.

[Under Design Recommendation 1.3, carbon neutral biomass will be excluded from the cap-and-trade program. A WCI Partner jurisdiction, however, may, in its discretion, choose to require carbon dioxide emissions from the combustion of biomass fuel to be included in the determination of the verification threshold in order to obtain a complete inventory of the fuels being combusted in the jurisdiction.]

(4) Owners or operators may exclude carbon dioxide emissions from the combustion of biomass fuels that [jurisdiction] has deemed carbon neutral from the scope of verification.

(5) Emissions designated "reporting only" in this article shall be excluded from the determination regarding verification applicability.

[A WCI Partner jurisdiction may, in its discretion, choose to require carbon dioxide emissions from the combustion of biomass fuel to be included in the scope of verification.]

~~(5)~~(6) Notwithstanding WCI.8(a)(2) and (3), any facility, fuel supplier or electricity importer subject to a cap-and-trade program for CO_2e emissions established by [the jurisdiction] shall obtain verification of reported annual emissions.

(b) Requirements for Annual Verification of Emissions Data Reports.

(1) Verification bodies shall conduct verification processes and design verification procedures to determine whether there is a reasonable level of assurance for each separate emissions data report every year of the verification cycle. The verification team shall find that there is a reasonable level of assurance for an emissions data report if the report

(A) contains no material misstatement; and

(B) conforms to the requirements of this article.

(2) The verification body must provide verification services in compliance with WCI.8.

(3) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification shall be subject to full verification requirements in the first year that

verification is required for an emissions data report. Upon completion of a positive verification statement under full verification requirements, the facility owner or operator, fuel supplier, or electricity importer may be eligible for two years of less intensive verification services as ~~described~~ defined in section WCI.8(x)~~9~~. This cycle may be repeated in subsequent three-year cycles; however, full verification requirements shall apply at least once every three years.

(4) Facility owners or operators, fuel suppliers, and electricity importers required to obtain annual verification will be required to obtain full verification services if any of the following apply:

(A) There has been a change in the verification body from the previous year; or

(B) A verification body issued an adverse verification statement for that facility's previous year's emissions data report.

(C) Reporters subject to the verification requirements of this section, must complete their verification process, including submittal of a verification statement to [the jurisdiction], by September 1 of the year following the reporting year.

(c) Accreditation Requirements for Verification Bodies.

(1) The accreditation requirements specified in this subsection shall apply to all verification bodies that wish to provide verification services under this rule.

(2) A verification body is qualified to conduct verification services ~~for the WCI~~ in [the jurisdiction] if

(A) it has demonstrated knowledge of [the ~~WCI~~ jurisdiction] reporting requirements; ~~and~~

(B) it has the characteristics and capabilities deemed necessary by [the jurisdiction] to perform verification services; and

(C) it is accredited to ISO 14065 through

(i) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum~~.~~; or

(ii) a program developed or authorized [the jurisdiction] under [the jurisdiction's] required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011.

[Note the details of the WCI's specific accreditation process for verification bodies ~~(which~~ has yet to be developed~~) will be consistent with ISO 14065 through an accreditation program that will developed under ISO 17011 and will include demonstrated knowledge of the WCI reporting requirements~~. The WCI will explore additional accreditation requirements and/or other criteria for individual lead verifiers, general verifiers, and/or sector specialists.]

(3) Prior to January 1, 2013, accreditation by the California Air Resources Board under Title 17, California Code of Regulation, section 95132, may be substituted for the accreditation required under WCI.8(c)(2)(B).

(d) Requirements for Verification Services. The following verification services must be provided for each emissions data report.

(1) As part of the verification services, the verification team shall review documents submitted, assess risks of a material misstatement, develop a verification plan (that includes a sampling plan), evaluate the emissions data report against the verification requirements, and assess the materiality of errors, omissions and misstatements identified.

(2) The verification team shall request any information and documents needed for verification services. Such information shall include, but is not limited to original records and supporting data for the emissions data report.

(e) A verification team must include the following:

(1) a Lead Verifier;

(2) an Independent Peer Reviewer;

(3) any subcontractor elected to provide verification services under WCI.8(f).

(f) Subcontracting. The following requirements shall apply to any verification body that elects to subcontract verification services.

(1) The primary verification body must assume full legal responsibility for verification services performed by subcontracted verifiers or verification bodies.

(2) A verification body or verifier acting as a subcontractor to the primary verification body will not further subcontract that same work to another firm or individual.

(3) A verification body or verifier acting as a subcontractor is subject to all Conflict of Interest requirements in Section WCI.8(g).

(4) A verification body or verifier acting as a subcontractor must be identified by the primary verification body as part of the verification team.

(g) Conflict of Interest Requirements for Verification Bodies. The conflict of interest provisions of this section shall apply to the verification body, entities related to the verification body, and the verification team accredited according to the requirements of the WCI to perform verification services for the WCI program. Member for purposes of this section means any employee or subcontractor of the verification body or entities related to the verification body. Member also includes any individual with a majority equity share in the verification body or entities related to the verification body.

(1) Prior to a jurisdiction accepting a verification statement, and prior to a jurisdiction accepting the associated emissions report for consideration for approval, the AVA must determine that the verification body has a low potential for conflict of interest as described under WCI.8(g)(6). To inform this determination by the AVA, a self-evaluation of the potential for any conflict of interest that the verification body, entities related to the verification body, and members of the verification team, including subcontractors, may have with the owner or operator or their related entities for which verification services will be or have been provided shall be submitted to the AVA. This self-evaluation must include an evaluation of any threats to the verification body's

independence including: [*note: a standardized Conflict of Interest Assessment form will be developed for the WCI*]

[To facilitate timely determinations of conflict-of-interest potential, and to reduce the risk of finding medium or high conflict-of-interest potential after verification services have been initiated, it is recommended that jurisdictions require that the self evaluations be submitted and evaluated by the AVA prior to the initiation of verification services. A jurisdiction may elect to allow verification services to commence prior to the determination of the conflict-of-interest potential by the AVA.]

(A) Threats created by the reporting operation offering inducements to the verification body, subcontractors or verification team members for a positive opinion;

(B) Threats created by members of the verification body, verification team members, subcontractors, or family of subcontractors or team members having a financial interest in the reporting operation or its operator;

(C) Threats created by members of the verification body reviewing work of the verification body, subcontractors, members of the verification team, or related companies, including but not limited to any situation where the body, subcontractors, team members or companies have provided services related to greenhouse gases;

(D) Threats created by members of the verification body, verification team members, or subcontractors having a close relationship with the reporting operation, such that they might become too sympathetic to the interests of the reporting operation; and

(E) Threats created by members of the verification body, verification team members, or subcontractors being deterred from acting objectively or exercising professional skepticism by threats, actual or perceived, from the reporting operation.

(2) The verification body shall deem the potential for conflict of interest to be low if

(A) No threats as listed in WCI.8(g)(1) exist, and

(B) Any non-verification services provided by the verification body to the owner or operator within the last three years are valued at less than five percent of the verification body's annual revenue in each of those years.

(3) The verification body shall deem the potential for conflict of interest to be high if threats as listed in WCI.8(g)(1)(A) or (E) exist.

[A jurisdiction may expand the list of high threats (i.e. un-mitigatable conflicts) with the items included in paragraph 2 of the Conflict of Interest section of Supplement 1 below.]

(4) The verification body shall deem the potential for a conflict of interest to be medium if the potential for a conflict of interest is not deemed to be either low or high as specified in sections WCI.8(g)(2)-(3).

(5) If a verification body deems the potential for conflict of interest to be medium and wishes to provide verification services for the owner or operator, then the verification body shall submit, in addition to the self-evaluation, a plan to avoid, neutralize, or mitigate the potential conflict of interest situation.

(6) Conflict of Interest Determinations. The AVA shall review the self-evaluation submitted by the verification body and determine the verification body's potential conflict of interest in performing verification services for the owner or operator.

[In addition to the AVA determination, a jurisdiction may elect to conduct audits of conflict of interest submissions for compliance verification and enforcement purposes.]

(A) The AVA shall notify the verification body in writing when the conflict of interest evaluation information submitted under section WCI.8(g)(1) is deemed complete. Within 45 days after deeming the evaluation information complete, the AVA shall determine the conflict-of-interest potential and shall notify the verification body or owner or operator if the potential conflict of interest is determined to be medium or high.

(B) If the AVA determines the verification body or any member of the verification team has any threats specified in section WCI.8(g)(1), the AVA shall find a high potential conflict of interest and verification services may not proceed.

(C) If the AVA determines that there is a low potential conflict of interest prior to the verification services being provided, verification services may proceed.

(D) If the AVA determines that the verification body and verification team have a medium potential for a conflict of interest, the AVA shall evaluate the conflict of interest mitigation plan and may request additional information from the applicant to complete the determination. In determining potential conflict of interest, the AVA may consider factors including, but not limited to, the nature of previous work performed, the current and past relationships between the verification body and its subcontractors with the owner or operator, and the cost of the verification services to be performed. The AVA will determine whether these factors when considered in combination with the mitigation plan demonstrate a low level of potential conflict of interest or a high level. If the AVA determines that there is a low potential conflict of interest prior to the verification services being initiated, verification services may proceed. If a high potential is determined prior to verification services being initiated, verification services may not proceed. If a high potential is determined after verification services have been initiated, the verification statement shall not be accepted..

(7) Monitoring Conflict of Interest Situations.

(A) After commencement of verification services, the verification body shall monitor and immediately make full disclosure in writing to the AVA regarding any potential for a conflict of interest situation that arises. This disclosure shall include a description of actions that the verification body has taken or proposes to take to avoid, neutralize, or mitigate the potential for a conflict of interest.

(B) The verification body shall monitor arrangements or relationships that may be present for a period of one year after the completion of verification services. During that period, within 30 calendar days of any change in arrangements or relationships with the owner or operator for which the verification body has provided verification services that may create a medium or high threat of conflict of interest, the verification body shall notify the AVA of the change and provide a description of the nature of the change. The AVA will make a conflict of interest determination under WCI.8(g)(6).

(C) The verification body shall report to the AVA any changes in its organizational structure, including mergers, acquisitions, or divestitures that may have created a medium or high threat of conflict of interest for one year after completion of verification services within 30 days and submit an evaluation of how the change(s) impacts the potential for conflict of interest.

(D) The AVA may invalidate a verification finding if a medium or high threat of a conflict of interest has arisen for the verification body or any member of the verification team and, in the case of a medium threat, the threat has not been adequately mitigated. In such a case, the owner or operator shall be provided 180 calendar days to have their emissions report verified by a different verification body.

(E) If the verification body or its subcontractor(s) are found to have violated the conflict of interest requirements of this section, the AVA may rescind its accreditation for any appropriate period of time . Additionally, the AVA may separately revoke its recognition of an accredited Verification Body under WCI.8(w). *[The WCI intends to develop more detailed accreditation requirements in the future.]*

(h) Notice of Verification Services. Prior to commencing verification services for a facility owner or operator, fuel supplier, and electricity importer, the verification body shall submit a notice of verification services to the AVA. Verification activities shall not proceed for 15 business days or until the verification body receives written approval to proceed from the AVA, whichever is earlier. If the AVA does not respond to the verification body within 15 business days, the verification body may begin to conduct verification activities.

[The NOVS form will be standardized across WCI and developed later.]

(i) Verification Plan.

(1) Accounting for requirements set by WCI.8, the verification plan shall document:

(A) the scope of the verification;

(B) the level of assurance;

(C) the verification standard;

(D) the verification criteria;

(E) the objectives of the verification;

(F) the timing of the verification, including site visits;

(G) the nature of the communications required;

(H) the resources required to conduct the verification, including the role of verification team members; and

(I) the nature, timing and extent of the verification procedures, including the sampling plan.

(2) The verification body shall retain the verification plan in paper, electronic, or other format for a period of not less than seven years following the submission of each verification statement.

(j) Site visits. In years for which full verification services are required under WCI.8(b)(3), at least one member of the verification team shall at a minimum make one onsite site visit to each facility or fuel supply location *[Note that exact location of fuel supplier site visits remains TBD]* for which an emissions data report is submitted. The verification team member(s) shall also conduct an onsite visit of the headquarters or other location of central data management, if different from the facility or fuel supply location, when the owner or operator is an electricity importer.

(k) Owners or operators shall make available to the verification team all information and documentation used to calculate and report emissions, electricity transactions, and other information required under this rule, as applicable.

(l) As applicable for electricity importers, the verification team shall review electricity transaction records, including receipts of power attributed to the Northwest or Southwest region as verifiable via North American Electric Reliability Corporation (NERC) E-Tags, settlements data, or other information as confirmation of the region of origin. [*Note that this procedure is subject to change pending WCI Electricity Committee review.*]

(m) Data Checks. To determine the reliability of the submitted emissions data report, the verification team shall use data checks as defined in WCI.~~9~~8(x). Verifiers will use their professional judgment in determining how many data checks are needed to provide a reasonable level of assurance.

(n) Emissions Data Report Modifications. If as a result of review by the verification team and prior to completion of a verification statement the owner or operator chooses to make improvements or corrections to the submitted emissions data report, a revised emissions data report must be submitted to [the jurisdiction] as specified by section WCI.8(q). The owner or operator shall maintain documentation to support any revisions made to the initial emissions data report. Documentation for all emissions data report submittals shall be retained by the operator for seven years pursuant to section ~~WCI.4~~ 98.3(g).

(o) Materiality and Conformance Assessment Criteria. The verifier shall determine if the annual emissions report is prepared in such a way that it satisfies WCI.8(b)(1).

(1) A verification team shall determine that an emission data report contains a material misstatement, if either of the following is true:

(A) Based on the verification team's own determination of the level of emissions subject to verification based on the sampling plan, the verification team concludes that total reported emissions are less than 95 percent accurate using the following equation:

$$PA = 100 - [(SOU/TRE) \cancel{*} \times 100)]$$

Where:

PA = Percent accuracy

SOU	=	The net result of summing overstatements and understatements resulting from errors, omissions and misreporting
TRE	=	Total reported emissions

(B) The individual or aggregate effect of one or more errors, omissions or misstatements identified in the course of verification make it probable that the judgment of a reasonable person regarding the total reported emissions would have been changed or influenced by the error, omission or misrepresentation.

(2) To assess conformance with this rule the verification team shall review the methods and factors used to develop the emissions data report for adherence to the requirements of this rule.

(3) The verification team shall keep a log of any issues identified in the course of verification activities that may affect determinations of material misstatement and nonconformance, and how those issues were resolved.

(p) Completion of verification services shall include:

(1) Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall prepare either a positive or adverse verification statement, for each emissions data report, based on its findings during the verification process. The verification body shall provide the verification statement(s) to the reporter and to the AVA [alternatively, this could be the reporter's responsibility to submit the statement to the AVA], according to the schedule specified in section WCI.2(b). Before each statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.

~~Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall complete a verification statement for each emissions data report, and provide that statement to the owner or operator and [the jurisdiction or other body] according to the schedule specified in section WCI.2(b). Before that statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.~~

~~The verification body shall provide either a positive or adverse verification statement to the reporter and to the AVA *[alternatively, this could be the reporter's responsibility to submit the statement to the AVA]* based on its findings during the verification process.~~

(2) The lead verifier in the verification team shall attest on the verification statement that the verification team has carried out all verification services as required by this rule, and the Independent Peer Reviewer shall attest to his or her independent review on behalf of the verification body and his or her concurrence with the verification findings. If the Independent Peer Reviewer does not determine that the verification team has carried out all verification services as required by the rule or if the Independent Peer Reviewer rejects the verification team's findings, then the verification body cannot issue a positive verification statement.

(3) The verification body shall provide to the owner or operator a detailed verification report. The verification report shall at minimum include the detailed comparison of the

data checks with the submitted emissions data report, errors, omissions and misstatements identified during the course of the verification, any corrections made to the original annual emissions report as a result of the verification, and observations about the data management systems that are connected to the errors, omissions and misstatements identified, as well as any qualifying comments on findings during verification services. The detailed verification report shall be made available to [the jurisdiction] upon request.

(q) Prior to the verification body providing an adverse verification statement pursuant to WCI.8(p)(2), the owner or operator shall be provided at least 14 working days to modify the emissions data report to correct any material misstatement or nonconformance found by the verification team. The modified report and verification statement must be submitted to [the jurisdiction] before the applicable verification deadline, unless the operator makes a request to [the jurisidiction*]* as follows:

(1) If the owner or operator and the verification body cannot reach agreement on modifications to the emissions data report that result in a positive verification statement, the operator may petition the AVA to make a final decision as to the verifiability of the submitted emissions data report.

(2) If the AVA determines that the emissions data report does not meet the standards and requirements specified in this article, the owner or operator shall have the opportunity to submit within 60 calendar days of the date of this decision *[Note that this time frame may need to be changed pending details of cap-and-trade system design and needs.]* any emissions data report revisions that address the AVA's determination, for re-verification of the emissions data report. In re-verifying a revised emissions data report, the verification body and verification team shall be subject to the requirements in section WCI.8(q)-(s).

(3) Upon provision of the verification statement to [the jurisdiction], the emissions data report shall be considered final and no changes shall be made except as provided in section WCI.8(n) or (q). All verification requirements of this rule shall be considered complete upon provision of the verification statement.

(r) In addition to initiating WCI's dispute resolution process, the operator and verification body must inform the applicable accreditation body of the dispute.

(s) The AVA may make void the positive verification statement submitted by the verification body if:

(1) The AVA finds a high level of conflict of interest existed between a verification body and an owner or operator; or,

(2) An emissions data report that received a positive verification statement fails an audit by the AVA.

(t) Upon request by the AVA, the owner or operator shall provide the data used to generate an emissions data report, including all data available to a verification body. The AVA may also review the full verification report given by the verification body to the owner or operator. The full verification report shall be provided to the AVA upon request.

(u) Upon written notification by the AVA, the verification body shall make itself available for a verification services audit.

(v) Duration of verification services by one verification body. Facility owners or operators, fuel suppliers, or electricity importers subject to annual verification shall not use the same verification body for a period of more than six consecutive years. If a facility owner or operator, fuel supplier, or electricity importer is required or elects to contract with another verification body, they may contract verification services from the previous verification body only after not using the previous verification body for at least three years. If a verification body or verification team member has been providing verification services for an owner or operator in a greenhouse gas reporting or reductions program other than [the jurisdiction's] within the previous three years, those years of services will count towards the six consecutive year limit in this section.

(w) Revocation of Recognition. A jurisdiction may review, and for good cause, work to revoke or modify the accreditation status of a recognized verification body. If a recognized verification body is suspended in any other mandatory or voluntary GHG reporting or trading program, that verification body will not be allowed to provide any verification services until that suspension ends. If a recognized verification body has its accreditation revoked under any other mandatory or voluntary GHG reporting or trading program, that verification body will no longer be allowed to provide verification services under WCI.8 until it is reaccredited.

(x) Definitions. The following definitions shall apply to terms used in this section:

"Accreditation and Verification Authority" or "AVA" means [the jurisdiction] or any entity or entities to which [the jurisdiction] assigns any of the responsibilities for oversight and execution of the accreditation and verification program established in WCI.8.

"Adverse verification statement" means a verification statement rendered by a verification body stating that the verification body cannot conclude that there is a reasonable level of assurance for an emissions data report.

"Conflict of interest" means a situation in which, because of financial or other activities or relationships with other persons or organizations, a person or body is unable or potentially unable to render an impartial verification opinion of a potential client's greenhouse gas emissions, or the person or body's objectivity in performing verification services is or might be otherwise compromised.

"Data check" means an independent calculation or checking of data conducted by a verifier to recreate the emissions for a discreet source included in an emissions data report.

"Full verification" means all verification services as provided in section WCI.8(b).

"Less Intensive Verification" means the verification services provided in interim years between full verifications; less intensive verification only requires risk assessment and data checks on an owner or operator's emissions data report based on the most current sampling plan developed as part of the most current full verification services. This level of verification may only be used if the verifier can provide findings with a reasonable level of assurance.

"Material misstatement" means an error or omission, or a collection of errors or omissions, that results in a determination that a verification statement contains a material misstatement under WCI.8(o)(1)(A) or (B).

“Positive verification statement” means a verification statement rendered by a verification body stating that the verification body can say with reasonable assurance that the submitted emissions data report is free of material misstatement and that the emissions data report conforms to the requirements of this article.

“Verification” means a systematic, independent and documented process for the evaluation of an operator’s emissions data report against the WCI’s reporting procedures and methods for calculating and reporting GHG emissions.

“Verification body” means a firm accredited by the [Accreditation Body TBD] and recognized by the jurisdiction or its designee, that is able to render a verification statement and provide verification services for operators subject to reporting under this article.

“Verification cycle” means three years of verification activities. Each verification cycle must include at least one year of full verification, and may include two years of less intensive verification, if eligible.

“Verification statement” means the final written declaration rendered by a verification body attesting whether an operator’s emissions data report is free of material misstatement and whether the emissions data report conforms to the requirements of this article.

“Verification services” means services provided during verification as specified in WCI.8, including but not limited to reviewing an operator’s emissions data report, verifying its accuracy according to the standards specified in this article, assessing the operator’s compliance with this rule, and submitting a verification opinion to the *[jurisdiction or its agent]*.

“Verification team” means all of those working for a verification body, including all subcontractors, to provide verification services for an operator.

“Verifier” means an individual employed or contracted by an accredited verification body who has been deemed competent by the verification body to carry out verification services as specified in section WCI.8.

Verification Supplement 1

Note: the additional content in this Supplement must either be included in regulatory text in the appropriate subsections of WCI.8 or enforceable guidance documents by jurisdictions. The language in this section provides further explanation of items required in WCI.8 or alternative, more prescriptive language of those requirements.

Preliminary Activities and Verification Plan

The verification team shall discuss with the owner or operator the scope and objective of the verification services and obtain information from the owner or operator necessary to develop a verification plan. Such information shall include but is not limited to:

- Information to allow the verification team to develop a general understanding of facility or entity boundaries, operations, emissions sources, electricity transactions, as applicable;
- Information about the data management system used to track GHG emissions, electricity transactions, and other required measurement data as applicable;
- Information regarding the training or qualifications of personnel involved in developing the GHG emissions data report;
- Description of the specific methodologies used to quantify and report GHG emissions, electricity transactions, and other required data as applicable;
- Records of measured data related to emissions and operations for the prior and current period;
- Inventory of sources and their associated emissions for the reporting period, and
- Any prior verification reports, if applicable.

In developing the verification plan, the verifier shall:

- Gain an understanding of the organization and the process that emit greenhouse gases;
- Conduct a risk assessment to evaluate inherent, control and detection risk;
- Conduct preliminary analytical testing to identify anomalies in the data;
- Conduct a sensitivity analysis to assess the relative contribution of each source in the inventory to the reported annual emissions, and
- Consider any other relevant developments at the facility, in the regulations, or legal environment.

Sampling Plan

As part of the verification procedures, the verification team shall develop a sampling plan that, when combined with the other verification procedures, provides sufficient and appropriate evidence to allow the verifier to arrive at a conclusion. The sampling plan shall be designed to achieve the specified verification objective. The sample plan shall consider:

- Statistical versus non-statistical approaches
- Design of the sample, including the population characteristics
- Stratification (categorization of population into subgroups)
- Emission weighted selection
- Sample size

- Sample selection

As relevant information becomes available during the course of verification activities, the verification team must modify the sampling plan as necessary to address potential issues emerge of material misstatement or nonconformance with the requirements of this rule.

Data Checks

The verification team conducts data checks throughout the verification process and shall focus first on the largest and most uncertain estimates of emissions and electricity transactions.

- In establishing the verification plan, the verification team shall use professional judgment to determine the number of data checks required for the team to conclude with reasonable assurance whether the reported emissions and transactions are free of material misstatement and the emissions data report otherwise conforms to the requirements of this rule.
- The verification team shall choose emissions sources, and electricity transactions data as applicable, for data checks based on their relative sizes and risks of material misstatement as indicated in the verification plan;
- The verification team, through the conformance assessment, shall ensure that the appropriate methodologies and emission factors have been applied for the emissions sources and electricity transactions for sampled data covered under sections WCI.20 through WCI.XX;

Site Visits

During the site visit, the verification team member(s) shall conduct the following:

- Observe whether all sources at the site are represented in the emissions report as specified in sections WCI.20 to WCI.XX as applicable to the owner or operator.
- Assess whether the source inventory is identified, categorized, and reported appropriately. Collect evidence as to explanations for data anomalies identified in the verification plan.
- Understand the data trail used by the owner or operator to measure, quantify, and report greenhouse gas emissions and, when applicable, electricity transactions.
- Understand and evaluate the associated data controls used by the owner to ensure the completeness and accuracy of the data

Materiality Assessment

In assessing whether misstatements are material, the verification team shall determine whether the total reported emissions are at least 95 percent accurate using the following equation:

Percent accuracy = 100 – (sum of (errors, omissions, misreporting) * 100 / (total reported emissions))

To assess conformance with this rule the verification team shall review the methods and factors used to develop the emissions data report for adherence to the requirement of this rule. The verification team shall keep a record of any errors, omissions or misstatements identified in the course of verification activities that may affect determinations of material misstatement and nonconformance, and how those issues were resolved.

Conflict of Interest (*could replace more general procedural language in Section WCI.8*)

(1) Conflict of Interest Submittal Requirements for Accredited Verification Bodies.

(A) Before the start of any work related to providing verification services to an owner or operator, a verification body must first be authorized in writing by *the AVA* to provide verification services. To obtain authorization the verification body shall submit to *the AVA* a self-evaluation of the potential for any conflict of interest that the verification body, entities related to the verification body, and members of the verification team including, subcontractors may have with the owner or operator or their related entities for which it will perform verification services. For the purposes of this section, the term member refers to staff on the verification team, in the verification body and any subcontractors. The submittal shall include the following:

(i) Identification of whether the potential for conflict of interest is high, low, or medium based on factors specified in this section;

(ii) An organizational chart of the business structure of the verification body, including its related entities and brief description of the primary work done by the verification body and related entities;

(iii) iii. Identification of whether any member of the verification body, entities related to the verification body, or the verification team including subcontractors has previously provided verification services for the owner or operator or its related entities and, if so, the years in which such verification services were provided;

(iv) Identification of whether any member of the verification body, entities related to the verification body, or the verification team or including subcontractors has engaged in any non-verification services of any nature with the owner or operator or related entities either within or outside the WCI region during the previous three years. The verification body must also disclose any services listed under section (high COI list) it has provided to the owner or operator, regardless of when these services occurred. If non-verification services have previously been provided, the following information shall also be submitted:

(v) Identification of the nature and location of the work performed for the owner or operator and whether the work is similar to the type of work to be performed during verification, such as emissions inventory auditing, energy efficiency, renewable energy, or other work with implications for the operator's greenhouse gas emissions or the accounting of greenhouse gas emissions or electricity transactions;

(vi) The nature of past, present or future relationships the verification body, entities related to the verification body, and members of the verification team including subcontractors have with the owner or operator or related entity including:

- Instances when any member has performed or intends to perform work for the owner or operator;
- Identification of whether work is currently being performed for the owner or operator and, if so, the nature of the work;

- Whether any member has any contracts or other arrangements to perform work for the owner or operator or a related entity;
- Identify how much work was performed in each of the last three years, as a percentage of the verification body's total gross income for each of the last three years;
- Identify how much work related to greenhouse gases or electricity transactions was has performed for the owner or operator or related entities in each of the last three years, as a percentage of the verification body's income for each of the last three years;
- Identify how much work was performed by each subcontractor for the operator in each of the last three years, as a percentage of each subcontractor's total gross income for each of the last three years.

(vii) Explanation of how the amount and nature of work previously performed is such that any member of the verification team's credibility and lack of bias should not be under question.

(viii) A list of names of the verification team members that will perform verification services for the owner or operator and a description of any instances of personal or family relationships with management or employees of the owner or operator that potentially represent a conflict of interest; and,

(ix) Identification of any other circumstances or relevant information known to the verification body or owner or operator that could result in a conflict of interest, or any situation where the appearance of impartiality could undermine confidence in the verification body's ability to assess the reported emissions.

(2) The potential for a conflict of interest shall be deemed to be high where:

(A) The verification body and owner or operator share any management staff or board of directors membership, or any of the management staff of the owner or operator have been employed by the verification body, or vice versa, within the previous three years; or

(B) Within the previous three years, any member of the verification body, any entity related to the verification body, and the verification team has provided to the owner or operator any of the following non-verification services:

(i) Designing, developing, implementing, or maintaining an inventory or information or data management system for facility greenhouse gases, or, where applicable, electricity transactions;

(ii) Developing greenhouse gas emission factors or other greenhouse gas-related engineering analysis;

(iii) Designing energy efficiency, renewable power, or other projects which explicitly identify greenhouse gas reductions as a benefit;

(iv) Preparing or producing greenhouse gas-related manuals, handbooks, or procedures specifically for the reporting facility;

(v) Appraisal services of carbon or greenhouse gas liabilities or assets;

(vi) Brokering in, advising on, or assisting in any way in carbon or greenhouse gas-related markets;

(vii) Managing any health, environment or safety functions which explicitly identify greenhouse gas reductions as a benefit;

(viii) Bookkeeping or other services related to the accounting records or financial statements, unless those services limited to financial auditing;

(ix) Any service related to information systems, unless those systems will not be part of the verification process and excluding third-party auditor or registration services;

(x) Appraisal and valuation services, both tangible and intangible related to GHG emissions or reductions inventories;

(xi) Fairness opinions and contribution-in-kind reports in which the verification body has provided its opinion on the adequacy of consideration in a transaction, unless the resulting services shall not be part of the verification process;

(xii) Any actuarially oriented advisory service involving the determination of amounts recorded in financial statements and related accounts;

(xiii) Any internal audit service as provided under section (GHG plan) that has been outsourced by the operator that relates to the owner's or operator's internal accounting controls, financial systems or financial statements, unless no consulting or advice was provided as part of the audit;

(xiv) Acting as a broker-dealer (registered or unregistered), promoter or underwriter on behalf of the owner or operator;

(xv) Any legal services related to GHG emissions;

(xvi) Expert services to the owner or operator or his or her legal representative for the purpose of advocating his or her's interests in litigation or in a regulatory or administrative proceeding or investigation involving GHG emissions, unless providing factual testimony.

(C) The potential for a conflict of interest shall also be deemed to be high where any staff member of the verification body, entity related to the verification body, or the verification team has provided verification services for the owner or operator for six consecutive years or within three years of the termination of a previous GHG verification contract with the owner or operator. If a verification body or verification team member has been providing verification services for a [operator/owner] in a greenhouse gas reporting or reductions program other than WCI within the past three years, those years of services will count towards the six consecutive year limit in the WCI.

(D) The potential for a conflict of interest shall be deemed high where the Independent Peer Reviewer for the verification team has provided verification or non-verification services for the operator during the current reporting year.

(3) The potential for a conflict of interest shall be deemed to be low where no potential for a conflict of interest is found under section WCI.8(g) *[may need to be updated, depending upon final version of WCI.8)* and any non-verification services provided by all members of the verification body and the verification team to the owner or operator within the last three years are valued at less than five percent of the verification body's revenue.

****

WCI.8 OPTIONAL GUIDANCE

Note: This text is supporting material and not intended as part of the essential requirements.

Collection of Evidence

The verification body shall obtain sufficient and appropriate evidence to be able to draw reasonable conclusions on which to base the verification statement. The verification body obtains evidence by performing verification procedures. Verification procedures are classified as:

- **Computation (or Recalculation)** is the checking of mathematical accuracy of documents or records
- **Observation** of a process or procedure
- **Confirmation** is obtaining representations from a third party
- **Enquiry** is seeking information from a knowledgeable person
- **Inspection** of Records or Documents/Assets
- **Re-performance** is the verifiers independent execution of procedures or controls
- **Analysis** is the evaluation of information made by studying the plausible relationships among different types of data

Some or all of these techniques can be used to obtain sufficient and appropriate evidence. Site visits are used to obtain evidence that is readily available at that location.

6 Modifications to the General Provisions 8

1 Introduction

This document and the attachments provide an overview of the amendments made to WCI Final Essential Requirements of Mandatory Reporting for harmonization of reporting for Canadian jurisdictions.

On July 15, 2009, the WCI partners published the Final Essential Requirements for Mandatory Reporting (the “ERs”) to be implemented by the WCI Partner jurisdictions. On September 22, 2009, U.S. EPA adopted its final Mandatory Greenhouse Gas Reporting Rule (the “EPA rule”), implementing its Greenhouse Gas (GHG) Reporting Program. Many U.S. facilities in the WCI region will be subject to both reporting programs.

The WCI partners were concerned that the existence of two different reporting systems in a WCI state could result in the imposition of duplicative or conflicting reporting obligations on facilities subject to both programs. The Partners therefore directed the WCI Reporting Committee to develop amended ERs that are harmonized with the EPA rule.

On November 12, 2010, the WCI published the “Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule” (U.S. ER’s), WCI’s approach for harmonizing the ERs and the EPA rule in U.S. jurisdictions. It takes the form of a markup of the EPA rule showing the changes to the EPA program that are needed to support a cap-and-trade program. WCI jurisdictions in the U.S., particularly those implementing a cap-and-trade program, may implement the harmonized U.S. ERs by adopting a rule that incorporates the EPA rule by reference with the changes shown in the markup.

To ensure that the amended ERs are provided that are methodologically consistent with the harmonized U.S. ERs but appropriate for use in the Canadian partner jurisdictions, the WCI released two packages to stakeholders. The first draft for stakeholder comment “Harmonization of Essential Requirements for Mandatory Reporting in Canadian Jurisdictions with the WCI Essential Requirements for Mandatory Reporting and the EPA Greenhouse Gas Reporting Program“ covering most reporting sectors was released on September 8, 2010 and the second draft covering the remainder was released on October 29, 2010.

This “Final Essential Requirements for Mandatory Reporting – Canadian Harmonization Version” (Canadian ERs) represents WCI’s adoption of the amended quantification methods for use in Canadian Partner jurisdictions for all source categories as modified in WCI.1(a)(1). These methods replace the original ERs in use for 2010 reporting and are designed to be adopted for use by Canadian jurisdictions for 2011 calendar year emissions, reported in 2012.

To ensure that a complete package of quantification methods can be referenced, the ER for imported electricity is re-published within the amended ERs. Several modifications to the general provisions in the ERs made in the November 12, 2010 U.S. harmonization document are also incorporated into the Canadian version. The format of the harmonized Canadian ERs follows the original WCI format, a format that had already been used in guidance documents and regulations in several Canadian WCI jurisdictions.

Since the U.S. EPA only finalized quantification methods for Petroleum and Natural Gas Systems (Subpart W) on November 8, 2010 it has been possible to incorporate only a subset of elements, some addressing stakeholder comments, into the WCI Canadian ERs. In 2011, the WCI will develop cap and trade quality requirements for sources covered by Subpart W for use in both Canadian and U.S. jurisdictions.

Further evaluation with respect to "reporting only" sources within the scope of the methods in ERs, particularly for specific oil and gas sources will be occurring as will analysis and incorporation of further reporting implementation and compliance requirements for cap and trade system.

This document and the attachments provide an overview of the amendments made to WCI Final Essential Requirements of Mandatory Reporting for harmonization of reporting for Canadian jurisdictions. A summary of the comments received and WCI's response is set forth in section 5. Changes made to the general provisions of the harmonized ERs are listed in section 6 below.

2 Harmonization Principles

2.1 For U.S. Jurisdictions

The harmonization principles for U.S. jurisdictions are outlined in the "Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule[1].

2.2 For Canadian Jurisdictions

In developing harmonized ERs for use in Canadian Partner jurisdictions that modify the existing ERs, the WCI Reporting Committee adhered to the following principles:

1. A Canadian facility should apply the same functions, equations, sampling protocols and measurement criteria as U.S. facilities subject to the U.S. version of the harmonized ERs. This means that the harmonized ERs will achieve the same level of reporting accuracy for Canadian and U.S. facilities, but the U.S. version may require more data elements to be reported to harmonize with the EPA rule.

[1] http://www.westernclimateinitiative.org/news-and-updates/125-harmonization-of-essential-requirements-for-mandatory-reporting-in-us-jurisdictions-with-epa-mandatory-reporting-rule

2. The quantification methods included in the harmonized ERs must remain sufficiently reliable and accurate to be employed in a GHG cap-and-trade program.

3. The WCI reporting system must remain suitable for use in Canadian Partner jurisdictions. For example, it must allow reporting in metric as well as English units and must where necessary include Canada-specific emission factors.

4. The harmonized ERs should facilitate harmonization with Canadian federal reporting. Some Canadian Partner jurisdictions are working with Environment Canada to develop a one-window reporting tool for provincial and national GHG reporting requirements.

WCI intends to follow the same principles with regard to future additions or amendments to the EPA rule, such as the recently finalized Subpart W for the oil and gas industry, and the recently proposed revisions to Subpart A (general provisions) and several source category subparts.[2] WCI will review each proposed revision to assess its suitability for cap-and-trade before incorporating it into the harmonized ERs.

3 Harmonization Approach

3.1 For U.S. Jurisdictions

The harmonization approach for U.S. jurisdictions is outlined in the "Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule"[3].

3.2 For Canadian Jurisdictions

For the Canadian jurisdictions, the key requirement is that the WCI reporting system as a whole require the use of comparable methodologies and produce comparable results for facilities of the same type, so that a "tonne is a tonne" in both the U.S. and Canada. For Canadian jurisdictions it is not nearly as important to avoid small differences between the ERs and the EPA rule as it is for the U.S. jurisdictions, where such differences could create a risk of inadvertent non-compliance.

Canadian Partners have invested substantial resources in developing regulations to implement the existing WCI ERs. In addition, the provinces face technical and legal issues with the

[2] Pre-publication version posted on July 20, 2010 at: http://www.epa.gov/climatechange/emissions/technical-corrections.html#revisions
[3] http://www.westernclimateinitiative.org/news-and-updates/125-harmonization-of-essential-requirements-for-mandatory-reporting-in-us-jurisdictions-with-epa-mandatory-reporting-rule

incorporation by reference of the EPA rule that do not apply to the states. Therefore, in this document, the WCI finalizes amendments to the existing WCI ERs to assure that they conform in substance with the U.S. version of the harmonized ERs, as well as facilitating harmonization with Environment Canada and the use of Canada-specific reporting metrics and factors.

3.3 Verification

Consistent with the Design Recommendations for the WCI Regional Cap-and-Trade Program, the harmonized U.S. and Canadian ERs require third party verification of emission reports by entities and facilities included in the cap. Minor revisions to the verification rule, WCI.8, are included in Section 6 of this document as an amendment to the Canadian ERs.

The amount of data to be reported for Canadian jurisdictions has been reduced to reflect third party verification requirements for emissions reports at a certain threshold of emissions as compared to that which is required to be reported to the EPA for their internal verification.

3.4 Missing Data Procedures

The EPA rule includes procedures in each subpart for replacing missing data resulting from monitoring failures. With the exception of methodologies for facilities subject to 40 CFR Part 75 (the acid rain program), these missing data procedures do not appear to be sufficiently rigorous to support a cap-and-trade system. There is no limitation on the amount of data that may be missing, and replacement methods appear to be both inadequate (for example, many use only one or two available data points) and inequitable (for example, Part 75 power plants have to apply punitive methods, while other facilities do not).

In order to move forward with a harmonization proposal in time to allow implementation for the 2011 reporting year, the Canadian harmonized ERs incorporate the EPA missing data procedures. Before implementation of the cap-and-trade program, however, the WCI intends to revisit this issue. The WCI is investigating how the EPA missing data procedures can be modified to be more consistent with the needs of a cap-and-trade program while adhering to the harmonization principles and intends to propose and implement the necessary modifications in time for the 2012 reporting year.

As a partial measure to address the possibility of gaming, the harmonized ERs include a provision making it clear that the use of a missing data procedure does not excuse a facility's failure to follow the monitoring requirements of the rule.

4 Summary of Changes to the Original WCI ERs

The following table summarizes the changes to the ER's general provisions that the WCI is finalizing for implementation in Canadian jurisdictions. The specific language for the amendments to the general provisions is made in Section 6 of this document. The specific language for the changes to the quantification methods is set forth in the republished Final Essential Requirements of Mandatory Reporting – Amended for Canadian Harmonization.

Section	Change to WCI Rule	Rationale
WCI.1(a)(1)	Revised and updated source category list	Reflects current state of WCI quantification methods.
WCI.1(g)	Creates preliminary list of "reporting only" sources for identification of data that will be reported for informational purposes only	Provides indication of which source categories and/or specific emission sources are considered reporting only by the WCI.
WCI.2(b)(2)(B)	Post-2011 verification date established as September 1.	Clarifies verification date for WCI jurisdictions.
WCI.2(h)	Added a method for calculating weighted averages.	This subsection provides clarity on how to determine averages from samples, and produces more accurate emissions estimates.
WCI.4(b)	Modifies requirement to submit records to within 20 days of a request from a WCI jurisdiction.	Modified from 10-day response time in existing WCI.4(b) in response to stakeholder comments.
WCI.5(c)	Added section make it clear the missing data procedures included in the harmonized ERs do not excuse facilities from possible enforcement action for failure to conduct the monitoring required by the rule.	See section 3.4.

Section	Change to WCI Rule	Rationale
WCI.8(a)(4.1)	Added new section to ensure that "reporting only" sources will not be counted towards the threshold for verification. Consequential change required to section WCI.8(a)(1)	Not all quantification methods specified by the harmonized ERs are suitable for a cap-and-trade system. The "reporting only" label provides notice to stakeholders on WCI's current view on which emissions should not be subject to the cap-and-trade program.
WCI.8(b)(4)(C)	Modification of language for oversight and accreditation of verification bodies	Clarifies language on verification body oversight and accreditation
WCI.8(p)(1) and (2)	Modification of requirements for a verification statement	Clarifies verification statement requirements

5 Stakeholder Comments and Response

5.1 General Comments

Twenty separate stakeholder responses were received on the Canadian harmonization proposals. The majority of these comments were from companies active in the oil and gas industry and addressed specific items in the general stationary combustion, petroleum and natural gas systems, and natural gas transmission and distribution quantification methods. Several comments were also received from the forest products industry.

Each comment was reviewed and modifications made to the quantification methods where appropriate. Comments addressing policy items were noted and will be discussed by the Reporting Committee. Several commenters indicated the need to declare further sources as "reporting only" (as discussed in the table in Section 4, above).

Since the amended package was built off of the "Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule"[4], the response to stakeholder comments in that document can be referenced as a preliminary way of understanding the modifications that were made.

6 Modifications to the General Provisions

The following is a list of the modifications to the general provisions (WCI.1 to WCI.9) as published by the WCI on July 15, 2009 that are being made in the "Final Essential Requirements of Mandatory Reporting – Canadian Harmonization version", published on December 17, 2010.

WCI.1(a)(1) is replaced by the following:
(1) Any facility that emits 10,000 metric tons CO2e or more per year in combined emissions from one or more of the source categories listed in this paragraph in any calendar year starting in 2010.

Adipic acid manufacturing [WCI.050]
Aluminum manufacturing [WCI.070]
Ammonia manufacturing [WCI.080]
Carbon dioxide transfer recipients [still being assessed]
Cement manufacturing [WCI.090]
Coal storage [WCI.100]
Copper and nickel [WCI.260]
Electricity generation [WCI.040]
Electricity transmission [WCI.230]
Electronics manufacturing [WCI.110]
Ferroalloy production [WCI.270]
General stationary fuel combustion [WCI.020]
Glass Production [WCI.140] HCFC-22 production [WCI.120]
Hydrogen production [WCI.130]
Industrial wastewater [WCI.203(g)]
Iron and steel manufacturing [WCI.150]
Lead production [WCI.160]
Lime manufacturing [WCI.170]
Magnesium production [WCI.290]
Miscellaneous uses of carbonates [WCI.180]
Natural gas transmission and distribution systems [WCI.350]
Nitric acid manufacturing [WCI.310]
Mobile equipment [WCI.280]

[4] http://www.westernclimateinitiative.org/news-and-updates/125-harmonization-of-essential-requirements-for-mandatory-reporting-in-us-jurisdictions-with-epa-mandatory-reporting-rule

Petroleum and natural gas systems [WCI.360]
Petrochemical production [WCI.300]
Petroleum refineries [WCI.200]
Phosphoric acid production [WCI.340]
Pulp and paper manufacturing [WCI.210]
Refinery fuel gas [WCI.030]
Soda ash manufacturing [WCI.220]
Underground coal mines [WCI.250]
Zinc production [WCI.240]

WCI.1(g) is added:

1(g): The following emissions data shall be submitted for information only and may not be subject to cap-and-trade requirements[5]:

(1) Data submitted by a source category designated as "reporting only." This provision does not apply to emissions from general stationary combustion at a source in a "reporting only" category.
(2) Emissions data calculated with a methodology identified as "reporting only."
(3) Reporting only sources are identified as the following:
Carbon dioxide from biomass determined to be carbon neutral by the jurisdiction
Fugitive HFC emissions in electrical generation
Coal storage
Asphalt blowing at refineries
Equipment leaks at refineries
Storage tanks at refineries
Industrial wastewater treatment
Product loading at refineries
Mobile equipment

WCI.2(b)(2)(B) is modified to read:

"For reporting years 2012 and later*, ~~[date to be determined]~~* by September 1 of the year following the reporting year.'

WCI.2(h) is added:

(j) The following shall apply unless in conflict with any other provision in the quantification methods
(1) Samples must be spaced apart as evenly as possible over time, taking into account the operating schedule of the relevant unit or facility.
(2) A weighted average of the values derived from the samples must be calculated and reported by using the following formula:

[5] The identification of data as "reporting only" may be subject to review before the adoption of a cap-and-trade program. On adoption the jurisdiction will likely substitute a citation to the rules implementing the program for the words "cap-and-trade requirements." Further analysis of reporting only sources is occurring, particularly for specific emission sources within the Petroleum and Natural Gas Systems and Natural Gas Transmission and Distribution quantification methods.

$$V_E = \frac{\sum_{j=1}^{n}(V_j \times M_j)}{\sum_{j=1}^{n} M_j}$$

Where:

VE = The value of the parameter to be reported under the quantification method for period E.

j = Each period during period E for which a sample is required by [jurisdiction] under the applicable quantification method

n = The number of periods j in period E.

Vj = The value of the sample for period j.

Mj = The mass of the sampled material processed or otherwise used by the relevant unit or facility in period j.

(3) You must keep records of the date and result for each sample and mass measurement used in the equation in subsection (2) and of the calculation of each weighted average included in your report must be kept.

WCI.4(b) is modified to read:

(b) Upon request by *[jurisdiction],* the operator shall provide within ~~10~~ 20 ~~working~~ days all documents and data used to develop an emissions data report.

WCI.5(c) is added

(c) Notwithstanding the missing data procedures in the quantification methods the failure to conduct monitoring in accordance with these methods shall constitute a violation.

WCI.8(a)(1) is modified to read:

(1) Except as provided in WCI.8(a)(2) through (~~4~~4.1) owners or operators [Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices] are required to obtain annual verification for a facility that emits 25,000 metric tons CO2e or more per year in combined emissions from one or more of the source categories listed in WCI.1 in any calendar year starting on or after 2010.

WCI.8(a)(4.1) is added:

"Emissions designated "reporting only" in this article shall be excluded from the determination regarding verification applicability.

WCI.8(b)(4)(C) Accreditation Requirements for Verification Bodies is revised to read:

(1) The accreditation requirements specified in this subsection shall apply to all verification bodies that wish to provide verification services under this rule.

(2) A verification body is qualified to conduct verification services for the WCI in [the jurisdiction] if

(A) it has demonstrated knowledge of [the WCI jurisdiction] reporting requirements; and

(B) it has the characteristics and capabilities deemed necessary by [the jurisdiction] to perform verification services; and

(C) it is accredited to ISO 14065 through

(i) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum.; or

(ii) a program developed or authorized [the jurisdiction] under [the jurisdiction's] required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011.

[Note the details of the WCI's specific accreditation process for verification bodies ~~(which~~ has yet to be developed~~) will be consistent with ISO 14065 through an accreditation program that will developed under ISO 17011 and will include demonstrated knowledge of the WCI reporting requirements.~~ The WCI will explore additional accreditation requirements and/or other criteria for individual lead verifiers, general verifiers, and/or sector specialists.]

WCI.8(p)(1) and (2) are revised as follows:

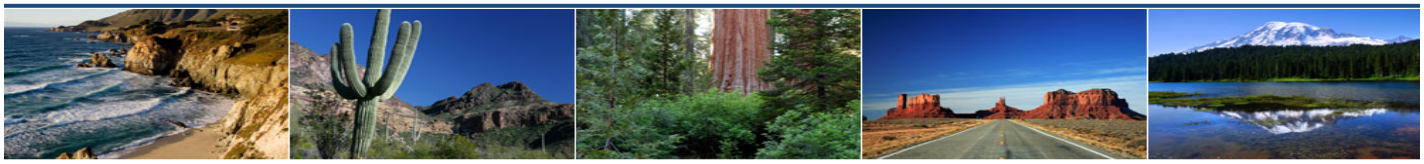
(p) Completion of verification services shall include:

(1) Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall prepare either a positive or adverse verification statement, for each emissions data report, based on its findings during the verification process. The verification body shall provide the verification statement(s) to the reporter and to the AVA [alternatively, this could be the reporter's responsibility to submit the statement to the AVA], according to the schedule specified in section WCI.2(b). Before each statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.

~~(1) Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall complete a verification statement for each emissions data report, and provide that statement to the owner or operator and [the jurisdiction or other body] according to the schedule specified in section WCI.2(b). Before that statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.~~

~~(2) The verification body shall provide either a positive or adverse verification statement to the reporter and to the AVA *[alternatively, this could be the reporter's responsibility to submit the statement to the AVA]* based on its findings during the verification process.~~

Western Climate Initiative

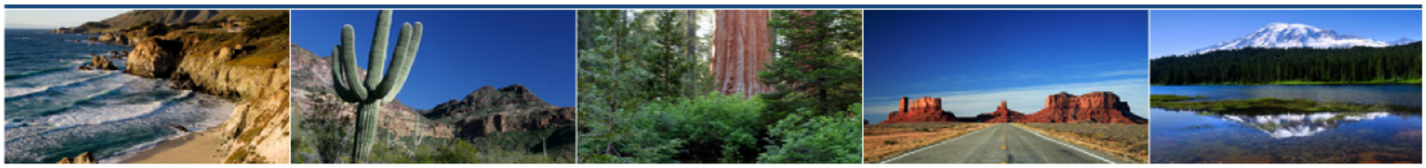


Final Essential Requirements of Mandatory Reporting

Amended for Canadian Harmonization

December 17, 2010

Western Climate Initiative



GENERAL PROVISIONS

§ WCI.0 through § WCI.10

EMISSIONS QUANTIFICATION, AND SAMPLING, ANALYSIS AND MEASUREMENT

§ WCI.20 General Stationary Combustion
§ WCI.30 Refinery Fuel Gas Combustion
§ WCI.40 Electricity Generation
§ WCI.50 Adipic Acid Manufacturing
§ WCI.60 Imported Electricity
§ WCI.70 Primary Aluminum Production
§ WCI.80 Ammonia Manufacturing
§ WCI.90 Cement Manufacturing
§ WCI.100 Coal Storage
§ WCI.110 Electronics Manufacturing
§ WCI.120 HCFC-22 Production and HFC-23 Destruction
§ WCI.130 Hydrogen Production
§ WCI.140 Glass Production
§ WCI.150 Iron and Steel Manufacturing
§ WCI.160 Lead Production
§ WCI.170 Lime Manufacturing
§ WCI.180 Carbonates Use
§ WCI.200 Petroleum Refineries
§ WCI.210 Pulp and Paper Manufacturing
§ WCI.220 Soda Ash Manufacturing
§ WCI.230 Electricity Transmission (and Emissions from Electrical Equipment in Electricity Generation)
§ WCI.240 Zinc Production

§ WCI.250 Underground Coal Mines
§ WCI.260 Nickel and Copper Metal Production
§ WCI.270 Ferroalloy Production
§ WCI.280 Mobile Equipment at Facilities
§ WCI.290 Magnesium Production
§ WCI.300 Petrochemical Manufacturing
§ WCI.310 Nitric Acid Manufacturing
§ WCI.340 Phosphoric Acid Production
§ WCI.350 Natural Gas Transmission and Distribution
§ WCI.360 Petroleum and Natural Gas Production and Natural Gas Processing

§ WCI.0 through § WCI.10

Refer to the Essential Requirements for Reporting published July 15, 2009, with the following changes:

WCI.1(a)(1) is replaced by the following:
(1) Any facility that emits 10,000 metric tons CO2e or more per year in combined emissions from one or more of the source categories listed in this paragraph in any calendar year starting in 2010.

Adipic acid manufacturing [WCI.050]
Aluminum manufacturing [WCI.070]
Ammonia manufacturing [WCI.080]
Carbon dioxide transfer recipients [still being assessed]
Cement manufacturing [WCI.090]
Coal storage [WCI.100]
Copper and nickel [WCI.260]
Electricity generation [WCI.040]
Electricity transmission [WCI.230]
Electronics manufacturing [WCI.110]
Ferroalloy production [WCI.270]
General stationary fuel combustion [WCI.020]
Glass Production [WCI.140] HCFC-22 production [WCI.120]
Hydrogen production [WCI.130]
Industrial wastewater [WCI.203(g)]
Iron and steel manufacturing [WCI.150]
Lead production [WCI.160]
Lime manufacturing [WCI.170]
Magnesium production [WCI.290]
Miscellaneous uses of carbonates [WCI.180]
Natural gas transmission and distribution systems [WCI.350]
Nitric acid manufacturing [WCI.310]
Mobile equipment [WCI.280]
Petroleum and natural gas systems [WCI.360]
Petrochemical production [WCI.300]
Petroleum refineries [WCI.200]
Phosphoric acid production [WCI.340]
Pulp and paper manufacturing [WCI.210]
Refinery fuel gas [WCI.030]
Soda ash manufacturing [WCI.220]

Underground coal mines [WCI.250]
Zinc production [WCI.240]

WCI.1(g) is added:

1(g): The following emissions data shall be submitted for information only and may not be subject to cap-and-trade requirements[1]:

(1) Data submitted by a source category designated as "reporting only." This provision does not apply to emissions from general stationary combustion at a source in a "reporting only" category.

(2) Emissions data calculated with a methodology identified as "reporting only."

(3) Reporting only sources are identified as the following:

Carbon dioxide from biomass determined to be carbon neutral by the jurisdiction
Fugitive HFC emissions in electrical generation
Coal storage
Asphalt blowing at refineries
Equipment leaks at refineries
Storage tanks at refineries
Industrial wastewater treatment
Product loading at refineries
Mobile equipment

WCI.2(b)(2)(B) is modified to read:
"For reporting years 2012 and later, ~~*[date to be determined]*~~ by September 1 of the year following the reporting year.'

WCI.2(h) is added:

(j) The following shall apply unless in conflict with any other provision in the quantification methods

(1) Samples must be spaced apart as evenly as possible over time, taking into account the operating schedule of the relevant unit or facility.

(2) A weighted average of the values derived from the samples must be calculated and reported by using the following formula:

$$V_E = \frac{\sum_{j=1}^{n}(V_j \times M_j)}{\sum_{j=1}^{n} M_j}$$

Where:

[1] The identification of data as "reporting only" may be subject to possible revision before the adoption of a cap-and-trade program. On adoption the jurisdiction will likely substitute a citation to the rules implementing the program for the words "cap-and-trade requirements." Further analysis of reporting only sources is occurring, particularly for specific emission sources within the Petroleum and Natural Gas Systems and Natural Gas Transmission and Distribution quantification methods.

VE = The value of the parameter to be reported under the quantification method for period E.
j = Each period during period E for which a sample is required by [jurisdiction] under the applicable quantification method
n = The number of periods j in period E.
Vj = The value of the sample for period j.
Mj = The mass of the sampled material processed or otherwise used by the relevant unit or facility in period j.

(3) You must keep records of the date and result for each sample and mass measurement used in the equation in subsection (2) and of the calculation of each weighted average included in your report must be kept.

WCI.4(b) is modified to read:

(b) Upon request by *[jurisdiction],* the operator shall provide within ~~10~~ 20 ~~working~~ days all documents and data used to develop an emissions data report.

WCI.5(c) is added

(c) Notwithstanding the missing data procedures in the quantification methods the failure to conduct monitoring in accordance with these methods shall constitute a violation.

WCI.8(a)(1) is modified to read:

(1) Except as provided in WCI.8(a)(2) through (44.1) owners or operators [Each jurisdiction will select the specific terminology for the regulated persons in accordance with their customary rule-writing practices] are required to obtain annual verification for a facility that emits 25,000 metric tons CO2e or more per year in combined emissions from one or more of the source categories listed in WCI.1 in any calendar year starting on or after 2010.

WCI.8(a)(4.1) is added:

"Emissions designated "reporting only" in this article shall be excluded from the determination regarding verification applicability.

WCI.8(b)(4)(C) Accreditation Requirements for Verification Bodies is revised to read:

(1) The accreditation requirements specified in this subsection shall apply to all verification bodies that wish to provide verification services under this rule.

(2) A verification body is qualified to conduct verification services for the WCI in [the jurisdiction] if

(A) it has demonstrated knowledge of [the WCI jurisdiction] reporting requirements; and
(B) it has the characteristics and capabilities deemed necessary by [the jurisdiction] to perform verification services; and
(C) it is accredited to ISO 14065 through
  (i) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum.; or
  (ii) a program developed or authorized [the jurisdiction] under [the jurisdiction's] required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011.

[Note the details of the WCI's specific accreditation process for verification bodies ~~(which~~ has yet to be developed~~) will be consistent with ISO 14065 through an accreditation program that will developed under ISO 17011 and will include demonstrated knowledge of the WCI reporting requirements.~~ The WCI will explore additional accreditation requirements and/or other criteria for individual lead verifiers, general verifiers, and/or sector specialists.]

WCI.8(p)(1) and (2) are revised as follows:

(p) Completion of verification services shall include:

(1) Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall prepare either a positive or adverse verification statement, for each emissions data report, based on its findings during the verification process. The verification body shall provide the verification statement(s) to the reporter and to the AVA [alternatively, this could be the reporter's responsibility to submit the statement to the AVA], according to the schedule specified in section WCI.2(b). Before each statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.

~~(1) Verification Statement. Upon completion of the verification services required by WCI.8, the verification body shall complete a verification statement for each emissions data report, and provide that statement to the owner or operator and [the jurisdiction or other body] according to the schedule specified in section WCI.2(b). Before that statement is completed, the verification body shall have the verification services and findings of the verification team independently reviewed and approved by an Independent Peer Reviewer.~~

~~(2) The verification body shall provide either a positive or adverse verification statement to the reporter and to the AVA *[alternatively, this could be the reporter's responsibility to submit the statement to the AVA]* based on its findings during the verification process.~~

§ WCI.20 GENERAL STATIONARY COMBUSTION

§ WCI.21 Source Category Definition

Stationary fuel combustion sources are devices that combust solid, liquid, or gaseous fuel generally for the purpose of producing electricity, generating steam or providing useful heat or energy for industrial, commercial, or institutional use; or reducing the volume of waste by removing combustible matter. Stationary fuel combustion sources are boilers, simple and combined cycle combustion turbines, engines, incinerators (including units that combust hazardous waste), process heaters, and any other stationary combustion device that is not specifically addressed under the methods for another source category. This source category does not include portable equipment, emergency generators, and emergency equipment (including emergency flares).

§ WCI.22 Greenhouse Gas Reporting Requirements

The emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in tonnes, reported as follows:

- (1) Total CO_2 emissions for fossil fuels, reported by fuel type.
- (2) Total CO_2 emissions for biomass, reported by fuel type.
- (3) Total CH_4 emissions, reported by fuel type.
- (4) Total N_2O emissions, reported by fuel type.

(b) Annual fuel consumption:

- (1) For gases, report in units of standard cubic meters.
- (2) For liquids, report in units of kilolitres.
- (3) For non-biomass solids, report in units of tonnes.
- (4) For biomass solid fuels, report in units of bone dry tonnes.

(c) Annual weighted average carbon content of each fuel, if used to compute CO_2 emissions.

(d) Annual weighted average high heat value of each fuel, if used to compute CO_2 emissions.

(e) Annual steam generation in kilograms, for units that burn biomass fuels or municipal solid waste and generate steam.

§ WCI.23 Calculation of CO_2 Emissions

For each fuel, calculate CO_2 mass emissions using one of the four calculation methodologies specified in this section, subject to the restrictions in WCI.23(e). If a fuel or fuels is not listed in all of Tables 20-1 through 20-7; or in Table C-1 or C-2 of U.S. EPA 40 CFR Part 98, Subpart C, then emissions from such fuels do not need to be reported so long as total emissions of these fuels do not exceed 0.5% of total facility emissions. If emissions from the sum of these fuels exceeds 0.5% of total facility emissions, then the requirements of WCI.023 stand so long as only a maximum of 0.5% of total facility emissions from unlisted fuels is not reported.

(a) Calculation Methodology 1. Calculate the annual CO_2 mass emissions for each type of fuel by substituting a fuel-specific default CO_2 emission factor, a default high heat value, and the annual fuel consumption into Equation 20-1:

$$CO_2 = Fuel \times HHV \times EF \times 0.001$$ **Equation 20-1**

Where:

CO_2 = Annual CO_2 mass emissions for the specific fuel type (tonnes).

Fuel = Mass or volume of fuel combusted per year (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).

HHV = Default high heat value of the fuel, from Table 20-1 and 20-1a (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).

EF = Fuel-specific default CO_2 emission factor, from Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable (kg CO_2/GJ).

(HHV x EF) instead of using separate HHV and EF values, you can replace the two values by using default emission factors from Tables 20-2, 20-3, or 20-5, as applicable (in units of kg CO_2 per tonne for solid fuel, kg CO_2 per kilolitre for liquid fuel, or kg CO_2 per cubic meter for gaseous fuel)

0.001 = Conversion factor from kilograms to tonnes.

(b) Calculation Methodology 2. Calculate the annual CO_2 mass emissions using a default fuel-specific CO_2 emission factor, a high heat value provided by the supplier or measured by the operator, using Equation 20-2, except for emissions from the combustion of biomass fuels, for which the operator may instead elect to use the method shown in Equation 20-3. For use of Calculation Methodology 2 for municipal solid waste, Equation 20-3 must be used.

(1) For any type of fuel for which an emission factor is provided in Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable, except biomass fuels when the operator elects to use the method in WCI.23(b)(2), use Equation 20-2:

$$CO_2 = \sum_{p=1}^{n} Fuel_p \times HHV_p \times EF \times 0.001$$ **Equation 20-2**

Where:

CO_2 = Annual CO_2 mass emissions for a specific fuel type (tonnes).

n = Number of required heat content measurements for the year as specified in WCI.25.

$Fuel_p$ = Mass or volume of the fuel combusted during the measurement period *p* (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).

HHV_p	=	High heat value of the fuel for the measurement period *p* (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).
EF	=	Fuel-specific default CO_2 emission factor, from Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable (kg CO_2/GJ).
0.001	=	Conversion factor from kilograms to tonnes.

(2) For units that combust municipal solid waste and that produce steam, use Equation 20-3. Equation 20-3 of this section may also be used for any solid biomass fuel listed in Table 20-2 of this subpart provided that steam is generated by the unit.

$$CO_2 = Steam \times B \times EF \times 0.001$$ **Equation 20-3**

Where:

CO_2	=	Annual CO_2 mass emissions from biomass solid fuel or municipal solid waste combustion (tonnes).
Steam	=	Total mass of steam generated by biomass solid fuel or municipal solid waste combustion during the reporting year (tonnes steam).
B	=	Ratio of the boiler's design rated heat input capacity to its design rated steam output capacity (GJ/tonne steam).
EF	=	Default emission factor for biomass solid fuel or municipal solid waste, from Table 20-2 or Table 20-7, as applicable (kg CO_2/GJ).[1]
0.001	=	Conversion factor from kilograms to tonnes.

(c) Calculation Methodology 3. Calculate the annual CO_2 mass emissions for each fuel by using measurements of fuel carbon content or molar fraction (for gaseous fuels only), conducted by the operator or provided by the fuel supplier, and the quantity of fuel combusted.

(1) For a solid fuel, except for the combustion of municipal solid waste, use Equation 20-4 of this section:

$$CO_2 = \sum_{i=1}^{n} Fuel_i \times CC_i \times 3.664$$ **Equation 20-4**

Where:

CO_2	=	Annual CO_2 mass emissions from the combustion of the specific solid fuel (tonnes).
n	=	Number of carbon content determinations for the year.
$Fuel_i$	=	Mass of the solid fuel combusted in measurement period *i* (tonnes).
CC_i	=	Carbon content of the solid fuel, from the fuel analysis results for measurement period *i* (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).
3.664	=	Ratio of molecular weights, CO_2 to carbon.

(2) For biomass fuels, in units that produce steam, use either Equation 20-4 above or Equation 20-5; for municipal solid waste combustion in units that produce steam, use Equation 20-5:

[1] The ER required development of a site-specific emission factor for MSW. For harmonization with Part 98, Subpart C, this requirement was deleted. However, jurisdictions may allow or require testing to develop a site-specific emission factor as an alternative to the default emission factors in Subpart C, Table C-1.

$$CO_2 = Steam \times B \times EF \times 0.001$$ **Equation 20-5**

Where:

CO_2	=	Annual CO_2 mass emissions from biomass solid fuel or municipal solid waste combustion (tonnes).
Steam	=	Total mass of steam generated by biomass solid fuel or municipal solid waste combustion during the reporting year (tonnes steam).
B	=	Ratio of the boiler's design rated heat input capacity to its design rated steam output capacity (GJ/tonne steam).
EF	=	Default emission factor for biomass solid fuel or municipal solid waste, from Table 20-2 or 20-7, as applicable (kg CO_2/GJ), adjusted no less often than every third year as provided in WCI.25(a)(7)(B).
0.001	=	Conversion factor from kilograms to tonnes.

(3) For a liquid fuel, use Equation 20-6 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i$$ **Equation 20-6**

Where:

CO_2	=	Annual CO_2 mass emissions from the combustion of the specific liquid fuel (tonnes).
n	=	Number of required carbon content determinations for the year, as specified in WCI.25.
$Fuel_i$	=	Volume of the liquid fuel combusted in measurement period *i* (kilolitres).
CC_i	=	Carbon content of the liquid fuel, from the fuel analysis results for measurement period *i* (tonne C per kilolitre of fuel).
3.664	=	Ratio of molecular weights, CO_2 to carbon.

(4) For a gaseous fuel, use Equation 20-7 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \times \frac{MW}{MVC} \times 0.001$$ **Equation 20-7**

Where:

CO_2	=	Annual CO_2 mass emissions from combustion of the specific gaseous fuel (tonnes).
n	=	Number of required carbon content and molecular weight determinations for the year, as specified in WCI.25.
$Fuel_i$	=	Volume of the gaseous fuel combusted in period *i* (a day or month, as applicable) (m^3) at the reference temperature and pressure conditions used by the facility. If a mass flow meter is used, measure the fuel combusted in period *i* in kg and replace the term "MW/MVC" with "1".
CC_i	=	Average carbon content of the gaseous fuel, from the fuel analysis results for the period *i* (day or month, as applicable) (kg C per kg of fuel).

MW	=	Molecular weight of the gaseous fuel, from fuel analysis (kg/kg-mole).
MVC	=	Molar volume conversion at the reference conditions $Fuel_i$ (m^3/kg-mole).
	=	8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascals] (which is 23.64 m^3 per kg-mole for STP of 15 °C and 1 atmosphere).
3.664	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to tonnes.

(d) Calculation Methodology 4. Calculate the annual CO_2 mass emissions from all fuels combusted in a unit, by using data from continuous emission monitoring systems (CEMS) as specified in (d)(1) through (d)(7). This methodology requires a CO_2 concentration monitor and a stack gas volumetric flow monitor, except as otherwise provided in paragraph (d)(2) of this section.

(1) For a facility that operates CEMS in response to federal, state, provincial, or local regulation, use CO_2 or O_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded).

(2) The operator shall report CO_2 emissions for the reporting year in tonnes based on the sum of hourly CO_2 mass emissions over the year, converted to tonnes.

(3) An oxygen (O_2) concentration monitor may be used in lieu of a CO_2 concentration monitor in a CEMS installed before January 1, 2012, to determine the hourly CO_2 concentrations, if the effluent gas stream monitored by the CEMS consists solely of combustion products (i.e., no process CO_2 emissions or CO_2 emissions from acid gas control are mixed with the combustion products) and if only the following fuels are combusted in the unit: coal, petroleum coke, oil, natural gas, propane, butane, wood bark, or wood residue.

(A) If the unit combusts waste-derived fuels (as defined in the General Provisions and including municipal solid waste), emissions calculations shall not be based on O_2 concentrations.

(B) If the operator of a facility that combusts biomass fuels uses O_2 concentrations to calculate CO_2 concentrations, annual source testing must demonstrate that calculated CO_2 concentrations, when compared to measured CO_2 concentrations, meet the Relative Accuracy Test Audit (RATA) requirements in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded).

(4) If both biomass fuel (including fuels that are partially biomass) and fossil fuel are combusted during the year, determine and report the biogenic CO_2 mass emissions separately, as described in paragraph (f) of this section.

(5) For any units for which CO_2 emissions are reported using CEMS data, the operator is relieved of the requirement to separately report process emissions from combustion emissions for that unit or to report emissions separately for different fossil fuels for that

unit when only fossil fuels are co-fired. In this circumstance, operators shall still report fuel use by fuel type as otherwise required.

(6) If a facility is subject to requirements for continuous monitoring of gaseous emissions, and the operator chooses to add devices to an existing CEMS for the purpose of measuring CO_2 concentrations or flue gas flow, the operator shall select and operate the added devices pursuant to the appropriate requirements for the facility as applicable in Canada.

(7) If a facility does not have a CEMS and the operator chooses to add one in order to measure CO_2 concentrations, the operator shall select and operate the CEMS pursuant to the appropriate requirements or equivalent requirements as applicable in Canada. Operators who add CEMS under this paragraph are subject to the specifications in paragraphs (d)(1) through (d)(5), if applicable.

(e) Use of the Four CO_2 Calculation Methodologies. Use of the four CO_2 emissions calculation methodologies described in paragraphs (a) through (d) of this section is subject to the following requirements and restrictions:

(1) Calculation Methodology 1 (Equation 20-1).

(A) May be used by a facility that is not subject to the verification requirements by regulation for any type of fuel for which a default high heat value (Table 20-1 and 20-1a) and a default CO_2 emission factor (Tables 20-1a, 20-2, 20-3, or 20-5, as applicable) is specified.

(B) May be used for a facility emitting at any level for the combustion of natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter, and for the combustion of any of the fuels listed in Table 20-1a.

(C) May be used for a facility emitting at any level for the combustion of municipal solid waste in a unit that does not generate steam.

(D) May be used for the combustion of biomass listed in Table 20-2 that is exempted from verification requirements by the jurisdiction, unless it is specifically addressed under the provisions for another source category (e.g., spent pulping liquor from pulp and paper facilities).

(E) May not be used at a facility emitting at any level for a fuel for which you routinely perform fuel sampling and analysis for the fuel high heat value or can obtain the results of fuel sampling and analysis for the fuel high heat value from the fuel supplier at the minimum frequency specified in WCI.25(a), or at a greater frequency. In such cases, Calculation Method 2, 3 or 4 shall be used for those fuels.

(2) Calculation Methodology 2 (Equations 20-2 and 20-3).

(A) May not be used by a facility that is subject to the verification requirements by regulation, except as specified in paragraphs (e)(2)(B) through (E) of this section. Otherwise, Calculation Methodology 2 may be used for any type of fuel combusted for which a default CO_2 emission factor for the fuel is specified in Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable.

(B) Calculation Methodology 2 may be used for the combustion of natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter at a facility emitting at any level. Notwithstanding the provisions in paragraph (e)(1) of this section, Calculation Methodology 2, 3, or 4 shall be used for combustion in any unit with a rated heat input capacity greater than 264 GJ/hr (250mmBtu/hr) and that has operated for more than 1,000 hours in any of the past three years, when the fuel is natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter.

(C) Calculation Methodology 2 may be used at a facility emitting at any level for the combustion of any of the fuels listed in Table 20-1a, and for biomass that has been determined by [the jurisdiction] not to be subject to a compliance obligation under the cap-and-trade program.

(D) Equation 20-3 may be used for the combustion of municipal solid waste only at facilities that are not subject to verification by regulation.

(E) Equation 20-2 may not be used for the combustion of municipal solid waste.

(3) Calculation Methodology 3 (Equations 20-4 through 20-7) may be used for the combustion of any type of fuel, except as specified in paragraph (e)(3)(A) through (E) of this section.

(A) Notwithstanding the provisions in paragraph (e)(1) and (e)(2) of this section, Calculation Methodology 3 or 4 must be used at a facility subject to verification for all combustion in any unit with a rated heat input capacity greater than 264 GJ/hr (250mmBtu/hr) and that has operated for more than 1,000 hours in any of the past three years, except when the fuel is natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter, the fuel is listed in Table 20-1a, or the fuel is biomass that has been determined by [the jurisdiction] not to be subject to a compliance obligation under the cap-and-trade program.

(B) Must be used for all other combustion at a facility subject to verification, except for combustion of fuels for which Calculation Methodology 1 or 2 is permitted, as described in paragraphs (e)(1) and (e)(2) of this section.

(C) May not be used when the use of Calculation Methodology 4 is required.

(D) Equation 20-4 may not be used for the calculation of emissions from combustion of municipal solid waste.

(E) Equation 20-5 may be used for the combustion of municipal solid waste at a facility emitting at any level; however, it must be used for the combustion of municipal solid waste if the facility is subject to verification by regulation, unless Calculation Methodology 4 is required.

(4) Calculation Methodology 4 may be used for a unit combusting any type of fuel. Notwithstanding the provisions in paragraphs (e)(1) through (3) of this section, Calculation Methodology 4 must be used for a combustion unit with a CEMS that is required by any federal, provincial, or local regulation and that includes both a stack gas volumetric flow rate monitor and a CO_2 concentration monitor.

(5) You may elect to use any applicable higher calculation methodology for one or more of the fuels combusted in a unit. For example, if a unit combusts natural gas and distillate

fuel oil, you may elect to use Calculation Methodology 1 for natural gas and Calculation Methodology 2 for the fuel oil, even though Calculation Methodology 1 could have been used for both fuels. However, for units that use Calculation Methodology 4, CO_2 emissions from the combustion of all fuels shall be based solely on CEMS measurements.

(f) CO_2 emissions from combustion of mixtures of biomass or biomass fuel and fossil fuel. Use the procedures of this paragraph (f) to estimate biogenic CO_2 emissions from units that combust a combination of biomass and fossil fuels, including combustion of waste-derived fuels (e.g., municipal solid waste, tires, etc,) that are partially biomass.

(1) If CEMS are not used to measure CO_2 and the facility combusts biomass fuels that do not include waste-derived fuels (e.g., municipal solid waste and tires), use Calculation Methodology 1, 2, or 3, as applicable, to calculate the annual biogenic CO_2 mass emissions from the combustion of biomass fuels. Determine the mass of biomass combusted using either company records, or, for premixed fuels that contain biomass and fossil fuels (e.g., mixtures containing biodiesel), use best available information to determine the mass of biomass fuels and document the procedure.

(2) If a CEMS is used to measure CO_2 (or O_2 as a surrogate) and the facility combusts biomass fuels that do not include waste-derived fuels (as defined in the General Provisions), use Calculation Methodology 1, 2, or 3 to calculate the annual CO_2 mass emissions from the combustion of fossil fuels. Calculate biomass fuel emissions by subtracting the fossil fuel-related emissions from the total CO_2 emissions determined from the CEMS-based methodology.

(3) If the owner or operator that combusts fuels or fuel mixtures for which the biomass fraction is unknown or cannot be documented (e.g., municipal solid waste, tire-derived fuel, etc.), or if the owner or operator combusts a biomass fuel for which a CO_2 emission factor is not provided in Table 20-2, use the following to estimate biogenic CO_2 emissions:

(A) Use Calculation Methodology 1, 2, 3, or 4 to calculate the total annual CO_2 mass emissions, as applicable.

(B) Determine the biogenic portion of the CO_2 emissions using ASTM D6866-08 "Standard Test Methods for Determining the Biobased Content of Solid, Liquid, and Gaseous Samples Using Radiocarbon Analysis", as specified in this paragraph. This procedure is not required for fuels that contain less than 5 percent biomass by weight or for waste-derived fuels that are less than 30 percent by weight of total fuels combusted in the year for which emissions are being reported, except where the operator wishes to report a biomass fuel fraction of CO_2 emissions.

(C) The operator shall conduct ASTM D6866-08 analysis on a representative fuel or exhaust gas sample at least every three months. The exhaust gas samples shall be collected over at least 24 consecutive hours following the standard practice specified by ASTM D7459-08 "Standard Practice for Collection of Integrated Samples for the Speciation of Biomass (Biogenic) and Fossil-Derived Carbon Dioxide Emitted from Stationary Emissions Sources." If municipal solid waste is combusted, the ASTM D6866-08 analysis must be performed on the exhaust gas stream.

(D) The operator shall divide total CO_2 emissions between biomass fuel emissions and non-biomass fuel emissions using the average proportions of the samples analyzed for the year for which emissions are being reported.

(E) If there is a common fuel source to multiple units at the facility, the operator may elect to conduct ASTM D6866-06a testing for only one of the units sharing the common fuel source.

(4) If Equation 20-1 of this section is selected to calculate the annual biogenic mass emissions for wood, wood waste, or other solid biomass-derived fuel, Equation 20-8 of this section may be used to quantify biogenic fuel consumption, provided that all of the required input parameters are accurately quantified. Similar equations and calculation methodologies based on steam generation and boiler efficiency may be used, provided that they are documented.

$$(Fuel)_p = \frac{[H \times S] - (HI)_{nb}}{(HHV)_{bio} \times (Eff)_{bio}} \qquad \textbf{Equation 20-8}$$

Where:

$(Fuel)_p$	=	Quantity of biomass consumed during the measurement period *p* (tonnes/year or tonnes/month, as applicable).
H	=	Average enthalpy of the boiler steam for the measurement period (GJ/tonne).
S	=	Total boiler steam production for the measurement period (tonne/month or tonne/year, as applicable).
$(HI)_{nb}$	=	Heat input from co-fired fossil fuels and non-biomass-derived fuels for the measurement period, based on company records of fuel usage and default or measured HHV values (GJ/month or GJ/year, as applicable).
$(HHV)_{bio}$	=	Default or measured high heat value of the biomass fuel (GJ/tonne).
$(Eff)_{bio}$	=	Percent efficiency of biomass-to-energy conversion, expressed as a decimal fraction.

(g) Calculation of CO_2 from sorbent.

(1) When a unit is a fluidized bed boiler, is equipped with a wet flue gas desulfurization system, or uses other acid gas emission controls with sorbent injection, use Equation 20-9 of this section to calculate the CO_2 emissions from the sorbent, if those CO_2 emissions are not monitored by CEMS:

$$CO_2 = S \times R \times \left(\frac{MW_{CO2}}{MW_S}\right) \qquad \textbf{Equation 20-9}$$

Where:

CO_2	=	CO_2 emitted from sorbent for the reporting year (tonnes).
S	=	Limestone or other sorbent used in the reporting year, from company records (tonnes).
R	=	1.00, the calcium-to-sulphur stoichiometric ratio.

MW_{CO2} = Molecular weight of carbon dioxide.
MW_S = Molecular weight of sorbent.

(2) The annual CO_2 mass emissions for the unit shall be the sum of the CO_2 emissions from the combustion process and the CO_2 emissions from the sorbent.

§ WCI.24 Calculation of CH_4 and N_2O Emissions

Calculate the annual CH_4 and N_2O mass emissions from stationary fuel combustion sources using the procedures in paragraph (a), (b), or (c), as appropriate. You are not required to calculate the annual CH_4 and N_2O emissions for fuels that are not listed in Tables 20-2, 20-3, 20-4 and 20-6. However, you may use engineering estimates to calculate the annual CH_4 and N_2O emissions for fuels that are not listed in Tables 20-2, 20-3, 20-4 and 20-6.

(a) If the high heat value of the fuel is not measured for CO_2 estimation, calculate CH_4 and N_2O emissions using Equation 20-10 for all fuels except coal. For coal, use Equation 20-11:

$$CH_4 \text{ or } N_2O = Fuel \times HHV_D \times EF \times 0.000001 \qquad \textbf{Equation 20-10}$$

$$CH_4 \text{ or } N_2O = Fuel \times EF_c \times 0.001 \qquad \textbf{Equation 20-11}$$

Where:
CH_4 or N_2O = Combustion emissions from specific fuel type (tonnes CH_4 or N_2O per year).
Fuel = Mass or volume of fuel combusted per year (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).
HHV_D = Default high heat value specified by fuel type provided in Table 20-1, (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).
EF = Default CH_4 or N_2O emission factor provided in Tables 20-2 or 20-4, as applicable, grams CH_4 or N_2O per GJ. The facility may also use equipment-specific factors from U.S. EPA AP-42 for the specific equipment as appropriate.
EF_c = Default CH_4 or N_2O emission factor for coal provided in Table 20-6 (grams CH_4 or N_2O per kg of coal). The facility may also use equipment specific factors from U.S. EPA AP-42 for the specific equipment as appropriate.
0.000001 = Factor to convert grams to tonnes in Equation 20-10.
0.001 = Factor to convert g/kg to tonne/tonne in Equation 20-11.

(b) If the high heat value of the fuel is measured or provided by the fuel supplier for CO_2 estimation, calculate CH_4 and N_2O emissions using Equation 20-12 for all fuels except coal. For coal, use Equation 20-13:

$$CH_4 \text{ or } N_2O = \sum_{p=1}^{n} Fuel_p \times HHV_p \times EF \times 0.000001 \qquad \textbf{Equation 20-12}$$

$$CH_4 \text{ or } N_2O = \sum_{p=1}^{n} Fuel_p \times EF_c \times 0.000001 \qquad \textbf{Equation 20-13}$$

Where:

CH_4 or N_2O = CH_4 or N_2O emissions from a specific fuel type (tonnes CH_4 or N_2O per year).

$Fuel_p$ = Mass or volume of the fuel combusted during the measurement period *p* (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).

HHV_p = High heat value measured directly or provided by the fuel supplier for the measurement period *p* specified by fuel type (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).

EF = Default CH_4 or N_2O emission factor provided in Tables 20-2 or 20-4, as applicable (grams CH_4 or N_2O per GJ). The facility may also use equipment-specific factors from U.S. EPA AP-42 for the specific equipment as appropriate.

EF_c = CH_4 or N_2O emission factor for coal, either measured directly or provided by the fuel supplier (grams CH_4 or N_2O per tonne of coal).

0.000001 = Factor to convert grams to tonnes.

(c) For biomass and municipal solid waste combustion where Equation 20-3 or 20-5 are used to calculate CO_2 emissions, use Equation 20-14 of this section to estimate CH_4 and N_2O emissions:

$$CH_4 \ or \ N_2O = Steam \times B \times EF \times 0.000001$$ **Equation 20-14**

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a municipal solid waste (tonnes).

Steam = Total mass of steam generated by municipal solid waste combustion during the reporting year (tonnes steam).

B = Ratio of the boiler's design rated heat input capacity to its design rated steam output (GJ/tonne steam).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Tables 20-2, 20-4, or 20-6, as applicable (grams CH_4 or N_2O per GJ).

0.000001 = Conversion factor from grams to tonnes.

(d) Use Equation 20-15 of this section for units that use Calculation Methodology 4 and for which heat input is monitored on a year round basis.

$$CH_4 \ or \ N_2O = (HI)_A \times EF \times 0.000001$$ **Equation 20-15**

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (tonnes).

$(HI)_A$ = Cumulative annual heat input from the fuel (GJ), derived from the electronic data reports or estimated from the best available information (e.g., fuel feed rate measurements, fuel heating values, engineering analysis, etc.).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Tables 20-2, 20-4, or 20-6, as applicable (grams CH_4 or N_2O per GJ).

0.000001 = Conversion factor from grams to tonnes.

(1) If only one type of fuel is combusted during normal operation, substitute the cumulative annual heat input from combustion of the fuel into Equation 20-15 of this section to calculate the annual CH_4 or N_2O emissions.

(2) If more than one type of fuel listed is combusted during normal operation, use Equation 20-15 of this section separately for each type of fuel.

(e) When multiple fuels are combusted during the reporting year, sum the fuel-specific results from Equations 20-8, 20-9, 20-10, or 20-11 of this section (as applicable) to obtain the total annual CH_4 and N_2O emissions, in tonnes.

(f) The operator may elect to calculate CH_4 or N_2O emissions using source-specific emission factors derived from source tests conducted at least annually under the supervision of the regulator. Upon approval of a source test plan, the source test procedures in that plan shall be repeated in each future year to update the source specific emission factors annually.

(g) Use of the four CH_4 and N_2O Calculation Methodologies. Use of the four CH_4 and N_2O emissions calculation methodologies described in paragraphs (a) through (d) of this section is subject to the following requirements and restrictions:

(1) WCI.24(a) may not be used by a facility that is subject to the verification requirements of WCI.8, except for stationary combustion units that combust natural gas with a higher heating value between 36.3 and 40.98 MJ per cubic meter. Otherwise, WCI.24(a) may be used for any type of fuel for which a default CH_4 or N_2O emission factor (Tables 20-2, 20-4, 20-6, and 20-7) and a default higher heat value (Table 20-1 and 20-1a) is specified.

(2) WCI.24(b) may be used for a unit of any size combusting any type of fuel.

(3) WCI.24(c) may only be used for biomass or municipal solid waste combustion. WCI.24(c) must be used instead of WCI.24(a) for any unit combusting municipal solid waste that generates steam.

(4) WCI.24(d) may be used for a unit of any size combusting any type of fuel, and must be used for any units for which Calculation Methodology 4 is used to estimate CO_2 emissions and heat input is monitored on a year round basis.

§ WCI.25 Sampling, Analysis, and Measurement Requirements

(a) Fuel Sampling Requirements. Fuel sampling must be conducted or fuel sampling results must be received from the fuel supplier at minimum at the frequency specified in paragraphs (a)(1) through (a)(7) of this section, subject to the requirements of WCI.23(e) and WCI.24(g). All fuel samples shall be taken at a location in the fuel handling system that provides a representative of the fuel combusted.

(1) Once for each new fuel shipment or delivery for coal.

(2) Once for each new fuel shipment or delivery of fuels, or quarterly for each of the fuels listed in Table 20-1a (when required).

(3) Semiannually for natural gas (when required).

(4) Quarterly for liquid fuels and fossil fuel-derived gaseous fuels other than fuels listed in Table 20-1a (when Table 20-1a is used).

(5) Quarterly for gases derived from biomass including landfill gas and biogas from wastewater treatment or agricultural processes.

(6) For gaseous fuels other than natural gas, gases derived from biomass, and biogas, daily sampling and analysis to determine the carbon content and molecular weight of the fuel is required if the necessary equipment is in place to make these measurements. For 2011 calendar year emissions only, if the necessary equipment is not in place to make the measurements, weekly sampling and analysis shall be performed. If on-line instrumentation is to be used, the equipment necessary to perform daily sampling and analysis of carbon content and molecular weight must determine fuel carbon content accurate to ±5 percent.

(7) Monthly for solid fuels other than coal and waste-derived fuels (including municipal solid waste), as specified below:

(A) The monthly solid fuel sample shall be a composite sample of weekly samples.

(B) The solid fuel shall be sampled at a location after all fuel treatment operations but before fuel mixing, and the samples shall be representative of the fuel chemical and physical characteristics immediately prior to combustion.

(C) Each weekly sub-sample shall be collected at a time (day and hour) of the week when the fuel consumption rate is representative and unbiased.

(D) Four weekly samples (or a sample collected during each week of operation during the month) of equal mass shall be combined to form the monthly composite sample.

(E) The monthly composite sample shall be homogenized and well mixed prior to withdrawal of a sample for analysis.

(F) One in twelve composite samples shall be randomly selected for additional analysis of its discrete constituent samples. This information will be used to monitor the homogeneity of the composite.

(8) For biomass fuels and waste-derived fuels (including municipal solid waste), the following may apply in lieu of WCI.25(a)(5):

(A) If CO_2 emissions are calculated using Equation 20-2 in WCI.23(b)(1) or Equation 20-4 in WCI.23(c)(1), the source-specific high heat value or carbon content is determined annually. If CO_2 emissions are calculated using Equation 20-5 in WCI.23(c)(2) (biomass fuels and municipal solid waste only), the operator shall adjust the emission factor, in kg CO_2/GJ not less frequently than every third year, through a stack test measurement of CO_2 and use of the applicable ASME Performance Test Code to determine heat input from all heat outputs, including the steam, flue gases, ash and losses.

(b) Fuel Consumption Monitoring Requirements.

(1) Facilities may determine fuel consumption on the basis of direct measurement or recorded fuel purchase or sales invoices measuring any stock change (measured in MJ, litres, million standard cubic meters, tonnes or bone dry tonnes) using Equation 20-16. For facilities that are covered by WCI.360 (Petroleum and Natural Gas Production and

Gas Processing) but are less than 10,000 tonnes in individual size, an operator may calculate fuel consumption for propane and diesel without correcting for the difference in inventory at the beginning and end of the year.

Equation 20-16

Fuel Consumption in the Report Year = Total Fuel Purchases – Total Fuel Sales + Amount Stored at Beginning of Year – Amount Stored at Year End

(2) Fuel consumption measured in MJ values shall be converted to the required metrics of mass or volume using heat content values that are either provided by the supplier, measured by the facility, or provided in Table 20-1.

(3) All oil and gas flow meters (except for gas billing meters) shall be calibrated prior to the first year for which GHG emissions are reported under this rule, using an applicable flow meter test method listed in by regulation or the calibration procedures specified by the flow meter manufacturer. Fuel flow meters shall be recalibrated either annually or at the minimum frequency specified by the manufacturer.

(4) For fuel oil, tank drop measurements may also be used.

(5) Fuel flow meters that measure mass flow rates may be used for liquid fuels, provided that the fuel density is used to convert the readings to volumetric flow rates. The density shall be measured at the same frequency as the carbon content, using ASTM D1298-99 (Reapproved 2005) "Standard Test Method for Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and Liquid Petroleum Products by Hydrometer Method."

(6) Facilities using Calculation Methods 1 or 2 for CO_2 emissions may use the following default density values for fuel oil, in lieu of using the ASTM method in paragraph (b)(5) of this section: 0.81 kg/litre for No. 1 oil; 0.86 kg/litre for No. 2 oil; 0.97 kg/litre for No. 6 oil. These default densities may not be used for facilities using Calculation Method 3.

(c) Fuel Heat Content Monitoring Requirements. High heat values shall be based on the results of fuel sampling and analysis received from the fuel supplier or determined by the operator, in either case using an applicable analytical method listed by regulation.

(1) For gases, use ASTM D1826-94 (Reapproved 2003) "Standard Test Method for Calorific (Heating) Value of Gases in Natural Gas Range by Continuous Recording Calorimeter", ASTM D3588-98 (Reapproved 2003) "Standard Practice for Calculating Heat Value, Compressibility Factor, and Relative Density of Gaseous Fuels", or ASTM D4891-89 (Reapproved 2006), GPA Standard 2261-00 "Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography." The operator may alternatively elect to use on-line instrumentation that determines heating value accurate to within ±5.0 percent. Where existing on-line instrumentation provides only low heat value, the operator shall convert the value to high heat value as follows:

$$HHV = LHV \times CF$$ **Equation 20-17**

Where:

HHV = fuel or fuel mixture high heat value (MJ/scm).

LHV = fuel or fuel mixture low heat value (MJ/scm).
CF = conversion factor.

For natural gas, a CF of 1.11 shall be used. For refinery fuel gas and mixtures of refinery fuel gas, a weekly average fuel system-specific CF shall be derived as follows:

(A) By concurrent LHV instrumentation measurements and HHV determined by on-line instrumentation or laboratory analysis as part of the daily carbon content determination; or,

(B) By the HHV/LHV ratio obtained from the laboratory analysis of the daily samples.

(2) For middle distillates and oil, or liquid waste-derived fuels, use ASTM D240-02 (Reapproved 2007) "Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter" or ASTM D4809-06 (Reapproved 2005) "Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (Precision Method)."

(3) For solid biomass-derived fuels, use ASTM D5865-07a "Standard Test Method for Gross Calorific Value of Coal and Coke."

(4) For waste-derived fuels, use ASTM D5865-07a or ASTM D5468-02 (Reapproved 2007) "Standard Test Method for Gross Calorific and Ash Value of Waste Materials." Operators who combust waste-derived fuels that are not pure biomass fuels shall determine the biomass fuel portion of CO_2 emissions using the method specified in WCI.23(f), if applicable

(5) Use Equation 20-18 to calculate the weighted annual average heat content of the fuel, if the measured heat content is used to calculate CO_2 emissions.

$$(HHV)_{annual} = \frac{\sum_{p=1}^{n} (HHV)_p \times (Fuel)_p}{\sum_{p=1}^{n} (Fuel)_p}$$ **Equation 20-18**

Where:

$(HHV)_{annual}$ = Weighted annual average high heat value of the fuel (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).

$(HHV)_p$ = High heat value of the fuel, for measurement period *p* (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).

$(Fuel)_p$ = Mass or volume of the fuel combusted during measurement period *p* (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).

n = Number of measurement periods in the year that fuel is burned in the unit.

(d) Fuel Carbon Content Monitoring Requirements. Fuel carbon content and either molecular weight or molar fraction for gaseous fuels shall be based on the results of fuel sampling and analysis received from the fuel supplier or determined by the operator, in either case using an applicable analytical method listed by regulation.

(1) For coal and coke, solid biomass fuels, and waste-derived fuels; use ASTM 5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal".

(2) For liquid fuels, use the following ASTM methods: For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291-02 (Reapproved 2007) "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants," ultimate analysis of oil or computations based on ASTM D3238-95 (Reapproved 2005), and either ASTM D2502-04 "Standard Test Method for Estimation of Mean Relative Molecular Mass of Petroleum Oils From Viscosity Measurements" or ASTM D2503-92 (Reapproved 2007) "Standard Test Method for Relative Molecular Mass (Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure."

(3) For gaseous fuels, use ASTM D1945-03 (Reapproved 2006) "Standard Test Method for Analysis of Natural Gas by Gas Chromatography" or ASTM D1946-90 (Reapproved 2006) "Standard Practice for Analysis of Reformed Gas by Gas Chromatography."

(4) Use Equation 20-19 to calculate the weighted annual average carbon content of the fuel, if the measured carbon content is used to calculate CO_2 emissions.

$$(CC)_{annual} = \frac{\sum_{p=1}^{n}(CC)_p \times (Fuel)_p}{\sum_{p=1}^{n}(Fuel)_p}$$ **Equation 20-19**

Where:

$(CC)_{annual}$ = Weighted annual average carbon content of the fuel (percent C by weight for solid fuel, tonne C per kilolitre for liquid fuel, or kg C per kg fuel for gaseous fuel).

$(CC)_p$ = Carbon content of the fuel, for measurement period *p* (percent C by weight for solid fuel, tonne C per kilolitre for liquid fuel, or kg C per kg fuel for gaseous fuel).

$(Fuel)_p$ = Mass or volume of the fuel combusted during measurement period *p* (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).

n = Number of measurement periods in the years that fuel is burned in the unit.

(e) Fuel Analytical Data Capture. When the applicable emissions estimation methodologies in WCI.23 and WCI.24 require periodic collection of fuel analytical data for an emissions source, the operator shall demonstrate every reasonable effort to obtain a fuel analytical data capture rate of 100 percent for each report year.

(1) If the operator is unable to obtain fuel analytical data such that more than 20 percent of emissions from a source cannot be directly accounted for, the emissions from that source shall be considered unverifiable for the report year.

(2) If the fuel analytical data capture rate is at least 80 percent but less than 100 percent for any emissions source identified in WCI.23 and WCI.24, the operator shall use the methods in WCI.26(b) to substitute for the missing values for the period of missing data.

(f) Specific Requirements for Petroleum and Natural Gas Production and Gas Processing. For field or process gas combustion or general stationary combustion of natural gas within facilities covered by WCI.360, legislative or regulatory requirements, such as those required by the Petroleum and Natural Gas Act of British Columbia are sufficient for the points of measurement that are metered. For British Columbia, combustion sources specifically covered by the Petroleum and Natural Gas Act are to be calculated in the manner prescribed by the Act and its regulations, guidelines, and policies. Combustion sources not covered by the Act must be metered according to the following sampling and measurement requirements:

(1) For combustion emission sources where meters are not required by legislation or regulation, a calculated shrinkage value is sufficient but must be assigned using engineering estimation techniques to the various sources, if required for reporting.

(2) For field, pipeline quality natural gas or process gas combustion emission sources where metering is not required by law or regulation and shrinkage is not calculated, engineering estimation techniques that consolidate to common meter points such as that at the input to a processing plant used for financial purposes are sufficient. As required, fuel use must be allocated (using equipment specifications, operating hours, and flow rates) to specific emission sources.

(3) For upstream sources, a meter is required at each installation or at a point where fuel use can allocated to multiple combustion sources such that the aggregated of all combustion sources are metered.

All combustion estimates must be calculated in such a manner that ensures that fugitive, flaring, and venting emissions as calculated under WCI.360 are uniquely reported and that no double-counting of emissions in one or more categories occurs.

Carbon content and molecular weight of the field or process gas determined annually by a company or operator for a specific field for operational and regulatory purposes must be used as inputs to Equation 20-7. When this is data is not available, the generic emission factors provided in Table 360-3 (or as provided by the jurisdiction) must be used by a company or operator for the specific gas field in question.

(g) Specific Requirements for Natural Gas Transmission and Distribution. Measurement and Metering Act of Canada standards (or other appropriate standards if the Measurement and Metering Act is not applicable) are deemed to be sufficiently rigorous for the sampling, analysis and measurement for the combustion of pipeline quality natural gas (including for derivation of standard gas composition) for facilities covered by WCI.350 – Natural Gas Transmission and Distribution. If a required meter is not covered by the Measurement and Metering Act, it must exist and meet the requirements of the applicable greenhouse gas reporting regulation for the jurisdiction.

§ WCI.26 Procedures for Estimating Missing Data.

Whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For all units subject to the requirements of WCI.20 that monitor and report emissions using a CEMS, the missing data backfilling procedures in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded) shall be followed for CO_2 concentration, stack gas flow rate, fuel flow rate, high heating value, and fuel carbon content.

(b) For units that use Calculation Methodologies 1, 2, 3, or 4, perform missing data substitution as follows for each parameter:

(1) For each missing value of the high heating value, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the “after” value has not been obtained by the time that the GHG emissions must be calculated, you may use the “before” value for missing data substitution or the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production, operating hours). If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(2) For missing records of CO_2 concentration, stack gas flow rate, percent moisture, fuel usage, and sorbent usage, the substitute data value shall be the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production, operating hours, etc.). You must document and retain records of the procedures used for all such estimates.

§ WCI.27 Definitions

Except as specified in this section, all terms used in this subpart have the same meaning given in the General Provisions.

Emergency generator means a stationary combustion device, such as a reciprocating internal combustion engine or turbine that serves solely as a secondary source of mechanical or electrical power whenever the primary energy supply is disrupted or discontinued during power outages or natural disasters that are beyond the control of the owner or operator of a facility. An emergency generator operates only during emergency situations, for training of personnel under simulated emergency conditions, as part of emergency demand response procedures, or for standard performance testing procedures as required by law or by the generator manufacturer. A generator that serves as a back-up power source under conditions of load shedding, peak shaving, power interruptions pursuant to an interruptible power service agreement, or scheduled facility maintenance shall not be considered an emergency generator.

Emergency equipment means any auxiliary fossil fuel-powered equipment, such as a fire pump, that is used only in emergency situations.

Pipeline quality natural gas means natural gas having a high heat value equal to or greater than 36.1 MJ/m^3 or less than 40.98 MJ/m^3, and which is at least 90 percent methane by volume, and which is less than 5 percent carbon dioxide by volume.

Portable means designed and capable of being carried or moved from one location to another. Indications of portability include but are not limited to wheels, skids, carrying handles, dolly, trailer, or platform. Equipment is not portable if any one of the following conditions exists:

(1) The equipment is attached to a foundation.

(2) The equipment or a replacement resides at the same location for more than 12 consecutive months.

(3) The equipment is located at a seasonal facility and operates during the full annual operating period of the seasonal facility, remains at the facility for at least two years, and operates at that facility for at least three months each year.

(4) The equipment is moved from one location to another in an attempt to circumvent the portable residence time requirements of this definition.

U.S. AP-42 means the Fifth Edition, Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources, U.S. EPA., as amended from time to time

Table 20-1: Default High Heat Value by Fuel Type

Liquid Fuels	**High Heat Value (GJ/kl)**
Asphalt & Road Oil	44.46
Aviation Gasoline	33.52
Diesel	38.3
Aviation Turbo Fuel	37.4
Kerosene	37.68
Propane	25.31
Ethane	17.22
Butane	28.44
Lubricants	39.16
Motor Gasoline – Off-Road	35
Light Fuel Oil	38.8
Residual Fuel Oil (No. 5 & No. 6)	42.5
Crude Oil	38.32
Naphtha	35.17
Petrochemical Feedstocks	35.17
Petroleum Coke – Refinery Use	46.35
Petroleum Coke – Upgrader Use	40.57
Ethanol (100%)	21.04
Biodiesel (100%)	32.06

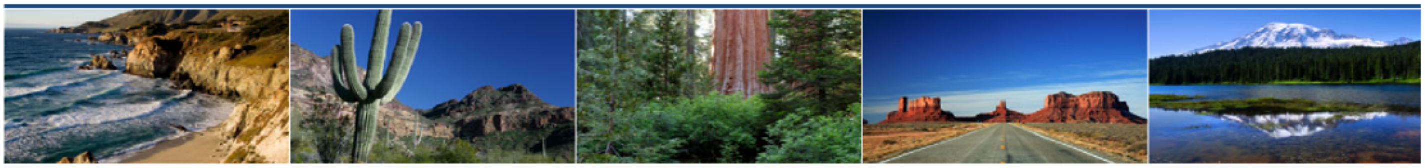
The WCI notes the significant difference in both the black liquor and solid biomass emission factors published by the EPA and Environment Canada (as well as those submitted by industry associations). In lieu of recommending a single emission factor at this time (as there is no certainty as to which is most accurate) the WCI is presenting both. The WCI will be working with experts in the two federal agencies and other organizations to ascertain the most accurate emission factor to use for both Metric and English unit versions of the Essential Requirements of Mandatory Reporting.



§ WCI.30 REFINERY FUEL GAS COMBUSTION

§ WCI.31 Source Category Definition

This source category consists of any combustion device that is located at a petroleum refinery and that combusts refinery fuel gas, still gas, flexigas, or associated gas.

§ WCI.32 Greenhouse Gas Reporting Requirements

In addition to the information required by the regulation, the emissions data report shall include the following information at the facility level:

(a) Annual CO_2, CH_4, and N_2O emissions from refinery fuel gas combustion in tonnes.

(b) Annual fuel consumption in units of standard cubic metres.

(c) Average carbon content of each fuel used to compute CO_2 emissions.

§ WCI.33 Calculation of Greenhouse Gas Emissions

(a) Calculation of CO_2 Emissions: Owners and operators shall calculate daily CO_2 emissions for each fuel gas system using any of the methods specified in paragraphs (a)(1) through (a)(4) of this section. Calculate the total annual CO_2 emissions from combustion of all fuel gas by summing the CO_2 emissions from each fuel gas system.

(1) Use a CEMS that complies with the provisions in section WCI.23(d).

(2) Calculate CO_2 emissions from each refinery fuel gas system and flexigas system using measured carbon content and molecular weight of the gas and Equation 30-1.

$$CO_2 = \sum_{i=1}^{n} Fuel_i \times CC_i \times \frac{MW}{MVC} \times 3.664 \times 0.001$$

Equation 30-1

Where:

CO_2 = Carbon dioxide emissions (tonnes/year).
$Fuel_i$ = Daily refinery fuel or flexigas combusted (Rm^3) at reference temperature and pressure conditions as used by the facility. If a mass flow meter is used, measure the daily fuel combusted in kg and replace the term "MW/MVC" with "1".
CC_i = Daily sample of carbon content of the fuel (kg C/kg fuel).
MW = Daily sample of molecular weight of fuel (kg/kg-mole).
MVC = Molar volume conversion factor at the same reference conditions as the variable $Fuel_i$ (Rm^3/kg-mole).
= 8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal].
3.664 = Conversion factor for carbon to carbon dioxide.
0.001 = Conversion factor for kg to tonnes.
n = Number of days in a year.

(3) For associated gas, low heat content gas, or other fossil fuels; follow the requirements for general stationary source combustion sources in WCI .23(b) or (c), as appropriate for each fuel.

(4) Where individual fuels are mixed prior to combustion, the operator may choose to calculate CO_2 emissions for each fuel prior to mixing instead of using the methods in paragraphs (a)(1) or (a)(2) of this section. In this case, the operator must determine the fuel flow rate and appropriate fuel specific parameters (e.g. carbon content, HHV) of each fuel stream prior to mixing, calculate CO_2 emissions for each fuel stream, and sum the emissions of the individual fuel streams to determine total CO_2 emissions from the mixture. CO_2 emissions for each fuel stream must be estimated using the following methods:

(A) For natural gas and associated gas, use the appropriate methodology specified in section WCI.23(b) or (c).

(B) For refinery fuel gas, flexigas, and low heat content gas, use the methodology in paragraph (a)(2) of this section.

(b) Calculation of CH_4 and N_2O Emissions. Owners and operators shall use the methods specified in section WCI.24 to calculate the annual CH_4 and N_2O emissions.

§ WCI.34 Sampling, Analysis, and Measurement Requirements

(a) Measure the fuel consumption rate daily using methods specified in WCI.25(b).

(b) Daily sampling and analysis to determine the carbon content and molecular weight of the fuel is required if there is sampling at a frequency of daily or more currently or if there is online instruments in place to monitor carbon content. Otherwise, weekly sampling and analysis of carbon content and molecular weight shall be performed. The equipment necessary to perform daily sampling and analysis of carbon content and molecular weight for refinery fuel gas must be installed no later than January 1, 2012.

(c) Measure the carbon content for fuel gas and flexigas using either ASTM D1945-03 (Reapproved 2006) or ASTM D1946-90 (Reapproved 2006). Where these methods do not adequately quantify all major hydrocarbons, then an owner or operator may request use of an alternative ASTM or other method to be approved by the regulator. Alternatively, the results of chromatographic analysis of the fuel gas may be used, provided that the gas chromatograph is operated, maintained, and calibrated according to the manufacturer's instructions; and the methods used for operation, maintenance, and calibration of the gas chromatograph are documented in a plan.

§ WCI.35 Procedures for estimating missing data.

Whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations by following the requirements of WCI.26.

§ WCI.40 ELECTRICITY GENERATION

§ WCI.41 Source Category Definition

An electricity generating unit is any combustion device that combusts solid, liquid, or gaseous fuel for the purpose of producing electricity either for sale or for use onsite. This source category includes cogeneration (combined heat and power) units. This source category does not include portable or emergency generators less than 10 MW in nameplate generating capacity as defined in WCI.27.

§ WCI.42 Greenhouse Gas Reporting Requirements

For each electricity generating unit, the emissions data report shall include the following information:

(a) Annual greenhouse gas emissions in tonnes, reported as follows:

(1) Total CO_2 emissions for fossil fuels, reported by fuel type.

(2) Total CO_2 emissions for all biomass fuels combined.

(3) Total CH_4 emissions for all fuels combined.

(4) Total N_2O emissions for all fuels combined.

(b) Annual fuel consumption:

(1) For gases, report in units of standard cubic meters.

(2) For liquids, report in units of kilolitres.

(3) For non-biomass solids, report in units of tonnes.

(4) For biomass-derived solid fuels, report in units of bone dry tonnes.

(c) Annual weighted average carbon content of each fuel, if used to compute CO_2 emissions as specified in WCI.43.

(d) Annual weighted average high heating value of each fuel, if used to compute CO_2 emissions as specified WCI.43.

(e) The nameplate generating capacity in megawatts (MW) and net power generated in the reporting year in megawatt hours (MWh).

(f) For each cogeneration unit, indicate whether topping or bottoming cycle and provide useful thermal output as applicable, in MJ. Where steam or heat is acquired from another facility for the generation of electricity, report the provider and amount of acquired steam or heat in MJ. Where supplemental firing has been applied to support electricity generation, report this purpose and fuel consumption by fuel type using the units in WCI.42(b).

(g) Process CO_2 emissions from acid gas scrubbers and acid gas reagent.

(h) Fugitive emissions of each of the HFCs from cooling units that support power generation.

(i) Fugitive CO_2 emissions from geothermal facilities.

(j) Fugitive CH_4 emissions from coal storage at coal-fired electricity generating facilities shall be reported as specified in section WCI.100.

§ WCI.43 Calculation of Greenhouse Gas Emissions

If a facility combusts natural gas or diesel in more than one electrical generating unit, and each unit is not individually metered (or, in the case of diesel, does not have a dedicated tank) and no CEMS is in place, the facility may calculate CO_2, CH_4, and N_2O emissions for each unit by using a common meter or tank that meets the requirement of this method, of WCI.020, and/or regulation, as appropriate.

To disaggregate emissions from the common meter for each unit, an engineering estimation approach that takes into account total emissions, relative operating hours of each unit, and combustion efficiency of each unit must be used. For diesel generating facilities in non-integrated remote areas, the disaggregation may be performed by calculation of MWh energy delivered by the facility and each diesel generating unit in combination with the amount of fuel used.

(a) Calculation of CO_2 Emissions.

Operators shall use CEMS to measure CO_2 emissions if required to operate a CEMS by any other federal, provincial, or local regulation and that includes both a stack gas volumetric flow rate monitor and a CO_2 concentration monitor. Operators not required to operate a CEMS by another regulation may use either CEMS or the calculation methods specified in paragraphs (a)(1) through (a)(7). Operators may use such a CEMS for calculation of CO_2 emissions from electrical generating units for any fuel covered in WCI.43, if applicable to the situation at the facility. Operators using CEMS to determine CO_2 emissions shall comply with the provisions in section WCI.23(d).

(1) Fuels Listed in Table 20-1a and Natural Gas. For electric generating units combusting natural gas (with a high heat value greater than or equal to 36.3 MJ/scm and less than or equal to 40.98 MJ/scm) or fuels in Table 20-1a, use methods in accordance with WCI.23.

(A) Calculation Methodology 1 may not be used at a facility for a fuel for which you routinely perform fuel sampling and analysis for the fuel high heat value or can obtain the results of fuel sampling and analysis for the fuel heat value from the fuel supplier at the frequency specified in WCI.25(a), or at a greater frequency. In such cases, Calculation Methodologies 2, 3, or 4 shall be used for those fuels.

(B) Natural Gas. For electric generating units combusting natural gas with a high heat value less than 36.3 MJ/scm or greater than 40.98 MJ/scm use the measured carbon content of the fuel and the Calculation Methodology 3 in WCI.23(c) or Calculation Methodology 4 in WCI.23(d).

(2) Coal or Petroleum Coke. For electric generating units combusting coal or petroleum coke, use the measured carbon content of the fuel and Calculation Methodology 3 in WCI.23(c).

(3) Middle Distillates, Gasoline, Residual Oil, or Liquid Petroleum Gases that are not listed in Table 20-1a. For electric generating units combusting middle distillates, gasoline, residual oil, or LPG, that are not listed in Table 20-1a, use one of the following methods:

(A) The measured carbon content of the fuel and Calculation Methodology 3 in WCI.23(c); or

(B) The measured heat content of the fuel and Calculation Methodology 2 in WCI.23(b), provided the facility is not subject to verification requirements by regulation.

(4) Refinery Fuel Gas, Flexigas, or Associated Gas. For electric generating units combusting refinery fuel gas, flexigas, or associated gas, use the methods specified in WCI.30.

(5) Landfill Gas, Biogas, or Biomass. For electric generating units combusting landfill gas, biogas, or biomass, use methods in accordance with WCI.23.

(6) Municipal Solid Waste. Electric generating units combusting municipal solid waste, may use the measured steam generated, the default emission factor in WCI.20 Table 20-7, and the calculation methodology in WCI.23(b)(2), provided the facility is not subject to verification requirements by regulation. If the facility is subject to verification requirements by regulation, the operator shall use CEMS to measure CO_2 emissions in accordance with WCI.23(d), or calculate emissions using steam flow and a CO_2 emission factor according to the provisions of WCI.23(c)(2).

(7) Start-up Fuels. The operators of generating facilities that primarily combust biomass-derived fuels but combust fossil fuels during start-up, shut-down, or malfunction operating periods only, shall calculate CO_2 emissions from fossil fuel combustion using one of the following methods. Malfunction means the unplanned outage of equipment; breakdown of equipment; or failure of equipment to operate normally, associated with the operation of a combustion device for an electricity generation unit(s). It does not include normal changes in operation conditions such as variations in combustion temperature, oxygen levels or moisture content of the fuel.

(A) The default emission factors from Tables 20-1a, 20-2, 20-3, 20-5 or 20-7, and default HHV from Tables 20-1 or 20-1a, as applicable, and calculation methodology 1 provided in WCI.23(a);

(B) The measured heat content of the fuel and Calculation Methodology 2 provided in WCI.23(b);

(C) The measured carbon content of the fuel and Calculation Methodology 3 provided in WCI.23(c); or

(D) For combustion of refinery fuel gas, the measured heat content and carbon content of the fuel, and the calculation methodology provided in WCI.30.

(8) Co-fired Electricity Generating Units. For electricity generating units that combust more than one type of fuel, the operator shall calculate CO_2 emissions as follows.

(A) For co-fired electricity generators that burn only fossil fuels, CO_2 emissions shall be determined using one of the following methods:

(i) A continuous emission monitoring system in accordance with Calculation Methodology 4 in WCI.23(d). Operators using this method need not report emissions separately for each fossil fuel.

(ii) For units not equipped with a continuous emission system, calculate the CO_2 emissions separately for each fuel type using the methods specified in paragraphs (a)(1) through (a)(4) of this section.

(B) For co-fired electricity generators that burn biomass-derived fuel with a fossil fuel, CO_2 emissions shall be determined using one of the following methods:

(i) A continuous emission monitoring system in accordance with Calculation Methodology 4 in WCI.23(d). Operators using this method shall determine the portion of the total CO_2 emissions attributable to the biomass-derived fuel and portion of the total CO_2 emissions attributable to the fossil fuel using the methods specified in WCI.23(d)(4).

(ii) For units not equipped with a continuous emission system, calculate the CO_2 emissions separately for each fuel type using the methods specified in paragraphs (a)(1) through (a)(7) of this section.

(b) Calculation of CH_4 and N_2O Emissions. Operators of electricity generating units shall use the methods specified in WCI.24 to calculate the annual CH_4 and N_2O emissions. For coal combustion, use the default CH_4 emission factor(s) in Table 20-6.

(c) Calculation of CO_2 Emissions from Acid Gas Scrubbing. Operators of electricity generating units that use acid gas scrubbers or add an acid gas reagent to the combustion unit shall calculate the annual CO_2 emissions from these processes using Equation 40-1 if these emissions are not already captured in CO_2 emissions determined using a continuous emissions monitoring system.

$$CO_2 = S \times R \times \left(CO_{2MW} / Sorbent_{MW}\right) \qquad \textbf{Equation 40-1}$$

Where:

CO_2	=	CO_2 emitted from sorbent for the report year (tonnes).
S	=	Limestone or other sorbent used in the report year (tonnes).
R	=	Ratio of moles of CO_2 released upon capture of one mole of acid gas.
$CO_{2\ MW}$	=	Molecular weight of carbon dioxide (44).
$Sorbent_{MW}$	=	Molecular weight of sorbent (if calcium carbonate, 100).

(d) Calculating Fugitive HFC Emissions from Cooling Units. Operators of electricity generating facilities shall calculate fugitive HFC emissions for each HFC compound used in cooling units that support power generation or are used in heat transfers to cool stack gases using either the methodology in paragraph (d)(1) or (d)(2). The Operator is not required to report GHG emissions from air or water cooling systems or condensers that do not contain HFCs or from heating ventilation and air conditioning systems used for cooling of control rooms, offices and buildings at the facility.

(1) Use Equation 40-2 to calculate annual HFC emissions:

$$HFC = HFC_{inventory} + HFC_{purchases/acquisitions} - HFC_{sales/disbursements} + HFC_{\Delta capacity}$$ **Equation 40-2**

Where:

HFC	=	Annual fugitive HFC emission (tonnes).
$HFC_{inventory}$	=	The difference between the quantity of HFC in storage at the beginning of the year and the quantity in storage at the end of the year. Stored HFC includes HFC contained in cylinders (such as 115-pound storage cylinders), gas carts, and other storage containers. It does not include HFC gas held in operating equipment. The change in inventory will be negative if the quantity of HFC in storage increases over the course of the year.
$HFC_{purchases/acquisitions}$	=	The sum of all HFC acquired from other entities during the year either in storage containers or in equipment.
$HFC_{sales/disbursements}$	=	The sum of all the HFC sold or otherwise transferred offsite to other entities during the year either in storage containers or in equipment.
$HFC_{\Delta capacity}$	=	The net change in the total nameplate capacity (i.e. the full and proper charge) of the cooling equipment. The net change in capacity will be negative if the total nameplate capacity at the end of the year is less than the total nameplate capacity at the beginning of the year.

(2) Use service logs to document HFC usage and emissions from each cooling unit. Service logs should document all maintenance and service performed on the unit during the report year, including the quantity of HFCs added to or removed from the unit, and include a record at the beginning and end of each report year. The operator may use service log information along with the following simplified material balance equations to quantify fugitive HFCs from unit installation, servicing, and retirement, as applicable. The operator shall include the sum of HFC emissions from the applicable equations in the greenhouse gas emissions data report.

$$HFC_{Install} = R_{new} - C_{new}$$ **Equation 40-2a**

$$HFC_{Service} = R_{recharge} - R_{Recover}$$ **Equation 40-2b**

$$HFC_{Retire} = C_{retire} - R_{retire}$$ **Equation 40-2c**

Where:

$HFC_{Install}$	=	HFC emitted during initial charging/installation of the unit (kilograms).
$HFC_{Service}$	=	HFC emitted during use and servicing of the unit for the report year (kilograms).

HFC_{Retire} = HFC emitted during the removal from service/retirement of the unit (kilograms).
R_{new} = HFC used to fill new unit (omit if unit was pre-charged by the manufacturer), (kilograms).
C_{new} = Nameplate capacity of new unit (omit if unit was pre-charged by the manufacturer) (kilograms).
$R_{recharge}$ = HFC used to recharge the unit during maintenance and service (kilograms).
$R_{recover}$ = HFC recovered from the unit during maintenance and service (kilograms).
C_{retire} = Nameplate capacity of the retired unit (kilograms).
R_{retire} = HFC recovered from the retired unit (kilograms).

(e) Fugitive CO_2 Emissions from Geothermal Facilities. Operators of geothermal electricity generating facilities shall calculate the fugitive CO_2 emissions using one of the following methods:

(1) Calculate the fugitive CO_2 emissions using Equation 40-3:

$$CO_2 = 7.14 \times Heat \times 0.001$$ **Equation 40-3**

Where:

CO_2 = CO_2 emissions (tonnes per year).
7.14 = Default fugitive CO_2 emission factor for geothermal facilities (kg per GJ).
Heat = Heat taken from geothermal steam and/or fluid (GJ/yr).
0.001 = Conversion factor from kg to tonnes.

(2) Calculate CO_2 emissions using source specific emission factor approved by the regulator for this rule..

§ WCI.44 Sampling, Analysis, and Measurement Requirements

(a) CO_2, CH_4 and N_2O Emissions from Fuel Combustion. Operators using CEMS to estimate CO_2 emissions from fuel combustion shall comply with the requirements in WCI.23(d). Operators using methods other than CEMS shall comply with the applicable fuel sampling, fuel consumption monitoring, heat content monitoring, carbon content monitoring, and calculation methods specified in WCI.25.

(b) CO_2 Emissions from Acid Gas Scrubbing. Operators of electricity generating units that use acid gas scrubbers or add an acid gas reagent to the combustion unit shall measure the amount of limestone or other sorbent used during the reporting year.

(c) CO_2 Emissions from Geothermal Facilities. Operators of geothermal facilities shall measure the heat recovered from geothermal steam. If using source specific emission factor instead of the default factor, the operator shall conduct an annual test of the CO_2 emission rate using a method approved by the regulator. The operator shall submit a test plan to the regulator for approval. Once approved, the annual tests shall be conducted in accordance with the approved test plan under the supervision of the regulator .

§ WCI.45 Procedures for estimating missing data.

Whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For all units using CEMS to measure CO_2 emissions, follow the missing data procedures in WCI.26(a)

(b) For all other missing parameters used to calculate GHG emissions, follow the missing data procedures in WCI.26(b).

§ WCI.46 Definitions

Except as specified in this section, all terms used in this subpart have the same meaning given in the General Provisions.

<u>Bottoming cycle plant</u> means a cogeneration plant in which the energy input to the system is first applied to a useful thermal energy application or process, and at least some of the rejected heat emerging from the application or process is then used for electricity production.

<u>Cogeneration unit</u> means a stationary fuel combustion device which simultaneously generates electrical and thermal energy that is (a) used by the operator of the facility where the cogeneration unit is located; or (b) transferred to another facility for use by that facility.

<u>Cogeneration system</u> means individual cogeneration components, including the prime mover (heat engine), generator, heat recovery, and electrical interconnection, configured into an integrated system that provides sequential generation of multiple forms of useful energy (usually electrical and thermal), at least one form of which the facility consumes on-site or makes available to other users for an end-use other than electricity generation.

<u>Topping cycle plant</u> means a cogeneration plant in which the energy input to the plant is first used to produce electricity, and at least some of the reject heat from the electricity production process is then used to provide useful thermal output.

§ WCI.50 ADIPIC ACID MANUFACTURING

§ WCI.51 Source Category Definition

The adipic acid production source category consists of all adipic acid production facilities that use oxidation to produce adipic acid.

§ WCI.52 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation, the annual emissions data report for adipic acid manufacturing shall include the following information at the facility level calculated in accordance this method:

(a) Annual process N_2O emissions from adipic acid production (tonnes).

(b) Annual adipic acid production (tonnes).

(c) Emissions of CO_2, CH_4, and N_2O from stationary combustion must report under WCI.20 (General Stationary Fuel Combustion Sources) following the requirements of WCI.20.

§ WCI.53 Calculation of N_2O Emissions

(a) You must determine annual N_2O emissions from adipic acid production according to paragraphs (a)(1) or (a)(2) of this section.

(1) Use a site-specific emission factor and production data according to paragraphs (b) through (g) of this section.

(2) Request approval by the Director for an alternative method of determining N_2O emissions.

(b) You must conduct an annual performance test or use continuous monitors according to paragraphs (b)(1) through (b)(3) of this section.

(1) You must conduct the test on the waste gas stream from the nitric acid oxidation step of the process using the methods specified in WCI.54 (b) through (d) or use a continuous monitoring system.

(2) You must conduct the performance test under normal process operating conditions and without using N_2O abatement technology or use a continuous monitoring system.

(3) You must measure the adipic acid production rate during the test and calculate the production rate for the test period or the continuous monitoring period in tonnes per hour.

(c) You must determine an N_2O emissions factor to use in Equation 50-2 of this section according to paragraphs (c)(1) or (c)(2) of this section.

(1) You may request Director approval for an alternative method of determining N_2O concentrations according to the procedures in paragraphs (a)(2) of this section.

(2) Using the results of the test or continuous monitors in paragraph (b) of this section, you must calculate a facility-specific emissions factor according to Equation 50-1 for performance testing and 50-1a for continuous monitors of this section:

$$EF_{N2O} = \frac{\sum_{1}^{n} \frac{C_{N2O} * 1.826\times10^{-6} * Q}{P}}{n}$$ **Equation 50-1**

$$EF_{N2O} = \frac{C_{N2O} * 1.826\times10^{-6} * Q}{P}$$ **Equation 50-1a**

Where:

EF_{N2O}	=	Average facility-specific N_2O emissions factor (kg N_2O generated/tonne adipic acid produced).
C_{N2O}	=	N_2O concentration per test run during the performance test or average hourly concentrations for continuous monitors (ppm N_2O).
$1.828x10^{-6}$	=	Conversion factor (kg/dsm^3-ppm N_2O).
Q	=	Volumetric flow rate of effluent gas per test run during the performance test or hourly readings for continuous monitor (dsm^3/hr).
P	=	Production rate per test run during the performance test or the average hourly production rate for continuous monitors (tonnes adipic acid produced/hr).
n	=	Number of test runs.

(d) If applicable, you must determine the destruction efficiency for each N_2O abatement technology used at your facility according to paragraphs (d)(1), (d)(2), (d)(3) or (d)(4) of this section.

(1) Use the manufacturer's specified destruction efficiency.

(2) Estimate the destruction efficiency through process knowledge. Examples of information that could constitute process knowledge include calculations based on material balances, process stoichiometry, or previous test results provided the results are still relevant to the current vent stream conditions. You must document how process knowledge was used to determine the destruction efficiency.

(3) Calculate the destruction efficiency by conducting an additional performance test on the emissions stream following the N_2O abatement technology.

(4) Calculate the destruction efficiency by the use of continuous monitors on the controlled and uncontrolled emissions.

(e) If applicable, you must determine the abatement factor for each N_2O abatement technology used at your facility. The abatement factor is calculated for each adipic acid facility according to Equation 50-2 of this section.

$$AF = \frac{P_{a\ Abate}}{P_a}$$ **Equation 50-2**

Where:

AF	=	Abatement factor of N_2O abatement technology (fraction of annual production that abatement technology is operating).
$P_{a\ Abate}$	=	Annual adipic acid production during which N_2O abatement was used (tonne acid produced).
P_a	=	Total annual adipic acid production (tonne acid produced).

(f) You must determine the annual amount of adipic acid produced and the annual adipic acid production during which N_2O abatement is operating.

(g) You must calculate annual adipic acid production process emissions of N_2O by multiplying the emissions factor (determined using Equation 50-1 of this section) by the adipic acid production for each period and accounting for N_2O abatement, according to Equation 50-3 of this section:

$$N_2O = \sum_{i=1}^{N} \frac{EF_{N20i} * P_{ai} * (1-(DF_i * AF_i))}{1000}$$ **Equation 50-3**

Where:

N_2O	=	Annual N_2O mass emissions from adipic acid production (tonnes).
EF_{N2Oi}	=	Facility-specific N_2O emissions factor for the period *i* (kg N_2O generated/tonne adipic acid produced).
P_{ai}	=	Adipic acid produced in the period *i* (tonnes).
DF_i	=	Destruction efficiency of N_2O abatement technology for the period *i* (abatement device destruction efficiency, percent of N_2O removed from air stream).
AF_i	=	Abatement factor of N_2O abatement technology for the period *i* (fraction of annual production abatement technology is operating).
1000	=	Conversion factor (kg/tonne).
N	=	Number of different periods in the year. For performance test, the period would be the time between each test (e.g., N is 1 year if performance test conducted annually). For continuous monitors, N would be the number of months in the year (or more) with P_{ai}, EF_{N2Oi}, DF_i and AF_i to be calculated for each month.

§ WCI.54 Monitoring Requirements

(a) You must conduct a new performance test and calculate a new facility-specific emissions factor according to the frequency specified in paragraphs (a)(1) of this section, or use continuous monitors to calculate a facility-specific emissions factor and destruction efficiency according to paragraphs (a)(2) of this section.

(1) Performance Test

(i) Conduct the performance test annually.

(ii) Conduct the performance test when your adipic acid production process is changed either by altering the ratio of cyclohexanone to cyclohexanol or by installing abatement equipment.

(2) Continuous Monitors

(i) Use continuous monitors to determine the uncontrolled emissions and the controlled N_2O emissions to derive an N_2O emission factor and abatement system destruction factor.

(ii) The continuous monitors shall be operated in accordance with quality assurance and quality control program approved by the Director.

(b) You must measure the N_2O concentration during the performance test using one of the methods in paragraphs (b)(1) through (b)(3) of this section.

(1) EPA Method 320, Measurement of Vapor Phase Organic and Inorganic Emissions by Extractive Fourier Transform Infrared (FTIR) Spectroscopy in 40 CFR part 63 (U.S.), Appendix A;

(2) ASTM D6348-03 Standard Test Method for Determination of Gaseous Compounds by Extractive Direct Interface Fourier Transform Infrared (FTIR) Spectroscopy; or

(3) An equivalent method or continuous monitors, with Director approval.

(c) You must determine the production rate(s) during the performance test according to paragraph (c)(1) or (c)(2) of this section.

(1) Direct measurement (such as using flow meters or weigh scales).

(2) Existing plant procedures used for accounting purposes.

(d) You must conduct all required performance tests according to the methods in WCI.54(b). For each test, the facility must prepare an emissions factor determination report that must include the items in paragraphs (d)(1) through (d)(3) of this section:

(1) Analysis of samples, determination of emissions, and raw data.

(2) All information and data used to derive the emissions factor.

(3) The production rate(s) during the performance test and how each production rate was determined.

(e) You must determine the monthly adipic acid production quantity and the monthly adipic acid production during which N_2O abatement technology is operating according to the methods in paragraphs (c)(1) or (c)(2) of this section.

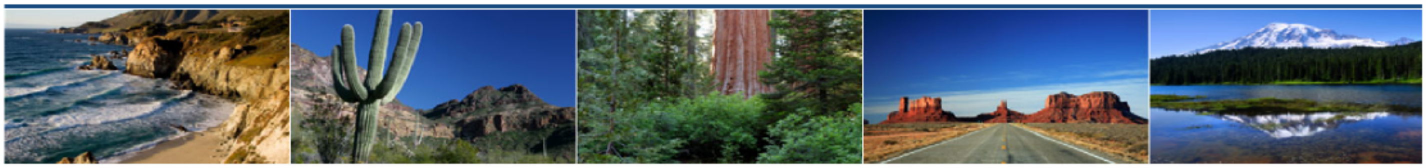
(f) You must determine the annual adipic acid production quantity and the annual adipic production quantity during which N_2O abatement technology is operating by summing the respective monthly adipic acid production quantities.

§ WCI.55 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section.

(a) For each missing value of monthly adipic acid production, the substitute data shall be the best available estimate based on all available process data or data used for accounting purposes (such as sales records).

(b) For missing values related to the performance test, including emission factors, production rate, and N_2O concentration, you must conduct a new performance test according to the procedures in §98.54 (a) through (d).



§ WCI.60 IMPORTED ELECTRICITY

[*The requirements in this attachment do not include the default emissions factors necessary for reporting imported electricity from asset-controlling suppliers or imports from unspecified sources. Default factors for unspecified sources are under development by the Electricity Committee and asset-controlling suppliers will need to approach each jurisdiction for approval of a differentiated default factor.*]

§ WCI.61 Definitions

"Asset-controlling supplier" means any entity that owns or operates electricity generating facilities or serves as an exclusive marketer for certain generating facilities even though it does not own them, and is assigned a supplier-specific identification number for its fleet of generating facilities by [*the jurisdiction*].

"Balancing authority" means a responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance within a Balancing Authority Area, and supports interconnection frequency in real time.

"Balancing authority area" means the collection of generation, transmission, and loads within the metered boundaries of a balancing authority. A balancing authority maintains load-resource balance within this area.

"Busbar" means a power conduit of an electricity generating facility that serves as the starting point for the electricity transmission system.

"Electricity generating facility" means a facility that generates electricity and includes one or more electricity generating units at the same location.

"Electricity importer" means [common boundary FJD] an owner of imported electricity [*or electricity wheeled through the WCI Region*] as it is delivered to the first point of delivery in the WCI Region or; [individual boundary FJD] an owner of imported electricity [*or electricity wheeled through the WCI Region*] as it is delivered to the first point of delivery in the WCI Partner jurisdiction of the final point of delivery. [The definition used may vary by jurisdiction.]

"Electricity transaction" means the purchase, sale, import, export or exchange of electric power.

"Electricity wheeled through the WCI Region" means electricity that is imported into the WCI Region but is simultaneously exported out of the WCI Region and has a final point of delivery in a location outside of the WCI Region.

"Entity" means a person, firm, association, organization, partnership, business trust, corporation, limited liability company, company, or government agency.

"Exchange agreement" means a commitment between electricity market participants to swap energy for energy. Exchange transactions do not involve transfers of payment or receipts of money for the full market value of the energy being exchanged, but may include payment for net differences due to market price differences between the two parts of the transaction or to settle minor imbalances.

“Final point of delivery” means the last point of delivery for a given electricity transaction.

“First Jurisdictional Deliverer” means the owner or operator of an electricity generating facility in a WCI Partner jurisdiction or an electricity importer that is jurisdictional to the regulatory authority of a WCI Partner jurisdiction or the immediate downstream purchaser or recipient of electricity from a non-jurisdictional electricity importer.

“Gross generation” means the total electrical output of the generating unit, expressed in megawatt hours (MWh) per year.

“Imported electricity” means electric power generated outside the WCI Region, delivered into the WCI Region and having a final point of delivery in the WCI Region.

“Megawatt hour” or “MWh” means the electrical energy unit of measure equal to one million watts of power supplied to, or taken from, an electric circuit steadily for one hour.

“Multi-jurisdictional retail provider” means a retail provider that provides electricity to consumers in [*the jurisdiction*] and in one or more other non-WCI jurisdictions in a contiguous service territory.

“Nameplate generating capacity” means the maximum rated output of a generator under specific conditions designated by the manufacturer, expressed in megawatts (MW) or kilowatts (kW).

“Net power generated” means the gross generation minus station service or unit service power requirements, expressed in megawatt hours (MWh) per year. In the case of cogeneration, this value is intended to include internal consumption of electricity for the purposes of a production process, as well as power put on the grid.

“NERC E-tag” means North American Electric Reliability Corporation (NERC) energy tag representing transactions on the North American bulk electricity market scheduled to flow between or across balancing authority areas.

“Point of delivery” means a point on an electricity transmission or distribution system where a power supplier delivers electricity to the receiver of that energy. This point can be an interconnection with another system or a substation where the transmission provider’s transmission and distribution systems are connected to another system, or a distribution substation where electricity is imported into the WCI region over a multi-jurisdictional retail provider’s distribution system.

“Power contract” means an arrangement for the purchase of electricity. Power contracts may be, but are not limited to, power purchase agreements and tariff provisions.

“Purchasing/selling entity” means an entity that purchases or sells energy or capacity and reserves transmission services between or among balancing authority areas.

“Renewable energy” means energy from sources that constantly renew themselves or that are regarded as practically inexhaustible. Renewable energy includes, but is not limited to, energy derived from solar, wind, geothermal, hydroelectric, wood, biomass, tidal power, sea currents, and ocean thermal gradients.

“Renewable energy certificate” or “renewable energy credit” means a certificate of proof issued by an approved generation information system or third-party verifier that one MWh of electricity was generated by a renewable energy source.

“Retail provider” means an entity that provides electricity to retail end users in [*the jurisdiction*].

“Specified source” means a specific electricity generating unit or electricity generating facility which can be matched to a reported electricity transaction due to full or partial ownership by the first jurisdictional deliverer or due to its identification in a power contract with the first jurisdictional deliverer.

“Unspecified source” means electricity generation that cannot be matched to a specific electricity generating facility or electricity generating unit. Unspecified sources of electricity may include electricity purchased from entities that own fleets of generating facilities such as independent power producers, retail providers, and federal power agencies and power purchased from electricity marketers, brokers, and markets.

“Western Climate Initiative” or “WCI” means a collaborative effort of the U.S. states and Canadian provinces that comprise the WCI Region to reduce greenhouse gas emissions in their respective jurisdictions.

“WCI Region” means the Canadian provinces of British Columbia, Manitoba, Ontario, and Quebec plus the U.S. states of Arizona, California, Montana, New Mexico, Oregon, Utah, and Washington, excluding lands that are not subject to state or provincial jurisdiction.

§ WCI.62 Greenhouse Gas Emissions Data Report: First Jurisdictional Deliverers of Imported Electricity

(a) General Requirements. First jurisdictional deliverers shall meet the following general requirements in preparing their greenhouse gas emissions data report for each report year. When reporting emissions and electricity transactions, first jurisdictional deliverers, excluding imported electricity that is imported at the distribution level by multi-jurisdictional retail providers, shall:

(1) Specify the amount of greenhouse gas emissions in metric tons CO_2e;

(2) Specify the amount of electricity in MWh;

(3) Aggregate imported electricity and emissions from specified sources by electricity generating facility or electricity generating unit, as applicable;

(4) For electricity from specified sources, specify the facility name, the facility ID, and, if applicable, the electricity generating unit ID for the unit generating the electricity;

(5) Report the amount of imported electricity from specified sources as measured at the busbar;

(6) For imported electricity transactions from specified sources where measurements at the busbar are not known, report the amount of imported electricity from the applicable specified sources as measured at the first point of delivery in [*the jurisdiction]* and report estimated transmission losses for each specified source;

(7) Report the amount of electricity from unspecified sources as measured at the first point of delivery in [*the jurisdiction*];

(8) For electricity from unspecified sources, disaggregate imported electricity by the balancing authority area or other geographic area as defined by [*the jurisdiction*] from which the electricity originated;

(9) Report the amount of electricity from asset-controlling suppliers as measured at the first point of delivery in [*the jurisdiction*];

(10) For electricity from asset-controlling suppliers, disaggregate imported electricity by the asset-controlling or asset-owning supplier from which the electricity was purchased;

(11) Report the number of renewable energy certificates from sources not in the WCI region that are retired, or whose greenhouse gas source specification fields are retired, as applicable, associated with imported electricity from an unspecified source or imported electricity from a specified source having an emission rate equal to or less than the default rate for the balancing authority where the specified generating facility is located;

(12) Specify electricity imported under exchange agreements as you would other import transactions;

(13) Report quantities of electricity wheeled through the WCI Region as measured at the first point of delivery inside [*the jurisdiction*];

(14) Retain for purposes of verification NERC E-tags, power contracts, settlements data, and all other information needed to confirm the transactions.

(b) Report Content. First Jurisdictional Deliverers shall include the following information in the greenhouse gas emissions data report for each report year.

(1) Specified Imported Electricity Transactions. Imported electricity and emissions from specified sources for which the First Jurisdictional Deliverer is the electricity importer or that the First Jurisdictional Deliverer purchased or received immediately downstream from a non-jurisdictional electricity importer.

(A) Electricity imported into the WCI Region from a specified hydroelectric generating facility with nameplate capacity of greater than 30 MW that was operational prior to January 1, 2008 or from a specified nuclear facility that was operational prior to January 1, 2008 shall be listed as one of the following:

(i) Electricity purchased with a contract in effect prior to January 1, 2008 that remains in effect or has been renegotiated for the same facility for the same share or quantity of net generation within one year of contract expiration;

(ii) Electricity purchased not meeting WCI.62(b)(1)(A)(i) and that is not associated with an increase in the facility's generating capacity;

(iii) Electricity purchased not meeting WCI.62(b)(1)(A)(i) that is associated with an increase in the facility's generating capacity due to increased efficiencies or other capacity increasing actions;

(iv) Electricity purchased from hydroelectric generating facilities during a "spill or sell" situation where power not purchased is lost;

(v) Electricity purchased that does not meet WCI.62(b)(1)(A)(i) due to federal power redistribution polices for federally owned resources and not related to price bidding.

(2) Unspecified Imported Electricity Transactions. Imported electricity and emissions from unspecified sources for which the First Jurisdictional Deliverer is the electricity importer or that the First Jurisdictional Deliverer purchased or received immediately downstream from a non-jurisdictional electricity importer.

(3) Imported Electricity from Asset-Controlling Suppliers. Imported electricity and emissions from asset-controlling suppliers for which the First Jurisdictional Deliverer is the electricity importer or that the First Jurisdictional Deliverer purchased or received immediately downstream from a non-jurisdictional electricity importer.

(4) Electricity Wheeled Through the WCI Region. Electricity wheeled through the WCI Region for which the First Jurisdictional Deliverer is the electricity importer or that the First Jurisdictional Deliverer purchased or received immediately downstream from a non-jurisdictional electricity importer.

§ WCI.63 Calculation of Emissions from Specified Sources

For each specified source, calculate CO_2 mass emissions using one of the two calculation methodologies specified in this section.

(a) Calculation Methodology 1: If the specified source reports emissions to [*the jurisdiction*], The Climate Registry, the U.S.EPA under 40 CFR Part 75 or to Environment Canada under Section 71 of the Canadian Environmental Protection Act calculate emissions using Equation 60-1:

$$CO_2 = CO_{2t} \times \frac{MWh_{imp}}{MWh_t} \qquad \textbf{Equation 60-1}$$

Where:

CO_2 = Annual CO_2 mass emissions for imported electricity from the specified source (metric tons).

CO_{2t} = Total annual CO_2 mass emissions from the specified source (metric tons) reported, in order of preference, to [*the jurisdiction*], The Climate Registry, or to the U.S.EPA or Environment Canada.

MWh_{imp} = Megawatt-hours of electricity imported from the specified source, including estimated losses for transactions not measured at the busbar.

MWh_t = Total megawatt-hours of net power generated by the specified source.

(b) Calculation Methodology 2: If the specified source does not report emissions to [*the jurisdiction*], The Climate Registry, the U.S.EPA under 40 CFR Part 75 or to Environment Canada under Section 71 of the Canadian Environmental Protection Act, calculate emissions using Equation 60-2:

$$CO_2 = \sum HHV_f \times EF_f \times 0.001 \times \frac{MWh_{imp}}{MWh_t} \qquad \textbf{Equation 60-2}$$

Where:

CO_2	=	Annual CO_2 mass emissions for a specific fuel type (metric tons).
HHV_f	=	Higher heating value of the fuel *f* consumed for electricity production as reported in U.S. EIA Form 923, or its successor (mmBtu).
EF_f	=	Fuel-specific default CO_2 emission factor, from column 5 of Table 20-1 or from Table 20-2 (kg CO_2/mmBtu).
0.001	=	Conversion factor from kilograms to metric tons.
MWh_{imp}	=	Megawatt-hours of electricity imported from the specified source.
MWh_t	=	Total megawatt-hours of net power generated by the specified source as reported in U.S. EIA Form 923, or its successor.

§ WCI.64 Calculation of Emissions from Asset-Controlling Suppliers and Unspecified Sources

For imported electricity from asset-controlling suppliers or unspecified sources, calculate emissions using the methodology specified in this section.

(a) Calculation Methodology: Calculate the annual CO_2 mass emissions by multiplying the reported quantities of imported electricity from each asset-controlling supplier, balancing authority area, or other geographic region defined by [*the jurisdiction*] by the appropriate default emission factor according to Equation 60-3:

$$CO_2 = MWh \times DEF$$ **Equation 60-3**

Where:

CO_2	=	Annual CO_2 mass emissions for imported electricity from the specified source (metric tons).
MWh	=	Megawatt-hours of electricity imported from the asset-controlling supplier, balancing authority area, or other geographic region defined by [*the jurisdiction*].
DEF	=	The default emission factor corresponding to the asset-controlling supplier, balancing authority area, or other geographic region defined by [*the jurisdiction*].

§ WCI.65 Greenhouse Gas Emissions Data Report: Additional Requirements for Retail Providers Only

[*This section is optional. It is intended for any WCI jurisdiction that wishes to collect information about high-GHG generating facilities in other jurisdictions owned by retail providers serving its own jurisdiction.*]

Retail providers shall include the following information in the greenhouse gas emissions data report for each report year, in addition to the information identified in the sections above.

(a) If the retail provider holds a contract that entitles the retail provider to a specified percentage of the generation in the report year from an electricity generating facility not located in the WCI Region, the retail provider shall include electricity purchased or sold from that facility as being from a partially owned facility.

(b) For electricity generating facilities not located in the WCI Region that are fully or partially owned by the retail provider that have CO2 emissions greater than 500 kg of CO2 per MWh based on the most recent greenhouse gas emissions data report that received a positive verification opinion or on CO2 emissions reported to U.S.EPA under 40 CFR Part 75 or reported to Environment Canada under Section 71 of the Canadian Environmental Protection Act, the retail provider shall include:

(1) Facility name, state/province designated facility ID, state/province designated generating unit ID as applicable, percent ownership share at the facility level, ownership share at the generating unit level as applicable, and both net and gross power generated in the report year;

(2) Quantity of electricity sold by the retail provider or on behalf of the retail provider from the electricity generating facility or electricity generating unit having a final point of delivery outside the WCI Region, as measured at the busbar.

§ WCI.66 Greenhouse Gas Emissions Data Report: Additional Requirements for Multi-Jurisdictional Retail Providers Only.

[*This section applies only to jurisdictions with Multi-Jurisdictional Retail Providers, as defined.*]

Multi-jurisdictional retail providers that import electricity into the WCI Region at the distribution level shall include the following information in the greenhouse gas emissions data report for each report year in addition to the information identified in the sections above. Multi-jurisdictional retail providers meeting this condition shall provide:

(a) A report of the greenhouse gas emissions associated with serving the load of the service territory that includes consumers in [*the jurisdiction*] following [*the jurisdiction's*] reporting protocol for retail providers or The Climate Registry's Electric Power Sector Protocol;

(b) The total retail load served by the multi-jurisdictional retail provider in the service territory that includes consumers in [*the jurisdiction*];

(c) The retail load of customers served in [*the jurisdiction's*] portion of the service territory;

(d) The greenhouse gas emissions associated with the imported electricity as the quantity of emissions reported in WCI.64(a) multiplied by the ratio of the quantity of electricity reported in WCI.64(b) to the quantity of electricity reported in WCI.64(c); and

(e) If the average emission rates differ among the various state or provincial portions of the service territory due to mandatory factors such as different Renewable Portfolio Standard requirements in [*the jurisdiction*] and the other jurisdictions, the multi-jurisdictional retail provider may report an adjusted quantity of greenhouse emissions and file a report that describes how the quantity reported in WCI.64(d) was adjusted.

§ WCI.70 PRIMARY ALUMINUM PRODUCTION

§ WCI.71 Source Category Definition

A primary aluminum production process converts alumina mineral to aluminum metal using the Hall-Héroult manufacturing process, which includes electrolysis in prebake and Søderberg cells and anode baking for prebake cells.

§ WCI.72 Greenhouse Gas Reporting Requirements

For each facility that includes a primary aluminum production process, the emissions data report must contain the following information:

(a) CO_2 emissions from anode consumption from prebaked and Søderberg electrolysis cells.

(b) CO_2 emissions from anode and cathode baking.

(c) CF_4 and C_2F_6 emissions for anode effects.

(d) CO_2 emissions from green coke calcination.

(e) SF_6 emissions from cover gas consumption.

(f) CO_2, N_2O, and CH_4 emissions from stationary combustion units as specified in WCI.20.

(g) Annual aluminum production.

(h) Type of smelter technology used.

(i) CF_4 and C_2F_6 emissions from anode effects in all prebake and all Søderberg electrolysis cells combined.

(j) Anode effect minutes per cell-day (AE-mins/cell-day), anode effect frequency (AE/cell-day), and anode effect duration (minutes); alternatively, anode effect overvoltage factor (kg CF_4/metric ton Al) , potline overvoltage (mV/cell day), and current efficiency (%).

(k) Smelter-specific slope coefficients (or overvoltage emission factors) and the last date when the smelter-specific slope coefficients (or overvoltage emission factors) were measured.

(l) Method used to measure the frequency and duration of anode effects (or overvoltage).

(m) Annual anode consumption for prebake cells.

(n) Annual CO_2 emissions from the smelter for prebake cells.

(o) Annual paste consumption for Søderberg cells.

(p) Annual CO_2 emissions from the smelter for Søderberg cells.

(q) Smelter-specific inputs to the CO_2 process equations (e.g., levels of sulphur and ash) that were used in the calculation, on an annual basis.

§ WCI.73 Calculation of GHG Emissions

(a) Calculate CO_2 emissions from anode consumption using either Equation 70-1 or 70-2, as applicable.

(1) For Prebaked Anodes:

$$E_{CO_2} = \sum_{i=1}^{12} [NCC \times MP \times \frac{(100 - S_a - Ash_a)}{100} \times 3.664]_i \qquad \textbf{Equation 70-1}$$

Where:

E_{CO2}	=	Annual CO_2 emissions (tonnes).
NCC	=	Net anode consumption per metric ton of aluminum for month *i* (tonne/tonne aluminum).
MP	=	Aluminum production for month *i* (tonne).
S_a	=	Sulphur content in baked anodes for month *i* (wt %).
Ash_a	=	Ash content in baked anodes for month *i* (wt %).
3.664	=	Conversion factor from carbon to CO_2.

(2) For Søderberg Anodes:

$$E_{CO_2} = \sum_{i=1}^{12} \begin{bmatrix} (PC \times MP) - \left(BSM \times \frac{MP}{1000}\right) - \left(\frac{BC}{100} \times PC \times MP \times \left(\frac{S_p + Ash_p + H_p}{100}\right)\right) \\ -\left(\frac{100 - BC}{100} \times PC \times MP \times \frac{S_c + Ash_c}{100}\right) - (CD \times MP) \end{bmatrix}_i \times 3.664 \qquad \textbf{Equation 70-2}$$

Where:

E_{CO2}	=	Annual CO_2 emissions (tonnes).
PC	=	Paste consumption for month *i* (tonnes paste/tonne aluminum).
MP	=	Aluminum production for month *i* (tonnes).
BSM	=	Emissions of benzene-soluble matter (kilograms benzene-soluble matter/tonne aluminum).
BC	=	Average binder (pitch) content in paste for month *i* (wt %).
S_p	=	Sulphur content in pitch for month *i* (wt %).
Ash_p	=	Ash content in pitch (wt %).
H_p	=	Hydrogen content in pitch (wt %).
S_c	=	Sulphur content in calcinated coke (wt %).
Ash_c	=	Ash content in calcinated coke (wt %).
CD	=	Carbon in skimmed dust from Søderberg cells (tonne C/tonne aluminum).
3.664	=	Conversion factor from carbon to CO_2.

(b) If anode or cathode baking is performed onsite, calculate CO_2 emissions as specified in paragraphs (b)(1) or (2) as applicable. Total emissions as specified in paragraph (b)(3) if both (b)(1) and (2) are applicable.

(1) Calculate CO_2 emissions from packing coke using Equation 70-3.

$$EC_{CO_2} = \sum_{i=1}^{12} \left(PCC \times BAP \times \frac{100 - Ash_{pc} - S_{pc}}{100} \right)_i \times 3.664$$ **Equation 70-3**

Where:

EC_{CO2} = Annual CO_2 emissions (tonnes pre year).
PCC = Packing coke consumption per tonne of baked anode for month *i* (tonnes coke/tonne anodes).
BAP = Baked anode production for month *i* (tonnes).
Ash_{pc} = Ash content in packing coke for month *i* (wt %).
S_{pc} = Sulphur content in packing coke for month *i* (wt %).
3.664 = Conversion factor from carbon to CO_2.

(2) Calculate CO_2 emissions from pitch coking using Equation 70-4.

$$EP_{CO_2} = \sum_{i=1}^{12} \left(GAW - BAP - \left(\frac{H_p}{100} \times \frac{PC}{100} \times GAW \right) - RT \right)_i \times 3.664$$ **Equation 70-4**

Where:

EP_{CO2} = CO_2 emissions (tonnes pre year).
GAW = Green anode consumption for month *i* (tonnes).
BAP = Baked anode production for month *i* (tonnes).
H_p = Hydrogen content in pitch for month *i* (wt %).
PC = Pitch content in green anode for month *i* (wt %).
RT = Recovered tar for month *i* (tonnes).
3.664 = Conversion factor from carbon to CO_2.

(3) Calculate total CO_2 emissions for anode baking using Equation 70-5.

$$E_{anodebaking} = EC_{CO2} + EP_{CO2}$$ **Equation 70-5**

Where:

$E_{anodebaking}$ = Total annual CO_2 emissions from anode baking (tonnes).
EC_{CO2} = Annual CO_2 emissions from packing coke (tonnes).
EP_{CO2} = Annual CO_2 emissions from pitch coking (tonnes).

(c) Calculate CF_4 emissions using either paragraph (c)(1) or (c)(2) and calculate C_2F_6 emissions using paragraph (c)(3).

(1) Calculate CF_4 emissions from anode effect duration using Equation 70-6.

$$E_{CF_4} = \sum_{i=1}^{12} [S_{CF4} \times AEM \times MP]_i$$ **Equation 70-6**

Where:

E_{CF4} = Annual emissions of CF_4 (tonnes/yr).
S_{CF4} = Slope coefficient ([tonnes of CF_4/tonne aluminum]/[AE minutes/cell-days]).

AEM = Anode effect frequency (AE-minutes/cell-day), calculated monthly.
MP = Monthly aluminum production (tonnes).

(2) Calculate CF_4 emissions from overvoltage using Equation 70-7.

$$E_{CF_4} = \sum_{i=1}^{12} [EF_{CF_4} \times MP]_i$$ **Equation 70-7**

Where:
E_{CF4} = Annual emissions of CF_4 (tonnes/yr).
EF_{CF4} = Overvoltage emission factor (tonnes of CF_4/tonne aluminum).
MP = Monthly aluminum production (tonnes).

(3) Calculate C_2F_6 emissions from anode effects using Equation 70-8.

$$E_{C_2F_6} = \sum_{i=1}^{12} [E_{CF_4} \times F_{C_2F_6/CF_4}]_i$$ **Equation 70-8**

Where:
E_{C2F6} = Annual emissions of C_2F_6 (tonnes/yr).
E_{CF4} = Monthly emissions of CF_4 (tonnes/yr).
$F_{C2F6/CF4}$ = Weight fraction of C_2F_6/CF_4 (kg C_2F_6/kg CF_4).

(d) Calculate CO_2 emissions from onsite green coke calcination furnaces using Equation 70-9.

$$E_{CO_2} = \sum_{n=1}^{12} \left[\left[GC \times \frac{(100 - H_2O_{gc} - V_{gc} - S_{gc})}{100} - (CC + UCC + DE) \times \frac{(100 - S_{cc})}{100}\right] \times 3.664\right]_i + \left[GC \times 0.035 \times \frac{44}{16}\right]_i$$ **Equation 70-9**

Where:
E_{CO2} = CO_2 emissions (tonnes pre year).
GC = Green coke feed for month *i* (tonnes).
H_2O_{gc} = Humidity in green coke feed for month *i* (wt %).
V_{gc} = Volatiles in green coke feed for month *i* (wt %).
S_{gc} = Sulphur content in green coke feed in month *i* (wt %).
S_{cc} = Sulphur content in calcinated coke in month *i* (wt %).
CC = Calcinated coke produced in month *i* (tonnes).
UCC = Under-calcinated coke produced in month *i* (tonnes).
DE = Coke dust emissions for month *i* (tonnes).
3.664 = Conversion factor from carbon to CO_2.
0.035 = Assumed CH_4 and tar content in coke volatiles, contributing to CO_2 emissions.
44/16 = Conversion factor from methane to CO_2.

(e) Calculate SF_6 emissions from cover gas consumption using one of the following methods:

(1) Calculate the annual SF_6 emissions using inventory records and Equation 70-10:

$$E_{SF6} = S_{Inv-Begin} - S_{Inv-End} + S_{Purchased} - S_{Shipped} \qquad \textbf{Equation 70-10}$$

Where:

E_{SF6} = SF_6 emissions from cover gas (tonnes).
$S_{Purchased}$ = Quantity of SF_6 purchased (tonnes).
$S_{Shipped}$ = Quantity of SF_6 shipped offsite (tonnes).
$S_{Inv\text{-}Begin}$ = Quantity of SF_6 in storage at the beginning of the year, (tonnes).
$S_{Inv\text{-}End}$ = Quantity of SF_6 in storage at the end of the year (tonnes).

(2) Calculate the annual SF_6 emissions using Equation 70-11 and direct measurement of the SF_6 input to electrolysis cells and the SF_6 waste gases collected and transferred off-site:

$$E_{SF6} = \sum_{i=1}^{12} [(Q_{Input} \times C_{Input}) - (Q_{Output} \times C_{Output})]_i \qquad \textbf{Equation 70-11}$$

Where:

E_{SF6} = SF_6 emissions from cover gas (tonnes).
$Q_{in;put}$ = Quantity of SF_6 input to the electrolysis cell for month *i* (tonnes).
C_{Input} = Concentration of SF_6 input to the electrolysis cell for month *i* (tonnes).
Q_{Output} = Quantity of SF_6 gas collected during month *i* (if applicable) (tonnes).
C_{Output} = Concentration of SF_6 gas collected and sent off-site during month *i* (tonnes).

§ WCI.74 Monitoring Requirements

(a) Except as specified in paragraphs (b) through (c) of this section, all parameters must be measured monthly.

(b) Conduct performance tests once every 36 months to determine the slope or Pechiney coefficients for each pot line using the *Protocol for Measurement of Tetrafluoromethane and Hexafluoroethane Emissions from Primary Aluminum Production,* U.S. Environmental Protection Agency and International Aluminum Institute. April 2008. The test must be repeated whenever:

(1) Thirty-six months have passed since the last measurements;

(2) A change occurs in the control algorithm that affects the mix of types of anode effects or the nature of the anode effect termination routine; or

(3) Changes occur in the distribution or duration of anode effects (e.g. when the percentage of manual kills changes or if, over time, the number of anode effects decreases and results in a fewer number of longer anode effects) or, for Rio Tinto Alcan control technology, when the algorithm for bridge movements and anode effect overvoltage accounting changes.

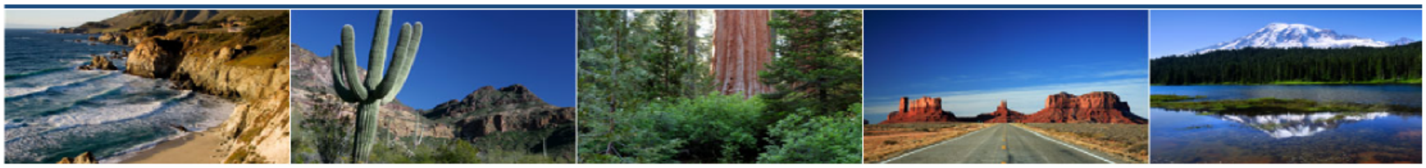
(c) If using the direct measurement approach in WCI.73(e)(2) to calculate SF_6 emissions from cover gas consumption, the quantity of SF_6 gas input to the electrolysis cell month and the quantity and SF_6 concentration of any waste gas collected and sent off-site must be measured.

§ WCI.75 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For each missing value of the carbon content and molecular weight, the substitute data value shall be the arithmetic average of the quality assured values of the parameter immediately preceding and immediately following the missing data incident. If no quality assured data are available prior to the missing data incident, the substitute data value shall be the first quality assured data value obtained after the missing data period.

(b) For missing feedstock and production values, the substitute data value shall be the best available estimate of the parameter, based on all available process data. You must document and retain records of the procedures used for all such estimates.



§ WCI.80 AMMONIA MANUFACTURING

§ WCI.81 Source Category Definition

The ammonia manufacturing source category comprises the process units listed in paragraphs (a) and (b) of this section.

(a) Ammonia manufacturing processes in which ammonia is manufactured from a fossil-based feedstock produced via steam reforming of a hydrocarbon.

(b) Ammonia manufacturing processes in which ammonia is manufactured through the gasification of solid and liquid raw material.

§ WCI.82 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation, the annual emissions data report for ammonia acid manufacturing shall include the following information at the facility level calculated in accordance this method:

(a) CO_2 process emissions from steam reforming of a hydrocarbon or the gasification of solid and liquid raw material following the requirements in this subpart.

(b) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit. You must report these emissions under WCI.20 (General Stationary Fuel Combustion Sources), by following the requirements of WCI.20.

(c) If a CEMS is used to measure CO_2 emissions, then you must report the relevant information required under WCI.23 for Calculation Methodology 4 and the following information:

Annual quantity of each type of feedstock consumed for ammonia manufacturing (sm^3 of feedstock or kilolitres of feedstock or tonnes of feedstock).

(d) If a CEMS is not used to measure emissions, then you must report the following information:

(1) Whether carbon content for each feedstock is based on reports from the supplier or analysis of carbon content.

(2) If a facility uses gaseous feedstock, the carbon content of the gaseous feedstock, for month *n*, (kg C per sm^3 of feedstock).

(3) If a facility uses liquid feedstock, the carbon content of the liquid feedstock, for month *n*, (kg C per kilolitre of feedstock).

(4) If a facility uses solid feedstock, the carbon content of the solid feedstock, for month *n*, (kg C per kg of feedstock).

(5) Annual CO_2 emissions associated with the waste recycle stream (tonnes).

(6) Carbon content of the waste recycle stream (kg C per kg of waste recycle stream).

(7) Volume of the waste recycle stream (sm^3).

(e) Annual urea production (tonnes).

§ WCI.83 Calculating GHG emissions

You must calculate and report the annual process CO_2 emissions from each ammonia manufacturing process unit using the procedures in either paragraph (a) or (b) of this section.

(a) Calculate and report under this subpart the process CO_2 emissions by operating and maintaining CEMS according to the Tier 4 Calculation Methodology specified in WCI.23 and all associated requirements for Tier 4 in WCI.20 (General Stationary Fuel Combustion Sources).

(b) Calculate and report under this subpart process CO_2 emissions using the procedures in paragraphs (b)(1) through (b)(6) of this section for gaseous feedstock, liquid feedstock, or solid feedstock, as applicable.

(1) Gaseous feedstock. You must calculate the CO_2 process emissions from gaseous feedstock according to Equation 80-1 of this section:

$$CO_{2,G,k} = \left(\sum_{n=1}^{12} 3.664 * Fdstk_{n,k} * CC_n * \frac{MW}{MVC}\right) * 0.001 \quad \textbf{Equation 80-1}$$

Where:

$CO_{2,G,k}$	=	Annual CO_2 emissions arising from gaseous feedstock consumption (tonnes).
$Fdstk_{n,k}$	=	Volume of the gaseous feedstock used in month *n* (Rm^3 of feedstock) at reference temperature and pressure conditions as used by the facility. If a mass flow meter is used, measure the feedstock used in the month *n* as kg feedstock and replace the term “MW/MVC” with “1”..
CC_n	=	Carbon content of the gaseous feedstock, for month *n*, (kg C per kg of feedstock), determined according to WCI.84(c).
MW	=	Molecular weight of the gaseous feedstock (kg/kg-mole).
MVC	=	Molar volume conversion factor at the same reference conditions as the above $Fdstk_{n,k}$ (Rm^3/kg-mole).
	=	8.3145 * [273.16 + reference temperature in °C] / [reference pressure in kilopascal]
3.664	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to tonnes.
k	=	Processing unit.
n	=	Number of months.

(2) Liquid feedstock. You must calculate, from each ammonia manufacturing unit, the CO_2 process emissions from liquid feedstock according to Equation 80-2 of this section:

$$CO_{2,L,k} = \left(\sum_{n=1}^{12} 3.664 * Fdstk_{n,k} * CC_n\right) * 0.001 \quad \textbf{Equation 80-2}$$

Where:

$CO_{2,L,k}$ = Annual CO_2 emissions arising from liquid feedstock consumption (tonnes).

$Fdstk_{n,k}$ = Volume of the liquid feedstock used in month *n* (kilolitres of feedstock). If a mass flow meter is used, measure the feedstock used in month *n* as kg of feedstock and measure the carbon content of feedstock in kg C per kg of feedstock.

CC_n = Carbon content of the liquid feedstock, for month *n* as determined according to WCI.84(c) (kg of C per kilolitre of feedstock when feedstock consumption is measured in kilolitres or kg of C per kg of feedstock when feedstock consumption is measured in kg).

3.664 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to tonnes.

k = Processing unit.

n = Number of months.

(3) Solid feedstock. You must calculate, from each ammonia manufacturing unit, the CO_2 process emissions from solid feedstock according to Equation 80-3 of this section:

$$CO_{2,S,k} = (\sum_{n=1}^{12} 3.664 * Fdstk_{n,k} * CC_n) * 0.001 \qquad \textbf{Equation 80-3}$$

Where:

$CO_{2,S,k}$ = Annual CO_2 emissions arising from solid feedstock consumption (tonnes).

$Fdstk_{n,k}$ = Mass of the solid feedstock used in month *n* (kg of feedstock).

CC_n = Carbon content of the solid feedstock, for month *n*, (kg C per kg of feedstock), determined according to WCI.84(c).

3.664 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to tonnes.

k = Processing unit.

n = Number of months.

(4) You must calculate the annual process CO_2 emissions from each ammonia processing unit *k* at your facility summing emissions, as applicable from Equation 80-1, 80-2, and 80-3 of this section using Equation 80-4.

$$E_{CO2_k} = CO_{2,G} + CO_{2,S} + CO_{2,L} \qquad \textbf{Equation 80-4}$$

Where:

E_{CO2k} = Annual CO_2 emissions from each ammonia processing unit *k* (tonnes).

k = Processing unit.

(5) You must determine the combined CO_2 emissions from all ammonia processing units at your facility using Equation 80-5 of this section.

$$CO_2 = \sum_{k=1}^{n} E_{CO2_k}$$

Equation 80-5

Where:

CO_2 = Annual combined CO_2 emissions from all ammonia processing units (tonnes).

E_{CO2k} = Annual CO_2 emissions from each ammonia processing unit *k* (tonnes).

k = Processing unit.

n = Total number of ammonia processing units.

(6) If applicable, ammonia manufacturing facilities that utilize the waste recycle stream as a fuel must calculate emissions associated with the waste stream for each ammonia process unit according to Equation 80-6 of this section:

$$CO_2 = \left(\sum_{n=1}^{12} 3.664 * RecycleStream_n * CC_n * \frac{MW}{MVC}\right) * 0.001$$

Equation 80-6

Where:

CO2 = Annual CO_2 contained in waste recycle stream (tonnes).

$RecycleStream_n$ = Volume of the waste recycle stream in month *n* (Rm^3) at reference temperature and pressure conditions as used by the facility. If a mass flow meter is used, measure the waste recycle stream in month *n* as kg and replace the term "MW/MVC" with "1".

CC_n = Carbon content of the waste recycle stream, for month *n*, (kg C per kg of waste recycle stream) determined according to WCI.84(f).

MW = Molecular weight of the waste recycle stream (kg/kg-mole).

MVC = Molar volume conversion factor at the same reference conditions as the above $RecycleStream_n$ (Rm^3/kg-mole).

= 8.3145 * [273.16 + reference temperature in °C] / [reference pressure in kilopascal].

3.664 = Ratio of molecular weights, CO_2 to carbon.

0.001 = Conversion factor from kg to tonnes.

n = Number of month

(c) If GHG emissions from an ammonia manufacturing unit are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with the Tier 4 Calculation Methodology in WCI.23 (General Stationary Fuel Combustion Sources), then the calculation methodology in paragraph (b) of this section shall not be used to calculate process emissions. The owner or operator shall report under this subpart the combined stack emissions according to the Tier 4 Calculation Methodology in WCI.23 and all associated requirements for Methods 4 in WCI.23.

§ WCI.84 Monitoring and QA/QC Requirements

(a) You must continuously measure the quantity of gaseous or liquid feedstock consumed using a flow meter. The quantity of solid feedstock consumed can be obtained from company records and aggregated on a monthly basis.

(b) You must document the procedures used to ensure the accuracy of the estimates of feedstock consumption.

(c) You must determine monthly carbon contents and the average molecular weight of each feedstock consumed from reports from your supplier. As an alternative to using supplier information on carbon contents, you can also collect a sample of each feedstock on a monthly basis and analyze the carbon content and molecular weight of the fuel using any of the following methods listed in paragraphs (c)(1) through (c)(8) of this section, as applicable.

(1) ASTM D1945-03 Standard Test Method for Analysis of Natural Gas by Gas Chromatography (incorporated by reference, see regulation).

(2) ASTM D1946-90 (Reapproved 2006) Standard Practice for Analysis of Reformed Gas by Gas Chromatography (incorporated by reference, see regulation).

(3) ASTM D2502-04 (Reapproved 2002) Standard Test Method for Estimation of Mean Relative Molecular Mass of Petroleum Oils from Viscosity Measurements (incorporated by reference, see regulation).

(4) ASTM D2503-92 (Reapproved 2007) Standard Test Method for Relative Molecular Mass (Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure (incorporated by reference, see regulation).

(5) ASTM D3238-95 (Reapproved 2005) Standard Test Method for Calculation of Carbon Distribution and Structural Group Analysis of Petroleum Oils by the n-d-M Method (incorporated by reference, see regulation).

(6) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants (incorporated by reference, regulation).

(7) ASTM D3176-89 (Reapproved 2002) Standard Practice for Ultimate Analysis of Coal and Coke (incorporated by reference, see regulation).

(8) ASTM D5373-08 Standard Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal (incorporated by reference, see regulation).

(d) Calibrate all oil and gas flow meters (except for gas billing meters) and perform oil tank measurements according to the monitoring and QA/QC requirements for Method 3 in WCI.25.

(e) For quality assurance and quality control of the supplier data, on an annual basis, you must measure the carbon contents of a representative sample of the feedstocks consumed using the appropriate ASTM Method as listed in paragraphs (c)(1) through (c)(8) of this section.

(f) Facilities must continuously measure the quantity of waste gas recycled using a flow meter, as applicable. You must determine the carbon content and the molecular weight of the waste recycle stream by collecting a sample of each waste recycle stream on a monthly basis and analyzing the carbon content using the appropriate ASTM Method as listed in paragraphs (c)(1) through (c)(8) of this section.

(g) If CO_2 from ammonia production is used to produce urea at the same facility, you must determine the quantity of urea produced using methods or plant instruments used for accounting purposes (such as sales records). You must document the procedures used to ensure the accuracy of the estimates of urea produced.

§ WCI.85 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever the monitoring and quality assurance procedures in WCI.84 cannot be followed (e.g., if a meter malfunctions during unit operation), a substitute data value for the missing parameter shall be used in the calculations following paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing data on monthly carbon contents of feedstock or the waste recycle stream, the substitute data value shall be the arithmetic average of the quality-assured values of that carbon content in the month preceding and the month immediately following the missing data incident. If no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon content obtained in the month after the missing data period.

(b) For missing feedstock supply rates or waste recycle stream used to determine monthly feedstock consumption or monthly waste recycle stream quantity, you must determine the best available estimate(s) of the parameter(s), based on all available process data.

§ WCI.90 CEMENT MANUFACTURING

§ WCI.91 Source Category Definition

Cement manufacturing is comprised of all processes that are used to manufacture Portland, natural, masonry, pozzolanic, or other hydraulic cements.

§ WCI.92 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2, CH_4, and N_2O in tonnes.

(b) Annual CO_2 process emissions from calcination (tonnes) and the following information:

(1) Monthly plant specific clinker emission factors (tonnes CO_2/tonnes clinker).

(A) Monthly quantities of clinker produced (tonnes).

(B) Monthly total calcium content of clinker, expressed as calcium oxide (CaO) (weight fraction, tonne CaO/tonne clinker).

(C) Monthly total magnesium content of clinker, expressed as magnesium oxide (MgO) (weight fraction, tonne MgO/tonne clinker).

(D) Monthly non-calcined calcium oxide content of clinker, expressed as CaO (weight fraction, tonne CaO/tonne clinker).

(E) Monthly non-calcined magnesium oxide content of clinker, expressed as MgO (weight fraction, tonne MgO/tonne clinker).

(F) Monthly quantity of non-carbonate raw materials entering the kiln (tonnes).

(2) Quarterly cement kiln dust (CKD) emission factor (tonne CO_2/tonne CKD not recycled back to the kiln).

(A) Quarterly quantity of CKD not recycled back to the kiln (tonnes).

(c) Annual CO_2 process emissions from organic carbon oxidation (tonnes) and the following information:

(1) Amount of raw material consumed in the report year (tonnes).

(2) Annual organic carbon content of raw material (weight fraction).

(d) Annual CO_2, CH_4, and N_2O emissions from fuel combustion in all kilns combined, following the calculation methods and reporting requirements specified in WCI.93(c) (tonnes).

(e) Annual CO_2, CH_4, and N_2O emissions from all other fuel combustion units combined (kilns excluded), following the calculation methods and reporting requirements specified in WCI.20 (tonne).

(f) If a continuous emissions monitor is used to measure CO_2 emissions from kilns, then the requirements of paragraphs (b) and (c) of this section do not apply for CO_2. Cement plants that measure CO_2 emissions using CEMS shall report fuel usage by fuel type for kilns.

(g) Operators of cement plants shall also comply with the reporting requirements for any other applicable source category listed by regulation, including but not limited to the following:

(1) Coal fuel storage as specified in WCI.100.

(2) Electricity generating as specified in WCI.40.

(3) Cogeneration systems as specified in WCI.42(f).

(h) Number of times missing data procedures were used to determine clinker production, non-calcined calcium oxide, magnesium oxide content of clinker, CKD not recycled, non-calcined calcium oxide, magnesium oxide content of CKD, organic carbon content, and raw material consumption.

§ WCI.93 Calculation of Greenhouse Gas Emissions From Kilns

(a) Determine CO_2 emissions as specified under either paragraph (a)(1) or (a)(2) of this section.

(1) Calculate the total process and combustion CO_2 emissions from all the kilns using a continuous emissions monitoring system (CEMS) as specified in WCI.23(d) and combustion CO_2 emissions from all the kilns using the calculation methodologies specified in paragraph (c) of this section.

(2) Calculate the sum of CO_2 process emissions from kilns and CO_2 fuel combustion emissions from kilns using the calculation methodologies specified in paragraph (b) and (c) of this section.

(b) Process CO_2 Emissions Calculation Methodology. Calculate total CO_2 process emissions as the sum of emissions from calcination, using the method specified in paragraph (b)(1) of this section; and from organic carbon oxidation, using the method specified in paragraph (b)(2) of this section (Equation 90-1).

$$E_{CO2\text{-}P} = E_{CO2\text{-}C} + E_{CO2\text{-}F} \qquad \textbf{Equation 90-1}$$

Where:

$E_{CO2\text{-}P}$ = Annual process CO_2 emissions (tonne/year).
$E_{CO2\text{-}C}$ = Annual process CO_2 emissions from calcination (tonne/year).
$E_{CO2\text{-}F}$ = Annual process CO_2 emissions from feed oxidation (tonne/year).

(1) Calcination Emissions. Calculate CO_2 process emissions from calcination using Equation 90-2 and a plant-specific clinker emission factor and a plant-specific cement kiln dust (CKD) emission factor as specified in this section.

$$E_{CO2-C} = \sum_{m=1}^{12}\left[Q_{cli,m} \times EF_{cli,m}\right] + \sum_{q}^{4}\left[Q_{CKD,q} \times EF_{CKD,q}\right] \qquad \textbf{Equation 90-2}$$

Where:

$E_{CO2\text{-}C}$ = Annual process CO_2 emissions from calcination (tonnes).
$Q_{Cli,m}$ = Quantity of clinker produced in month *m* (tonnes).
$EF_{Cli,m}$ = CO_2 emission factor for clinker produced in month *m*, computed as specified in paragraph (b)(1)(A) of this section (tonnes CO_2/tonne clinker).
$Q_{CKD,q}$ = Quantity CKD not recycled to the kiln in quarter *q* (tonnes).
$EF_{CKD,q}$ = CO_2 emission factor for CKD not recycled to the kiln in quarter *q*, computed as specified in paragraph (b)(1)(B) of this section (tonne CO_2/tonne CKD).

(A) Clinker Emission Factor. Calculate a plant-specific clinker emission factor (EF_{Cli}) for each month based on monthly measurements of the weight fractions of calcium (as CaO) and magnesium (as MgO) content in the clinker and in the non-carbonate raw materials entering the kiln, using Equation 90-3.

$$EF_{Cli} = (CaO_{Cli} - CaO_{f}) \times 0.785 + (MgO_{Cli} - MgO_{f}) \times 1.092$$

Equation 90-3

Where:
EF_{Cli} = Monthly CO_2 emission factor for clinker (tonne CO_2/tonne clinker).
CaO_{Cli} = Monthly total calcium content of clinker expressed as calcium oxide (tonne CaO/tonne clinker).
CaO_f = Monthly non-calcined calcium oxide content of clinker (tonne CaO/tonne clinker).
MgO_{Cli} = Monthly total magnesium content of clinker expressed as magnesium oxide (tonne MgO/tonne clinker).
MgO_f = Monthly non-calcined magnesium oxide content of clinker (tonne MgO/tonne clinker).
0.785 = Ratio of molecular weights of CO_2 to CaO.
1.092 = Ratio of molecular weights of CO_2 to MgO.

(B) CKD Emission Factor. If CKD is generated and not recycled back to the kiln, then calculate a plant-specific CKD emission factor based on quarterly sampling. The CKD emission factor shall be calculated using Equation 90-4.

$$EF_{CKD} = (CaO_{CKD} - CaO_{f}) \times 0.785 + (MgO_{ckd} - MgO_{f}) \times 1.092$$

Equation 90-4

Where:
EF_{CKD} = Quarterly CO_2 emission factor for CKD not recycled to the kiln (tonne CO_2/tonne CKD).
CaO_{CKD} = Quarterly total calcium oxide content of CKD (tonne CaO/tonne CKD).
CaO_f = Quarterly non-calcined calcium oxide content of CKD (tonne CaO/tonne CKD).
MgO_{CKD} = Quarterly total magnesium oxide content of CKD (tonne MgO/tonne CKD).
MgO_f = Quarterly non-calcined magnesium oxide content of CKD (tonne MgO/tonne CKD).
0.785 = Ratio of molecular weights of CO_2 to CaO.
1.092 = Ratio of molecular weights of CO_2 to MgO.

(2) Organic Carbon Oxidation Emissions. Calculate CO_2 process emissions from the total organic content in raw materials by using Equation 90-5.

$$E_{CO_2-F} = TOC_{RM} \times RM \times 3.664 \qquad \textbf{Equation 90-5}$$

Where:

E_{CO2-F}	=	Annual process CO_2 emissions from raw material oxidation (tonnes).
TOC_{RM}	=	Total organic carbon content in raw material (wt. fraction), measured using the method in WCI.94(g) or using a default of 0.002 (0.2%).
RM	=	Amount of raw material consumed (tonnes/year).
3.664	=	CO_2 to carbon molar ratio.

(c) Fuel Combustion Emissions in Kilns. Calculate CO_2, CH_4, and N_2O emissions from stationary fuel combustion following the calculation methods specified in WCI.20. Cement plants that combust pure biomass-derived fuels and combust fossil fuels only during periods of start-up, shut-down, or malfunction may report CO_2 emissions from fossil fuels using the emission factor methodology in WCI.23(a). “Pure” means that the biomass-derived fuels account for at least 97 percent of the total amount of carbon in the fuels burned.

§ WCI.94 Sampling, Analysis, and Measurement Requirements

(a) Determine monthly, the plant-specific weight fractions of total calcium (as CaO) and total magnesium (as MgO) in clinker using ASTM C114, an equivalent industry method, or a method approved by the Director. The monitoring must be conducted either daily from clinker drawn from the exit of the kiln or monthly from clinker drawn from bulk storage.

(b) Determine quarterly, the plant-specific weight fractions of total calcium (as CaO) and total magnesium (as MgO) in CKD using ASTM C114, an equivalent industry method, or a method approved by the Director. The monitoring must be conducted daily from CKD samples drawn from the exit of the kiln or quarterly from CKD samples drawn from bulk storage.

(c) Determine monthly, the plant-specific weight fractions of calcium oxide (CaO) and magnesium oxide (MgO) that enters the kiln as a non-carbonate species to clinker by chemical analysis of feed material using documented analytical method, the appropriate industrial standard practice, or a value of 0.0.

(d) Determine quarterly, the plant-specific weight fractions of calcium oxide (CaO) and magnesium oxide (MgO) that enters the kiln as a non-carbonate species to CKD by chemical analysis of feed material using documented analytical method, the appropriate industrial standard practice, or a value of 0.0.

(e) Determine monthly, the plant-specific weight fractions of calcium oxide (CaO) and magnesium oxide (MgO) that remains in clinker by chemical analysis of feed material using documented analytical method, the appropriate industrial standard practice, or a value of 0.0.

(f) Determine quarterly, the plant-specific weight fractions of calcium oxide (CaO) and magnesium oxide (MgO) that remains in CKD by chemical analysis of feed material using documented analytical method, the appropriate industrial standard practice, or a value of 0.0.

(g) Determine annually, the total organic carbon contents of raw materials using ASTM C114, an equivalent industry method, method approved for total organic carbon determination in raw mineral material, or use a default value of 0.002 (0.2%). The analysis must be conducted on sample material drawn from bulk raw material storage for each category of raw material.

(h) The quantity of clinker produced must be determined monthly by either:

(1) Direct weight measurement using the same plant techniques used for accounting purposes, such as reconciling weigh hoppers or belt weigh feeders measurements against inventory measurements, or

(2) Direct measurement of raw kiln feed and application of a kiln-specific feed-to-clinker factor. Facilities that opt to use a feed to clinker factor must verify the accuracy of this factor on a monthly basis.

(i) The quantity of CKD not recycled back to the kiln must be determined quarterly by either using the same plant techniques used for accounting purposes, such as direct weight measurement using weigh hoppers or belt weigh feeders, and/or material balances.

(j) The quantity of raw materials consumed (i.e. limestone, sand, shale, iron oxide, alumina, and non-carbonate raw material) must be determined monthly by direct weight measurement using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

§ WCI.95 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations. The owner or operator must document and keep records of the procedures used for all such estimates.

(a) If the CEMS approach is used to determine combined process and combustion CO_2 emissions, the missing data procedures in WCI.20 apply.

(b) For CO_2 process emissions from cement manufacturing facilities calculated according to WCI.93(b), if data on the carbonate content (of clinker or CKD), noncalcined content (of clinker or CKD) or the annual organic carbon content of raw materials are missing, facilities must undertake a new analysis.

(c) For each missing value of monthly clinker production, the substitute data value must be the best available estimate of the monthly clinker production based on information used for accounting purposes, or use the maximum tons per day capacity of the system and the number of days per month.

(d) For each missing value of monthly raw material consumption, the substitute data value must be the best available estimate of the monthly raw material consumption based on information used for accounting purposes (such as purchase records), or use the maximum tons per day raw material throughput of the kiln and the number of days per month.

§ WCI.100 COAL STORAGE

§ WCI.101 Source Category Definition

Coal storage piles are located at any facilities that combust coal. Coal storage piles release fugitive CH_4 emissions. Within natural coal deposits, CH_4 is either trapped under pressure within porous void spaces or adsorbed to the coal. Coal mining, post-mining activities, and coal-handling activities release pressurized CH_4 to the atmosphere; adsorbed CH_4 is also released until the CH_4 in the coal reaches equilibrium with the surrounding atmospheric conditions.

§ WCI.102 Greenhouse Gas Reporting Requirements

The emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in tonnes, reported as follows:

  (1) Total CH_4 emissions.

(b) Annual coal purchases (tons for U.S.; tonnes for Canada).

(c) Source of coal purchases:

  (1) Coal basin.

  (2) State/province.

  (3) Coal mine type (surface or underground).

§ WCI.103 Calculation of CH_4 Emissions

Note that this methodology for calculation of methane emissions uses emission factors for post-mining operations including all processes occurring after mining at the coal deposit and prior to combustion (e.g., preparation, handling, processing, transportation, storage, etc.) even though coal storage piles are only a subset of the overall post-mining operations. This follows the approach in the Climate Action Reserve reporting protocol, attributing all post-mining fugitive methane emissions to the facility combusting the coal, which is ultimately responsible for the coal having been processed and delivered to the facility.

Calculate fugitive CH_4 emissions from coal storage piles as specified under paragraph (a), (b), or (c) of this section.

(a) For coal purchased from U.S. sources, calculate fugitive CH_4 emissions using Equation 100-1 and Table 100-1.

(b) For coal purchased from Canadian sources, calculate fugitive CH_4 emissions using Equation 100-1 and Table 100-2.

(c) For coal purchased from non-U.S. and non-Canadian sources, owners or operators should use either WCI.103(a) or WCI.103(b), whichever is the most applicable. This chosen approach is subject to approval by the regulator.

$$CH_4 = \sum_i (PC_i \times EF_i) \times 0.6772 / 1{,}000$$ **Equation 100-1**

Where:

CH_4 = Fugitive emissions from coal storage piles for each coal category *i*, (tonnes CH_4 per year);
PC_i = Purchased coal for each coal category *i* (tonnes per year);
EF_i = Default CH_4 emission factor for each coal category *i* specified by location and mine type that coal originated from, provided in Table 100-1 or Table 100-2 (m^3 CH_4 per tonne of coal);
0.6772 = Methane conversion factor to convert m^3 to kg;
1,000 = Factor to convert kg to tonnes.

§ WCI.104 Sampling, Analysis, and Measurement Requirements

(a) Coal Purchase Monitoring Requirements.

Facilities may determine the quantity of coal purchased either using records provided by the coal supplier(s) or monitoring coal purchase quantities using the same plant instruments used for accounting purposes, such as weigh hoppers or belt weigh feeders.

§ WCI.105 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraph (a) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing feedstock and production values, the substitute data value shall be the best available estimate of the parameter, based on all available process data. You must document and retain records of the procedures used for all such estimates.

Source: *Management of Methane Emissions from Coal Mines: Environmental, Engineering, Economic and Institutional Implications of Options*. Prepared by Brian G. King, Neill and Gunter (Nova Scotia) Limited, Darmouth, Nova Scotia for Environment Canada. Contract Number K2031-3-7062. March 1994. This document is cited by Environment Canada in the NIR 1990-2007 (Final Submission, April 2009), , but post-mining emission factors are not provided, so they were developed for WCI purposes by Province. Surface emission factors were derived from Table 3.1 (Coal production statistics [Column A] and post-mining emissions [Column F]). Underground emission factors were derived from Table 3.2 (Coal production statistics and post-mining emissions).

§ WCI.110 ELECTRONICS MANUFACTURING

§ WCI.111 Source Category Definition

Electronics manufacturing facilities include, but are not limited to, facilities that manufacture semiconductors, liquid crystal displays (LCDs), micro-electro-mechanical systems (MEMS), and photovoltaic cells (PV). The electronics source category consists of any of the processes listed in paragraphs (a) through (f) of this section that are located at electronics manufacturing facilities.

(a) Processes in which the etching process uses plasma-generated fluorine atoms and other reactive fluorine-containing fragments, which chemically react with exposed thin-films (e.g., dielectric, metals) and silicon to selectively remove portions of material.

(b) Processes in which chambers used for depositing thin films are cleaned periodically using plasma-generated fluorine atoms and other reactive fluorine-containing fragments from fluorinated and other gases.

(c) Processes in which wafers are cleaned using plasma-generated fluorine atoms or other reactive fluorine-containing fragments to remove residual material from wafer surfaces.

(d) Processes in which some fluorinated compounds can be transformed in the plasma processes into different fluorinated compounds which are then exhausted, unless abated, into the atmosphere.

(e) Processes in which the chemical vapor deposition process or other manufacturing processes use N_2O.

(f) Processes in which fluorinated GHGs are used as heat transfer fluids to cool process equipment, control temperature during device testing, and solder semiconductor devices to circuit boards.

§ WCI.112 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of N_2O and fluorinated GHGs. The fluorinated GHGs that are emitted from electronics production processes include, but are not limited to, those listed in Table 110-1 of this subpart. The process that must be reported include: fluorinated GHGs from plasma etching, fluorinated GHGs from chamber cleaning, fluorinated GHGs from wafer cleaning, N_2O from chemical vapor deposition and other manufacturing processes, and fluorinated GHGs from heat transfer fluid use.

(b) CO_2, N_2O, and CH_4 emissions from stationary combustion units as specified in WCI.20.

(c) The method of emissions calculation used in WCI.113.

(d) Production in terms of substrate surface area (e.g., silicon, PV-cell, LCD).

(e) Emission factors used for process utilization and by-product formation rates and the source for each factor for each fluorinated GHG and N_2O.

(f) Where process categories for semiconductor facilities as defined in WCI.113(a)(1)(i) through (a)(1)(iii) are not used, descriptions of individual processes or process categories used to estimate emissions.

(g) For each fluorinated GHG and N_2O, annual gas consumed during the reporting year and facility-wide gas-specific heel-factors used.

(h) The apportioning factors for each process category (i.e., fractions of each gas fed into each individual process or process category used to calculate fluorinated GHG and N_2O emissions) and a description of the engineering model used for apportioning gas usage per WCI.114(b). If the method used to develop the apportioning factors permits the development of facility-wide consumption estimates that are independent of the estimates calculated in Equation 110-6 of this subpart (e.g., that are based on wafer passes for each individual process or process category), report the independent facility-wide consumption estimate for each fluorinated GHG and N_2O.

(i) Fraction of each gas fed into each process type that is fed into tools with abatement systems.

(j) Description of all abatement systems through which fluorinated GHGs or N_2O flow at the facility, including the number of devices of each manufacturer, model numbers, manufacturers guaranteed destruction or removal efficiencies, if any, and record of destruction or removal efficiency measurements over its in-use life. The inventory of abatement systems shall also include a description of the associated tools and/or processes for which these systems treat exhaust.

(k) For each abatement system through which fluorinated GHGs or N_2O flow at the facility, for which controlled emissions are reported, the following:

(1) Certification that each abatement system used at the facility is installed, maintained, and operated in accordance with manufacturers' specifications.

(2) The uptime and the calculations to determine uptime for that reporting year.

(3) The default destruction or removal efficiency value or properly measured destruction or removal efficiencies for each abatement system used in that reporting year to reflect controlled emissions.

(4) Where the default destruction or removal efficiency value is used to report controlled emissions, certification that the abatement systems for which controlled emissions are being reported are specifically designed for fluorinated GHG and N_2O abatement.

(5) Where properly measured destruction or removal efficiencies or class averages of destruction or removal efficiencies are used to report controlled emissions, the following:

(i) A description of the class including the abatement system manufacturer and model number, and the fluorinated GHG and N_2O in the process effluent stream;
(ii) The total number of systems in that class for the reporting year.
(iii) The total number of systems for which destruction or removal efficiency was measured in that class for the reporting year.

(iv) A description of the calculation used to determine the class average, including all inputs of the calculation.

(v) A description of method of randomly selecting class members for testing.

(l) For heat transfer fluid emissions, inputs to the mass-balance equation, Equation 110-8 of this subpart for each fluorinated GHG.

(m) Example calculations for fluorinated GHG, N_2O, and heat transfer fluid emissions.

§ WCI.113 Calculation of GHG Emissions

(a) For each fluorinated GHG and each process type used at the facility (i.e., plasma etching, chamber cleaning, or wafer cleaning) as appropriate, calculate annual facility-level emissions using Equations 110-1 and 110-2 of this section and according to the procedures in paragraph (a)(1), (a)(2), or (a)(3) of this section.

$$processtypeE_i = \sum_{j=1}^{N} E_{ij}$$ **Equation 110-1**

Where:

$processtypeE_i$	=	Annual emissions of input gas *i* from the processes type (tonnes);
E_{ij}	=	Annual emissions of input gas *i* from individual process *j* or process category *j* (tonnes); and
N	=	Total number of individual processes *j* or process categories *j*, which depend on the electronics manufacturing facility and emission calculation methodology.

$$processtypeBE_k = \sum_{j=1}^{N} \sum_{i} BE_{kij}$$ **Equation 110-2**

Where:

$processtypeBE_k$	=	Annual emissions of by-product gas *k* from the processes type (tonnes);
BE_{kij}	=	Annual emissions of by-product *k* formed from input gas *i* during individual process *j* or process category *j* (tonnes); and
N	=	Total number of individual processes *j* or process categories *j*, which depend on the electronics manufacturing facility and emission calculation methodology.

(1) Semiconductor facilities that fabricate devices on wafers measuring 300 mm or less in diameter shall calculate annual facility-level emissions of each fluorinated GHG used at a facility for each fluorinated GHG-using process type, either from all individual processes at that facility in accordance with WCI.114(c), or from process categories as defined in this paragraph (a)(1).

(i) All etching process categories for which annual fluorinated GHG emissions shall be calculated are defined in this paragraph (a)(1)(i).

(A) Oxide etch means any process using fluorinated GHG reagents to selectively remove SiO_2, SiO_x-based, or fully organic-based thin-film material that has been deposited on a wafer during semiconductor device manufacturing.

(B) Nitride etch means any process using fluorinated GHG reagents to selectively remove SiN, SiON, Si_3N_4, SiC, SiCO, SiCN, etc. (represented by the general chemical formula, $Si_wO_xN_yX_z$ where *w*, *x*, *y* and *z* are zero or integers and *X* can be some other element such as carbon) that has been deposited on a wafer during semiconductor manufacturing.

(C) Silicon etch also often called polysilicon etch, means any process using fluorinated GHG reagents to selectively remove silicon during semiconductor manufacturing.

(D) Metal etch means any process using fluorinated GHG reagents associated with removing metal films (such as aluminum or tungsten) that have been deposited on a wafer during semiconductor manufacturing.

(ii) All chamber cleaning process categories for which annual fluorinated GHG emissions shall be calculated are defined in this paragraph (a)(1)(ii).

(A) In situ plasma means cleaning thin-film production chambers, after processing one or more wafers, with a fluorinated GHG cleaning reagent that is dissociated into its cleaning constituents by a plasma generated inside the chamber where the film was produced.

(B) Remote plasma system means cleaning thin-film production chambers, after processing one or more wafers, with a fluorinated GHG cleaning reagent dissociated by a remotely located (e.g., upstream) plasma source.

(C) In situ thermal means cleaning thin-film production chambers, after processing one or more wafers, with a fluorinated GHG cleaning reagent that is thermally dissociated into its cleaning constituents inside the chamber where the thin-film (or thin films) was (were) produced.

(iii) All wafer cleaning process categories for which annual fluorinated GHG emissions shall be calculated are defined in this paragraph (a)(1)(iii) .

(A) Bevel cleaning means any process using fluorinated GHG reagents with plasma to clean the edges of wafers during semiconductor manufacture.

(B) Ashing means any process using fluorinated GHG reagents with plasma to remove photoresist materials during wafer manufacture.

(2) Semiconductor facilities that fabricate devices on wafers measuring greater than 300 mm in diameter shall calculate annual facility-level emissions of each fluorinated GHG used at a facility for all individual processes at that facility in accordance with WCI.114(c).

(3) All other electronics facilities shall calculate annual facility-level emissions of each fluorinated GHG used at a facility for each process type, including etching and chemical vapor deposition chamber cleaning.

(b) For each fluorinated GHG and each individual process, process category, or process type used at the facility as appropriate, calculate annual facility-level emissions using Equations 110-3 and 110-4 of this section, and according to the procedures in either paragraph (b)(1), (b)(2), or (b)(3) of this section.

$$E_{ij} = C_{ij}\left(1 - U_{ij}\right)\left(1 - a_{ij} \times d_{kj}\right) \times 0.001$$

Equation 110-3

Where:

E_{ij}	=	Annual emissions of input gas *i* from individual process, process category, or process type *j* (tonnes);
C_{ij}	=	Amount of input gas *i* consumed in individual process, process category, or process type *j*, as calculated in Equation 110-6 (kg) of this section and apportioned pursuant to WCI.114(b);
U_{ij}	=	Process utilization for input gas *i* during individual process, process category, or process type *j*;
a_{ij}	=	Fraction of input gas *i* used in individual process, process category, or process type *j* with abatement systems;
d_{ij}	=	Fraction of input gas *i* destroyed in abatement systems connected to individual process, process category, or process type *j*, accounting for uptime as specified in WCI.114(e)(2). This is zero unless the facility adheres to requirements in WCI.114(e); and
0.001	=	Conversion factor from kg to tonnes.

$$BE_{ijk} = B_{ijk} \times C_{ij} \times \left(1 - a_{ij} \times d_{kj}\right) \times 0.001$$

Equation 110-4

Where:

BE_{ijk}	=	Annual emissions of by-product *k* formed from input gas *i* during individual process, process category, or process type *j* (tonnes);
B_{ijk}	=	Amount of gas *k* created as a by-product per amount of input gas *i* (kg) consumed in individual process, process category, or process type *j* (kg);
C_{ij}	=	Amount of input gas *i* consumed in individual process, process category, or process type *j*, as calculated in Equation 110-6 (kg) of this section and apportioned pursuant to WCI.114(b);
a_{ij}	=	Fraction of input gas *i* used in individual process, process category, or process type *j* with abatement systems;
d_{kj}	=	Fraction of by-product gas k destroyed in abatement systems connected to individual process, process category, or process type j, accounting for uptime as specified in WCI.114(e)(2). This is zero unless the facility adheres to requirements in WCI.114(e); and
0.001	=	Conversion factor from kg to tonnes.

(1) Semiconductor facilities that fabricate devices on wafers measuring 300 mm or less in diameter shall use the procedures in either paragraph (b)(1)(i) or (b)(1)(ii) of this section.

(i) Except as provided in paragraph (b)(1)(ii), use default process category emission factors for process utilization and by-product formation rates shown in Tables 110-2, 110-3, and 110-4 of this subpart as appropriate.

(ii) Recipe-specific measurements may be used instead of the process category default factors provided that the methods in WCI.114(c) are followed.

(2) Semiconductor facilities that fabricate devices on wafers measuring greater than 300 mm in diameter shall use recipe-specific measurements and follow methods in WCI.114(c) to calculate emissions from each fluorinated GHG-using process type. Equations 110-1 through 110-4 shall be used to calculate fluorinated GHG emissions from all fluorinated GHG-using process recipes.

(3) All other electronics facilities shall use the default process type-specific emission factors for process utilization and by-product formation rates shown in Tables 110-5, 110-6, and 110-7 of this subpart for MEMS, LCD, and PV manufacturing, respectively.

(c) Calculate annual facility-level N_2O emissions from electronics manufacturing processes, using Equation 110-5 of this section and the methods in this paragraph (c).

(1) Use a factor for N_2O utilization for chemical vapor deposition processes pursuant to either paragraph (c)(1)(i) or (c)(1)(ii) of this section.

(i) Develop a facility-specific N_2O utilization factor averaged over all N_2O-using recipes used for chemical vapor deposition processes in accordance with WCI.114(d).

(ii) If a facility-specific N_2O utilization factor for chemical vapor deposition processes is not available, a value of 20 percent must be used as the default utilization factor for N_2O from chemical vapor deposition processes.

(2) Use a factor for N_2O utilization for other manufacturing processes pursuant to either paragraph (c)(2)(i) or (c)(2)(ii) of this section.

(i) Develop a facility-specific N_2O utilization factor averaged over all N_2O-using recipes used for manufacturing processes other than chemical vapor deposition processes in accordance with WCI.114(d).

(ii) If a facility-specific N_2O utilization factor for manufacturing processes other than chemical vapor deposition is not available, a value of 0 percent must be used as a default utilization factor for N_2O from manufacturing processes other than chemical vapor deposition.

(3) If a facility employs abatement systems and wishes to quantify and document N_2O emission reductions due to these systems, it must adhere to the requirements in WCI.114(e).

(4) Calculate annual facility-level N_2O emissions for all processes at the facility using Equation 110-5 of this section.

$$E(N_2O) = \sum_j C_{N_2O,j}\left(1 - U_{N_2O,j}\right)\left(1 - a_{N_2O,j} \times d_{N_2O,j}\right) \times 0.001$$

Equation 110-5

Where:

$E(N_2O)$	=	Annual emissions of N_2O (tonnes/year);
$C_{N2O,j}$	=	Amount of N_2O consumed for N_2O-using process *j*, as calculated in Equation 110-6 of this section and apportioned to N_2O-using process *j* (kg);
$U_{N2O,j}$	=	Process utilization for N_2O-using process *j*;
$a_{N2O,j}$	=	Fraction of N_2O used in N_2O-using process *j* with abatement systems;
$d_{N2O,j}$	=	Fraction of N_2O for N_2O-using process *j* destroyed by abatement systems connected to process *j*, accounting for uptime as specified in WCI.114(e)(2). This is zero unless the facility adheres to requirements in WCI.114(e); and
0.001	=	Conversion factor from kg to tonnes.

(d) Calculate gas consumption for each fluorinated GHG and N_2O used at the facility using facility-wide gas-specific heel factors, as determined in WCI.114(a), and using Equation 110-6 of this section.

$$C_i = \left(I_{Bi} - I_{Ei} + A_i - D_i\right) \times 0.001$$

Equation 110-6

Where:

C_i	=	Annual consumption of input gas *i* (tonnes /year);
I_{Bi}	=	Inventory of input gas *i* stored in cylinders or other containers at the beginning of the year, including heels (kg);
I_{Ej}	=	Inventory of input gas *i* stored in cylinders or other containers at the end of the year, including heels (kg);
A_i	=	Acquisitions of gas *i* during the year through purchases or other transactions, including heels in cylinders or other containers returned to the electronics manufacturing facility (kg);
D_i	=	Disbursements under exceptional circumstances of gas *i* through sales or other transactions during the year, including heels in cylinders or other containers returned by the electronics manufacturing facility to the chemical supplier, calculated using Equation 110-7 of this section (kg); and
0.001	=	Conversion factor from kg to tonnes.

(e) Calculate disbursements of gas *i* using Equation 110-7 of this section.

$$D_i = h_i \times N_i \times F_i + X_i$$

Equation 110-7

Where:

D_i = Disbursements of gas *i* through sales or other transactions during the year, including heels in cylinders or other containers returned by the electronics manufacturing facility to the gas distributor (kg);
h_i = Facility-wide gas-specific heel factor for input gas *i* (%), as determined in WCI.114 of this subpart;
N_i = Number of cylinders or other containers returned to the gas distributor containing the standard heel of gas *i*;
F_i = Full capacity of cylinders or other containers containing gas *i* (kg); and
X_i = Disbursements under exceptional circumstances of gas *i* through sales or other transactions during the year. These include returns of containers whose contents have been weighed due to an exceptional circumstance as specified in WCI.114(a)(5) of this subpart (kg).

(f) For facilities that use fluorinated heat transfer fluids, you shall report the annual emissions of fluorinated GHG heat transfer fluids using the mass balance approach described in Equation 110-8 of this section.

$$E_i = \rho_i\left(I_{ib} + P_i - N_i + R_i - I_{ie} - D_i\right) \times 0.001 \qquad \textbf{Equation 110-8}$$

Where:

E_i = Emissions of fluorinated GHG heat transfer fluid *i*, (tonnes/year);
ρ_i = Density of fluorinated heat transfer fluid *i* (kg/litre);
I_{ib} = Inventory of fluorinated heat transfer fluid *i* (in containers, not equipment) at the beginning of the reporting year (litres). The inventory at the beginning of the reporting year must be the same as the inventory at the end of the previous reporting year;
P_i = Acquisitions of fluorinated heat transfer fluid *i* during the current reporting year (litres). Includes amounts purchased from chemical suppliers, amounts purchased from equipment suppliers with or inside of equipment, and amounts returned to the facility after off-site recycling;
N_i = Total nameplate capacity (full and proper charge) of equipment that uses fluorinated heat transfer fluid *i* and that is newly installed during the reporting year (litres);
R_i = Total nameplate capacity (full and proper charge) of equipment that uses fluorinated heat transfer fluid *i* and that is removed from service during the current reporting year (litres);
I_{ie} = Inventory of fluorinated heat transfer fluid *i* (in containers, not equipment) at the end of current reporting year (litres);
D_i = Disbursements of fluorinated heat transfer fluid *i* during the current reporting year (litres). Includes amounts returned to chemical suppliers, sold with or inside of equipment, and sent off site for verifiable recycling or destruction. Disbursements should include only amounts that are properly stored and transported so as to prevent emissions in transit; and
0.001 = Conversion factor from kg to tonnes.

§ WCI.114 Sampling, Analysis, and Measurement Requirements

(a) For purposes of Equation 110-6 of this section, you must estimate facility-wide gas-specific heel factors for each cylinder/container type for each gas used according to the procedures in paragraphs (a)(1) through (a)(6) of this section.

(1) Base the facility-wide gas-specific heel factors on the residual weight or pressure of a gas cylinder/container that the facility uses to change out that cylinder/container for each cylinder/container type for each gas used.

(2) The residual weight or pressure used for WCI.114(a)(1) shall be determined by monitoring the mass or the pressure of your cylinders/containers. If monitoring the pressure, convert the pressure to mass using the ideal gas law, as displayed in Equation 110-9 of this section, with an appropriately selected *Z* value.

$$pV = ZnRT \qquad \textbf{Equation 110-9}$$

Where:

p	=	Absolute pressure of the gas (Pa);
V	=	Volume of the gas (m^3);
Z	=	Compressibility factor;
n	=	Amount of substance of the gas (moles);
R	=	Gas constant (8.314 Joule/Kelvin mole); and
T	=	Absolute temperature (K).

(3) Use the facility-wide gas-specific cylinder/container residual mass, determined from WCI.114(a)(1) and (a)(2), to calculate the unused gas for each container, which when expressed as fraction of the initial mass in the cylinder/container is the heel factor.

(4) The initial mass used to calculate the facility-wide gas-specific heel factor may be based on the weight of the gas provided in the gas supplier documents; however, the facilities remain responsible for the accuracy of these masses and weights under this subpart.

(5) In the exceptional circumstance that a cylinder/container is changed at a residual mass or pressure that differs by more than 20 percent from the facility-wide gas-specific determined values, that cylinder shall be weighed, or the pressure of that cylinder shall be measured with a pressure gauge, in place of using a heel factor.

(6) Recalculate facility-wide gas-specific heel factors applied at the facility in the event that the residual weight or pressure of the gas cylinder/container that the facility uses to change out that cylinder/container differs by more than 1 percentage point from that used to calculate the previous gas-specific heel factor.

(b) Semiconductor facilities shall apportion fluorinated GHG consumption by process category, as defined in WCI.113(a)(1)(i) through (a)(1)(iii), or by individual process using a facility-specific engineering model based on wafer passes.

(c) If factors for fluorinated GHG process utilization and by-product formation rates are used other than the defaults provided in Tables 110-2 through 110-4 of this subpart, the factors must have been measured using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006). Factors for fluorinated GHG process utilization and by-product formation rates measured by manufacturing equipment suppliers may be used if the conditions in paragraphs (c)(1) and (c)(2) of this section are met.

(1) The manufacturing equipment supplier has measured the GHG emission factors for process utilization and by-product formation rates using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006).

(2) The conditions under which the measurements were made are representative of the facility's fluorinated GHG emitting processes.

(d) If N_2O utilization factors other than those defaults provided in WCI.113(c)(1)(ii) or (c)(2)(ii) are used, factors that have been measured using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006) must be used. Utilization factors measured by manufacturing equipment suppliers may be used if the conditions in paragraphs (d)(1) and (d)(2) of this section are met.

(1) The manufacturing equipment supplier has measured the N_2O utilization factors using the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006).

(2) The conditions under which the measurements were made are representative of the facility's N_2O emitting processes.

(e) If the facility employs abatement systems and wishes to reflect emission reductions due to these systems in appropriate calculations in WCI.113, the facility must adhere to the procedures in paragraphs (e)(1) and (e)(2) of this section. If the facility uses the default destruction or removal efficiency of 60 percent, the facility must adhere to procedures in paragraph (e)(3) of this section. If the facility uses either a properly measured destruction or removal efficiency, or a class average of properly measured destruction or removal efficiencies during a reporting year, the facility must adhere to procedures in paragraph (e)(4) of this section.

(1) The facility must certify and document that the systems are properly installed, operated, and maintained according to manufacturers' specifications by adhering to the procedures in paragraphs (e)(1)(i) and (e)(1)(ii) of this section.

(i) Proper installation must be verified by certifying the systems are installed in accordance with the manufacturers' specifications.
(ii) Proper operation and maintenance must be verified by certifying the systems are operated and maintained in accordance with the manufacturers' specifications.

(2) The facility must take into account and report the uptime of abatement systems when using destruction or removal efficiencies to reflect emission reductions. Abatement system uptime is expressed as the sum of an abatement system's operational productive, standby, and engineering times divided by the total operations time of its associated

manufacturing tool(s) as referenced in SEMI Standard E-10-0340 "Specification for Definition and Measurement of Equipment Reliability, Availability, and Maintainability" (2004).

(3) To report controlled emissions using the default destruction or removal efficiency, the facility must certify and document that the abatement systems at the facility for which it is reporting controlled emissions are specifically designed for fluorinated GHG and N_2O abatement and you shall use a default destruction or removal efficiency of 60 percent for those abatement systems.

(4) If the facility does not use the default destruction or removal efficiency value to report controlled emissions, the facility must use either a properly measured destruction or removal efficiency, or a class average of properly measured destruction or removal efficiencies during a reporting year, determined in accordance with procedures in paragraphs (e)(4)(i) through (e)(4)(v) of this section.

(i) Destruction or removal efficiencies must be properly measured in accordance with EPA's "Protocol for Measuring Destruction or Removal Efficiency of Fluorinated Greenhouse Gas Abatement Equipment in Electronics Manufacturing" (March 2010).

(ii) A facility must annually select and properly measure the destruction or removal efficiency for a random sample of abatement systems to include in a Random Sampling Abatement System Testing Program (RSASTP) in accordance with procedures in paragraphs (e)(4)(ii)(A) and (e)(4)(ii)(B) of this section.

(A) Each reporting year a random sample of three or 20 percent of installed abatement systems, whichever is greater, for each abatement system class shall be tested. In instances where 20 percent of the total number of abatement systems in each class does not equate to a whole number, the number of systems to be tested shall be determined by rounding up to the nearest integer.

(B) The facility must select the random sample each reporting year for the RSASTP without repetition of systems in the sample, until all systems in each class are properly measured in a 5-year period.

(iii) If a facility has measured the destruction or removal efficiency of a particular abatement system during the previous two-year period, the facility shall calculate emissions from that system using the destruction or removal efficiency most recently measured for that particular system.

(iv) If an individual abatement system has not yet undergone proper destruction or removal efficiency testing during the previous two-year period, the facility may apply a simple average of the properly measured destruction or removal efficiencies for all systems of that class, in accordance with the RSASTP. The facility shall maintain or exceed the RSASTP schedule and regime if it wishes to apply class average destruction or removal efficiency factors to abatement systems that have not been properly measured as per the RSASTP.

(v) In instances where redundant abatement systems are used, the facility may account for the total abatement system uptime calculated for a specific exhaust stream during the reporting year.

(f) Facilities must adhere to the QA/QC procedures of this paragraph when estimating fluorinated GHG and N_2O emissions from all electronics manufacturing processes:

(1) Facilities must follow the QA/QC procedures in the "International SEMATECH Manufacturing Initiative's Guideline for Environmental Characterization of Semiconductor Process Equipment" (December 2006) when estimating facility-specific, recipe-specific fluorinated GHG and N_2O utilization and by-product formation rates.

(2) Facilities must follow the QA/QC procedures in EPA's "Protocol for Measuring Destruction or Removal Efficiency of Fluorinated Greenhouse Gas Abatement Equipment in Electronics Manufacturing" (March 2010) when estimating abatement systems destruction or removal efficiency.

(3) Facilities must certify that gas consumption is tracked to a high degree of precision as part of normal facility operations ensuring that the inventory at the beginning of the reporting is the same as the inventory at the end of the previous year.

(g) Facilities must adhere to the QA/QC procedures of this paragraph when estimating fluorinated GHG emissions from heat transfer fluid use and annual gas consumption for each fluorinated GHG and N_2O used at the facility:

(1) Facilities must review all inputs to Equations 110-6 and 110-8 of this section to ensure that all inputs and outputs to the facility's system are accounted for.

(2) Facilities must not enter negative inputs into the mass balance Equations 110-6 and 110-8 of this section and shall ensure that no negative emissions are calculated.

(3) Facilities must ensure that the beginning of year inventory matches the end of year inventory from the previous year.

(h) All instruments (e.g., mass spectrometers and fourier transform infrared measuring systems) used to determine the concentration of fluorinated GHG and N_2O in process streams shall be calibrated just prior to destruction or removal efficiency, gas utilization, or by-product formation measurement through analysis of certified standards with known concentrations of the same chemicals in the same ranges (fractions by mass) as the process samples. Calibration gases prepared from a high-concentration certified standard using a gas dilution system that meets the requirements specified in Method 205, 40 CFR part 51, Appendix M may also be used.

(i) All flowmeters, weigh scales, pressure gauges, and thermometers used to measure quantities that are monitored under this section or used in calculations under §WCI.113 shall have an accuracy and precision of one percent of full scale or better.

§ WCI.115 Missing Data Procedures

(a) Except as provided in paragraph WCI.115(b), a complete record of all measured parameters used in the fluorinated GHG and N_2O emissions calculations in WCI.113 andWCI.114 is required.

(b) If a facility uses heat transfer fluids and is missing data for one or more of the parameters in Equation 110-8 of this subpart, the facility must estimate heat transfer fluid emissions using the arithmetic average of the emission rates for the year immediately preceding the period of missing data and the months immediately following the period of missing data. Alternatively, you may estimate missing information using records from the heat transfer fluid supplier. The facility must document the method used and values estimated for all missing data values.

Table 110-1. Examples of Fluorinated GHGs Used by the Electronics Industry

Product Type	Fluorinated GHGs used during manufacturing
Electronics	CF_4, C_2F_6, C_3F_8, c-C_4F_8, c-C_4F_8O, C_4F_6, C_5F_8, CHF_3, CH_2F_2, NF_3, SF6,and HTFs [CF_3-(O-CF(CF_3)-CF_2)$_n$-(O-CF_2)$_m$-O-CF_3, C_nF_{2n+2}, $C_nF_{2n+1}(O)C_mF_{2m+1}$, $C_nF_{2n}O$, $(C_nF2_{n+1})_3N$].

§ WCI.120 HCFC-22 PRODUCTION AND HFC-23 DESTRUCTION

§ WCI.121 Source Category Definition

The HCFC-22 production and HFC-23 destruction source category consists of HCFC-22 production processes and HFC-23 destruction processes. An HCFC-22 production process produces HCFC-22 ($CHClF_2$ or chlorodifluoromethane) from chloroform ($CHCl_3$) and hydrogen fluoride (HF). An HFC-23 destruction process is any process in which HFC-23 (CHF_3 or trifluoromethane) undergoes destruction. An HFC-23 destruction process may or may not be co-located at the same facility with an HCFC-22 production process.

§ WCI.122 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) HFC-23 emissions from HCFC-22 production processes and HFC-23 destruction processes (tonnes).

(b) HCFC-22 production facilities shall report the following information at the facility level:

(1) Annual mass of HCFC-22 produced (tonnes).

(2) Loss Factor used to account for the loss of HCFC-22 upstream of the measurement.

(3) Annual mass of reactants fed into the process (tonnes).

(4) Mass of materials other than HCFC-22 and HFC-23 (i.e., unreacted reactants, HCl and other by-products) that occur in more than trace concentrations and that are permanently removed from the process (tonnes).

(5) Method for tracking startups, shutdowns, and malfunctions and HFC-23 generation/emissions during these events.

(6) Names and addresses of facilities to which any HFC-23 was sent for destruction, and the quantities of HFC-23 (tonnes) sent to each.

(7) Annual mass of the HFC-23 generated (tonnes).

(8) Annual mass of any HFC-23 sent off site for sale (tonnes).

(9) Annual mass of any HFC-23 sent off site for destruction (tonnes).

(10) Mass of HFC-23 in storage at the beginning and end of the year (tonnes).

(11) Annual mass of HFC-23 emitted (tonnes).

(12) Annual mass of HFC-23 emitted from equipment leaks (tonnes).

(13) Annual mass of HFC-23 emitted from process vents (tonnes).

(c) Each HFC-23 destruction facility shall report the concentration (mass fraction) of HFC-23 measured at the outlet of the destruction device during the facility's annual HFC-23 concentration measurements at the outlet of the device..

(d) By the date of the first report or within 60 days of commencing HFC-23 destruction, HFC-23 destruction facilities shall submit a one-time report including the following information for each destruction process:

(1) Destruction efficiency (DE).

(2) Methods used to determine destruction efficiency.

(3) Methods used to record the mass of HFC-23 destroyed.

(4) Name of other relevant federal or provincial regulations that may apply to the destruction process.

(5) If any changes are made that affect HFC-23 destruction efficiency or the methods used to record volume destroyed, then these changes must be reflected in a revision to this report. The revised report must be submitted to regulators within 60 days of the change.

§ WCI.123 Calculation of GHG Emissions

(a) The mass of HFC-23 generated from each HCFC-22 production process shall be estimated using either paragraph (1) or (2) of this section.

(1) Where the mass flow of the combined stream of HFC-23 and another reaction product (e.g., HCl, etc.) is measured, multiply the weekly (or more frequent) HFC-23 concentration measurement (which may be the average of more frequent concentration measurements) by the weekly (or more frequent) mass flow of the combined stream of HFC-23 and the other product. To estimate annual HFC-23 production, sum the weekly (or more frequent) estimates of the quantities of HFC-23 produced over the year. This calculation is shown in Equation 120-1.

$$G_{23} = \sum_{p=1}^{n} c_{23} \times F_p \times 10^{-3}$$

Equation 120-1

Where:

G_{23}	=	Mass of HFC-23 generated annually (tonnes).
c_{23}	=	Fraction HFC-23 by weight in HFC-23/other product stream.
F_p	=	Mass flow of HFC-23/other product stream during the period *p* (kg).
p	=	Period over which mass flows and concentrations are measured.
n	=	Number of concentration and flow measurement periods for the year.
10^{-3}	=	Conversion factor from kilograms to tonnes.

(2) Where the mass of only a reaction product other than HFC-23 (either HCFC-22 or HCl) is measured, multiply the ratio of the weekly (or more frequent) measurement of the HFC-23 concentration and the weekly (or more frequent) measurement of the other product concentration by the weekly (or more frequent) mass produced of the other product. To estimate annual HFC-23 production, sum the weekly (or more frequent) estimates of the quantities of HFC-23 produced over the year. If the other product is HCFC-22, then used Equation 120-2. If the other product is HCl, then use Equations 120-2 and 120-3 substituting HCl for HCFC-22.

$$G_{23} = \sum_{p=1}^{n} \left(\frac{c_{23}}{c_{22}} \right) \times P_{22} \times 10^{-3}$$

Equation 120-2

Where:

G_{23}	=	Mass of HFC-23 generated annually (tonnes).
c_{23}	=	Fraction HFC-23 by weight in HCFC-22/HFC-23 stream.
c_{22}	=	Fraction HCFC-22 by weight in HCFC-22/HFC-23 stream.
P_{22}	=	Mass of HCFC-22 produced over the period *p* (kg) (calculated using Equation 120-3).
p	=	Period over which mass flows and concentrations are measured.
n	=	Number of concentration and flow measurement periods for the year.
10^{-3}	=	Conversion factor from kilograms to tonnes.

(b) The mass of HCFC-22 produced over the period *p* shall be estimated using Equation 120-3.

$$P_{22} = LF \times (O_{22} - U_{22})$$

Equation 120-3

Where:

P_{22}	=	Mass of HCFC-22 produced over the period *p* (kg).
O_{22}	=	Mass of HCFC-22 that is measured coming out of the production process over the period *p* (kg).
U_{22}	=	Mass of used HCFC-22 that is added to the production process upstream of the output measurement over the period *p* (kg).
LF	=	Factor to account for the loss of HCFC-22 upstream of the measurement. The loss factor shall either have the value of 1.015 or another value that can be demonstrated to account for losses of HCFC-22 between the reactor and the point of measurement at the facility where production is being estimated.

(c) For HCFC-22 production facilities that do not use a thermal oxidizer or that have a thermal oxidizer that is not directly connected to the HCFC-22 production equipment, HFC-23 emissions shall be estimated using Equation 120-4.

$$E_{23} = G_{23} - \left(S_{23} + OD_{23} + D_{23} + I_{23}\right)$$

Equation 120-4

Where:

E_{23}	=	Mass of HFC-23 emitted annually (tonnes).
G_{23}	=	Mass of HFC-23 generated annually (tonnes).
S_{23}	=	Mass of HFC-23 sent off site for sale annually (tonnes).
OD_{23}	=	Mass of HFC-23 sent off site for destruction (tonnes).
D_{23}	=	Mass of HFC-23 destroyed on site (tonnes).
I_{23}	=	Increase in HFC-23 inventory (HFC-23 in storage at end of year – HFC-23 in storage at beginning of year (tonnes).

(d) For HCFC-22 production facilities that use a thermal oxidizer connected to the HCFC-22 production equipment, HFC-23 emissions shall be estimated using Equation 120-5.

$$E_{23} = E_L + E_{PV} + E_D$$

Equation 120-5

Where:

E_{23}	=	Mass of HFC-23 emitted annually (tonnes).
E_L	=	Mass of HFC-23 emitted annually from equipment leaks (tonnes) (calculated using Equation 120-6).
E_{PV}	=	Mass of HFC-23 emitted annually from process vents (tonnes) (calculated using Equation 120-7).
E_D	=	Mass of HFC-23 emitted annually from thermal oxidizer (tonnes) (calculated using Equation 120-8).

(1) The mass of HFC-23 emitted annually from equipment leaks (for use in Equation 120-5) shall be estimated by using Equation 120-6.

$$E_L = \sum_{p=1}^{n} \sum_{t} c_{23} \times \left(F_{Gt} \times N_{Gt} + F_{Lt} \times N_{Lt}\right) \times 10^{-3}$$

Equation 120-6

Where:

E_L	=	Mass of HFC-23 emitted annually from equipment leaks (tonnes).
c_{23}	=	Fraction HFC-23 by weight in the streams in the equipment.
F_{Gt}	=	Applicable leak rate specified in Table 120-1 for each source of equipment type and service *t* with a screening value greater than or equal to 10,000 ppmv (kg/hr/source).
N_{Gt}	=	Number of sources of equipment type and service *t* with screening values greater than or equal to 10,000 ppmv (kg/hr/source).
F_{Lt}	=	Applicable leak rate specified in Table 120-1 for each source of equipment type and service *t* with a screening value less than 10,000 ppmv (kg/hr/source).
N_{Lt}	=	Number of sources of equipment type and service *t* with screening values less than 10,000 ppmv (kg/hr/source).
p	=	One hour.
n	=	Number of hours during the year during which equipment contained HFC-23.
t	=	Equipment type and service as specified in Table 120-1.
10^{-3}	=	Conversion factor from kilograms to tonnes.

(2) The mass of HFC-23 emitted annually from process vents (for use in Equation 120-5) shall be estimated by using Equation 120-7.

$$E_{PV} = \sum_{p=1}^{n} ER_T \times \left(\frac{PR_p}{PR_T}\right) \times l_p \times 10^{-3}$$

Equation 120-7

Where:

E_{PV}	=	Mass of HFC-23 emitted annually from process vents (tonnes).
ER_T	=	HFC-23 emission rate from the process vents during the period of the most recent test (kg/hr).
PR_p	=	HCFC-22 production rate during the period *p* (kg/hr).
PR_T	=	HCFC-22 production rate during the most recent test period (kg/hr).
l_p	=	Length of period *p* (hours).
10^{-3}	=	Conversion factor from kilograms to tonnes.

(3) The mass of HFC-23 emitted from destruction devices (for use in Equation 120-5) shall be estimated by using Equation 120-8.

$$E_D = F_D - D_{23}$$

Equation 120-8

Where:

E_D = Mass of HFC-23 emitted annually from destruction device (tonnes).
F_D = Mass of HFC-23 annual fed into the destruction device (tonnes).
D_{23} = Mass of HFC-23 destroyed annually (tonnes).

(4) For facilities that destroy HFC-23, the total mass of HFC-23 destroyed (for use in Equations 120-4 and 120-8) shall be estimated by using Equation 120-9.

$$D_{23} = F_D \times DE$$

Equation 120-9

Where:

D_{23} = Mass of HFC-23 destroyed annually (tonnes).
F_D = Mass of HFC-23 annual fed into the destruction device (tonnes).
DE = Destruction efficiency of the destruction device (fraction).

§ WCI.124 Sampling, Analysis, and Measurement Requirements

The measurements that are reported for this category or used to estimate quantities used in the WCI.123 calculation methodologies shall be determined as specified in paragraphs (a) through (q).

(a) The concentrations (fractions by weight) of HFC23 (c_{23} in Equations 120-1 and 120-2) and HCFC-22 (c_{22} in Equation 120-2) in the product stream shall be measured at least weekly using equipment and methods (e.g., gas chromatography) with an accuracy and precision of 5 percent or better at the concentrations of the process samples.

(b) The mass flow of the product stream containing the HFC-23 (F_p in Equation 120-1) shall be measured at least weekly using weigh scales, flowmeters, or a combination of volumetric and density measurements with an accuracy and precision of 1.0 percent of full scale or better.

(c) The mass of HCFC-22 (O_{22} in Equation 120-3) or HCl (substituted value for O_{22} in Equation 120-3) coming out of the production process shall be measured at least weekly using weigh scales, flowmeters, or a combination of volumetric and density measurements with an accuracy and precision of 1.0 percent of full scale or better.

(d) The mass of any used HCFC-22 added back into the production process upstream of the output measurement in paragraph (c) of this section (U_{22} in Equation 120-3) shall be measured (when being added) using flowmeters, weigh scales, or a combination of volumetric and density measurements with an accuracy and precision of 1.0 percent of full scale or better. If the mass in paragraph (c) of this section is measured by weighing containers that include returned heels as well as newly produced fluorinated GHGs, the returned heels shall be considered used fluorinated HCFC-22 for purposes of this paragraph (d) of this section and WCI.123(b).

(e) The loss factor LF of this subpart for the mass of HCFC-22 produced (*LF* in Equation 120-3) shall have the value 1.015 or another value that can be demonstrated, to the satisfaction of the jurisdiction, to account for losses of HCFC-22 between the reactor and the point of measurement at the facility where production is being estimated.

(f) The mass of HFC-23 sent off site for sale (S_{23} in Equation 120-4) shall be measured at least weekly (when being packaged) using flowmeters, weigh scales, or a combination of volumetric and density measurements with an accuracy and precision of 1.0 percent of full scale or better.

(g) The mass of HFC-23 sent off site for destruction (OD_{23} in Equation 120-4) shall be measured at least weekly (when being packaged) using flowmeters, weigh scales, or a combination of volumetric and density measurements with an accuracy and precision of 1.0 percent of full scale or better. If the measured mass includes more than trace concentrations of materials other than HFC-23, the concentration of the fluorinated GHG shall be measured at least weekly using equipment and methods (e.g., gas chromatography) with an accuracy and precision of 5 percent or better at the concentrations of the process samples. This concentration (mass fraction) shall be multiplied by the mass measurement to obtain the mass of the HFC-23 sent to another facility for destruction.

(h) The masses of HFC-23 in storage at the beginning and end of the year (I_{23} in Equation 120-4) shall be measured using flowmeters, weigh scales, or a combination of volumetric and density measurements with an accuracy and precision of 1.0 percent of full scale or better.

(i) The number of sources of equipment type t with screening values greater than or equal to 10,000 ppmv (N_{Gt} in Equation 120-6) shall be determined using EPA Method 21 at 40 CFR part 60, appendix A-7, and defining a leak as follows:

(1) A leak source that could emit HFC-23, and

(2) A leak source at whose surface a concentration of fluorocarbons equal to or greater than 10,000 ppm is measured.

(j) The number of sources of equipment type t with screening values less than 10,000 ppmv (N_{Lt} in Equation 120-6) shall be the difference between the number of leak sources of equipment type t that could emit HFC-23 and the number of sources of equipment type t with screening values greater than or equal to 10,000 ppmv as determined under paragraph (i) of this section.

(k) The mass of HFC-23 emitted from process vents (E_{PV} in Equation 120-5) shall be estimated at least monthly by incorporating the results of the most recent emissions test into Equation 120-7 of this subpart. HCFC-22 production facilities that use a destruction device connected to the HCFC-22 production equipment shall conduct emissions tests at process vents at least once every five years or after significant changes to the process. Emissions tests shall be conducted in accordance with EPA Method 18 at 40 CFR part 60, appendixA-6, under conditions that are typical for the production process at the facility. The sensitivity of the tests shall be sufficient to detect an emission rate that would result in annual emissions of 200 kg of HFC-23 if sustained over one year.

(l) For purposes of Equation 120-9 of this subpart, the destruction efficiency must be equated to the destruction efficiency (*DE*) determined during a new or previous performance test of the destruction device. HFC-23 destruction facilities shall conduct annual measurements of HFC-23 concentrations at the outlet of the destruction device in accordance with EPA Method 18 at 40 CFR part 60, appendix A-6. Three samples shall be taken under conditions that are typical for the production process and destruction device at the facility, and the average concentration of HFC-23 shall be determined. The sensitivity of the concentration measurement shall be sufficient to detect an outlet concentration equal to or less than the outlet concentration determined in the destruction efficiency performance test. If the concentration measurement indicates that the HFC-23 concentration is less than or equal to that measured during the performance test that is the basis for the destruction efficiency, continue to use the previously determined destruction efficiency. If the concentration measurement indicates that the HFC-23 concentration is greater than that measured during the performance test that is the basis for the destruction efficiency, facilities shall either:

(1) Substitute the higher HFC-23 concentration for that measured during the destruction efficiency performance test and calculate a new destruction efficiency, or

(2) Estimate the mass emissions of HFC-23 from the destruction device based on the measured HFC-23 concentration and volumetric flow rate determined by measurement of volumetric flow rate using EPA Method 2, 2A, 2C,2D, or 2F at 40 CFR part 60, appendix A-1, or Method 26 at 40 CFR part 60, appendix A-2. Determine the mass rate of HFC-23 into the destruction device by measuring the HFC23 concentration and volumetric flow rate at the inlet or by a metering device for HFC-23 sent to the device. Determine a new destruction efficiency based on the mass flow rate of HFC-23 into and out of the destruction device.

(m) HCFC-22 production facilities shall account for HFC-23 generation and emissions that occur as a result of startups, shutdowns, and malfunctions, either recording HFC-23 generation and emissions during these events, or documenting that these events do not result in significant HFC-23 generation and/or emissions.

(n) The mass of HFC-23 fed into the destruction device (F_D in Equations 120-8 and 120-9) shall be measured at least weekly using flowmeters, weigh scales, or a combination of volumetric and density measurements with an accuracy and precision of 1.0 percent of full scale or better. If the measured mass includes more than trace concentrations of materials other than HFC23, the concentrations of the HFC-23 shall be measured at least weekly using equipment and methods (e.g., gas chromatography) with an accuracy and precision of 5 percent or better at the concentrations of the process samples. This concentration (mass fraction) shall be multiplied by the mass measurement to obtain the mass of the HFC-23 destroyed.

(o) In their estimates of the mass of HFC-23 destroyed, HFC-23 destruction facilities shall account for any temporary reductions in the destruction efficiency that result from any startups, shutdowns, or malfunctions of the destruction device, including departures from the operating conditions defined in state or local permitting requirements and/or destruction device manufacturer specifications.

(p) Calibrate all flow meters, weigh scales, and combinations of volumetric and density measures using NIST-traceable standards and suitable methods published by a consensus standards organization (e.g., ASTM, ASME, ISO, or others). Recalibrate all flow meters, weigh scales, and combinations of volumetric and density measures at the minimum frequency specified by the manufacturer.

(q) All gas chromatographs used to determine the concentration of HFC-23 in process streams (c_{23} in Equations 120-1 and 120-2) shall be calibrated at least monthly through analysis of certified standards (or of calibration gases prepared from a high-concentration certified standard using a gas dilution system that meets the requirements specified in Method 205 at 40 CFR part 51, appendix M) with known HFC-23 concentrations that are in the same range (fractions by mass) as the process samples.

§ WCI.125 Missing Data Procedures

(a) A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required process sample is not taken), a substitute data value for the missing parameter shall be used in the calculations, according to the following requirements:

(1) For each missing value of the HFC-23 or HCFC-22 concentration, the substitute data value shall be the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(2) For each missing value of the product stream mass flow or product mass, the substitute value of that parameter shall be a secondary product measurement where such a measurement is available. If that measurement is taken significantly downstream of the usual mass flow or mass measurement (e.g., at the shipping dock rather than near the reactor), the measurement shall be multiplied by 1.015 to compensate for losses. Where a secondary mass measurement is not available, the substitute value of the parameter shall be an estimate based on a related parameter. For example, if a flowmeter measuring the mass fed into a destruction device is rendered inoperable, then the mass fed into the destruction device may be estimated using the production rate and the previously observed relationship between the production rate and the mass flow rate into the destruction device.

Table 120-1 – Emission Factors for Equipment Leaks

Equipment Type	Service	Emission Factor (kg/hr/source)	
		≥10,000 ppmv	<10,000 ppmv
Valves	Gas	0.0782	0.000131
Valves	Light liquid	0.0892	0.000165
Pump seals	Light liquid	0.243	0.00187
Compressor seals	Gas	1.608	0.0894
Pressure relief valves	Gas	1.691	0.0447
Connectors	All	0.113	0.0000810
Open-ended lines	All	0.01195	0.00150

§ WCI.130 HYDROGEN PRODUCTION

§ WCI.131 Source Category Definition

A hydrogen production process produces hydrogen gas by steam hydrocarbon reforming, partial oxidation of hydrocarbons, or other transformation of hydrocarbon feedstock. The hydrogen produced may be either transferred offsite or used onsite at petrochemical, ammonia production, refineries, and other plants.

§ WCI.132 Greenhouse Gas Reporting Requirements

For each facility, the annual emissions report must contain the following information:

(a) Process CO_2 Emissions. The CO_2 process emissions from the hydrogen production process.

(b) Feedstock Consumption (if estimating emissions using mass balance approach in WCI.133(b)). Annual feedstock consumption by feedstock type (including petroleum coke) reported in units of million standard metres for gases, litres for liquids, tonnes for non-biomass solids, and bone dry tonnes for biomass-derived solid fuels.

(c) Production. Annual hydrogen produced (tonnes).

(d) Stationary Combustion Units. Report CO_2, N_2O, and CH_4 emissions as specified in WCI.20.

§ WCI.133 Calculation of Greenhouse Gas Emissions

The owner or operator shall calculate and report CO_2 process emissions using the methods in paragraphs (a) or (b) of this section.

(a) Continuous Emission Monitoring Systems. The owner or operator may calculate CO_2 process emissions using CEMS. The owner or operator must comply with the requirements in section WCI.23.

(b) Feedstock Material Balance. The owner or operator may calculate CO_2 process emissions using the following method.

(1) <u>Gaseous fuel and feedstock.</u> You must calculate the annual CO_2 process emissions from gaseous fuel and feedstock according to Equation 130-1 of this section:

$$CO_2 = \left(\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n * \frac{MW}{MVC}\right) * 0.001 \qquad \textbf{Equation 130-1}$$

Where:

CO_2 = Annual CO_2 process emissions arising from fuel and feedstock consumption (tonnes/yr).

$Fdstk_n$	=	Volume of the gaseous fuel and feedstock used in month *n* (m^3 at standard conditions of 20°C and 1 atmosphere) of fuel and feedstock).
CC_n	=	Weighted average carbon content of the gaseous fuel and feedstock, from the results of one or more analyses for month *n* (Rm^3 at reference temperature and pressure conditions as used by the facility). If a mass flow meter is used, measure the feedstock used in month *n* in kg and replace the term "MW/MVC" with "1".
MW	=	Molecular weight of the gaseous fuel and feedstock (kg/kg-mole).
MVC	=	Molar volume conversion factor at the same reference conditions as the above $Fdstk_n$ (Rm^3/kg-mole). MVC can be 8.3145 * [273.16 + reference temperature in °C] / [reference pressure in kilopascal].
k	=	Months in the year.
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to tonnes.

(2) Liquid fuel and feedstock. You must calculate the annual CO_2 process emissions from liquid fuel and feedstock according to Equation 130-2 of this section:

$$CO_2 = \left(\sum_{n=1}^{k} \frac{44}{12} * Fdstk_n * CC_n\right) * 0.001 \qquad \textbf{Equation 130-2}$$

Where:

CO_2	=	Annual CO_2 emissions arising from fuel and feedstock consumption (tonnes/yr).
$Fdstk_n$	=	Volume of the liquid fuel and feedstock used in month *n* (m^3 of fuel and feedstock). If a mass flow meter is used, measure the fuel and feedstock used in month *n* in kg and measure the carbon content of feedstock in kg of C per kg of feedstock.
CC_n	=	Weighted average carbon content of the liquid fuel and feedstock, from the results of daily analyses for month *n* (kg of C per m^3 of fuel and feedstock when the usage is measured in m^3, or kg of C per kg of feedstock and fuel when the usage is measured in kg).
k	=	Months in the year.
44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to tonnes.

(3) Solid fuel and feedstock. You must calculate the annual CO_2 process emissions from solid fuel and feedstock according to Equation 130-3 of this section:

$$CO_2 = \sum_{n=1}^{k} \frac{44}{12} * (Fdstk_n * CC_n) * 0.001 \qquad \textbf{Equation 130-3}$$

Where:

CO_2	=	Annual CO_2 emissions from fuel and feedstock consumption in tonnes per year (tonnes/yr).
$Fdstk_n$	=	Mass of solid fuel and feedstock used in month *n* (kg of fuel and feedstock).
CC_n	=	Weighted average carbon content of the solid fuel and feedstock, from the results of daily analyses for month *n* (kg carbon per kg of fuel and feedstock).
k	=	Months in the year.

44/12	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to tonnes.

(c) If GHG emissions from a hydrogen production process unit are vented through the same stack as any combustion unit or process equipment that reports CO_2 emissions using a CEMS that complies with WCI.23, then the calculation methodology in paragraph (b) of this section shall not be used to calculate process emissions. The owner or operator shall report the combined stack emissions according to the CEMS methodology in WCI.23.

§ WCI.134 Sampling, Analysis, and Measurement Requirements

(a) Owners or operators using CEMS to estimate CO_2 emissions shall comply with the monitoring requirements in section WCI.23.

(b) Owners or operators using the methods in section WCI.133 (b) or paragraph (c) of this section shall perform the following monitoring:

(1) The owner or operator shall measure the feedstock consumption rate daily.
(2) The owner or operator shall collect samples of each feedstock consumed and analyze each sample for carbon content using the methods specified in WCI.25(c). For natural gas feedstock not mixed with another feedstock prior to consumption, samples shall be collected and analyzed once per month. For all other feedstocks, samples shall be collected and analyzed daily and a weighted average established for month *n*. Daily samples may be combined to generate a monthly composite sample for carbon analysis. The samples shall be collected from a location in the feedstock handling system that provides samples representative of the feedstock consumed in the hydrogen production process.
(3) Owners or operators shall quantify the hydrogen produced daily.
(4) Owners or operators shall quantify the CO_2 and CO collected and transferred off-site quarterly.

(c) You must use the following methods, as applicable, to determine the carbon content of the feedstocks:

(1) ASTM D2013–07 Standard Practice of Preparing Coal Samples for Analysis.

(2) ASTM D2234/D2234M–07 Standard Practice for Collection of a Gross Sample of Coal.

(3) ASTM D2597–94 (Reapproved 2004) Standard Test Method for Analysis of Demethanized Hydrocarbon Liquid Mixtures Containing Nitrogen and Carbon Dioxide by Gas Chromatography.

(4) ASTM D3176–89 (Reapproved 2002), Standard Practice for Ultimate Analysis of Coal and Coke.

(5) ASTM D4057–06 Standard Practice for Manual Sampling of Petroleum and Petroleum Products.

(6) ASTM D4177–95 (Reapproved 2005) Standard Practice for Automatic Sampling of Petroleum and Petroleum Products.

(7) ASTM D6609–08 Standard Guide for Part-Stream Sampling of Coal.

(8) ASTM D6883–04 Standard Practice for Manual Sampling of Stationary Coal from Railroad Cars, Barges, Trucks, or Stockpiles.

(9) ASTM D7430–08ae1 Standard Practice for Mechanical Sampling of Coal.

(10) ASTM UOP539–97 Refinery Gas Analysis by Gas Chromatography.

(11) GPA 2261–00 Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography.

(12) ISO 3170: Petroleum Liquids— Manual sampling—Third Edition.

(13) ISO 3171: Petroleum Liquids— Automatic pipeline sampling—Second Edition.

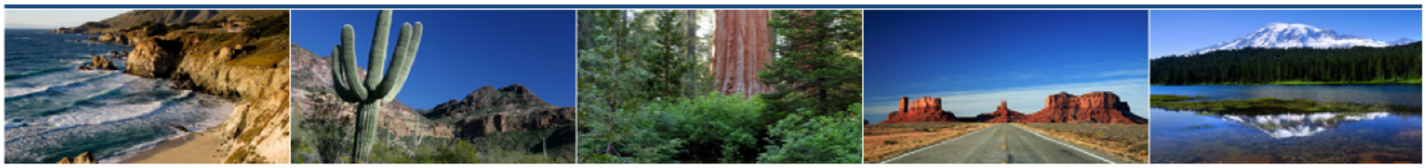
§ WCI.135 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation, etc.), a substitute data value for the missing parameter must be used in the calculations as specified in paragraphs (a), (b), and (c) of this section:

(a) For each missing value of the monthly fuel and feedstock consumption, the substitute data value must be the best available estimate of the fuel and feedstock consumption, based on all available process data (e.g., hydrogen production, electrical load, and operating hours). You must document and keep records of the procedures used for all such estimates.

(b) For each missing value of the carbon content or molecular weight of the fuel and feedstock, the substitute data value must be the arithmetic average of the quality-assured values of carbon contents or molecular weight of the fuel and feedstock immediately preceding and immediately following the missing data incident. If no quality-assured data on carbon contents or molecular weight of the fuel and feedstock are available prior to the missing data incident, the substitute data value must be the first quality-assured value for carbon contents or molecular weight of the fuel and feedstock obtained after the missing data period. You must document and keep records of the procedures used for all such estimates.

(c) For missing CEMS data, you must use the missing data procedures in WCI.20.



§ WCI.140 GLASS PRODUCTION

§ WCI.141 Source Category Definition

A glass manufacturing facility manufactures flat glass, container glass, pressed and blown glass, or wool fiberglass by melting a mixture of raw materials to produce molten glass and form the molten glass into sheets, containers, fibers, or other shapes. A glass manufacturing facility uses one or more glass melting furnaces to produce glass. A glass melting furnace that is an experimental furnace or a research and development process unit is not subject to this subpart.

§ WCI.142 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation the annual emissions data report shall include the following information:

(a) Total CO_2 process emissions from all glass melting furnaces.

(b) Total CO_2, CH_4 and N_2O combustion emissions from all glass melting furnaces. You must calculate and report these emissions under WCI.20 (General Stationary Fuel Combustion Sources) by following the requirements of WCI.20.

(c) Total CO_2, CH_4, and N_2O emissions from all stationary fuel combustion units other than glass melting furnaces. You must report these emissions under WCI.20 (General Stationary Fuel Combustion Sources) by following the requirements of WCI.20.

(d) If a CEMS is used to measure CO_2 emissions, then you must report under this method the relevant information required under WCI.23(d) for the Calculation Methodology 4 and the following information:

Annual quantity of glass produced (tonnes).

(e) If a CEMS is not used to determine CO_2 emissions from glass melting furnaces, and process CO_2 emissions are calculated according to the procedures specified in WCI.143(b), then you must report the following information:

(1) Annual quantity of each carbonate-based raw material charged (tonnes)for all furnaces combined.

(2) Annual quantity of glass produced (tonnes) from all furnaces combined.

(3) Total number of glass melting furnaces.

(f) The number of times in the reporting year that missing data procedures were followed to measure monthly quantities of carbonate-based raw materials or mass fraction of the carbonate-based minerals for each glass melting furnace

§ WCI.143 Calculation of GHG Emissions

You must calculate the annual process CO_2 emissions from each glass melting furnace using the procedure in paragraphs (a) and (b) of this section.

(a) For each glass melting furnace that meets the conditions specified in WCI.23(e)(4), you must calculate under this source the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Calculation Methodology 4 specified in WCI.23(d) and all associated requirements in WCI.20 (General Stationary Fuel Combustion Sources).

(b) For each glass melting furnace that is not subject to the requirements in paragraph (a) of this section, use either the procedure in paragraph (b)(1) or (b)(2) of this section.

(1) Calculate the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to the Calculation Methodology 4 specified in WCI.23(d) (General Stationary Fuel Combustion Sources).

(2) Calculate the process and combustion CO_2 emissions separately using the procedures specified in paragraphs (b)(2)(i) through (b)(2)(vi) of this section.

(i) For each carbonate-based raw material charged to the furnace, obtain from the supplier of the raw material the carbonate-based mineral mass fraction.

(ii) Determine the quantity of each carbonate-based raw material charged to the furnace.

(iii) Apply the appropriate emission factor for each carbonate-based raw material charged to the furnace, as shown in Table 140-1 to this subpart.

(iv) Use Equation 140-1 of this section to calculate process mass emissions of CO_2 for each furnace:

$$E_{CO2} = \sum_{i=1}^{n} \left(M_i \times MF_i \times EF_i \times F_i \right) \qquad \textbf{Equation 140-1}$$

Where:

E_{CO2} = Process emissions of CO_2 from the furnace (tonnes).

n = Number of carbonate-based raw materials charged to furnace.

MF_i = Annual average mass fraction of carbonate-based mineral *i* in carbonate-based raw material *i* (weight fraction).

M_i = Annual amount of carbonate-based raw material *i* charged to furnace (tonnes).

EF_i = Emission factor for carbonate-based mineral *i* (tonnes CO_2 per tonne carbonate-based mineral as shown in Table 140-1).

F_i = Fraction of calcination achieved for carbonate-based mineral *i*, 1.0 for completed calcination (weight fraction).

(v) You must calculate and report the total process CO_2 emissions from glass melting furnaces at the facility using Equation 140-2 of this section:

$$CO_2 = \sum_{i=1}^{k} E_{CO_2 i}$$

Equation 140-2

Where:

CO_2 = Annual process CO_2 emissions from glass manufacturing facility (tonnes).

E_{CO2i} = Annual CO_2 emissions from glass melting furnace i (tonnes).

k = Number of glass melting furnaces.

(vi) Calculate and report under WCI.20 (General Stationary Fuel Combustion Sources) the combustion CO_2 emissions in the glass furnace according to the applicable requirements in WCI.20.

§ WCI.144 Sampling, Analysis, and Measurement Requirements

(a) You must measure annual amounts of carbonate-based raw materials charged to each glass melting furnace from monthly measurements using plant instruments used for accounting purposes, such as calibrated scales or weigh hoppers. Total annual mass charged to glass melting furnaces at the facility shall be compared to records of raw material purchases for the year.

(b) You must measure carbonate-based mineral mass fractions at least annually to verify the mass fraction data provided by the supplier of the raw material; such measurements shall be based on sampling and chemical analysis conducted by a certified laboratory using ASTM D3682-01 (Reapproved 2006) Standard Test Method for Major and Minor Elements in Combustion Residues from Coal Utilization Processes (incorporated by reference, see regulation).

(c) You must determine the annual average mass fraction for the carbonate-based mineral in each carbonate-based raw material by calculating an arithmetic average of the monthly data obtained from raw material suppliers or sampling and chemical analysis.

(d) As an alternative to data provided by the raw material supplier, a value of 1.0 can be used for the monthly mass fraction (MF_i) of carbonate-based mineral i in Equation 140-1 of this section.

(e) You must determine on an annual basis the calcination fraction for each carbonate consumed based on sampling and chemical analysis using an industry consensus standard. This chemical analysis must be conducted using an x-ray fluorescence test or other enhanced testing method published by an industry consensus standards organization (e.g., ASTM, ASME, API, etc.).

§ WCI.145 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., carbonate raw materials consumed, etc.). If the monitoring and quality assurance procedures in WCI.144 cannot be followed and data is missing, you must use the most appropriate of the missing data procedures in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such missing value estimates.

(a) For missing data on the monthly amounts of carbonate-based raw materials charged to any glass melting furnace use the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes, such as purchase records.

(b) For missing data on the mass fractions of carbonate-based minerals in the carbonate-based raw materials assume that the mass fraction of each carbonate based mineral is 1.0.

Table 140-1 —CO_2 Emission Factors for Carbonate-Based Minerals

Carbonate-Based Raw Material – Mineral	CO_2 Emission Factor[a]
Limestone – $CaCO_3$	0.43971
Dolomite – $CaMg(CO_3)_2$	0.47732
Sodium carbonate/soda ash – Na_2CO_3	0.41492

[a] Emission factors in units of tonnes of CO_2 emitted per tonne of carbonate-based mineral charged to the furnace.

§ WCI.150 IRON AND STEEL MANUFACTURING

§ WCI.151 Source Category Definition

Iron and steel manufacturing comprises five categories: taconite iron ore processing, primary facilities that produce both iron and steel, secondary steelmaking facilities, iron production facilities, and offsite production of metallurgical coke. These processes may occur together in an "integrated" facility or they may occur in separate offsite facilities.

§ WCI.152 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual process CO_2 emissions (tonnes) for the following processes:

(1) Taconite indurating furnace

(2) Basic oxygen furnace (BOF)

(3) Coke making operation

(4) Sinter process

(5) Electric arc furnace (EAF)

(6) Argon-oxygen decarburization vessel

(7) Direct reduction furnace

(8) Blast furnace

(b) Annual production/usage quantities (tonnes) for the following processes:

(1) Taconite indurating furnace – fired pellets produced on-site

(2) BOF – steel produced on-site

(3) Coke making operation – coke produced and coal charged

(4) Sinter process – sinter produced

(5) EAF – steel produced on-site

(6) Argon-oxygen decarburization vessel – molten steel charged

(7) Direct reduction furnace – iron produced

(8) Blast furnace – iron produced

(c) CO_2, N_2O, and CH_4 emissions, not accounted for elsewhere in WCI.150, from stationary combustion units as specified in WCI.20. Report these emissions from stationary combustion for each of the following devices:

(1) Taconite indurating furnace

(2) BOF

(3) Coke making operation (coke oven batteries)

(4) Sinter process (sintering furnace)

(5) EAF

(6) Argon-oxygen decarburization vessel

(7) Direct reduction furnace

(8) Blast furnace

(9) Any other stoves, boiler, process heaters, reheat furnaces and other combustion sources.

§ WCI.153 Calculation of CO_2 Emissions

(a) Process CO_2 emissions. Determine process CO_2 emissions as specified under either paragraph (1) or (2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Calculation methodologies specified in paragraph (b) of this section.

[CEMS and mass balance approach are based on IPCC Tier 3 methods.)

(b) Process CO_2 Emissions Calculation Methodology. Calculate CO_2 process emissions for each taconite indurating furnace, basic oxygen furnace, non-recovery coke oven battery, sinter process, EAF, argon-oxygen decarburization vessel, blast furnace, and direct reduction furnace using the following mass balance approaches specified in paragraphs (b)(1) through (b)(8). Specific process inputs or outputs that contribute less than 1 percent of the total mass of carbon into or out of the process do not have to be included in the paragraphs (b)(1) through (b)(8) mass balances.

(1) Calculate taconite indurating furnace CO_2 emissions using Equation 150-1:

$$E_T = \left[\left(T \times C_T \right) - \left(P \times C_P \right) - \left(R \times C_R \right) \right] \times 3.664 \qquad \textbf{Equation 150-1}$$

Where:

E_T	=	Annual CO_2 emissions from taconite indurating furnace (tonnes);
T	=	Annual mass of greenball (taconite) pellets fed to furnace (tonnes);
C_T	=	Carbon content of greenball (taconite) pellets (tonnes C/tonnes taconite pellets);
P	=	Annual mass of fired pellets producted by the furnace (tonnes);
C_P	=	Carbon content of fired pellets (tonnes C/tonnes fired pellets);
R	=	Annual mass of air pollution control residue collected (tonnes);

C_R	=	Carbon content of air pollution control residue (tonnes C/tonnes residue);
3.664	=	Conversion factor from tonnes of C to tonnes of CO_2.

(2) Calculate basic oxygen process furnace CO_2 emissions using Equation 150-2:

$$E_{BOF} = [(I \times C_I) + (SC \times C_{SC}) + (FL \times C_{FL}) + (CAR \times C_{CAR}) - (ST \times C_{ST}) - (SL \times C_{SL}) - (BOG \times C_{BOG}) - (R \times C_R)] \times 3.664$$

Equation 150-2

Where:

E_{BOF}	=	Annual CO_2 emissions from basic oxygen furnaces (tonnes);
I	=	Annual mass of molten iron charged to furnace (tonnes);
C_I	=	Carbon content of molten iron (tonnes C/tonnes molten iron);
SC	=	Annual mass of ferrous scrap charged to furnace (tonnes);
C_{SC}	=	Carbon content of ferrous scrap (tonnes C/tonnes ferrous scrap);
FL	=	Annual mass for flux materials (e.g., limestone, dolomite, etc.) charged to furnace (tonnes);
C_{FL}	=	Carbon content of flux materials (tonnes C/tonnes flux material);
CAR	=	Annual mass of carbonaceous material (e.g., coal, coke, etc.) charged to furnace (tonnes);
C_{CAR}	=	Carbon content of carbonaceous material (tonnes C/tonnes carbonaceous material);
ST	=	Annual mass of molten raw steel produced by furnace (tonnes);
C_{ST}	=	Carbon content of steel (tonnes C/tonnes steel);
SL	=	Annual mass of slag produced by furnace (tonnes);
C_{SL}	=	Carbon content of slag (tonnes C/tonnes slag);
BOG	=	Annual mass of basic oxygen furnace gas transferred off site (tonnes);
C_{BOG}	=	Carbon content of basic oxygen furnace gas transferred off site (tonnes C/tonnes basic oxygen furnace gas);
R	=	Annual mass of air pollution control residue collected (tonnes);
C_R	=	Carbon content of air pollution control residue (tonnes C/tonnes residue);
3.664	=	Conversion factor from tonnes of C to tonnes of CO_2.

(3) Calculate coke oven battery CO_2 emissions using Equation 150-3:

$$E_{coke} = [(CC \times C_{CC}) - (CO \times C_{CO}) - (BY \times C_{BY}) - (R \times C_R) - (COG \times C_{COG})] \times 3.664$$

Equation 150-3

Where:

E_{coke}	=	Annual CO_2 emissions from coke production (tonnes);

CC	=	Annual mass of coking coal charged to battery (tonnes);
C_{CC}	=	Carbon content of coking coal (tonnes C/tonnes coking coal);
CO	=	Annual mass of coke produced (tonnes);
C_{CO}	=	Carbon content of coke (tonnes C/tonnes coke);
BY	=	Annual mass of by-product from by-product coke oven battery (tonnes);
C_{BY}	=	Carbon content of by-product (tonnes C/tonnes by-product);
R	=	Quantity of air pollution control residue collected (tonnes);
C_R	=	Carbon content of air pollution control residue (tonnes C/tonnes residue);
COG	=	Annual mass of coke oven gas transferred off site (tonnes);
C_{COG}	=	Carbon content of coke oven gas transferred off site (tonnes C/tonnes coke oven gas);
3.664	=	Conversion factor from tonnes of C to tonnes of CO_2.

(4) Calculate sinter process CO_2 emissions using Equation 150-4:

$$E_{sinter} = [(CAR \times C_{CAR}) + (FE \times C_{FE}) - (S \times C_S) - (R \times C_R)] \times 3.664$$

Equation 150-4

Where:

E_{sinter}	=	Annual CO_2 emissions from sinter process (tonnes);
CAR	=	Annual mass of carbonaceous material (e.g., coal, coke, etc.) charged to furnace (tonnes);
C_{CAR}	=	Carbon content of carbonaceous material (tonnes C/ tonnes carbonaceous material);
FE	=	Annual mass of sinter feed material (tonnes);
C_{FE}	=	Carbon content of sinter feed material (tonnes C/tonnes sinter feed material);
S	=	Annual mass of sinter produced (tonnes);
C_S	=	Carbon content of sinter produced (tonnes C/tonnes sinter);
R	=	Quantity of air pollution control residue collected (tonnes);
C_R	=	Carbon content of air pollution control residue (tonnes C/ tonnes residue);
3.664	=	Conversion factor from tonnes of C to tonnes of CO_2.

(5) Calculate electric arc furnace (EAF) CO_2 emissions using Equation 150-5:

$$E_{EAF} = [(I \times C_I) + (SC \times C_{SC}) + (FL \times C_{FL}) + (EL \times C_{EL}) + (CAR \times C_{CAR}) - (ST \times C_{ST}) - (SL \times C_{SL}) - (R \times C_R)] \times 3.664$$

Equation 150-5

Where:

E_{EAF}	=	Annual CO_2 emissions from EAF (tonnes);
I	=	Annual mass of direct reduced iron (if any) charged to furnace (tonnes);
C_I	=	Carbon content of direct reduced iron (tonnes C/ tonnes direct reduced iron);
SC	=	Annual mass of ferrous scrap charged to furnace (tonnes);
C_{SC}	=	Carbon content of ferrous scrap (tonnes C/ tonnes ferrous scrap);

FL	=	Annual mass for flux materials (e.g., limestone, dolomite, etc.) charged to furnace (tonnes);
C_{FL}	=	Carbon content of flux materials (tonnes C/ tonnes flux material);
EL	=	Annual mass for carbon electrodes consumed (tonnes);
C_{EL}	=	Carbon content of carbon electrodes (tonnes C/ tonnes carbon electrode);
CAR	=	Annual mass of carbonaceous material (e.g., coal, coke, etc.) charged to furnace (tonnes);
C_{CAR}	=	Carbon content of carbonaceous material (tonnes C/ tonnes carbonaceous material);
ST	=	Annual mass of molten raw steel produced by furnace (tonnes);
C_{ST}	=	Carbon content of steel (tonnes C/ tonnes steel);
SL	=	Annual mass of slag produced by furnace (tonnes);
C_{SL}	=	Carbon content of slag (tonnes C/ tonnes slag);
R	=	Annual mass of air pollution control residue collected (tonnes);
C_R	=	Carbon content of air pollution control residue (tonnes C/ tonnes residue);
3.664	=	Conversion factor from tonnes of C to tonnes of CO_2.

(6) Calculate argon-oxygen decarburization vessel CO_2 emissions using Equation 150-6:

$$E_{AOD} = \left[Steel \times \left(C_{in} - C_{out}\right) - \left(R \times C_R\right)\right] \times 3.664$$ **Equation 150-6**

Where:

E_{AOD}	=	Annual CO_2 emissions from argon-oxygen decarburization vessels (tonnes);
Steel	=	Annual mass of molten steel charged to vessel (tonnes);
C_{in}	=	Carbon content of molten steel before decarburization (tonnes C/ tonnes molten steel);
C_{out}	=	Carbon content of molten steel after decarburization (tonnes C/ tonnes molten steel);
R	=	Annual mass of air pollution control residue collected (tonnes);
C_R	=	Carbon content of air pollution control residue (tonnes C/ tonnes residue);
3.664	=	Conversion factor from tonnes of C to tonnes of CO_2.

(7) Calculate direct reduction furnace CO_2 emissions using Equation 150-7:

$$E_{DR} = \left[\left(Ore \times C_{Ore}\right) + \sum\left(CAR \times C_{CAR}\right) + \sum\left(OT \times C_{OT}\right) - \left(I \times C_I\right) - \left(NM \times C_{NM}\right) - \left(R \times C_R\right)\right] \times 3.664$$

Equation 150-7

Where:

E_{DR}	=	Annual CO_2 emissions from direct reduction furnace (tonnes);
Ore	=	Annual mass of iron ore or iron ore pellets fed to the furnace (tonnes);
C_{Ore}	=	Carbon content of iron ore or iron ore pellets (tonnes C/ tonnes iron ore or iron ore pellets);
CAR	=	Annual mass of non-fuel carbonaceous materials (e.g., coal, coke, by-products, etc.) charged to furnace (tonnes);

C_{CAR} = Carbon content of non-fuel carbonaceous materials (tonnes C/ tonnes non-fuel carbonaceous material);
OT = Annual mass of other materials charged to furnace (tonnes);
C_{OT} = Carbon content of other materials (tonnes C/ tonnes other materials);
I = Annual mass of iron produced (tonnes);
C_I = Carbon content of iron (tonnes C/ tonnes iron);
NM = Annual mass for non-metallic materials produced (tonnes);
C_{NM} = Carbon content of non-metallic materials (tonnes C/ tonnes non-metallic minerals);
R = Annual mass of air pollution control residue collected (tonnes);
C_R = Carbon content of air pollution control residue (tonnes C/ tonnes residue);
3.664 = Conversion factor from tonnes of C to tonnes of CO_2.

(8) Calculate blast furnace CO_2 emissions using Equation 150-8:

$$E_{BF} = \left[(Ore \times C_{Ore}) + \sum(CAR \times C_{CAR}) + \sum(F \times C_F) + \sum(OT \times C_{OT}) - (I \times C_I) - (NM \times C_{NM}) - (BG \times C_{BG}) - (R \times C_R)\right] \times 3.664$$

Equation 150-8

Where:

E_{BF} = Annual CO_2 emissions from blast furnace (tonnes);
Ore = Annual mass of iron ore or iron ore pellets fed to the furnace (tonnes);
C_{Ore} = Carbon content of iron ore or iron ore pellets (tonnes C/ tonnes iron ore or iron ore pellets);
CAR = Annual mass of non-fuel carbonaceous materials (e.g., coal, coke, by-products, etc.) charged to furnace (tonnes);
C_{CAR} = Carbon content of non-fuel carbonaceous materials (tonnes C/ tonnes non-fuel carbonaceous material);
F = Annual mass for flux materials (e.g., limestone, dolomite, etc.) charged to furnace (tonnes);
C_F = Carbon content of flux materials (tonnes C/ tonnes flux material);
OT = Annual mass of other materials charged to furnace (tonnes);
C_{OT} = Carbon content of other materials (tonnes C/ tonnes other materials);
I = Annual mass of iron produced (tonnes);
C_I = Carbon content of iron (tonnes C/ tonnes iron);
NM = Annual mass for non-metallic materials produced (tonnes);
C_{NM} = Carbon content of non-metallic materials (tonnes C/ tonnes non-metallic minerals);
BG = Annual mass for blast furnace gas transferred off-site (tonnes);
C_{BG} = Carbon content of blast furnace gas (tonnes C/ tonnes blast furnace gas);
R = Annual mass of air pollution control residue collected (tonnes);
C_R = Carbon content of air pollution control residue (tonnes C/ tonnes residue);
3.664 = Conversion factor from tonnes of C to tonnes of CO_2.

(9) Calculate total CO_2 emissions using Equation 150-9:

$$E_{CO2} = E_T + E_{BOF} + E_{coke} + E_{\sin ter} + E_{EAF} + E_{AOD} + E_{DR} + E_{BF} \quad \textbf{Equation 150-9}$$

Where:

E_{CO2} = Total CO_2 emissions (tonnes);
E_T = Emissions from taconite indurating furnace (tonnes);
E_{BOF} = Emissions from basic oxygen furnace (BOF) (tonnes);
E_{coke} = Emissions from coke production (tonnes);
E_{sinter} = Emissions from sinter production (tonnes);
E_{EAF} = Emissions from electric arc furnace (EAF) (tonnes);
E_{AOD} = Emissions from argon-oxygen decarburization vessels (tonnes);
E_{DR} = Emissions from direct reduction furnace (tonnes);
E_{BF} = Emissions from blast furnace (tonnes);

§ WCI.154 Calculation of CH_4 Emissions

(a) Process CH_4 emissions. Determine process CH_4 emissions as specified under either paragraph (1) or paragraph (2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Site-specific emission factors.

§ WCI.155 Sampling, Analysis, and Measurement Requirements

The annual mass of each material used in the WCI.153 mass balance methodologies shall be determined using plant instruments used for accounting purposes, including either direct measurement of the quantity of material used in the process or by calculations using process operating information.

The average carbon content of each material used shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For iron ore, taconite pellets, and other iron-bearing materials, use ASTM E1915-07a “Standard Test Methods for Analysis of Metal Bearing Ores and Related Materials by Combustion Infrared-Absorption Spectrometry”.

(2) For iron and ferrous scrap, use ASTM E1019-08 “Standard Test Methods for Determination of Carbon, Sulphur, Nitrogen, and Oxygen in Steel, Iron, Nickel, and Cobalt Alloys by Various Combustion and Fusion Techniques”.

(3) For coal, coke, and other carbonaceous materials (e.g., electrodes, etc.), use ASTM D5373-08 “Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal” or ASTM D5142-09 “Standard Test Methods for Proximate Analysis of the Analysis Sample of Coal and

Coke by Instrumental Procedures", for petroleum liquid based fuels and liquid waste-derived fuels.

(4) For steel, use one of the methods described in subparagraph (i) through (iv):

(i) ASM CS-104 UNS No. G10460 "Carbon Steel of Medium Carbon Content".

(ii) ISO/TR 15349-1: 1998 "Unalloyed steel – Determination of low carbon content, Part 1: Infrared absorption method after combustion in an electric resistance furnace (by peak separation) (1998-10-15) – First Edition".

(iii) ISO/TR 15349-3: 1998 "Unalloyed steel – Determination of low carbon content, Part 3: Infrared absorption method after combustion in an electric resistance furnace (with preheating) (1998-10-15) – First Edition".

(iv) ASTM E415-08 "Standard Test Method for Atomic Emission Vacuum Spectrometric Analysis of Carbon and Low-Alloy Steel".

(5) For flux (i.e., limestone or dolomite) and slag, use ASTM C25-06 "Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime".

(6) For fuels, determine carbon content and molecular weight (if applicable) using the applicable methods listed in §WCI.20.

(7) For steel production by-products (e.g., blast furnace gas, coke oven gas, coal tar, light oil, sinter off gas, slag dust, etc.), use an online instrument that determines carbon content to ±5%, or use sampling and analysis as contained in WCI.25(a) and WCI.25(d).

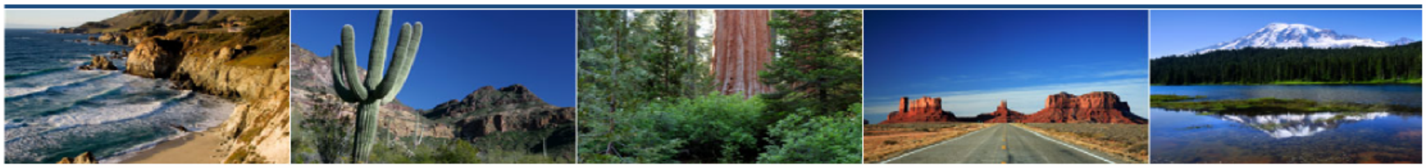
(b) Obtain carbon content from material vendor or supplier.

§ WCI.156 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Whenever the sampling procedures in WCI.155 cannot be followed (e.g., if a meter malfunctions during unit operation), a substitute data value for the missing parameter shall be used in accordance with paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing data on monthly carbon contents of feedstock or the waste recycle stream, the substitute data value shall be the arithmetic average of the quality-assured values of that carbon content in the month preceding and the month immediately following the missing data incident. If no quality-assured data is available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon content obtained in the month after the missing data period.

(b) For missing feedstock supply rates or waste recycle stream used to determine monthly feedstock consumption or monthly waste recycle stream quantity, you must determine the best available estimate(s) of the parameter(s), based on all available process data.



§ WCI.160 LEAD PRODUCTION

§ WCI.161 Source Category Definition

The lead production category includes two primary production processes used to produce lead from lead concentrates (i.e., the sintering/smelting process and the direct smelting process). In addition, secondary production or recycling of lead (primarily from scrapped lead acid batteries) is included in the category.

§ WCI.162 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation the annual emissions data report shall contain the following information:

(a) Annual emissions of CO_2 at the facility level (tonnes).

(b) Annual quantities of each material used (tonnes).

(c) Carbon content of each material used (tonnes C/ tonne reducing agent).

(d) Inferred waste-based carbon-containing material emission factor (if waste-based reducing agent quantification method used).

(e) If you use the missing data procedures in WCI.165(b), you must report how the monthly mass of carbon-containing materials with missing data was determined and the number of months the missing data procedures were used.

(f) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit. You must report these emissions under WCI.20 (General Stationary Fuel Combustion Sources), by following the requirements of WCI.20.

§ WCI.163 Calculation of CO_2 Emissions

Calculate total CO_2 emissions as specified under paragraph (a) or (b) of this section.

(a) Determine facility CO_2 emissions using continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(b) Calculate total CO_2 emissions using Equation 160-1. Specific materials that in aggregate contribute less than 0.5% of the total carbon into the process may be excluded from the calculation performed using Equation 160-1.

$$E_{Pb} = \sum_{x} (RA_x \times C_x) \times 3.664 \qquad \textbf{Equation 160-1}$$

Where:

E_{Pb} = Annual CO_2 emissions from lead production (tonnes);
RA_x = Annual quantity of material x used (tonnes);
C_x = Carbon content of material x (tonnes C/ tonnes of x);
3.664 = Conversion factor from tonnes of C to tonnes of CO_2.

§ WCI.164 Sampling, Analysis, and Measurement Requirements

The annual mass of each material introduced into the smelting furnace shall be determined by summing the monthly mass for the material determined for each month of the calendar year. The monthly mass may be determined using plant instruments used for accounting purposes, including either direct measurement of the quantity of the material placed in the unit or by calculations using process operating information.

The average carbon content of each material introduced into the smelting furnace shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For solid carbonaceous reducing agents and carbon electrodes, use ASTM D5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal".

(2) For liquid reducing agents, use one of the methods described in subparagraph (i) through (iv):

i. ASTM D2502-04 (Reapproved 2002) "Standard Test Method for Estimation of Molecular Weight (Relative Molecular Mass) of Petroleum Oils from Viscosity Measurements".

ii. ASTM D2503-92 (Reapproved 2002) "Standard Test Method for Relative Molecular Mass (Relative Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure".

iii. ASTM D3238-95 (Reapproved 2005) "Standard Test Method for Calculation of Carbon Distribution and Structural Group Analysis of Petroleum Oils by the n-d-M Method".

iv. ASTM D5291-02 (Reapproved 2007) "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants".

(3) For gaseous reducing agents, use one of the methods described in subparagraph (i) or (ii):

i. ASTM D1945-03 "Standard Test Method for Analysis of Natural Gas by Gas Chromatography".

ii. ASTM D1946-90 "Standard Practice for Analysis of Reformed Gas by Gas Chromatography".

(4) For waste-based carbon-containing material, determine carbon content by operating the smelting furnace both with and without the waste-reducing agents while keeping the composition of other material introduced constant.

i. To ensure representativeness of waste-based carbon-containing material variability, the specific testing plan (e.g. number of test runs, other process variables to keep constant, timing of runs) for these trials must be approved by the jurisdiction.

(b) Obtain carbon content from material vendor or supplier.

§ WCI.165 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations in WCI.163 is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in the paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For each missing data for the carbon content for the smelting furnaces at your facility that estimate annual process CO_2 emissions using the carbon mass balance procedure in WCI.163, 100 percent data availability is required. You must repeat the test for average carbon contents of inputs according to the procedures in WCI.164 if data are missing.

(b) For missing records of the monthly mass of carbon-containing materials, the substitute data value must be based on the best available estimate of the mass of the material from all available process data or data used for accounting purposes (such as purchase records).

§ WCI.170 LIME MANUFACTURING

§ WCI.171 Source Category Definition

Lime manufacturing is comprised of all processes that are used to manufacture a lime product (e.g., calcium oxide, high calcium quicklime, calcium hydroxide, hydrated lime, dolomitic quick lime, dolomitic hydrate, or other products) by calcination of limestone or other highly calcareous materials such as dolomite, aragonite, chalk, coral, marble, and shell.

This source category includes all lime manufacturing plants unless the plant is located at a kraft pulp mill, soda pulp mill, sulfite pulp mill, or only processes sludge containing calcium carbonate from water softening processes. The lime manufacturing source category consists of marketed and non-marketed lime manufacturing facilities.

Lime kilns at pulp and paper manufacturing facilities must report emissions under WCI.210 (Pulp and Paper Manufacturing).

§ WCI.172 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2, CH_4, and N_2O in tonnes.

(b) CO_2 process emissions from lime production (tonnes) for all kilns combined and the following information:

(1) For lime production:

(A) The emission factor (kg CO_2/ tonne) for each lime type for each month.

(B) The quantity of each type of lime produced (tonnes) each month.

(C) The calcium oxide (CaO) content (weight fraction) of each lime type for each month.

(D) The magnesium oxide (MgO) content (weight fraction) of each lime type for each month.

(2) For the production of calcined byproducts and wastes:

(A) The emission factor (kg CO_2/ tonne) for each calcined byproduct/waste type for each quarter.

(B) The quantity of each type of calcined byproduct/waste type produced each quarter.

(C) The calcium oxide (CaO) content (weight fraction) of each calcined byproduct/waste type for each quarter.

(D) The magnesium oxide (MgO) content (weight fraction) of each calcined byproduct/waste type for each quarter.

(3) Number of times during the reporting year that missing data procedures were followed to measure lime production.

(c) CO_2, CH_4, and N_2O emissions from fuel combustion in all kilns combined, following the calculation methods and reporting requirements specified in WCI.173(c) (tonnes).

(d) CO_2, CH_4, and N_2O emissions from all other fuel combustion units combined (kilns excluded), following the calculation methods and reporting requirements specified in WCI.20 (tonnes).

(e) If a continuous emissions monitor is used to measure CO_2 emissions from kilns, then the requirements of paragraph (b) of this section do not apply for CO_2.

(f) Operators of lime plants shall also comply with the reporting requirements for any other applicable source category listed by regulation, including but not limited to the following:

(1) Coal fuel storage as specified in WCI.100.

(2) Electricity generating as specified in WCI.40.

(3) Cogeneration systems as specified in WCI.42(f).

§ WCI.173 Calculation of greenhouse Gas Emissions from Kilns

(a) Determine process CO_2 emissions as specified under either paragraph (a)(1) or (a)(2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Calculate the sum of CO_2 process emissions from kilns and CO_2 fuel combustion emissions from kilns using the calculation methodologies specified in paragraph (b) and (c) of this section**.**

(b) Process CO_2 Emissions Calculation Methodology. Calculate total CO_2 process emissions as the sum of emissions from lime production, using the method specified in paragraph (b)(1) of this section.

(1) CO_2 Process Emissions. Calculate CO_2 emissions from the production of each type of lime using Equation 170-1 and a plant-specific lime emission factor and a plant-specific calcined byproduct/waste emission factor as specified in this section.

$$CO_2 = \sum_{m}^{12}\sum_{i}\left[QL_{mi} \times EF_{QL_{mi}}\right] + \sum_{q}^{4}\sum_{j}\left[CBW_{qj} \times EF_{CBW_{qj}}\right] \qquad \textbf{Equation 170-1}$$

Where:

CO_2 = CO_2 emissions in tonnes/yr.

QL_{mi} = Quantity of lime type *i* produced in month *m*, tonnes.

EF_{QLmi} = Emission factor of lime type *i* produced in month *m*, tonnes CO_2/tonne lime computed as specified in paragraph (b)(2) of this section.

CBW_{qj} = Quantity of calcined byproduct/waste type *j*, including LKD, scrubber sludge and other calcined wastes produced in quarter *q*, tonnes.

EF_{CBWqj}= Emission factor of calcined byproduct/waste type *j* produced in quarter *q*, computed as specified in paragraph (b)(3) of this section.

(2) Monthly Lime Emission Factor. Calculate a plant-specific lime emission factor (EF_{QL}) for each type of lime and month based on the measured CaO and MgO contents in lime and using Equation 170-2.

$$EF_{QL} = (f_{CaO} \times 0.785) + (f_{MgO} \times 1.092)$$ **Equation 170-2**

Where:

EF_{QL} = Process CO_2 emission factor for lime produced, tonnes CO_2/ tonnes lime.

f_{CaO} = CaO content of lime, calculated by subtracting CaO content of lime in uncalcined $CaCO_3$ remaining in lime from total CaO content of lime, tonnes CaO/ tonne lime

0.785 = Ratio of molecular weights of CO_2 to CaO.

f_{MgO} = MgO content of lime, calculated by subtracting MgO content of lime in uncalcined $MgCO_3$ remaining in lime from total MgO content of lime, tonnes MgO/ tonne lime.

1.092 = Ratio of molecular weights of CO_2 to MgO

(3) Quarterly Calcined Byproduct/Waste Emission Factor. The calcined byproduct/waste emission factor shall be calculated using Equation 170-3.

$$EF_{CBW} = (f_{CaO} \times 0.785) + (f_{MgO} \times 1.092)$$ **Equation 170-3**

Where:

EF_{CBW} = Calcined byproduct/waste emission factor.

f_{CaO} = CaO content of byproduct and waste, calculated by subtracting CaO content of byproduct and waste in uncalcined $CaCO_3$ remaining in calcined byproduct and waste from total CaO content of byproduct and waste, tonnes CaO/ tonne byproduct and waste.

0.785 = Ratio of molecular weights of CO_2 to CaO .

f_{MgO} = MgO content of byproduct and waste, calculated by subtracting MgO content of byproduct and waste in uncalcined $MgCO_3$ remaining in byproduct and waste from total MgO content of byproduct and waste, tonnes MgO/ tonnes byproduct and waste .

1.092 = Ratio of molecular weights of CO_2 to MgO

(c) Fuel Combustion Emissions in Kilns. Calculate CO_2, CH_4, and N_2O emissions from stationary fuel combustion emissions following the calculation methods specified in WCI.20. Operators of lime manufacturing plants that primarily combust biomass-derived fuels and combust fossil fuels only during periods of start-up, shut-down, or malfunction may report CO_2 emissions from fossil fuels using the emission factor methodology in WCI.23(a).

"Pure" means that the biomass-derived fuels account for 97 percent of the total amount of carbon in the fuels burned.

§ WCI.174 Sampling, Analysis, and Measurement Requirements

(a) You must determine the chemical composition (CaO and MgO contents) of each type of lime and each type of calcined byproduct/waste according to paragraph (a)(1) and (a)(2) of this section. Samples for analysis of the calcium oxide and magnesium oxide content of each lime type and each calcined byproduct/waste type should be collected during the same month or quarter as the production data. At least one sample must be collected monthly for each lime type produced during the month and quarterly for each calcined byproduct/waste type produced.

(1) ASTM C25-06 Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime.

(2) The National Lime Association's CO_2 Emissions Calculation Protocol for the Lime Industry English Units Version, February 5, 2008 Revision – National Lime Association.

(b) The quantity of lime produced and sold is to be estimated monthly using direct measurements (such as rail and truck scales) of lime sales for each lime type, and adjusted to take into account the difference in beginning- and end-of-period inventories of each lime type. The inventory period shall be annual at a minimum.

(c) The quantity of calcined byproduct/waste sold is to be estimated monthly using direct measurements (such as rail and truck scales) of calcined byproduct/waste sales for each calcined byproduct/waste type, and adjusted to take into account the difference in beginning- and end-of-period inventories of each calcined byproduct/waste type. The inventory period shall be annual at a minimum. The quantity of calcined byproduct/waste not sold is to be determined no less often than annually for each calcined/byproduct waste type using direct measurements (such as rail and truck scales), or a calcined byproduct/waste generation rate (i.e. calcined byproduct produced as a factor of lime production).

(d) Follow the quality assurance/quality control procedures (including documentation) in National Lime Association's CO_2 Emissions Calculation Protocol for the Lime Industry English Units Version, February 5, 2008 Revision – National Lime Association.

§ WCI.175 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., oxide content, quantity of lime products, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For each missing value of the quantity of lime produced (by lime type), and quantity of byproduct/waste produced and sold, the substitute data value shall be the best available estimate based on all available process data or data used for accounting purposes.

(b) For missing values related to the CaO and MgO content, you must conduct a new composition test.

§ WCI.180 CARBONATES USE

§ WCI.181 Source Category Definition

This source category includes any equipment that uses carbonates listed in Table 180-1 in manufacturing processes that emit carbon dioxide. Table 180-1 includes the following carbonates: limestone, dolomite, ankerite, magnesite, siderite, rhodochrosite, or sodium carbonate. Facilities are considered to emit CO_2 if they consume at least 1,800 tonnes per year of carbonates heated to a temperature sufficient to allow the calcination reaction to occur.

This source category does not include equipment that uses carbonates or carbonate-containing minerals that are consumed in the production of cement, copper and nickel, electricity generation, ferroalloys, glass, iron and steel, lead, lime, phosphoric acid, pulp and paper, soda ash, sodium bicarbonate, sodium hydroxide, or zinc.

This source category does not include carbonates used in sorbent technology used to control emissions from stationary fuel combustion equipment. Emissions from carbonates used in sorbent technology are reported under WCI.20 (Stationary Fuel Combustion Sources).

§ WCI.182 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation, the annual emissions data report for carbonate use shall include the following information at the facility level calculated in accordance with this method:

(a) Annual CO_2 emissions from miscellaneous carbonate use (tonnes).

(b) Annual mass of each carbonate type consumed (tonnes).

(c) If you followed the calculation method of WCI.183(a), you must report the following information:

(1) Annual carbonate consumption by carbonate type (tonnes).

(2) Annual calcination fractions used in calculations.

(d) If you followed the calculation method of WCI.183(b), you must report the following information:

(1) Annual carbonate input by carbonate type (tonnes).

(2) Annual carbonate output by carbonate type (tonnes).

(e) Number of times in the reporting year that missing data procedures were followed to measure carbonate consumption, carbonate input or carbonate output (months).

§ WCI.183 Calculating GHG emissions.

You must determine CO_2 process emissions from carbonate use in accordance with the procedures specified in either paragraphs (a) or (b) of this section.

(a) Calculate the process emissions of CO_2 using calcination fractions with Equation 180-1 of this section.

$$E_{CO2} = \sum_{i=1}^{n} \left(M_i \times EF_i \times F_i \right)$$

Equation 180-1

Where:

ECO_2	=	Annual CO_2 mass emissions from consumption of carbonates (tonnes).
M_i	=	Annual mass of carbonate type *i* consumed (tonnes).
EF_i	=	Emission factor for the carbonate type *i*, as specified in Table 180-1 to this Subpart, tonnes CO_2/tonne carbonate consumed.
F_i	=	Fraction calcination achieved for each particular carbonate type *i* (weight fraction). As an alternative to measuring the calcination fraction, a value of 1.0 can be used.
n	=	Number of carbonate types.

(b) Calculate the process emissions of CO_2 using actual mass of output carbonates with Equation 180-2 of this section.

$$E_{CO2} = \left[\sum_{k=1}^{m} \left(M_k \times EF_k \right) - \sum_{j=1}^{n} \left(M_j \times EF_j \right) \right]$$

Equation 180-2

Where:

ECO_2	=	Annual CO_2 mass emissions from consumption of carbonates (tonnes).
M_k	=	Annual mass of input carbonate type *k* (tonnes).
EF_k	=	Emission factor for the input carbonate type *k*, as specified in Table 180-1 of this method (tonnes CO_2/tonne carbonate input).
M_j	=	Annual mass of output carbonate type *j* (tonnes).
EF_j	=	Emission factor for the output carbonate type *j*, as specified in Table 180-1 of this method (tonnes CO_2/tonne carbonate input).
m	=	Number of input carbonate types.
n	=	Number of output carbonate types.

§ WCI.184 Monitoring and QA/QC requirements.

(a) The annual mass of carbonate consumed (for Equation 180-1 of this subpart) or carbonate inputs (for Equation 180-2 of this subpart) must be determined annually from monthly measurements using the same plant instruments used for accounting purposes including purchase records or direct measurement, such as weigh hoppers or weigh belt feeders.

(b) The annual mass of carbonate outputs (for Equation 180-2 of this subpart) must be determined annually from monthly measurements using the same plant instruments used for accounting purposes including purchase records or direct measurement, such as weigh hoppers or belt weigh feeders.

(c) If you follow the procedures of WCI.183(a), as an alternative to assuming a calcination fraction of 1.0, you can determine on an annual basis the calcination fraction for each carbonate consumed based on sampling and chemical analysis using a suitable method such as using an x-ray fluorescence standard method or other enhanced industry consensus standard method published by an industry consensus standard organization (e.g., ASTM, ASME, etc.).

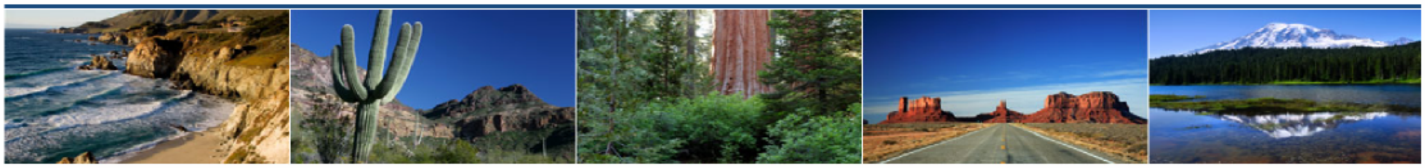
§ WCI.185 Procedures for estimating missing data.

(a) A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraph (b) of this section. You must document and keep records of the procedures used for all such estimates.

(b) For each missing value of monthly carbonate consumed, monthly carbonate output, or monthly carbonate input, the substitute data value must be the best available estimate based on the all available process data or data used for accounting purposes.

Table 180-1 — CO_2 Emission Factors for Common Carbonates

Mineral Name - Carbonate	CO_2 Emission Factor (tonnes CO_2/tonne carbonate)
Limestone - $CaCO_3$	0.43971
Magnesite - $MgCO_3$	0.52197
Dolomite - $CaMg(CO_3)_2$	0.47732
Siderite - $FeCO_3$	0.37987
Ankerite - $Ca(Fe,Mg,Mn)(CO_3)_2$	0.47572
Rhodochrosite - $MnCO_3$	0.38286
Sodium Carbonate/Soda Ash – Na_2CO_3	0.41492
Others	Facility specific factor to be determined through analysis or supplier information



§ WCI.200 PETROLEUM REFINERIES

§ WCI.201 Source Category Definition

(a) A petroleum refinery consists of all processes used to produce gasoline, aromatics, kerosene, distillate fuel oils, residual fuel oils, lubricants, asphalt, or other products through distillation of petroleum or through redistillation, cracking, rearrangement or reforming of unfinished petroleum derivatives.

(b) For the purposes of this subpart, facilities that distill only pipeline transmix (off-spec material created when different specification products mix during pipeline transportation) are not petroleum refineries, regardless of the products produced.

(c) This source category consists of the following sources at petroleum refineries: catalytic cracking units; fluid coking units; delayed coking units; catalytic reforming units; coke calcining units; asphalt blowing operations; blowdown systems; storage tanks; process equipment components (compressors, pumps, valves, pressure relief devices, flanges, and connectors) in gas service; marine vessel, barge, tanker truck, and similar loading operations; flares; sulphur recovery plants; and non-merchant hydrogen plants (i.e., hydrogen plants that are owned or under the direct control of the refinery owner and operator).

§ WCI.202 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions report must contain the following information reported at the facility level:

(a) Catalyst Regeneration. Report CO_2, CH_4, and N_2O emissions.

(b) Process Vents. Report CO_2, CH_4, and N_2O emissions.

(c) Asphalt Production. Report CO_2 and CH_4 emissions.

(d) Sulphur Recovery. Report CO_2 emissions.

(e) Flares and Other Control Devices. Report CO_2, CH_4, and N_2O emissions.

(f) Above-Ground Storage Tanks. Report CH_4 emissions.

(g) Wastewater Treatment. Report CH_4 and N_2O emissions from anaerobic treatment.

(h) Oil-water separators. Report CH_4 emissions from oil-water separators.

(i) Equipment Leaks. Report CH_4 emissions.

(j) Coke calcining units. Report CO_2, CH_4, and N_2O emissions.

(k) Uncontrolled blowdown systems. Report CH_4 emissions.

(l) Loading Operations. Report CH_4 emissions.

(m) Delayed Coking Units. Report CH_4 emissions.

(n) Stationary Combustion Units Other than Flares and Control Devices. CO_2, CH_4, and N_2O emissions as specified in WCI.30 for combustion of refinery fuel gas, still gas, flexigas, or associated gas and WCI.20 for combustion of all other fuels.

(o) Feedstock Consumption: Report feedstock consumption, by type, for all feedstocks which result in GHG emissions in the reporting year (including petroleum coke) in units of cubic meters for gases, kilolitres for liquids, tonnes for non-biomass solids, and bone dry tonnes for biomass-derived solid fuels.

(p) Fuel Consumption: Report fuel consumption by fuel type consumed in the reporting year in units of cubic meters for gases, kilolitres for liquids, tonnes for non-biomass solids, and bone dry tonnes for biomass-derived solid fuels.

§ WCI.203 Calculation of Greenhouse Gas Emissions

The operator shall calculate GHG emissions using the methods in paragraphs (a) through (m) of this section. If a continuous emissions monitor is used to measure CO_2 emissions from process vents, asphalt production, sulphur recovery, or other control devices then the operator shall calculate the CO_2 emissions from these processes using a continuous emissions monitoring system (CEMS) as specified in WCI.23(d). When the flue gas from two or more processes or stationary combustion sources are discharged through a common stack or duct before exiting to the atmosphere and if CEMS as specified in WCI.23(d) are used to continuously monitor the CO2 emissions, you may report the combined emissions from the processes or stationary combustion sources sharing the common stack or duct in lieu of separately reporting the GHG emission from individual processes or stationary combustion sources.

(a) Catalyst Regeneration. Operators shall calculate the CO_2, CH_4, and N_2O process emissions resulting from catalyst regeneration using the methods in paragraph (a)(1), (a)(2) and (a)(3), respectively.

(1) For units equipped with CEMS, operators shall calculate CO_2 process emissions resulting from catalyst regeneration using CEMS in accordance with WCI.20. In the absence of CEMS data, the operator shall use the methods in paragraphs (a)(1)(A) through (a)(1)(C).

(A) (i) The person shall calculate process CO_2 emissions from the continuous regeneration of catalyst material in fluid catalytic cracking units (FCCU) and fluid cokers using Equations 200-1, 200-1b, 200-2, and 200-3

$$CO_2 = \sum_{i=1}^{n} CR_i \times CF \times 3.664 \times 0.001$$ **Equation 200-1**

Where:

CO_2	=	CO_2 emissions (tonnes/yr).
n	=	Number of hours of operation in the report.
CR_i	=	Hourly coke burn rate in kg/week.
CF	=	Carbon fraction in coke burned.

3.664 = Ratio of molecular weights, CO_2 to carbon.
0.001 = Conversion factor from kg to tonnes.

(ii) Alternatively, the person may calculate process CO_2 emissions from the continuous regeneration of catalyst material in fluid catalytic cracking units (FCCU) and fluid cokers using Equations 200-1b and 200-2.

$$CO_2 = \sum_{p=1}^{n} \left[(Q_r)_p \times \frac{(\%CO_2 + \%CO)_p}{100\%} \times \frac{44}{MVC} \times 0.001 \right]$$ **Equation 200-1b**

Where:
CO_2 = CO_2 emissions (tonnes/yr).
Q_r = Volumetric flow rate of exhaust gas before entering the emission control system using Equation 200-2 and at reference temperature and pressure conditions as used by the facility (dRm^3/hr).
$\%CO_2$ = Average hourly CO_2 concentration in regenerator exhaust, per cent by volume – dry basis.
%CO = Average hourly CO concentration in regenerator exhaust, per cent by volume – dry basis. When there is no post-combustion device, assume %CO to be zero.
44 = Molecular weight of CO_2 (kg/kg-mole).
MVC = Molar volume conversion factor at the same reference conditions as the above Q_r (Rm^3/kg-mole).
= 8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal].
0.001 = Conversion factor from kg to tonnes.
n = Number of hours of operation in the report year.

(iii) Either continuously monitor the volumetric flow rate of exhaust gas from the fluid catalytic cracking unit regenerator or fluid coking unit burner prior to the combustion of other fossil fuels or calculate the volumetric flow rate of this exhaust gas stream using Equation 200-2 of this section.

$$Q_r = \frac{(79 * Q_a + (100 - \%O_{oxy}) * Q_{oxy})}{100 - \%CO_2 - \%CO - \%O_2}$$ **Equation 200-2**

Where:
Q_r = Volumetric flow rate of exhaust gas from regenerator before entering the emission control system at reference temperature and pressure conditions as used by the facility (dRm^3/min).
Q_a = Volumetric flow rate of air to regenerator, as determined from control room instrumentation at reference temperature and pressure conditions as used for variable Q_r (dRm^3/min).

O_{oxy}	=	Oxygen concentration in oxygen enriched air stream, percent by volume – dry basis.
Q_{oxy}	=	Volumetric flow rate of O_2 enriched air to regenerator as determined from catalytic cracking unit control room instrumentation at reference temperature and pressure conditions used for variable Q_r (dRm^3/min).
$\%CO_2$	=	Carbon dioxide concentration in regenerator exhaust, percent by volume – dry basis.
$\%CO$	=	CO concentration in regenerator exhaust, percent by volume – dry basis. When no auxiliary fuel is burned and a continuous CO monitor is not required, assume %CO to be zero.
$\%O_2$	=	O_2 concentration in regenerator exhaust, percent by volume – dry basis.

(iv) Calculate the hourly coke burn rate using Equation 200-3 or from facility measurement or engineering estimate:

$$CR_i = K_1 Q_r \times (\%CO_2 + \%CO) + K_2 Q_a - K_3 Q_r \times \left[\%CO/2 + \%CO_2 + \%O_2\right] + K_3 Q_{oxy} \times (\%O_{oxy})$$

Equation 200-3

Where:

CR_i	=	Hourly coke burn rate in kg/hour.
K_1, K_2, K_3	=	Material balance and conversion factors (K_1, K_2, and K_3 from Table 200-1 or from facility measurement or engineering estimate).
Q_r	=	Volumetric flow rate of exhaust gas before entering the emission control system from Equation 200-2 (dRm^3/min)
Q_a	=	Volumetric flow rate of air to regenerator as determined from control room instrumentation at reference temperature and pressure conditions used in variable Q_r (dRm^3/min)
$\%CO_2$	=	CO_2 concentration in regenerator exhaust, percent by volume – dry basis
$\%CO$	=	CO concentration in regenerator exhaust, percent by volume – dry basis
$\%O_2$	=	O_2 concentration in regenerator exhaust, percent by volume – dry basis
Q_{oxy}	=	Volumetric flow rate of O_2 enriched air to regenerator as determined from control room instrumentation at reference temperature and pressure conditions used in variable Q_r (dRm^3/min)
$\%O_{oxy}$	=	O_2 concentration in O_2 enriched air stream inlet to regenerator, percent by volume – dry basis

(B) The operator shall calculate process CO_2 emissions resulting from continuous catalyst regeneration in operations other than FCCUs and fluid cokers (e.g. catalytic reforming) using Equation 200-4.

$$CO_2 = CC_{irc} \times (CF_{spent} - CF_{regen}) \times H \times 3.664$$

Equation 200-4

Where:

CO_2	=	CO_2 emissions (tonnes/yr)
CC_{irc}	=	Average catalyst regeneration rate (tonnes/hr)
CF_{spent}	=	Weight carbon fraction of spent catalyst
CF_{regen}	=	Weight carbon fraction of regenerated catalyst (default = 0)
H	=	Hours regenerator was operational (hr/yr)
3.664	=	Ratio of molecular weights, CO_2 to carbon

(C) The operator shall calculate process CO_2 emissions resulting from periodic catalyst regeneration using Equations 200-5

$$CO_2 = \sum_{1}^{n} \left[\left(CB_Q \right)_n \times CC \times 3.664 \times 0.001 \right]$$ **Equation 200-5**

Where:

O_2	=	Annual CO_2 emissions (tonnes/year).
CB_Q	=	Coke burn-off quantity per regeneration cycle from engineering estimates (kg coke/cycle).
n	=	Number of regeneration cycles in the calendar year.
CC	=	Carbon content of coke based on measurement or engineering estimate (kg C per kg coke); default = 0.94.
3.664	=	Ratio of molecular weights, CO_2 to carbon
0.001	=	Conversion factor (tonne/kg).

(2) Calculate CH_4 emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-6 of this section.

$$CH_4 = \left(CO_2 \times \frac{EmF_2}{EmF_1} \right)$$ **Equation 200-6**

Where:

CH_4	=	Annual methane emissions from coke burn-off (tonnes CH_4/year).
CO_2	=	Emission rate of CO_2 from coke burn-off calculated in paragraph (a)(1) of this section, as applicable (metric tons/year).
EmF_1	=	Default CO_2 emission factor for petroleum coke of 97 kg CO_2/GJ.
EmF_2	=	Default CH_4 emission factor of 2.8×10^{-3} kg CH_4/GJ.

(3) Calculate N_2O emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-7 of this section.

$$N_2O = \left(CO_2 \times \frac{EmF_3}{EmF_1} \right)$$ **Equation 200-7**

Where:

N_2O	=	Annual nitrous oxide emissions from coke burn-off (tonnes N_2O/year).
CO_2	=	Emission rate of CO_2 from coke burn-off calculated in paragraphs (a)(1) of this section, as applicable (tonnes/year).
EmF_1	=	Default CO_2 emission factor for petroleum coke of 97 kg CO_2/GJ.
EmF_3	=	Default N_2O emission factor of 5.7 x 10^{-4} kg N_2O/GJ.

(b) **Process Vents.** Except for process emissions reported under other requirements of this regulation, the operator shall calculate process emissions of CO_2, CH_4, and N_2O from process vents using Equation 200-8 for each process vent that can be reasonably expected to contain greater than 2 percent by volume CO_2 or greater than 0.5 percent by volume of CH_4 or greater than 0.01 percent by volume (100 parts per million) of N_2O.

$$E_x = \sum_{i=1}^{n} VR_i \times F_{xi} \times (MW_x / MVC) \times VT_i \times 0.001$$ **Equation 200-8**

Where:

E_x	=	Annual emissions of *x* (tonnes/yr), where *x* = CO_2, N_2O, or CH_4.
VR_i	=	Average volumetric flow rate for venting event *i* from measurement data, process knowledge or engineering estimates at reference temperature and pressure conditions as used by the facility (Rm^3/unit time). If a mass flow meter is used, measure the flow rate in kg/unit time and replace the term "MW_x/MVC" with "1".
F_{xi}	=	Molar fraction of *x* in vent gas stream during event *i* from measurement data, process knowledge or engineering estimates.
MW_x	=	Molecular weight of *x* (kg/kg-mole).
MVC	=	Molar volume conversion factor at the same reference conditions as the above VR_i (Rm^3/kg-mole).
	=	8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal]
VT_i	=	Time duration of venting event *i*, in same units of time as VR_i.
n	=	Number of venting events in report year.
0.001	=	Conversion factor from kg to tonnes.

(c) **Asphalt Production**. The operator shall calculate CO_2 and CH_4 process emissions from asphalt blowing activities using either process vent method specified in paragraph (b) or according to the applicable provisions in paragraphs (c)(1) and (c)(2) of this section.

(1) For uncontrolled asphalt blowing operations or asphalt blowing operations controlled by vapor scrubbing, calculate CO_2 and CH_4 emissions using Equations 200-9 and 200-10 of this section, respectively.

$$CO_2 = (Q_{AB} \times EF_{AB.CO2})$$ **Equation 200-9**

Where:

CO_2	=	Annual CO_2 emissions from uncontrolled asphalt blowing (tonnes CO_2/year).
Q_{AB}	=	Quantity of asphalt blown (million barrels per year, MMbbl/year).

$EF_{AB,CO2}$ = Emission factor for CO_2 from uncontrolled asphalt blowing from facility-specific test data (tonnes CO_2/MMbbl asphalt blown); default = 1,100.

$$CH_4 = (Q_{AB} \times EF_{AB,CH4}) \quad \textbf{Equation 200-10}$$

Where:

CH_4 = Annual methane emissions from uncontrolled asphalt blowing (tonnes CH_4/year).
Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).
$EF_{AB,CH4}$ = Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (tonnes CH_4/MMbbl asphalt blown); default = 580.

(2) For asphalt blowing operations controlled by thermal oxidizer or flare, calculate CO_2 and CH_4 emissions using Equations 200-11 and 200-12 of this section, respectively, provided these emissions are not already included in the flare emissions calculated in paragraph (e) of this section or in the stationary combustion unit emissions required under WCI.20.

$$CO_2 = 0.98 \times (Q_{AB} \times CEF_{AB} \times 3.664) \quad \textbf{Equation 200-11}$$

Where:

CO_2 = Annual CO_2 emissions from controlled asphalt blowing (tonnes CO_2/year).
0.98 = Assumed combustion efficiency of thermal oxidizer or flare.
Q_{AB} = Quantity of asphalt blown (MMbbl/year).
CEF_{AB} = Carbon emission factor from asphalt blowing from facility-specific test data (tonnes C/MMbbl asphalt blown); default = 2,750.
3.664 = ratio of molecular weights, carbon dioxide to carbon

$$CH_4 = 0.02 \times (Q_{AB} \times EF_{AB,CH4}) \quad \textbf{Equation 200-12}$$

Where:

CH_4 = Annual methane emissions from controlled asphalt blowing (tonnes CH_4/year).
0.02 = Fraction of methane uncombusted in thermal oxidizer or flare based on assumed 98% combustion efficiency.
Q_{AB} = Quantity of asphalt blown (million barrels per year, MMbbl/year).
$EF_{AB,CH4}$ = Emission factor for CH_4 from uncontrolled asphalt blowing from facility-specific test data (tonnes CH_4/MMbbl asphalt blown); default = 580.

(d) **Sulphur Recovery**. The operator shall calculate CO_2 process emissions from sulphur recovery units (SRUs) using Equation 200-13. For the molar fraction (MF) of CO_2 in the sour gas, use either a default factor of 0.20 or a source specific molar fraction value approved by the regulator and derived from source tests conducted at least once per calendar year under the supervision of the regulator.

$$CO_2 = FR \times MW_{CO2} / MVC \times MF \times 0.001 \quad \textbf{Equation 200-13}$$

Where:

CO_2 = Emissions of CO_2 (tonnes/yr).
FR = Volumetric flow rate of acid gas to SRU at reference temperature and pressure conditions as used by the facility (Rm^3/year). If a mass flow meter is used, measure the acid gas flow in kg per year and replace the term "MW_{CO2}/MVC" with "1".
MW_{CO2} = Molecular weight of CO_2 (44 kg/kg-mole).
MVC = Molar volume conversion factor at the same reference conditions as the FR variable (Rm^3/kg-mole).
= 8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal].
MF = Molar fraction (%) of CO_2 in sour gas based on measurement or engineering estimate (default MF = 20% expressed as 0.20).
0.001 = Conversion factor from kg to tonnes.

(e) **Flares and Other Control Devices**.

(1) The operator shall calculate and report CO_2, CH_4 and N_2O emissions resulting from the combustion of flare pilot and purge gas using the appropriate method(s) specified in section WCI.20.

(2) The operator shall calculate and report CO_2 emissions resulting from the combustion of hydrocarbons routed to flares for destruction as follows:

(A) Heat value or carbon content measurement. If you have a continuous higher heating value monitor or gas composition monitor on the flare or if you monitor these parameters at least weekly, you must use the measured heat value or carbon content value in calculating the CO_2 emissions from the flare using the applicable methods in paragraphs (e)(2)(A)(i) and (e)(2)(A)(ii).

(i) If you monitor gas composition, calculate the CO_2 emissions from the flare using Equation 200-14 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation 200-14 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[3.664 \times (Flare)_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right) \quad \textbf{Equation 200-14}$$

Where:
CO_2 = Annual CO_2 emissions for a specific fuel type (tonnes/year).
0.98 = Assumed combustion efficiency of a flare.
0.001 = Unit conversion factor (tonnes per kilogram).
n = Number of measurement periods. The minimum value for *n* is 52 (for weekly measurements); the maximum value for *n* is 366 (for daily measurements during a leap year).
p = Measurement period index.
3.664 = Ratio of molecular weights, carbon dioxide to carbon

$(Flare)_p$ = Volume of flare gas combusted during measurement period at reference temperature and pressure conditions as used by the facility (Rm^3/period) . If a mass flow meter is used, measure flare gas flow rate in kg/period and replace the term "$(MW)_p/MVC$" with "1".

$(MW)_p$ = Average molecular weight of the flare gas combusted during measurement period *p* (kg/kg-mole). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.

MVC = Molar volume conversion factor at the same reference conditions as the above $(Flare)_p$ (Rm^3/kg-mole).

= 8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal].

$(CC)_p$ = Average carbon content of the flare gas combusted during measurement period *p* (kg C per kg flare gas). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.

(ii) If you monitor heat content but do not monitor gas composition, calculate the CO_2 emissions from the flare using Equation 200-15 of this section. If daily or more frequent measurement data are available, you must use daily values when using Equation 200-15 of this section; otherwise, use weekly values.

$$CO_2 = 0.98 \times 0.001 \times \sum_{p=1}^{n} \left[(Flare)_p \times (HHV)_p \times EmF \right] \qquad \textbf{Equation 200-15}$$

Where:

CO_2 = Annual CO_2 emissions for a specific fuel type (tonnes/year).

0.98 = Assumed combustion efficiency of a flare.

0.001 = Unit conversion factor (tonnes per kilogram).

n = Number of measurement periods. The minimum value for *n* is 52 (for weekly measurements); the maximum value for *n* is 366 (for daily measurements during a leap year).

p = Measurement period index.

$(Flare)_p$ = Volume of flare gas combusted during measurement period *p* at reference temperature and pressure conditions as used by the facility (Rm^3/period). If a mass flow meter is used, the person must also measure molecular weight and convert the mass flow to a volumetric flow as follows: Flare[m3] = Flare[kg] × $MVC/(MW)_p$, where MVC is the molar volume conversion factor at the same reference conditions as $(Flare)_p$ (Rm^3/kg-mole) and $(MW)_p$ is the average molecular weight of the flare gas combusted during measurement period *p* (kg/kg-mole).

$(HHV)_p$ = Higher heating value for the flare gas combusted during measurement period *p* (GJ per m^3). If measurements are taken more frequently than daily, use the arithmetic average of measurement values within the day to calculate a daily average.

EmF = Default CO_2 emission factor of 57 kilograms CO_2/GJ (HHV basis).

(B) Alternative Method. For startup, shutdown, and malfunctions during which you were unable to measure the parameters required by Equations 200-14 and 200-15 of this section, you must determine the quantity of gas discharged to the flare separately for each start-up, shutdown, or malfunction, and calculate the CO_2 emissions as specified in paragraphs (e)(2)(B)(i) and (e)(2)(B)(ii) of this section.

(i) For periods of start-up, shutdown, or malfunction, use engineering calculations and process knowledge to estimate the carbon content of the flared gas for each start-up, shutdown, or malfunction event.

(ii) For the reporting of emissions from normal operation flares in the year 2011, you may use the average heating value measured for the fuel gas for the heating value of the flare gas. If heating value is not measured, the heating value may be estimated from historic data or engineering calculation. If you are unable to use the methods in WCI.203(e)(2) in 2012 due to health or safety reasons, you may use the alternate method in the subsection in 2012 if it is consented to in writing by the Director.

(iii) Calculate the CO_2 emissions using Equation 200-16 of this section.

$$CO_2 = 0.98 \times 0.001 \times \left(\sum_{p=1}^{n} \left[3.664 \times (Flare_{SSM})_p \times \frac{(MW)_p}{MVC} \times (CC)_p \right] \right) \quad \textbf{Equation 200-16}$$

Where:

CO_2 = Annual CO_2 emissions for a specific fuel type (tonnes/year).

0.98 = Assumed combustion efficiency of a flare.

0.001 = Unit conversion factor (tonnes per kilogram, mt/kg).

n = Number of start-up, shutdown, and malfunction events during the reporting year.

p = Start-up, shutdown, and malfunction event index.

$(Flare_{SSM})_p$ = Volume of flare gas combusted during indexed start-up, shutdown, or malfunction event *p* from engineering calculations, at reference temperature and pressure conditions as used by the facility (Rm^3/event). If a mass flow meter is used, measure the flare gas combusted in kg per event and replace the term "(MW)p/MVC" with "1".

$(MW)_p$ = Average molecular weight of the flare gas, from the analysis results or engineering calculations for the event *p* (kg/kg-mole).

MVC = Molar volume conversion factor at the same reference conditions as the above $(Flare_{SSM})_p$ (Rm^3/kg-mole).

= 8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal].

$(CC)_p$ = Average carbon content of the flare gas, from analysis results or engineering calculations for the event *p* (kg C per kg flare gas).

3.664 = Ratio of molecular weights, carbon dioxide to carbon.

(3) The operator shall calculate and report CH_4 and N_2O emissions resulting from the combustion of hydrocarbons routed to flares for destruction using the methods specified in paragraphs (e)(3)(A) and (e)(3)(B):

(A) Calculate CH_4 using Equation 200-17 of this section.

$$CH_4 = \left(CO_2 \times \frac{\mathrm{EmF}_{CH4}}{\mathrm{EmF}} \right) + CO_2 \times \frac{0.02}{0.98} \times \frac{16}{44} \times f_{CH4}$$ **Equation 200-17**

Where:

CH_4 = Annual methane emissions from flared gas (tonnes CH_4/year).

CO_2 = Emission rate of CO_2 from flared gas calculated in paragraph (e)(1) and (e)(2) of this section (tonnes/year).

EmF_{CH4} = Default CH_4 emission factor for petroleum products of 2.8 x 10^{-3} kg/GJ.

EmF = Default CO_2 emission factor for flare gas of 57 kilograms CO_2/GJ (HHV basis).

0.02/0.98 = Correction factor for flare combustion efficiency.

16/44 = Correction factor ratio of the molecular weight of CH_4 to CO_2

f_{CH4} = Weight fraction of carbon in the flare gas prior to combustion that is contributed by methane from measurement values or engineering calculations (kg C in methane in flare gas/kg C in flare gas); default is 0.4.

(B) Calculate N_2O emissions using Equation 200-18 of this section.

$$N_2O = \left(CO_2 \times \frac{\mathrm{EmF}_{N2O}}{\mathrm{EmF}} \right)$$ **Equation 200-18**

Where:

N_2O = Annual nitrous oxide emissions from flared gas (tonnes N_2O/year).

CO_2 = Emission rate of CO_2 from flared gas calculated in paragraph (e)(1) and (e)(2) of this section (tonnes/year).

EmF_{N2O} = Default N_2O emission factor for petroleum products of 5.7 x 10^{-4} kg/GJ.

EmF = Default CO_2 emission factor for flare gas of 57 kilograms CO_2/GJ (HHV basis).

(4) The operator who uses methods other than flares (e.g. incineration, combustion as a supplemental fuel in heaters or boilers) to destroy low Btu gases (e.g. coker flue gas, gases from vapor recovery systems, casing vents and product storage tanks) shall calculate CO_2 emissions using Equation 200-19. The operator shall determine CC_A and MW_A quarterly using methods specified in WCI.20 and use the annual average values of CC_A and MW_A to calculate CO_2 emissions.

$$CO_2 = GV_A \times CC_A \times MW_A / MVC \times 3.664 \times 0.001$$ **Equation 200-19**

Where:

CO_2	=	CO_2 emissions (tonnes/year).
GV_A	=	Volume of gas *A* destroyed annually at reference temperature and pressure conditions as used by the facility (Rm^3/year). If a mass flow meter is used, measure the gas destroyed in kg and replace the term "MW_A/MVC" with "1".
CC_A	=	Carbon content of gas *A* (kg C/kg fuel).
MW_A	=	Molecular weight of gas *A*.
MVC	=	Molar volume factor at the same reference conditions as the GV_A variable (Rm^3/kg-mole).
	=	8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal].
3.664	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor – kg to tonnes.

(f) **Storage Tanks.** For storage tanks other than those processing unstabilized crude oil except as provided in paragraph (f)(3) of this section, calculate CH_4 emissions using the applicable methods in paragraphs (f)(1) and (f)(2) of this section.

(1) For storage tanks other than those processing unstabilized crude oil, you must either calculate CH_4 emissions from storage tanks that have a vapor-phase methane concentration of 0.5 volume percent or more using tank-specific methane composition data (from measurement data or product knowledge) and the AP-42 emission estimation methods provided in Section 7.1 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources", including TANKS Model (Version 4.09D) or similar programs, or estimate CH_4 emissions from storage tanks using Equation 200-20 of this section.

$$CH_4 = \left(0.1 \times Q_{\mathrm{Re}f}\right) \qquad \textbf{Equation 200-20}$$

Where:

CH_4	=	Annual methane emissions from storage tanks (tonnes/year).
0.1	=	Default emission factor for storage tanks (tonne CH_4/MMbbl).
Q_{Ref}	=	Quantity of crude oil plus the quantity of intermediate products received from off site that are processed at the facility (MMbbl/year).

(2) For storage tanks that process unstabilized crude oil, calculate CH_4 emissions from the storage of unstabilized crude oil using either tank-specific methane composition data (from measurement data or product knowledge) and direct measurement of the gas generation rate or by using Equation 200-21 of this section.

$$CH_4 = (995{,}000 \times Q_{un} \times \Delta P) \times MF_{CH4} \times \frac{16}{MVC} \times 0.001 \qquad \textbf{Equation 200-21}$$

Where:

CH_4	=	Annual methane emissions from storage tanks (tonnes/year).
Q_{un}	=	Quantity of unstabilized crude oil received at the facility (MMbbl/year).

ΔP = Pressure differential from the previous storage pressure to atmospheric pressure (pounds per square inch, psi).
MF_{CH4} = Mole fraction of CH_4 in vent gas from the unstabilized crude oil storage tank from facility measurements (kg-mole CH_4/kg-mole gas); use 0.27 as a default if measurement data are not available.
995,000 = Correlation Equation factor (scf gas per MMbbl per psi).
16 = Molecular weight of CH_4 (kg/kg-mole).
MVC = Molar volume conversion (849.5 scf/kg-mole).
0.001 = Conversion factor (tonne/kg).

(3) You do not need to calculate CH_4 emissions from storage tanks that meet any of the following descriptions:
(A) Units permanently attached to conveyances such as trucks, trailers, rail cars, barges, or ships;
(B) Pressure vessels designed to operate in excess of 204.9 kilopascals and without emissions to the atmosphere;
(C) Bottoms receivers or sumps;
(D) Vessels storing wastewater; or
(E) Reactor vessels associated with a manufacturing process unit.

(g) **Industrial Wastewater Processing**.

(1) The operator shall calculate CH_4 emissions from anaerobic wastewater treatment (such as anaerobic reactor, digester, or lagoon) using Equation 200-22 or Equation 200-23.

$$CH_4 = Q \times COD_{qave} \times B \times MCF \times 0.001$$ **Equation 200-22**

$$CH_4 = Q \times BOD_{5qave} \times B \times MCF \times 0.001$$ **Equation 200-23**

Where:
CH_4 = Emission of methane (tonnes/yr).
Q = Volume of wastewater treated (m^3/yr).
COD_{qave} = Average of quarterly determinations of chemical oxygen demand of the wastewater (kg/m^3).
BOD_{5qave} = Average of quarterly determinations of five-day biochemical oxygen demand of the wastewater (kg/m^3).
B = Methane generation capacity (B = 0.25 kg CH_4/kg COD and 0.06 kg CH_4/kg BOD_5).
MCF = Methane correction factor for anaerobic decay (0-1.0) from Table 200-2.
0.001 = Conversion factor – kg to tonnes.

(2) For anaerobic processes from which biogas is recovered and not emitted, you must adjust the CH_4 emissions calculated in paragraph (g)(1) by the amount of CH_4 collected.

(3) The operator shall calculate N_2O emissions from wastewater treatment using Equation 200-24.

$$N_2O = Q \times N_{qave} \times EF_{N2O} \times 1.571 \times 0.001 \quad \textbf{Equation 200-24}$$

Where:

N_2O	=	Emissions of N_2O (tonnes/yr).
Q	=	Volume of wastewater treated (m^3/yr).
N_{qave}	=	Average of quarterly determinations of N in effluent (kg N/m^3).
EF_{N2O}	=	Emission factor for N_2O from discharged wastewater (0.005 kg N_2O-N/kg N).
1.571	=	Conversion factor – kg N_2O-N to kg N_2O.
0.001	=	Conversion factor – kg to tonnes.

(h) **Oil-Water Separators.** The operator shall calculate CH_4 emissions from oil-water separators using Equation 200-25. For the CF_{NMHC} conversion factor, operators shall use either a default factor of 0.6 or species specific conversion factors determined by analysis using a sampling and analysis methodology approved by regulator.

$$CH_4 = EF_{sep} \times V_{water} \times CF_{NMHC} \times 0.001 \quad \textbf{Equation 200-25}$$

Where:

CH_4	=	Emission of methane (tonnes/yr).
EF_{sep}	=	NMHC (non methane hydrocarbon) emission factor (kg/m^3) from Table 200-3.
V_{water}	=	Volume of waste water treated by the separator (m^3/yr).
CF_{NMHC}	=	NMHC to CH_4 conversion factor.
0.001	=	Conversion factor from kg to tonnes.

(i) **Equipment leaks**. Calculate CH_4 emissions using the method specified in either paragraph (i)(1) or (i)(2) of this section.

(1) Use process-specific methane composition data (from measurement data or process knowledge) and any of the emission estimation procedures provided in the Protocol for Equipment Leak Emissions Estimates (EPA-453/R-95-017, NTIS PB96-175401).

(2) Use Equation 200-26 of this section.

$$CH_4 = (0.4 \times N_{CD} + 0.2 \times N_{PU1} + 0.1 \times N_{PU2} + 4.3 \times N_{H2} + 6 \times N_{FGS}) \quad \textbf{Equation 200-26}$$

Where:

CH_4	=	Annual methane emissions from equipment leaks (tonnes/year)
N_{CD}	=	Number of atmospheric crude oil distillation columns at the facility.

N_{PU1} = Cumulative number of catalytic cracking units, coking units (delayed or fluid), hydrocracking, and full-range distillation columns (including depropanizer and debutanizer distillation columns) at the facility.
N_{PU2} = Cumulative number of hydrotreating/hydrorefining units, catalytic reforming units, and visbreaking units at the facility.
N_{H2} = Total number of hydrogen plants at the facility.
N_{FGS} = Total number of fuel gas systems at the facility.

(j) **Coke Calcining.** The operator shall calculate GHG emissions according to the applicable provisions in paragraphs (j)(1) through (j)(3) of this section.

(1) If you operate and maintain a CEMS that measures CO_2 emissions according to WCI.20, you must calculate and report CO_2 emissions for coke calcining by following the CEMS Calculation Methodology specified in WCI.20. If the coke calcining unit is not equipped with CEMS must either install a CEMS that complies with the CEMS requirements in WCI.23, or follow the requirements of paragraph (j)(2) of this section.

(2) Calculate the CO_2 emissions from the coke calcining unit using Equation 200-27 of this section.

$$CO_2 = 3.664 \times \left(M_{in} \times CC_{GC} - (M_{out} + M_{dust}) \times CC_{MPC}\right)$$ **Equation 200-27**

Where:
CO_2 = Annual CO_2 emissions (tonnes/year).
M_{in} = Annual mass of green coke fed to the coke calcining unit from facility records (tonnes/year).
CC_{GC} = Average mass fraction carbon content of green coke from facility measurement data (tonne carbon/tonne green coke).
M_{out} = Annual mass of marketable petroleum coke produced by the coke calcining unit from facility records (tonnes petroleum coke/year).
M_{dust} = Annual mass of petroleum coke dust collected in the dust collection system of the coke calcining unit from facility records (tonne petroleum coke dust/year)
CC_{MPC} = Average mass fraction carbon content of marketable petroleum coke produced by the coke calcining unit from facility measurement data (tonne carbon/tonne petroleum coke).
3.664 = Ratio of molecular weights, carbon dioxide to carbon

(3) For all coke calcining units, use the CO_2 emissions from the coke calcining unit calculated in paragraphs (j)(1) or (j)(2), as applicable, and calculate CH_4 and N_2O using the following methods:

(A) Calculate CH_4 emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-28 of this section.

$$CH_4 = \left(CO_2 \times \frac{EmF_2}{EmF_1} \right)$$ **Equation 200-28**

Where:

CH_4 = Annual methane emissions (tonnes CH_4/year).

CO_2 = Emission rate of CO_2 calculated in paragraphs (j)(1) and (j)(2) of this section, as applicable (tonnes/year).

EmF_1 = Default CO_2 emission factor for petroleum coke (97 kg CO_2/GJ).

EmF_2 = Default CH_4 emission factor of 2.8 x 10^{-3} kg CH_4/GJ).

(B) Calculate N_2O emissions using either unit specific measurement data, a unit-specific emission factor based on a source test of the unit, or Equation 200-29 of this section.

$$N_2O = \left(CO_2 \times \frac{EmF_3}{EmF_1} \right)$$ **Equation 200-29**

Where:

N_2O = Annual nitrous oxide emissions (tonnes N_2O/year).

CO_2 = Emission rate of CO_2 from paragraphs (j)(1) and (j)(2) of this section, as applicable (tonnes/year).

EmF_1 = Default CO_2 emission factor for petroleum coke (97 kg CO_2/GJ)

EmF_3 = Default N_2O emission factor of 5.7 x 10^{-4} kg N_2O/GJ.

(k) **Uncontrolled Blowdown Systems**. For uncontrolled blowdown systems, you must use the methods for process vents in paragraph (b) of this section.

(l) **Loading Operations**. For crude oil, intermediate, or product loading operations for which the equilibrium vapor-phase concentration of methane is 0.5 volume percent or more, calculate CH_4 emissions from loading operations using product-specific, vapor-phase methane composition data (from measurement data or process knowledge) and the emission estimation procedures provided in Section 5.2 of the AP-42: "Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources." For loading operations in which the equilibrium vapor-phase concentration of methane is less than 0.5 volume percent, you may assume zero methane emissions.

(m) **Delayed coking units.** Calculate the CH_4 emissions from the depressurization of the coking unit vessel (i.e., the "coke drum") to the atmosphere using either of the methods provided in paragraphs (m)(1) or (m)(2), provided no water or steam is added to the vessel once it is vented to the atmosphere. You must use the method in paragraph (m)(1) of this section if you add water or steam to the vessel after it is vented to the atmosphere.

(1) Use the process vent method in paragraph (b) of this section and also calculate the CH_4 emissions from the subsequent opening of the vessel for coke cutting operations using Equation 200-30 of this section. If you have coke drums or vessels of different dimensions, use Equation 200-30 for each set of coke drums

or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

$$CH_4 = \left(N \times H \times \frac{(P_{CV} + 101.325)}{101.325} \times f_{void} \times \frac{\pi \times D^2}{4} \times \frac{16}{MVC} \times MF_{CH4} \times 0.001 \right) \quad \textbf{Equation 200-30}$$

Where:

CH_4	=	Annual methane emissions from the delayed coking unit vessel opening (tonnes/year).
N	=	Cumulative number of vessel openings for all delayed coking unit vessels of the same dimensions during the year.
H	=	Height of coking unit vessel (metres).
P_{CV}	=	Gauge pressure of the coking vessel when opened to the atmosphere prior to coke cutting or, if the alternative method provided in paragraph (m)(2) of this section is used, gauge pressure of the coking vessel when depressurization gases are first routed to the atmosphere (kilopascals).
101.325	=	Assumed atmospheric pressure (kilopascals).
f_{void}	=	Volumetric void fraction of coking vessel prior to steaming based on engineering judgement at reference temperature and pressure conditions as used by the facility (Rm^3 gas/m^3 of vessel).
D	=	Diameter of coking unit vessel (metres).
16	=	Molecular weight of CH_4 (kg/kg-mole).
MVC	=	Molar volume factor at the same reference conditions as the cooking vessel (Rm^3/kg-mole).
	=	8.3145 * [273.16 + reference temperature in °C]/[reference pressure in kilopascal].
MF_{CH4}	=	Average mole fraction of methane in coking vessel gas based on the analysis of at least two samples per year, collected at least four months apart (kg-mole CH_4/kg-mole gas, wet basis).
0.001	=	Conversion factor (tonne/kg).

(2) Calculate the CH_4 emissions from the depressurization vent and subsequent opening of the vessel for coke cutting operations using Equation 200-30 of this section and the pressure of the coking vessel when the depressurization gases are first routed to the atmosphere. If you have coke drums or vessels of different dimensions, use Equation 200-30 for each set of coke drums or vessels of the same size and sum the resultant emissions across each set of coke drums or vessels to calculate the CH_4 emissions for all delayed coking units.

§ WCI.204 Sampling, Analysis, and Measurement Requirements

Where the ASTM or other consensus based organization analysis or other measurement methods specified in this subsection are not offered by any supplier in the Jurisdiction, you may request approval by the Director in writing for another equivalent method.

(a) Catalyst Regeneration.

(1) For FCCUs and fluid coking units, the operators shall measure the following parameters:

(A) The daily oxygen concentration in the oxygen enriched air stream inlet to the regenerator.

(B) Continuous measurements of the volumetric flow rate of air and oxygen enriched air entering the regenerator.

(C) Weekly periodic measurements of the CO_2, CO and O_2 concentrations in the regenerator exhaust gas (or continuous measurements if the equipment necessary to make continuous measurements is already in place).

(D) Daily determinations of the carbon content of the coke burned.

(E) The number of hours of operation.

(F) The measured daily or weekly values can be used to derive the minute or hourly parameters as required by the corresponding equations.

(2) For periodic catalyst regeneration, the operators shall measure the following parameters.

(A) The mass of catalyst regenerated in each regeneration cycle.

(B) The weight fraction of carbon on the catalyst prior to and after catalyst regeneration.

(3) For continuous catalyst regeneration in operations other than FCCUs and fluid cokers, the operators shall measure the following parameters.

(A) The hourly catalyst regeneration rate.

(B) The weight fraction of carbon on the catalyst prior to and after catalyst regeneration.

(C) The number of hours of operation.

(b) Process vents. Operators shall measure the following parameters for each process vent.

(1) The vent flow rate for each venting event from measurement data, process knowledge or engineering estimates.

(2) The molar fraction of CO_2, N_2O, and CH_4 in the vent gas stream during each venting event from measurement data, process knowledge or engineering estimates.

(3) The duration of each venting event.

(c) Asphalt Production. Operators shall measure the mass of asphalt blown.

(d) Sulphur Recovery. The operator shall measure the volumetric flow rate of acid gas to the SRU. If using source specific molar fraction value that is based on measurements value instead of the default factor or engineering estimates, the person shall conduct an annual test of the molar fraction value.

(e) Flares and Other Control Devices. The operator shall measure the following:

(1) If you have a continuous flow monitor on the flare, you must use the measured flow rates when the monitor is operational and the flow rate is within the calibrated range of the

measurement device to calculate the flare gas flow. If you do not have a continuous flow monitor on the flare and for periods when the monitor is not operational or the flow rate is outside the calibrated range of the measurement device, you must use engineering calculations, company records, or similar estimates of volumetric flare gas flow.

(2) If using the method specified in WCI.203(e)(2)(A)(i), monitor the carbon content of the flare gas daily if the flare is already equipped with the necessary measurement devices (at least weekly if not).

(3) If using the method specified in WCI.203(e)(2)(A)(ii), monitor the high heat value of the flare gas daily if the flare is already equipped with the necessary measurement devices (at least weekly if not).

(f) Storage Tanks. The operator shall determine the annual throughput of crude oil, naphtha, distillate oil, asphalt, and gas oil for each storage tank using company record or applicable plant instruments.

(g) Wastewater Treatment. Operators shall measure the following parameters.

(1) You must collect samples representing wastewater influent to the anaerobic wastewater treatment process, following all preliminary and primary treatment steps (e.g., after grit removal, primary clarification, oil-water separation, dissolved air flotation, or similar solids and oil separation processes). You must collect and analyze samples for COD or BOD_5 concentration once each calendar week.

(2) You must measure the flowrate of wastewater entering anaerobic wastewater treatment process once each calendar week. The flow measurement location must correspond to the location used to collect samples analyzed for COD or BOD_5 concentration.

(3) The quarterly nitrogen content of the wastewater.

(h) Oil-Water Separators. Operators shall measure the daily volume of waste water treated by the oil-water separators .

(i) Coke Calcining. Determine the mass of petroleum coke as required using measurement equipment used for accounting purposes. Determine the carbon content of petroleum coke as using any one of the following methods:

(1) ASTM D3176-89 (Reapproved 2002) Standard Practice for Ultimate Analysis of Coal and Coke.

(2) ASTM D5291-02 (Reapproved 2007) Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants.

(3) ASTM D5373-08 Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal

§ WCI.205 Procedures for Estimating Missing Data.

A complete record of all measured parameters used in the GHG emissions calculations is required (e.g., concentrations, flow rates, fuel heating values, carbon content values). Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For stationary combustion sources, use the missing data procedures in WCI.20.
(b) For each missing value of the heat content, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the "after" value is not obtained by the end of the reporting year, you may use the "before" value for the missing data substitution. If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.
(c) For missing CO_2, CO, O_2, CH_4, or N_2O concentrations, gas flow rate, and percent moisture, the substitute data values shall be the best available estimate(s) of the parameter(s), based on all available process data (e.g., processing rates, operating hours, etc.). The owner or operator shall document and keep records of the procedures used for all such estimates.

§ WCI.206 Definitions

Except as specified in this section, all terms used in this subpart have the same meaning given in the General Provisions.

Unstabilized crude oil means crude oil that is pumped from the well to a pipeline or pressurized storage vessel for transport to the refinery without intermediate storage in a storage tank at atmospheric pressures. Unstabilized crude oil is characterized by having a true vapor pressure of 5 pounds per square inch absolute (psia) or greater.

Table 200-1. Coke burn rate material balance and conversion factors

	(kg min)/(hr dRm³%)	(lb min)/(hr dscf %)
K_1	0.2982	0.0186
K_2	2.0880	0.1303
K_3	0.0994	0.0062

Table 200-2. Default MCF Values for Industrial Wastewater

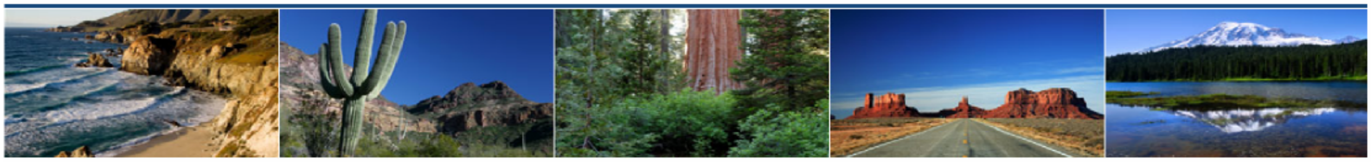
Type of Treatment and Discharge Pathway or System	Comments	MCF	Range
Untreated			
Sea, river and lake discharge	Rivers with high organic loading may turn anaerobic, however this is not considered here	0.1	0 - 0.2
Treated			
Aerobic treatment plant	Well maintained, some CH_4 may be emitted from settling basins	0	0 – 0.1
Aerobic treatment plant	Not well maintained, overloaded	0.3	0.2 – 0.4
Anaerobic digester for sludge	CH_4 recovery not considered here	0.8	0.8 – 1.0
Anaerobic reactor	CH_4 recovery not considered here	0.8	0.8 – 1.0
Anaerobic shallow lagoon	Depth less than 2 Meters	0.2	0 – 0.3
Anaerobic deep lagoon	Depth more than 2 Meters	0.8	0.8 – 1.0
For CH_4 generation capacity (B) in kg CH_4/kg COD, use default factor of 0.25 kg CH_4/kg COD.			

The emission factor for N_2O from discharged wastewater (EF_{N2O}) is 0.005 kg N_2O-N/kg-N. MCF = methane conversion factor (the fraction of waste treated anaerobically). COD = chemical oxygen demand (kg COD/m^3).

Table 200-3. Emission Factors for Oil/Water Separators

Separator Type	Emission factor (EF_{sep})[a] kg NMHC/m^3 wastewater treated
Gravity type - uncovered	1.11×10^{-1}
Gravity type - covered	3.30×10^{-3}
Gravity type – covered and connected to destruction device	0
DAF[b] or IAF[c] - uncovered	4.00×10^{-3}[d]
DAF or IAF - covered	1.20×10^{-04}[d]
DAF or IAF – covered and connected to a destruction device	0

[a] EFs do not include ethane
[b] DAF = dissolved air flotation type
[c] IAF = induced air flotation device
[d] EFs for these types of separators apply where they are installed as secondary treatment systems



§ WCI.210 PULP AND PAPER MANUFACTURING

§ WCI.211 Source Category Definition

The pulp and paper manufacturing source category consists of facilities that produce market pulp (i.e., stand-alone pulp facilities), manufacture pulp and paper (i.e., integrated facilities), produce paper products from purchased pulp, produce secondary fibre from recycled paper, convert paper into paperboard products (e.g., containers), or operate coating and laminating processes.

§ WCI.212 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions report must contain the following information:

(a) Annual CO_2, biogenic CO_2, CH_4, and N_2O process emissions from all recovery units and kilns combined in tonnes, as specified in WCI.213.

(b) Annual CO_2 emissions from addition of makeup chemicals ($CaCO_3$ and Na_2CO_3) in the chemical recovery areas of chemical pulp mills.

(c) CO_2, N_2O and CH_4 emissions from electricity generation units in tonnes, as specified in WCI.43. CO_2, N_2O, and CH_4 emissions from stationary combustion units in tonnes, as specified in WCI.23.

(d) Annual consumption of carbonate in tonnes.

(e) Annual black liquor production in tonnes.

(f) Annual CH_4 and N_2O emissions from onsite wastewater treatment plants in tonnes, as specified in WCI.200 (if required by regulation)

§ WCI.213 Calculation of GHG Emissions

Calculate emissions from each unit (i.e., kraft or soda chemical recovery furnace, sulfite chemical recovery combustion unit, stand-alone semichemical recovery combustion unit, or kraft or soda pulp mill lime kiln) as specified under paragraphs (a) through (d) of this section. CH_4 and N_2O emissions must be calculated as the sum of emissions from combustion of fossil fuels and combustion of biomass in spent liquor solids.

(a) Calculate fossil-fuel based CO_2 emissions from direct measurement of fossil fuels consumed and the methodology for stationary combustion sources specified by WCI.20, or the methodology for electricity generation specified by WCI.43, for the appropriate fuel type. For kraft or soda pulp mill lime kilns, if WCI.20 allows the use of default emission factors, use the default CO_2 emission factors listed in Table 210-1.

(b) Calculate fossil-fuel based CH_4 and N_2O emissions from direct measurement of fossil fuels consumed, default HHV, and default emission factors according to the methodology specified by WCI.20 or WCI.43. For kraft or soda pulp mill lime kilns, use the default CH_4 and N_2O emission factors listed in Table 210-1.

(c) Calculate biogenic CO_2 emissions and emissions of CH_4 and N_2O from biomass as specified under subparagraphs (1) through (3).

(1) For kraft or soda chemical recovery furnaces, calculate emissions using Equation 210-1:

$$Emissions = Solids \times HHV \times EF \qquad \textbf{Equation 210-1}$$

Where:

Emissions	=	Biogenic CO_2 emissions and emissions of CH_4 and N_2O from biomass (spent liquor solids) combustion (tonnes/year).
Solids	=	Mass of spent liquor solids combusted (tonnes/year).
HHV	=	Annual high heat value of spent liquor solids (GJ/kg).
EF	=	Default emission factor for CO_2, CH_4, and N_2O from Table 210-2 (kg/GJ)

(2) For sulfite or stand-alone semichemical chemical recovery combustion units, calculate CO_2 emissions using Equation 210-2:

$$E_{CO2} = 3.664 \times Solids \times CC \qquad \textbf{Equation 210-2}$$

Where:

E_{CO2}	=	Biogenic CO_2 emissions from spent liquor solids combustion (tonnes/year).
3.664	=	Ratio of molecular weights, CO_2 to carbon.
Solids	=	Mass of spent liquor solids combusted (tonnes/year).
CC	=	Annual carbon content of spent liquor solids (percent by weight, expressed as a decimal fraction).

(3) For sulfite or stand-alone semichemical chemical recovery combustion units, calculate emissions of CH_4 and N_2O from biomass using Equation 210-1.

(d) For make-up chemical use, calculate CO_2 emissions by using direct or indirect measurement of the quantity of chemicals added and ratios of the molecular weights of CO_2 and make-up chemicals using Equation 210-3:

$$CO_2 = \left(\left[M_{CaCO3} \times \frac{44}{100} \right] + \left[M_{Na2CO3} \times \frac{44}{105.99} \right] \right) \qquad \textbf{Equation 210-3}$$

Where:

CO_2	=	CO_2 emissions from make-up chemicals (tonnes/year).
M_{CaCO3}	=	Make-up quantity of $CaCO_3$ used for reporting year (tonnes/year).
M_{Na2CO3}	=	Make-up quantity of Na_2CO_3 used for reporting year (tonnes/year).
44	=	Molecular weight of CO_2.
100	=	Molecular weight of $CaCO_3$.
105.99	=	Molecular weight of Na_2CO_3.

§ WCI.214 Sampling, Analysis, and Measurement Requirements

At least annually, determine the following fuel properties. If measurements are performed more frequently than annually, then fuel properties must be based on the average of the representative measurements made during the year.

(a) Determine high heat values of black liquor using Technical Association of the Pulp and Paper Industry (TAPPI) T684 om-06 “Gross High Heating Value of Black Liquor”.

(b) Determine annual mass of spent liquor solids using one of the methods specified in subparagraph (1) or (2)

(1) Measure mass of annual spent liquor solids using TAPPI T650 om-05 “Solids Content of Black Liquor”.

(2) Determine mass of annual spent liquor solids based on records of measurements made with an online measurement system that determines the mass of spent liquor solids fired in a chemical recovery furnace or chemical recovery combustion unit. Measure the quantity of black liquor produced each month.

(c) Determine carbon content using ASTM D5373-08 “Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal”, or ASTM 5291 - Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants.

§ WCI.215 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required sample is not taken), a substitute data value for the missing parameter shall be used in the calculations, according to the requirements of paragraphs (a) through (c) of this section:

a) There are no missing data procedures for measurements of heat content and carbon content of spent pulping liquor. A re-test must be performed if the data from any annual measurements are determined to be invalid.
b) For missing measurements of the mass of spent liquor solids or spent pulping liquor flow rates, use the lesser value of either the maximum mass or fuel flow rate for the combustion unit, or the maximum mass or flow rate that the fuel meter can measure.
c) For the use of makeup chemicals ($CaCO_3$ and Na_2CO_3), the substitute data value shall be the best available estimate of makeup chemical consumption, based on available data (e.g., past accounting records, production rates). The owner or operator shall document and keep records of the procedures used for all such estimates.

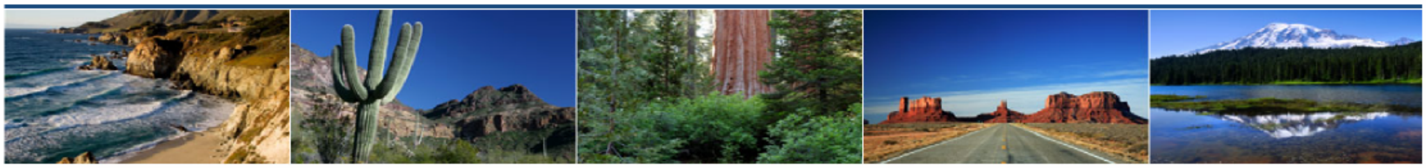
Table 210-1 . Kraft Lime Kiln and Calciner Emissions Factors for Fossil Fuel-Based CO_2, CH_4, and N_2O

Fuel	Fossil Fuel-Based Emissions Factors (kg/GJ HHV)					
	Kraft Lime Kilns			Kraft Calciners		
	CO_2	CH_4	N_2O	CO_2	CH_4	N_2O
Residual Oil	72.7	0.0026	0	72.7	0.0026	0.00028
Distillate Oil	69.7			69.7		0.00038
Natural Gas	53.1			53.1		0.00009
Biogas	0			0		0.00009

Table 210-2. Kraft Pulping Liquor Emissions Factors for Biomass-Based CO_2, CH_4, and N_2O

Wood Furnish	Biomass-Based Emissions Factors (kg/GJ HHV)		
	CO_2[a]	CH_4	N_2O
North American Softwood	89.5	0.028	0.0047
North American Hardwood	88.8		
Bagasse	90.5		
Bamboo	88.8		
Straw	90.2		

[a] Includes emissions from both the recovery furnace and pulp mill lime kiln.



§ WCI.220 SODA ASH MANUFACTURING

§ WCI.221 Source Category Definition

A soda ash manufacturing facility is any facility with a manufacturing line that produces soda ash by one of the methods in paragraphs (a) through (c) of this section:

(a) Calcining trona.

(b) Calcining sodium sesquicarbonate.

(c) Using a liquid alkaline feedstock process that directly produces CO_2.

In the context of the soda ash manufacturing sector, "calcining" means the thermal/chemical conversion of the bicarbonate fraction of the feedstock to sodium carbonate.

§ WCI.222 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, each annual report must contain the following information

(a) CO_2 process emissions from the soda ash manufacturing facility.

(b) CO_2, CH_4 and N_2O combustion emissions must be calculated and reported under WCI.20 (General Stationary Combustion) by following the requirements of WCI.20.

(c) If a CEMS is used to measure CO_2 emissions, then you must report under this method the relevant information required under WCI.23.

(d) Annual consumption of trona or liquid alkaline feedstock for each manufacturing line (tonnes).

(e) Annual production of soda ash (tonnes).

(f) Annual quantity of generated CO_2 recycled to carbonation towers (tonnes), if applicable.

(g) Number of times missing data procedures were used.

§ WCI.223 Calculation of Greenhouse Gas Emissions

Calculate and report the annual process CO_2 emissions from each soda ash manufacturing line using the procedures specified in paragraph (a) or (b) of this section.

(a) For each soda ash manufacturing line that meets the conditions specified in WCI.23(e), calculate and report under this method the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to Calculation Methodology 4 specified in WCI.23(d) and all associated requirements.

(b) For each soda ash manufacturing line that is not subject to the requirements in paragraph (a) of this section, calculate and report the process CO_2 emissions from the soda ash manufacturing line by using the procedure in either paragraphs (b)(1), (b)(2), or (b)(3) of this section; and the combustion CO_2 emissions using the procedure in paragraph (b)(4) of this section.

(1) Calculate and report under this method the combined process and combustion CO_2 emissions by operating and maintaining a CEMS to measure CO_2 emissions according to Calculation Methodology 4 specified in WCI.23(d) and all associated requirements for Calculation Method 4 in WCI.23(d) (General Stationary Combustion).

(2) Use either Equation 220-1 or Equation 220-2 of this section to calculate annual CO_2 process emissions from each manufacturing line that calcines trona to produce soda ash:

$$E_k = \sum_{n=1}^{12} [(IC_T)_n * (T_t)_n] * \frac{0.097}{1} \qquad \textbf{Equation 220-1}$$

$$E_k = \sum_{n=1}^{12} [(IC_{sa})_n * (T_{sa})_n] * \frac{0.138}{1} \qquad \textbf{Equation 220-2}$$

Where:

E_k = Annual CO_2 process emissions from each manufacturing line, *k* (tonnes).

$(IC_T)_n$ = Inorganic carbon content (percent by weight, expressed as a decimal fraction) in trona input, from the carbon analysis results for month *n*. This represents the ratio of trona to trona ore.

$(IC_{sa})_n$ = Inorganic carbon content(percent by weight, expressed as a decimal fraction) in soda ash output, from the carbon analysis results for month *n*. This represents the purity of the soda ash produced.

$(T_t)_n$ = Mass of trona input in month *n* (tonnes).

$(T_{sa})_n$ = Mass of soda ash output in month *n* (tonnes).

0.097/1 = Ratio of tonne of CO_2 emitted for each tonne of trona.

0.138/1 = Ratio of tonne of CO_2 emitted for each tonne of soda ash produced.

(3) Site-specific emission factor method. Use Equations 220-3, 220-4, and 220-5 of this section to determine annual CO_2 process emissions from manufacturing lines that use the liquid alkaline feedstock process to produce soda ash. You must conduct an annual performance test and measure CO_2 emissions and flow rates at all process vents from the mine water stripper/evaporator for each manufacturing line and calculate CO_2 emissions as described in paragraphs (b)(3)(i) through (b)(3)(iv) of this section.

(i) During the performance test, you must measure the process vent flow from each process vent during the test and calculate the average rate for the test period in tonnes per hour.

(ii) Using the test data, you must calculate the hourly CO_2 emission rate using Equation 220-3 of this section:

$$ER_{CO2} = [(C_{co2} * 10000) * 4.16 \times 10^{-8} * 44] * (Q * 60) * 0.001 \quad \textbf{Equation 220-3}$$

Where:

ER_{CO2}	=	CO_2 mass emission rate (tonnes/hour).
C_{CO2}	=	Hourly CO_2 concentration (per cent CO_2) as determined by WCI.224(c).
10000	=	Conversion factor from per cent to parts per million
4.16×10^{-8}	=	Conversion factor from ppm to kg-mole/dsm^3 (kg-mole/dsm^3/ppm).
44	=	kg per kg-mole of carbon dioxide.
Q	=	Stack gas volumetric flow rate per minute (dsm^3 per minute).
60	=	Minutes per hour
0.001	=	Conversion factor from kg to tonnes (tonnes/kg)

(iii) Using the test data, you must calculate a CO_2 emission factor for the process using Equation 220-4 of this section:

$$EF_{CO2} = \frac{ER_{CO2}}{V_t} \quad \textbf{Equation 220-4}$$

Where:

EF_{CO2}	=	CO_2 emission factor (tonnes CO_2/tonne of process vent flow from mine water stripper/evaporator).
ER_{CO2}	=	CO_2 mass emission rate (tonnes/hour).
V_t	=	Process vent mass flow rate from mine water stripper/evaporator during annual performance test (tonnes/hour).

(iv) Calculate annual CO_2 process emissions from each manufacturing line using Equation 220-5 of this section:

$$E_k = EF_{CO2} * V_a * H \quad \textbf{Equation 220-5}$$

Where:

E_k	=	Annual CO_2 process emissions for each manufacturing line, *k* (tonnes).
EF_{CO2}	=	CO_2 emission factor (tonnes CO_2/tonne of process vent flow from mine water stripper/evaporator).

V_a = Annual process vent mass flow rate from mine water stripper/evaporator (tonnes/hour).

H = Annual operating hours for the each manufacturing line.

(4) Calculate and report under WCI.20 (General Stationary Fuel Combustion Sources) the combustion CO_2, CH_4, and N_2O emissions in the soda ash manufacturing line according to the applicable requirements of WCI.20.

§ WCI.224 Sampling, Analysis, and Measurement Requirements

Section WCI.223 provides four different procedures for emission calculations. The appropriate paragraphs (a) through (d) of this section should be used for the procedure chosen.

(a) If you determine your emissions using WCI.223 (b)(2), Equation 220-1 of this subpart you must:

(1) Determine the monthly inorganic carbon content of the trona from a weekly composite analysis for each soda ash manufacturing line, using a modified version of ASTM E359-00(Reapproved 2005)e1, Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate). ASTM E359-00(Reapproved 2005)e1 is designed to measure the total alkalinity in soda ash, not in trona. The modified method of ASTM E359-00 adjusts the regular ASTM method to express the results in terms of trona. Although ASTM E359-00(Reapproved 2005)e1 uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of trona input produced by each soda ash manufacturing line on a monthly basis using belt scales or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of trona consumed.

(b) If you calculate CO_2 process emissions based on soda ash production using WCI.223(b)(2), Equation 220-2 of this subpart, you must:

(1) Determine the inorganic carbon content of the soda ash (i.e., soda ash purity) using ASTM E359-00(Reapproved 2005)e1 Standard Test Methods for Analysis of Soda Ash (Sodium Carbonate). Although ASTM E359-00(Reapproved 2005) uses manual titration, suitable autotitrators may also be used for this determination.

(2) Measure the mass of soda ash produced by each soda ash manufacturing line on a monthly basis using belt scales, by weighing the soda ash at the truck or rail load out points of your facility, or methods used for accounting purposes.

(3) Document the procedures used to ensure the accuracy of the monthly measurements of soda ash produced.

(c) If you calculate CO_2 emissions using the site-specific emission factor method in WCI.223(b)(3), you must:

(1) Conduct an annual performance test that is based on representative performance (i.e., performance based on normal operating conditions) of the affected process.

(2) Sample the stack gas and conduct three emissions test runs of 1 hour each.

(3) Conduct the stack test using EPA Method 3A at 40 CFR part 60, appendix A-2 to measure the CO2 concentration; and Method 2, 2A, 2C, 2D, or 2F at 40 CFR part 60, appendix A-1 or Method 26 at 40 CFR part 60, appendix A-2 to determine the stack gas volumetric flow rate. All QA/QC procedures specified in the reference test methods and any associated performance specifications apply. For each test, the facility must prepare an emission factor determination report that must include the items in paragraphs (c)(3)(i) through (c)(3)(iii) of this section.

(i) Analysis of samples, determination of emissions, and raw data.

(ii) All information and data used to derive the emissions factor(s).

(iii) You must determine the average process vent flow rate from the mine water stripper/evaporator during each test and document how it was determined.

(4) You must also determine the annual vent flow rate from the mine water stripper/evaporator from monthly information using the same plant instruments or procedures used for accounting purposes (i.e., volumetric flow meter).

WCI.225 Procedures for Estimating Missing Data

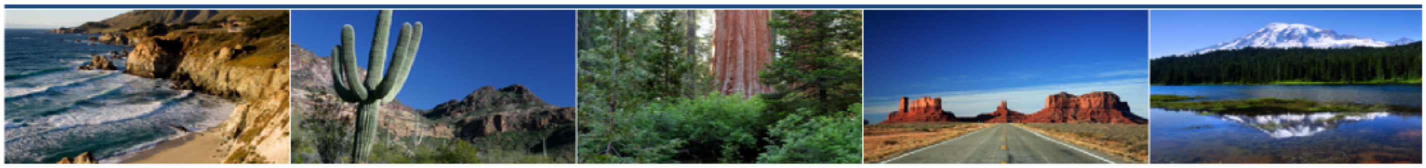
For the emission calculation methodologies in WCI.223(b)(2)and (b)(3), a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., inorganic carbon content values, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in the paragraphs (a) through (d) of this section. You must document and keep records of the procedures used for all such missing value estimates.

(a) For each missing value of the weekly composite of inorganic carbon content of either soda ash or trona, the substitute data value shall be the arithmetic average of the quality-assured values of inorganic carbon contents from the week immediately preceding and the week immediately following the missing data incident. If no quality-assured data on inorganic carbon contents are available prior to the missing data incident, the substitute data value shall be the first quality-assured value for carbon contents obtained after the missing data period.

(b) For each missing value of either the monthly soda ash production or the trona consumption, the substitute data value shall be the best available estimate(s) of the parameter(s), based on all available process data or data used for accounting purposes.

(c) For each missing value collected during the performance test (hourly CO_2 concentration, stack gas volumetric flow rate, or average process vent flow from mine water stripper/evaporator during performance test), you must repeat the annual performance test following the calculation and monitoring and QA/QC requirements under WCI.223(b)(3) and WCI.224(c).

(d) For each missing value of the monthly process vent flow rate from mine water stripper/evaporator, the substitute data value shall be the best available estimate(s) of the parameter(s), based on all available process data or the lesser of the maximum capacity of the system or the maximum rate the meter can measure.



§ WCI.230 ELECTRICITY TRANSMISSION (AND EMISSIONS FROM ELECTRICAL EQUIPMENT IN ELECTRICITY GENERATION)

§ WCI.231 Source Category Definition

Sulfur hexafluoride (SF_6) and perfluorocarbons (PFCs) are used as gaseous dielectric mediums for electric power distribution equipment, including transmission and distribution systems, substations, high-voltage circuit breakers, switches, and other electrical equipment. This category includes fugitive emissions from equipment that is located at a facility that the operator is responsible for maintaining in proper working order.

§ WCI.232 Greenhouse Gas Reporting Requirements

For each facility, the emissions data report shall include the following information:

(a) Annual greenhouse gas emissions in tonnes, reported as follows:

(1) Fugitive SF_6 emitted from equipment.

(2) Fugitive PFCs emitted from equipment

§ WCI.233 Calculation of SF_6 Emissions

SF_6 emissions must be calculated using either a mass-balance or direct measurement approach. Section (a) describes the mass balance approach; section (b) describes the direct measurement approach.

(a) Mass Balance Approach.

(1) Calculate the annual SF_6 emissions using a mass balance approach that tracks and systematically accounts for all operator uses of SF_6, as follows. Any quantity of SF_6 that cannot be accounted for is then assumed to have been emitted into the atmosphere.

(2) Calculate the change in inventory of SF_6 in storage using Equation 230-1.

$$\Delta S_{Inv} = S_{Inv-Begin} - S_{Inv-End} \qquad \textbf{Equation 230-1}$$

Where:

ΔS_{Inv} = Change in inventory of SF_6 in storage, kilograms ("Storage" includes cylinders, gas carts, and other storage containers, but excludes equipment. Value will be negative if quantity of SF_6 increases during the year);

$S_{Inv-Begin}$ = Quantity of SF_6 in storage at the beginning of the year, kilograms;

$S_{Inv-End}$ = Quantity of SF_6 in storage at the end of the year, kilograms.

(3) Calculate the sum of all SF_6 acquired from other entities during the year either in storage containers or in equipment using Equation 230-2.

Equation 230-2

$$S_{PA} = S_{Cyl} + S_{Equip} + S_{\mathrm{Re}cyc-ret}$$

Where:

S_{PA} = Sum of all SF_6 acquired from other entities during the year either in storage containers or in equipment, kilograms;

S_{Cyl} = Quantity of SF_6 purchased from producers or distributors in cylinders, kilograms;

S_{Equip} = Quantity of SF_6 provided by equipment manufacturers with/inside equipment, kilograms;

$S_{Recyc-ret}$ = Quantity of SF_6 returned to site after off-site recycling, kilograms.

(4) Calculate the sum of all SF_6 sold or otherwise disbursed during the year either in storage containers or in equipment using Equation 230-3.

$$S_{SD} = S_{Sales} + S_{\mathrm{Re}turns} + S_{Destruct} + S_{\mathrm{Re}cyc-off}$$ **Equation 230-3**

Where:

S_{SD} = Sum of all SF_6 sold or otherwise disbursed during the year either in storage containers or in equipment, kilograms;

S_{Sales} = Quantity of SF_6 sold to other entities (including gas left in equipment that is sold), kilograms;

$S_{Returns}$ = Quantity of SF_6 returned to suppliers, kilograms;

$S_{Destruct}$ = Quantity of SF_6 sent to destruction facilities, kilograms;

$S_{Recyc-off}$ = Quantity of SF_6 sent off-site for recycling, kilograms.

(5) Calculate the net increase in nameplate capacity of equipment using Equation 230-4.

$$\Delta S_{Cap} = S_{Cap-new} - S_{Cap-retire}$$

Equation 230-4

Where:

ΔS_{Cap} = Net increase in total nameplate capacity of equipment using SF_6 in storage, kilograms ("Total nameplate capacity" refers to the full and proper charge of the equipment rather than to the actual charge, which may reflect leakage.);

$S_{Cap-new}$ = Total nameplate capacity (proper full charge) of new equipment, kilograms;

$S_{Cap-retire}$ = Total nameplate capacity (proper full charge) of retired or sold equipment, kilograms.

(6) Calculate total annual emissions using Equation 230-5.

$$S = \left(\Delta S_{Inv} + S_{PA} - S_{SD} - \Delta S_{Cap} \right) / 1{,}000 \qquad \textbf{Equation 230-5}$$

Where:

S	=	Annual SF_6 emissions, tonnes;
ΔS_{Inv}	=	Change in inventory of SF_6 in storage, kilograms ("Storage" includes cylinders, gas carts, and other storage containers, but excludes equipment. Value will be negative if quantity of SF_6 increases during the year);
S_{PA}	=	Sum of all SF_6 acquired during the year either in storage containers or in equipment, kilograms;
S_{SD}	=	Sum of all SF_6 sold or otherwise disbursed during the year either in storage containers or in equipment, kilograms;
ΔS_{Cap}	=	Net increase in total nameplate capacity of equipment using SF_6 in storage, kilograms ("Total nameplate capacity" refers to the full and proper charge of the equipment rather than to the actual charge, which may reflect leakage.);
1,000	=	Factor to convert kilograms to tonnes.

(b) Direct Measurement Approach.

SF_6 emissions are estimated by directly measuring the mass of SF_6 added to electrical equipment during operation (operation phase) and the amount of SF_6 collected from any decommissioned equipment (decommissioning phase).

In the operation phase, SF_6 added to equipment can be measured using one of two methods: automated mass-flow measurement or weigh-scale measurement. In automated mass-flow measurement, mass-flow meters attached to electrical equipment directly measure the amount of SF_6 added to equipment. In weigh-scale measurement, an SF_6 cylinder is measured before and after its contents are added to electrical equipment with the difference being equal to the SF_6 added to the equipment. Annual SF_6 emissions for both methods are calculated according to Equation 230-6.

$$S_O = \sum_{i}^{N} s_i \qquad \textbf{Equation 230-6}$$

Where:

S_O	=	Annual SF_6 emissions during operation phase, kilograms;
N	=	Number of SF_6 additions in a given year;
s_i	=	SF_6 added to equipment during addition *i*, kilograms.

Annual SF_6 emissions during the decommissioning phase are calculated according to Equation 230-7.

$$S_D = \sum_{i}^{N}(NC_i - S_i)$$

Equation 230-7

Where:

S_D = Annual SF_6 emissions during decommissioning phase, kilograms;

N = Number of equipment decommissioned in a given year;

NC_i = Nameplate capacity of decommissioned equipment *i*, kilograms;

S_i = SF_6 collected from decommissioned equipment *i*, kilograms.

Total annual SF_6 emissions are calculated as the sum of SF_6 emissions from equipment operation and decommissioning, according to Equation 230-8.

$$S = \frac{S_O + S_D}{1,000}$$

Equation 230-8

Where:

S = Annual SF_6 emissions, tonnes;
S_O = Annual SF_6 emissions during operation phase, kilograms;
S_D = Annual SF_6 emissions during decommissioning phase, kilograms.

(c) The methods in either paragraph (a) or (b) of this section shall be used to estimate emissions of PFCs from power transformers, substituting the relevant PFC(s) for SF_6 in Equations 230-1 through 230-8.

§ WCI.234 Sampling, Analysis, and Measurement Requirements

Calibration of equipment used to measure the mass of SF_6 or PFCs used for top-ups to electrical equipment must be conducted as specified in paragraphs (a) and (b) of this section.

a) For automated mass-flow measurement, equipment must be calibrated according to regulation.

b) For weigh-scale measurement, equipment must be calibrated every 6 months by weighing objects of pre-determined mass and zeroing the weigh scale accordingly.

§ WCI.235 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Replace missing data, if needed, based on data from equipment with a similar nameplate capacity for SF_6 and PFCs, and from similar equipment repair, replacement, and maintenance operations.

§ WCI.240 ZINC PRODUCTION

§ WCI.241 Source Category Definition

The zinc production category includes three primary production processes used to produce zinc (i.e., electro-thermic distillation, pyrometallurgical, and electrolytic). In addition, secondary zinc production is also included in this category.

§ WCI.242 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of CO_2 at the facility level (tonnes).

(b) Annual quantities of each carbon-containing input material used (tonnes).

(c) Carbon content of each carbon-containing input material used (tonnes C/ tonne reducing agent).

(d) Inferred waste-based carbon-containing material emission factor (if waste-based reducing agent quantification method used).

(e) If you use the missing data procedures in WCI.245(b), you must report how the monthly mass of carbon-containing materials with missing data was determined and the number of months the missing data procedures were used.

(f) CO_2, CH_4, and N_2O emissions from each stationary fuel combustion unit. You must report these emissions under WCI.20 (General Stationary Fuel Combustion Sources), by following the requirements of WCI.20.

§ WCI.243 Calculation of CO_2 Emissions

Calculate total CO_2 emissions as specified under paragraph (a) or (b) of this section.

(a) Determine facility CO_2 emissions using continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(b) Calculate total CO_2 emissions using Equation 240-1. Specific materials that in aggregate contribute less than 0.5% of the total carbon into the process may be excluded from the calculation performed using Equation 240-1.

$$E_{CO_2} = \sum_i (Q_i \times C_i) \times 3.664 \qquad \textbf{Equation 240-1}$$

Where:

E_{CO2} = Annual CO_2 emissions from carbon-containing materials (tonnes);

Q_i = Annual quantity of carbon-containing material *i* (tonnes);

C_i = Carbon content of carbon-containing material *i* (tonnes C/ tonne process input);

3.664 = Stoichiometric conversion factor from C to CO_2.

§ WCI.244 Sampling, Analysis, and Measurement Requirements

The annual mass of each solid carbon-containing input material consumed shall be determined by summing the monthly mass for the material determined for each month of the calendar year. The monthly mass may be determined using facility instruments, procedures, or records used for accounting purposes, including either direct measurement of the quantity of the material consumed or by calculations using process operating information.

The average carbon content of each material consumed shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For zinc-bearing materials, use ASTM E1941-04 "Standard Test Method for Determination of Carbon in Refractory and Reactive Metals and Their Alloys".
(2) For carbonaceous reducing agents and carbon electrodes, use ASTM D5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal".
(3) For flux materials (i.e., limestone or dolomite), use ASTM C25-06 "Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime".
(4) For waste-based carbon-containing material, determine carbon content by operating the smelting furnace both with and without the waste-reducing agents while keeping the composition of other material introduced constant.
    i. To ensure representativeness of waste-based reducing agent variability, the specific testing plan (e.g. number of test runs, other process variables to keep constant, timing of runs) for these trials must be approved by the jurisdiction.

(b) Obtain carbon content from material vendor or supplier.

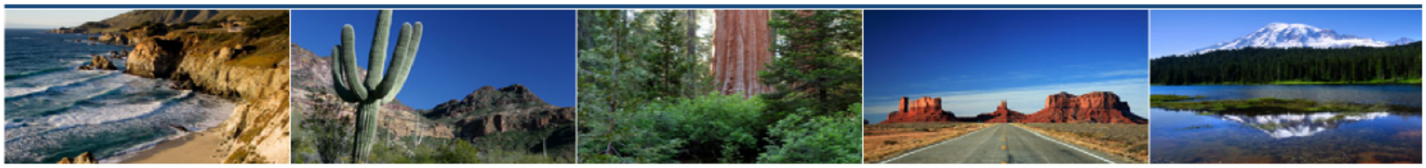
§ WCI.245 Procedures for Estimating Missing Data

For the carbon input procedure in WCI.243, a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., raw materials carbon content values, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing records of the carbon content of inputs for facilities that estimate emissions using the carbon input procedure in WCI.243; 100 percent data availability is required.

You must repeat the test for average carbon contents of inputs according to the procedures in WCI.245(b) if data are missing.

(b) For missing records of the annual mass of carbon-containing inputs using the carbon input procedure in WCI.243, the substitute data value must be based on the best available estimate of the mass of the input material from all available process data or information used for accounting purposes, such as purchase records.



§ WCI.250 UNDERGROUND COAL MINES

§ WCI.251 Source Category Definition

The underground coal mine source category consists of active underground coal mines, and any underground mines under development that have operational pre-mining degasification systems. An underground coal mine is a mine at which coal is produced by tunneling into the earth to the coalbed, which is then mined with underground mining equipment such as cutting machines and continuous, longwall, and shortwall mining machines, and transported to the surface.

(a) Underground coal mines are categorized as active if any one of the following five conditions apply:

   (1) Mine development is underway.

   (2) Coal has been produced within the last 90 days.

   (3) Mine personnel are present in the mine workings.

   (4) Mine ventilation fans are operative.

   (5) The mine operates on an intermittent basis.

(b) The underground coal mine source category includes the following:

   (1) Each ventilation well or shaft, including both those wells and shafts where gas is emitted and those where gas is sold, used onsite, or otherwise destroyed (including by flaring).

   (2) Each degasification system well or shaft, including degasification systems deployed before, during, or after mining operations are conducted in a mine area. This includes both those wells and shafts where gas is emitted, and those where gas is sold, used onsite, or otherwise destroyed (including by flaring).

(c) The underground coal mine source category does not include abandoned or closed mines, surface coal mines, or post-coal mining activities (i.e., storage or transportation of coal).

§ WCI.252 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Quarterly CH_4 destruction at all ventilation and degasification system destruction devices or point of offsite transport (tonnes CH_4).

(b) Quarterly CH_4 emissions (net) from all ventilation and degasification systems (tonnes CH_4).

(c) Quarterly CO_2 emissions from onsite destruction of coal mine gas CH_4, where the gas is not a fuel input for energy generation or use (e.g., flaring) (tonnes CO_2).

§ WCI.253 Calculation of GHG Emissions

(a) For each ventilation shaft, vent hole, or centralized point into which CH_4 from multiple shafts and/or vent holes are collected, calculate the quarterly CH_4 liberated from the ventilation system using Equation 250-1 of this section. Measure CH_4 content, flow rate, temperature, pressure, and moisture content of the gas using the procedures outlined in WCI.254.

$$CH_{4V} = n \times \left(V \times MCF \times \frac{C}{100\%} \times 0.6775 \times \frac{288.71K}{T} \times \frac{P}{1\ atm} \times 1{,}440 \right)$$

Equation 250-1

Where:

CH_{4V}	=	Quarterly CH_4 liberated from a ventilation monitoring point (tonnes CH_4);
V	=	Daily volumetric flow rate for the quarter (cubic meters) based on sampling or a flow rate meter. If a flow rate meter is used and the meter automatically corrects for temperature and pressure, replace "288.71K/T × P/1 atm" with "1";
MCF	=	Moisture correction factor for the measurement period, volumetric basis;
	=	1 when V and C are measured on a dry basis or if both are measured on a wet basis.
	=	1 - $(f_{H2O})_n$ when V is measured on a wet basis and C is measured on a dry basis.
	=	$1/[1-(f_{H2O})]$ when V is measured on a dry basis and C is measured on a wet basis.
(f_{H2O})	=	Moisture content of the CH_4 emitted during the measurement period, volumetric basis (cubic meter water per cubic meter emitted gas);
C	=	Daily CH_4 concentration of ventilation gas for the quarter (%, wet basis);
n	=	Number of days in the quarter where active ventilation of mining operations is taking place at the monitoring point;
0.6775	=	Density of CH_4 at 288.71 K (15.56 °C) and 1 atm (kg/m^3);
288.71K	=	288.71 Kelvin;
T	=	Temperature at which flow is measured (K) for the quarter;
P	=	Pressure at which flow is measured (atm); and
1,440	=	Conversion factor (min/day).

(1) Unless required to be modified to meet existing regulatory inspection schedules, the quarterly periods are:

(i) January 1 – March 31.

(ii) April 1 – June 30.

(iii) July 1 – September 30.

(iv) October 1 – December 31.

(2) Daily values of V, MCF, C, T, and P must be based on measurements taken at least once each quarter with no fewer than 6 weeks between measurements. If measurements are taken more frequently than once per quarter, then use the average value for all

measurements taken. If continuous measurements are taken, then use the average value over the time period of continuous monitoring.

(3) If a facility has more than one monitoring point, the facility must calculate total CH4 liberated from ventilation systems ($CH_{4VTotal}$) as the sum of the CH_4 from all ventilation monitoring points in the mine, as follows in Equation 250-2:

$$CH_{4VTotal} = \sum_{i=1}^{m} (CH_{4V})_i$$

Equation 250-2

Where:

$CH_{4VTotal}$	=	Total quarterly CH_4 liberated from ventilation systems (tonnes CH_4);
CH_{4V}	=	Quarterly CH_4 liberated from each ventilation monitoring point (tonnes CH_4); and
m	=	Number of ventilation monitoring points.

(b) For each monitoring point in the degasification system (this could be at each degasification well and/or vent hole, or at more centralized points into which CH_4 from multiple wells and/or vent holes are collected), calculate the weekly CH_4 liberated from the mine using CH_4 measured weekly or more frequently (including by CEMS) according to WCI.254(c), CH_4 content, flow rate, temperature, pressure, and moisture content, and Equation 250-3 of this section.

$$CH_{4D} = \sum_{i=1}^{n} \left(V_i \times MCF_i \times \frac{C_i}{100\%} \times 0.6775 \times \frac{288.71K}{T_i} \times \frac{P_i}{1\,atm} \times 1{,}440 \right)$$

Equation 250-3

Where:

CH_{4D}	=	Weekly CH_4 liberated from a monitoring point (tonnes CH_4);
V_i	=	Daily measured total volumetric flow rate for the days in the week when the degasification system is in operation at that monitoring point, based on sampling or a flow rate meter (cubic meters). If a flow rate meter is used and the meter automatically corrects for temperature and pressure, replace“288.71K/T × P/1 atm” with “1”;
MCF_i	=	Moisture correction factor for the measurement period, volumetric basis;
	=	1 when V_i and C_i are measured on a dry basis or if both are measured on a wet basis.
	=	$1-(f_{H2O})_i$ when V_i is measured on a wet basis and C_i is measured on a dry basis.
	=	$1/[1-(f_{H2O})_i]$ when V_i is measured on a dry basis and C_i is measured on a wet basis.
$(f_{H2O})_i$	=	Moisture content of the CH_4 emitted during the measurement period, volumetric basis (cubic meter water per cubic meter emitted gas);

C_i	=	Daily CH_4 concentration of gas for the days in the week when the degasification system is in operation at that monitoring point (%, wet basis);
n	=	Number of days in the week that the system is operational at that measurement point.
0.6775	=	Density of CH_4 at 288.71 K (15.56 °C) and 1 atm (kg/m^3);
288.71K	=	288.71 Kelvin;
T_i	=	Daily temperature at which flow is measured (K);
P_i	=	Daily pressure at which flow is measured (atm); and
1,440	=	Conversion factor (min/day).

(1) Daily values for V, MCF, C, T, and P must be based on measurements taken at least once each calendar week with at least 3 days between measurements. If measurements are taken more frequently than once per week, then use the average value for all measurements taken that week. If continuous measurements are taken, then use the average values over the time period of continuous monitoring when the continuous monitoring equipment is properly functioning.

(2) Quarterly total CH_4 liberated from degasification systems for the mine should be determined as the sum of CH_4 liberated determined at each of the monitoring points in the mine, summed over the number of weeks in the quarter, as follows in Equation 250-4:

$$CH_{4DTotal} = \sum_{i=1}^{m} \sum_{j=1}^{w} \left(CH_{4D}\right)_{i,j}$$

Equation 250-4

Where: :

$CH_{4DTotal}$	=	Quarterly CH_4 liberated from all degasification monitoring points (tonnes CH_4);
CH_{4D}	=	Weekly CH_4 liberated from a degasification monitoring point (tonnes CH_4);
m	=	Number of monitoring points; and
w	=	Number of weeks in the quarter during which the degasification system is operated.

(c) If gas from degasification system wells or ventilation shafts is sold, used onsite, or otherwise destroyed (including by flaring), calculate the quarterly CH_4 destroyed for each destruction device and each point of offsite transport to a destruction device, using Equation 250-5 of this section. You must measure CH_4 content and flow rate according to the provisions in WCI.254.

$$CH_{4Destroyed} = CH_4 \times DE$$

Equation 250-5

Where:

$CH_{4Destroyed}$	=	Quarterly CH_4 destroyed (tonnes);
CH_4	=	Quarterly CH_4 routed to the destruction device or offsite transfer point (tonnes); and

DE	=	Destruction efficiency (lesser of manufacturer's specified destruction efficiency and 0.99). If the gas is transported off-site for destruction, use DE = 1.

(d) Calculate total CH_4 destroyed as the sum of the methane destroyed at all destruction devices (onsite and offsite), using Equation 250-6 of this section.

$$CH_{4DestroyedTotal} = \sum_{i=1}^{d} \left(CH_{4Destroyed} \right)_d$$

Equation 250-6

Where:

$CH_{4DestroyedTotal}$	=	Quarterly total CH_4 destroyed at the mine (tonnes CH_4);
$CH_{4Destroyed}$	=	Quarterly CH_4 destroyed from each destruction device or offsite transfer point; and
d	=	Number of onsite destruction devices and points of offsite transport.

(e) Calculate the quarterly measured net CH4 emissions to the atmosphere using Equation 250-7 of this section.

$$CH_{emitted\,(net)} = CH_{4VTotal} + CH_{4DTotal} - CH_{4DestroyedTotal}$$

Equation 250-7

Where:

$CH_{4emitted\,(net)}$	=	Quarterly CH_4 emissions from the mine (tonnes).
$CH_{4VTotal}$	=	Quarterly sum of the CH_4 liberated from all mine ventilation monitoring points (CH_{4V}), calculated using Equation 250-2 of this section (tonnes).
$CH_{4DTotal}$	=	Quarterly sum of the CH_4 liberated from all mine degasification monitoring points (CH_{4D}), calculated using Equation 250-4 of this section (tonnes).
$CH_{4DestroyedTotal}$	=	Quarterly sum of the measured CH_4 destroyed from all mine ventilation and degasification systems, calculated using Equation 250-6 of this section (tonnes).

(f) For the methane collected from degasification and/or ventilation systems that is destroyed on site and is not a fuel input for energy generation or use (those emissions are monitored and reported under WCI.20), estimate the CO_2 emissions using Equation 250-8 of this section.

$$CO_2 = CH_{4Destroyed\ on\ site} \times \left(\frac{44}{16} \right)$$

Equation 250-8

Where:

CO_2	=	Total quarterly CO_2 emissions from CH_4 destruction (tonnes);
$CH_{4Destroyedonsite}$	=	Quarterly sum of the CH_4 destroyed, calculated as the sum of CH_4 destroyed for each onsite, non-energy use, as calculated individually in Equation 250-5 of this section (tonnes); and
44/16	=	Ratio of molecular weights of CO_2 to CH_4.

§ WCI.254 Sampling, Analysis, and Measurement Requirements

Emissions may be estimated by monitoring as specified under paragraphs (a) through (g).

(a) For CH_4 liberated from ventilation systems, CH_4 must be monitored from each ventilation well and shaft, from a centralized monitoring point, or from a combination of the two options. Operators are allowed flexibility for aggregating emissions from more than one ventilation well or shaft, as long as emissions from all are addressed, and the methodology for calculating total emissions documented. Monitor using one of the following options:

(1) Collect quarterly or more frequent grab samples (with no fewer than 6 weeks between measurements) and make quarterly measurements of flow rate, temperature, and pressure. The sampling and measurements must be made at the same locations as MSHA inspection samples are taken (or appropriate equivalent in Canada), and should be taken when the mine is operating under normal conditions. Follow MSHA sampling procedures as set forth in the MSHA Handbook "General Coal Mine Inspection Procedures and Inspection Tracking System Handbook Number PH–08–V–1", January 1, 2008 or appropriate equivalent in Canada. Record the date of sampling, airflow, temperature, and pressure measured, the hand-held methane and oxygen readings (percent), the bottle number of samples collected, and the location of the measurement or collection.

(2) Obtain results of the quarterly (or more frequent) testing performed by appropriate equivalent to MSHA in Canada (if any).

(3) Monitor emissions through the use of one or more continuous emission monitoring systems (CEMS). If operators use CEMS as the basis for emissions reporting, they must provide documentation on the process for using data obtained from their CEMS to estimate emissions from their mine ventilation systems.

(b) For CH_4 liberated at degasification systems, CH_4 must be monitored from each well and gob gas vent hole, from a centralized monitoring point, or from a combination of the two options. Operators are allowed flexibility for aggregating emissions from more than one well or gob gas vent hole, as long as emissions from all are addressed, and the methodology for calculating total emissions documented. Monitor both gas volume and methane concentration by one of the following two options:

(1) Monitor emissions through the use of one or more continuous emissions monitoring systems (CEMS).

(2) Collect weekly (once each calendar week, with at least three days between measurements) or more frequent samples, for all degasification wells and gob gas vent

holes. Determine weekly or more frequent flow rates and methane composition from these degasification wells and gob gas vent holes. Methane composition should be determined either by submitting samples to a lab for analysis, or from the use of methanometers at the degasification well site. Follow the sampling protocols for sampling of methane emissions from ventilation shafts, as described in WCI.254(a)(1).

(c) Monitoring must adhere to one of the following standards:

(1) ASTM D1945–03 "Standard Test Method for Analysis of Natural Gas by Gas Chromatography"

(2) ASTM D1946–90 (Reapproved 2006) "Standard Practice for Analysis of Reformed Gas by Gas Chromatography"

(3) ASTM D4891–89 (Reapproved 2006) "Standard Test Method for Heating Value of Gases in Natural Gas Range by Stoichiometric Combustion"

(4) ASTM UOP539–97 "Refinery Gas Analysis by Gas Chromatography"

(d) All fuel flow meters, gas composition monitors, and heating value monitors that are used to provide data for the GHG emissions calculations shall be calibrated prior to the first reporting year, using the applicable methods specified in paragraphs (d)(1) through (7) of this section. Alternatively, calibration procedures specified by the flow meter manufacturer may be used. Fuel flow meters, gas composition monitors, and heating value monitors shall be recalibrated either annually or at the minimum frequency specified by the manufacturer, whichever is more frequent. For fuel, flare, or sour gas flow meters, the operator shall operate, maintain, and calibrate the flow meter using any of the following test methods or follow the procedures specified by the flow meter manufacturer. Flow meters must meet the accuracy requirements specified by regulation in the jurisdiction.

(1) ASME MFC–3M–2004 "Measurement of Fluid Flow in Pipes Using Orifice, Nozzle, and Venturi"

(2) ASME MFC–4M–1986 (Reaffirmed 1997) "Measurement of Gas Flow by Turbine Meters"

(3) ASME MFC–6M–1998 "Measurement of Fluid Flow in Pipes Using Vortex Flowmeters"

(4) ASME MFC–7M–1987 (Reaffirmed 1992) "Measurement of Gas Flow by Means of Critical Flow Venturi Nozzles"

(5) ASME MFC–11M–2006 "Measurement of Fluid Flow by Means of Coriolis Mass Flowmeters"

(6) ASME MFC–14M–2003 "Measurement of Fluid Flow Using Small Bore Precision Orifice Meters"

(7) ASME MFC–18M–2001 "Measurement of Fluid Flow using Variable Area Meters"

(e) For CH_4 destruction, CH_4 must be monitored at each onsite destruction device and each point of offsite transport for combustion using continuous monitors of gas routed to the device or point of offsite transport.

(f) All temperature and pressure monitors must be calibrated using the procedures and frequencies specified by the manufacturer.

(g) If applicable, the owner or operator shall document the procedures used to ensure the accuracy of gas flow rate, gas composition, temperature, and pressure measurements. These procedures include, but are not limited to, calibration of fuel flow meters, and other measurement devices. The estimated accuracy of measurements, and the technical basis for the estimated accuracy shall be recorded.

§ WCI.255 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable (e.g., if a meter malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations, in accordance with the following.

(a) For each missing value of CH_4 concentration, flow rate, temperature, and pressure for ventilation and degasification systems, the substitute data value shall be the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

§ WCI.260 NICKEL AND COPPER METAL PRODUCTION

§ WCI.261 Source Category Definition

The nickel and copper metal production category includes process-related sources at nickel and copper metal smelting and refining facilities. Metals addressed in other categories (i.e., iron and steel, ferroalloys, aluminum, magnesium, lead, and zinc) are not included in this category.

The nickel and copper metal production category includes three main processes that produce CO_2 emissions: removal of impurities from nickel or copper ore concentrate using carbonate flux reagents (i.e., limestone [$CaCO_3$] or dolomite [$CaCO_3 \cdot MgCO_3$]), the use of other reducing agents to extract metals from their oxides (e.g., metallurgical coke, coal, natural gas, etc.), and the use of material (e.g., coke) for slag cleaning and the consumption of graphite or carbon electrodes in electric arc furnaces. It is important to distinguish between fuels used for combustion and fuels used as reducing agents; only fuels used as reducing agents should be included in the base metal production category. Fuels used for combustion are reported in WCI.020.

§ WCI.262 Greenhouse Gas Reporting Requirements

In addition to the information required by the Reporting Regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of CO_2 at the facility level (tonnes).

(b) Annual quantities of each carbonate flux reagent used (tonnes).

(c) Fractional purity of each carbonate flux reagent used (tonnes carbonate/tonnes raw material).

(d) Annual quantities of other reducing agents used (tonnes).

(e) Carbon content of other reducing agent used or material used for slag cleaning (tonnes C/tonne reducing agent or material for slag cleaning).

(f) Annual quantity of ore processed (tonnes).

(g) Carbon content of ore processed (tonnes C/tonne ore).

§ WCI.263 Calculation of CO_2 Emissions

Calculate total CO_2 emissions as specified under paragraph (a) through (d) of this section.

(a) Calculate CO_2 emissions from carbonate flux reagents using Equation 260-1.

$$E_{cf} = Q_{ls} \times f_{ls} \times \left(\frac{44}{100}\right) + Q_d \times f_d \times \left(\frac{88}{184}\right) \qquad \textbf{Equation 260-1}$$

Where:

E_{cf} = Annual CO_2 emissions from carbonate flux reagents (tonnes);

Q_{ls} = Annual quantity of limestone consumed (tonnes);

f_{ls} = Fractional purity of limestone (tonnes $CaCO_3$/tonnes of raw material);

44/100 = Stoichiometric conversion factor from $CaCO_3$ to CO_2;

Q_d = Annual quantity of dolomite consumed (tonnes);

f_d = Fractional purity of dolomite (tonnes $CaCO_3 \cdot MgCO_3$/tonnes of raw material);

88/184 = Stoichiometric conversion factor from $CaCO_3 \cdot MgCO_3$ to CO_2.

(b) Calculate CO_2 emissions from other reducing agents or material used in slag cleaning using Equation 260-2.

$$E_{ra} = Q_a \times C_a \times 3.664$$

Equation 260-2

Where:

E_{ra} = Annual CO_2 emissions from other reducing agents or material used for slag cleaning (tonnes);

Q_a = Annual quantity of other reducing agents or material used for slag cleaning (tonnes);

C_a = Carbon content of other reducing agents or material used for slag cleaning (tonnes C/tonne of reducing agent or material used for slag cleaning);

3.664 = Stoichiometric conversion factor from C to CO_2.

(c) Calculate CO_2 emissions from release of carbon from metal ores using Equation 260-3.

$$E_{ore} = Q_{ore} \times C_{ore} \times 3.664$$

Equation 260-3

Where:

E_{ore} = Annual process CO_2 emissions from metal ore, tonnes

Q_{ore} = Annual quantity of nickel or copper metal ore consumed (tonnes);

C_{ore} = Carbon content of nickel or copper metal ore (tonnes C/tonne of nickel or copper ore);

3.664 = Stoichiometric conversion factor from C to CO_2.

(d) Calculate CO_2 emissions from carbon electrode consumption in electric arc furnaces (EAFs) using Equation 260-4.

$$E_{ce} = Q_{ce} \times C_{ce} \times 3.664$$

Equation 260-4

Where:

E_{ce} = Annual CO_2 emissions from carbon electrode consumption in EAFs (tonnes);

Q_{ce} = Quantity of carbon electrodes consumed (tonnes);

C_{ce} = Carbon content of carbon electrodes (tonnes C/tonne carbon electrodes);

3.664 = Stoichiometric conversion factor from C to CO_2.

§ WCI.264 Sampling, Analysis, and Measurement Requirements

The annual mass of each solid carbon-containing input material consumed shall be determined using facility instruments, procedures, or records used for accounting purposes, including either direct measurement of the quantity of the material consumed or by calculations using process operating information.

The average carbon content of each material consumed shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For coal and coke, use ASTM D5373-08 "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal and Coke".

(2) For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291-02 (Reapproved 2007) "Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants", ultimate analysis of oil or computations based on ASTM D3238-95 (Reapproved 2005) and either ASTM D2502-04 or ASTM D2503-92 (Reapproved 2007).

(3) For gaseous fuels, use ASTM D1945-03 or ASTM D1946-90 (Reapproved 2006).

(4) For carbonate flux reagents (i.e., limestone and dolomite), use ASTM C25-06 "Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime".

(b) Obtain carbon contents of the material, including carbon electrodes, from the vendor or supplier.

§ WCI.265 Procedures for Estimating Missing Data

For the carbon input procedure in WCI.263, a complete record of all measured parameters used in the GHG emissions calculations is required (e.g., raw materials carbon content values, etc.). Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For missing records of the carbon content of inputs for facilities that estimate emissions using the carbon input procedure in WCI.263; 100 percent data availability is required. You must repeat the test for average carbon contents of inputs according to the procedures in WCI.264 if data are missing.

(b) For missing records of the annual mass of carbon-containing inputs using the carbon input procedure in WCI.263, the substitute data value must be based on the best available estimate of the mass of the input material from all available process data or information used for accounting purposes, such as purchase records.

§ WCI.270 FERROALLOY PRODUCTION

§ WCI.271 Source Category Definition

Ferroalloy production consists of any facility that uses pyrometallurgical techniques to produce any of the following metals: ferrochromium, ferromanganese, ferromolybdenum, ferronickel, ferrosilicon, ferrotitanium, ferrotungsten, ferrovanadium, silicomanganese, or silicon metal.

§ WCI.272 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual process CO_2 emissions (tonnes) from each electric arc furnace (EAF) used in the production of any ferroalloy listed in WCI.271.

(b) Annual process CH_4 emissions (tonnes) from each electric arc furnace (EAF) used in the production of any ferroalloy listed in Table 270-1 (i.e., ferrosilicon [65%, 75%, or 90%] or silicon metal).

(c) CO_2, N_2O, and CH_4 emissions from stationary combustion units as specified in WCI.20.

(d) Annual facility ferroalloy product production capacity (tonnes).

(e) Annual production for each ferroalloy product from each EAF (tonnes).

(f) Total number of EAFs at facility used for production of ferroalloy products.

(g) Identification number of each EAF

(h) Annual material quantity for each material included for the calculation of annual process CO_2 emissions for each EAF.

(i) Annual average of the carbon content determinations for each material included for the calculation of annual process CO_2 emissions for each EAF.

(j) Method used for determination of carbon content for each material reported (e.g., supplier provided information, representative samples analyses, etc.)

(k) If missing data procedures used (WCI.275), how monthly mass of carbon-containing inputs and output with missing data was determined and the number of months the missing data procedures were used.

§ WCI.273 Calculation of GHG Emissions

(a) Process CO_2 emissions. Determine process CO_2 emissions as specified under either paragraph (1) or (2) of this section.

(1) Continuous emissions monitoring systems (CEMS) as specified in WCI.23(d).

(2) Calculation methodologies specified in paragraph (b) of this section.

(b) Process CO_2 Emissions Calculation Methodology. Calculate electric arc furnace (EAF) CO_2 emissions using the mass balance approach specified in paragraphs (b)(1) and (b)(2). Specific process inputs or outputs that contribute less than 1 percent of the total carbon into or out of the process do not have to be included in the paragraph (b)(1) and (b)(2) mass balances

(1) Calculate EAF CO_2 emissions using Equation 270-1:

$$E_{EAF} = \left[(RA \times C_{RA}) + (EL \times C_{EL}) + (Ore \times C_{Ore}) + (FL \times C_{FL}) - (PR \times C_{PR}) - (NP \times C_{NP})\right] \times 3.664$$

Equation 270-1

Where:

E_{EAF}	=	Annual CO_2 emissions from EAF (tonnes);
RA	=	Annual mass of reducing agent charged or introduced to EAF (tonnes);
C_{RA}	=	Carbon content of reducing agent (tonnes C/ tonnes reducing agent);
EL	=	Annual mass of carbon electrodes consumed (tonnes);
C_{EL}	=	Carbon content of carbon electrodes (tonnes C/ tonnes carbon electrode);
Ore	=	Annual mass of ore charged to EAF (tonnes);
C_{Ore}	=	Carbon content of ore (tonnes C/ tonnes carbon electrode);
FL	=	Annual mass of flux materials charged or introduced to EAF (tonnes);
C_{FL}	=	Carbon content of flux materials (tonnes C/ tonnes flux material);
PR	=	Annual mass of alloy product tapped from EAF (tonnes);
C_{PR}	=	Carbon content of alloy product (tonnes C/ tonnes alloy product);
NP	=	Annual mass of outgoing non-product material removed from EAF (tonnes);
C_{NP}	=	Carbon content of outgoing non-product material (tonnes C/tonnes non-product);
3.664	=	Conversion factor from tonnes of C to tonnes of CO_2.

(2) Determine combined annual CO_2 emissions from all EAFs at the facility using Equation 270-2:

$$E_{CO2-Fac} = \sum_{1}^{k} E_{EAF-k}$$

Equation 270-2

Where:

$E_{CO2\text{-}Fac}$	=	Annual process CO_2 emissions from EAFs at facility used for the production of any ferroalloy listed in listed in WCI.271 (tonnes).
$E_{EAF\text{-}k}$	=	Annual process CO_2 emissions calculated from EAF *k* using Equation 270-1 (tonnes).
k	=	Total number of EAFs at facility used for the production of any ferroalloy listed in WCI.271 (tonnes).

(c) Process CH_4 Emissions Calculation Methodology. For any ferroalloy listed in Table 270-1, calculate emissions using procedure specified in paragraphs (c)(1) and (c)(2).

(1) For each EAF, calculate annual CH_4 emissions using Equation 270-3:

$$E_{CH4} = \sum_{1}^{i} \left(M_i \times EF_i \right)$$ **Equation 270-3**

Where:

E_{CH4} = Annual process CH_4 emissions from an individual EAF (tonnes).
M_i = Annual mass of alloy product *i* produced in the EAF (tonnes).
EF_i = CH_4 emission factor for alloy product *i* from Table 270-1 (tonne CH_4/ tonne of alloy product *i*).

(2) Determine combined annual CH_4 emissions from all EAFs at the facility using Equation 270-4:

$$E_{CH4-Fac} = \sum_{1}^{j} E_{CH4-j}$$ **Equation 270-4**

Where:

$E_{CH4\text{-}Fac}$ = Annual process CH_4 emissions from EAFs at facility used for the production of ferroalloys listed in Table 270-1 (tonnes).
$E_{CH4\text{-}j}$ = Annual process CH_4 emissions calculated from EAF *j* using Equation 270-3 (tonnes).
j = Total number of EAFs at facility used for the production of ferroalloys listed in Table 270-1.

§ WCI.274 Sampling, Analysis, and Measurement Requirements

The annual mass of each material used in the WCI.273 mass balance methodologies shall be determined using plant instruments used for accounting purposes, including either direct measurement of the quantity of material used in the process or by calculations using process operating information.

The average carbon content of each material used shall be determined as specified under paragraph (a) or (b) of this section.

(a) Obtain carbon content by collecting and analyzing at least three representative samples of the material each year using one of the following methods:

(1) For metal ore and alloy product, use ASTM E1941-04 “Standard Test Method for Determination of Carbon in Refractory and Reactive Metals and Their Alloys”.

(2) For carbonaceous reducing agents and carbon electrodes, use ASTM D5373-08 “Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal”.

(3) For flux materials (e.g., limestone, dolomite, etc.), use ASTM C25-06 "Standard Test Methods for Chemical Analysis of Limestone, Quicklime, and Hydrated Lime".

(b) Obtain carbon content from material vendor or supplier.

§ WCI.275 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. Records must be documented and kept of the procedures used for all such estimates.

(a) If CO_2 emissions for EAFs are estimated using the carbon mass balance in WCI.273(b)(1), 100 percent data availability is required for the carbon content of the input and output materials. The test for average carbon contents according to WCI.274 must be repeated if data are missing.

(b) For each missing value of monthly mass of carbon-containing inputs and outputs, the substitute data value must be based on the best available estimate of the mass of inputs and outputs from all available process data or data used for accounting purposes.

(c) If CH_4 emissions for EAFs are required to be calculated, the estimate is based on an annual quantity of certain alloy products, so 100 percent data availability is required.

Table 270-1 —Electric Arc Furnace (EAF) CH_4 Emission Factors.

	CH_4 Emission Factor (metric ton CH_4 per metric ton product)		
	EAF Operation		
Alloy product produced in EAF	**Batch-Charging**	**Sprinkle-Charging[a]**	**Sprinkle-Charging and >750°C[b]**
Silicon metal	0.0015	0.0012	0.0007
Ferrosilicon 90%	0.0014	0.0011	0.0006
Ferrosilicon 75%	0.0013	0.0010	0.0005
Ferrosilicon 65%	0.0013	0.0010	0.0005

[a] Sprinkle-charging is charging intermittently every minute.

[b] Temperature measured in off-gas channel downstream of the furnace hood.

§ WCI.280 MOBILE EQUIPMENT AT FACILITIES

§ WCI.281 Source Category Definition

The mobile equipment at facilities category includes:

(a) Mobile equipment used for the on-site transportation or movement of substances, materials or products, and

(b) Other mobile equipment such as tractors, mobile cranes, log transfer equipment, mining machinery, graders, backhoes and bulldozers, and other industrial equipment,

but *does not include* on-road vehicles, aircraft, or marine vessels.

For clarity, an on-road vehicle means a motor vehicle that:

(a) Can exceed a speed of 40 kilometers per hour on a level paved surface, and

(b) Has features customarily associated with safe and practical highway use such as a reverse gear (unless the vehicle is a motorcycle), a differential, and safety features required by federal or provincial laws,

but *does not include* vehicles that exhibit features that render use on a highway unsafe, impractical, or highly unlikely, such as tracked road contact or inordinate size.

Mobile equipment that is part of normal facility operations that are operated by contractors is also included, as it is managed or controlled by the facility.

§ WCI.282 Greenhouse Gas Reporting Requirements

In addition to the information required by the British Columbia Reporting Regulation, the annual emissions data report shall contain the following information:

(a) Total emissions of CO_2, CO_2 from biomass, CH_4, and N_2O at the facility level by fuel type (including differentiation of biodiesel and ethanol from conventional fuel types) (tonnes).

(b) Annual and quarterly quantities of fuel used by fuel type (including differentiation of biodiesel and ethanol from conventional fuel types) (litres) from the sum of mobile equipment at the facility.

§ WCI.283 Calculation of CO_2 Emissions

Calculate the annual CO_2 mass emissions from mobile equipment using the procedures in paragraph (a) or (b). If neither (a) or (b) is appropriate for a source(s), method (c) may be used. Use method (d) as required.

(a) If fossil fuel quantities are measured, calculate total CO_2 emissions using Equation 280-1.

$$E_{i,CO2} = Q_i \times EF_i$$

Equation 280-1

Where:

$E_{i,CO2}$ = Quarterly CO_2 emissions from mobile equipment for fuel *i* (metric tons);

Q_i = Quarterly quantity of fuel *i* used in mobile equipment (litres);

EF_i = Emission factor for the fuel (metric tons CO_2e/litre, required emission factors provided in WCI.020).

(b) If fossil fuel quantities are not measured, use hours of operation for each mobile equipment to calculate total CO_2 emissions using Equations 280-2 and 280-3.

$$E_{i,k,CO2} = \left(h_{i,k} \times hp_{i,k} \times LF_{i,k} \times BSFC_{i,k}\right) \times EF_{i,CO2}$$ **Equation 280-2**

$$E_{Total,i,CO2} = \sum_k E_{i,k,CO2}$$ **Equation 280-3**

Where:

$E_{i,k,CO2}$ = Quarterly CO_2 emissions from mobile equipment *k* for fuel *i* (metric tons);

$h_{i,k}$ = Quarterly hours of operation for mobile equipment *k* for fuel *i* (hours);

$hp_{i,k}$ = Rated equipment horsepower for mobile equipment *k* for fuel *i* (horsepower);

$LF_{i,k}$ = Load factor for mobile equipment *k* for fuel *i* (unitless; ranges between 0 and 1);

$BSFC_{i,k}$ = Brake-specific fuel consumption for mobile equipment *k* for fuel *i* (litres/horsepower-hour);

$EF_{i,CO2}$ = Emission factor for fuel *i* (metric tons CO_2e/litre, required emission factors provided in WCI.020);

$E_{Total,i,CO2}$ = Total quarterly CO_2 emissions for fuel *i* (metric tons).

(c) If neither methods (a) or (b) is appropriate for a source(s), determine emissions using the site-specific emission factor method. Conduct analysis of hourly fuel use from mobile sources at the facility during a range of typical operations.

(i) A range of typical operating conditions for the mobile source(s) at the facility must be documented and analyzed (e.g., including the type of mobile equipment in operation).

(ii) The average hourly fuel use rate for each of the typical operations must be calculated.

(iii) The number of hours of each type of operation at the facility in the year must be determined.

(iv) The annual total mobile emissions must be calculated by multiplying the hours of operation with the average fuel use rate and the fuel-specific emission factor for each of the typical operations.

(d) CO_2 Emissions Calculation Methodology for Mixtures of Biomass Fuel and Fossil Fuel. Calculate biomass and non-biomass CO_2 emissions as specified in paragraph (1) of this section.

(1) The owner or operator that combusts fuels or fuel mixtures where there is a mixture of biofuel (i.e. biodiesel and ethanol) and other fuels shall determine the portion of the biofuel used by broad fuel category (i.e. gasoline and diesel) and use the appropriate emission factors for each of the biofuel and the conventional fuel. When reporting emissions, CO_2 from the biomass component of biofuels shall be reported separately from CO_2 from fossil fuels.

§ WCI.284 Calculation of CH_4 and N_2O Emissions

Calculate the annual CH_4 and N_2O mass emissions from mobile equipment using the procedures in paragraph (a) or (b), as appropriate. If neither (a) or (b) is appropriate, method (c) may be used. Annual emissions for each fuel type and GHG are calculated as the sum of the quarterly emissions. Annual emissions are reported by fuel and by GHG.

(a) If fossil fuel quantities are measured, calculate total CH_4 and N_2O emissions using Equation 280-4 and the emission factors provided in WCI.020.

$$E_{i,g} = Q_i \times EF_{i,g} \times \left(\frac{1}{10^6}\right) \qquad \textbf{Equation 280-4}$$

Where:

$E_{i,g}$ = Quarterly emissions of greenhouse gas *g* (CH_4 or N_2O) from mobile equipment for fuel *i* (metric tons);

Q_i = Quarterly quantity of fuel *i* (litres);

$EF_{i,g}$ = Greenhouse gas *g* (CH_4 or N_2O) mobile equipment emission factor for fuel *i* (grams/litre) (required emission factors provided in WCI.020);

$(1/10^6)$ = Conversion factor from grams to metric tons.

(b) If fossil fuel quantities are not measured, use hours of operation for each mobile equipment to calculate total CH_4 or N_2O emissions using Equations 280-5 and 280-6.

$$E_{i,k,g} = \left(h_{i,k} \times hp_{i,k} \times LF_{i,k} \times BSFC_{i,k}\right) \times EF_{i,g} \times \left(\frac{1}{10^6}\right) \qquad \textbf{Equation 280-5}$$

$$E_{Total,i,g} = \sum_{k} E_{i,k,g} \qquad \textbf{Equation 280-6}$$

Where:

$E_{i,k,g}$ = Quarterly greenhouse gas *g* (CH_4 or N_2O) emissions from mobile equipment *k* for fuel *i* (metric tons);

$h_{i,k}$ = Quarterly hours of operation for mobile equipment *k* for fuel *i* (hours);

$hp_{i,k}$ = Rated equipment horsepower for mobile equipment *k* for fuel *i* (horsepower);

$LF_{i,k}$ = Load factor for mobile equipment *k* for fuel *i* (unitless; ranges between 0 and 1);

$BSFC_{i,k}$ = Brake-specific fuel consumption for mobile equipment *k* for fuel *i* (litres/horsepower-hour);

$EF_{i,g}$ = Emission factor for greenhouse gas *g* (CH_4 or N_2O) for fuel *i* (grams/litre, required emission factors provided in WCI.020);

$(1/10^6)$ = Conversion factor from grams to metric tons;

$E_{Total,i,g}$ = Total quarterly emissions greenhouse gas *g* (CH_4 or N_2O) for fuel *i* (metric tons).

(c) If neither methods (a) or (b) is appropriate, determine emissions using the *site-specific emission factor method.* Conduct analysis of hourly fuel use from mobile sources at the facility during a range of typical operations.

(i) A range of typical operating conditions for the mobile source(s) at the facility must be documented and analyzed (e.g., include the type of mobile equipment in operation).
(ii) The average hourly fuel use rate for each of the typical operations must be calculated.
(iii) The number of hours of each type of operation at the facility in the year must be determined.
(iv) The annual total mobile emissions must be calculated by multiplying the hours of operation with the average fuel use rate and the fuel-specific emission factor for each of the typical operations.

§ WCI.285 Sampling, Analysis, and Measurement Requirements

Fuel use and emission factors shall be determined as specified under paragraphs (a), (b) and (c) of this section.

(a) For biofuels, the portion(s) of ethanol or biodiesel from vendor specifications.

(b) For conventional fuels and biofuels, required emission factors listed in WCI.020.

(c) Fuel volumes used shall be determined by vendor receipts, dipstick measurement, or other appropriate means on a quarterly basis, starting on January 1 of the calendar year.

§ WCI.290 MAGNESIUM PRODUCTION

§ WCI.291 Source Category Definition

Magnesium production and processing source category consists of any process in which magnesium metal is produced through smelting (including electrolytic smelting), refining, or remelting operations or in which molten magnesium is used in alloying, casting, drawing, extruding, forming, or rolling operations.

Two important sector-specific definitions are the following:

(a) *Cover gas* means SF_6, HFC–134a, fluorinated ketone (FK 5–1–12) or other gas used to protect the surface of molten magnesium from rapid oxidation and burning in the presence of air. The molten magnesium may be the surface of a casting or ingot production operation or the surface of a crucible of molten magnesium that feeds a casting operation.

(b) *Carrier gas* means the gas with which cover gas is mixed to transport and dilute the cover gas thus maximizing its efficient use. Carrier gases typically include CO_2, N_2, and/or dry air.

§ WCI.292 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual emissions of the following gases in tonnes per year resulting from their use as cover gases or carrier gases in magnesium production or processing:

(1) Sulfur hexafluoride (SF_6).

(2) HFC–134a.

(3) FK 5–1–12 (a fluorinated ketone).

(4) Carbon dioxide (CO_2).

(5) Any other GHGs (as defined by regulation).

(b) CO_2, N_2O, and CH_4 emissions from stationary combustion units as specified in WCI.20.

(c) Types of production processes at the facility (e.g., primary, secondary, die casting, etc.).

(d) Amount of magnesium produced or processed in metric tons for each process type, including the output of primary and secondary magnesium production processes and the input to magnesium casting processes.

(e) For any missing data, the length of time the data were missing for each cover gas or carrier gas, the method used to estimate emissions in their absence, and the quantity of emissions thereby estimated.

(f) If applicable, an explanation of any change greater than 30 percent in the facility's cover gas usage rate (e.g., installation of new melt protection technology, leak discovered in the cover gas delivery system that resulted in increased emissions, etc.).

(g) Description of any new melt protection technologies adopted to account for reduced or increased GHG emissions in any given year.

§ WCI.293 Calculation of GHG Emissions

(a) Calculate the mass of each GHG emitted from magnesium production or processing over the calendar year using either Equation 290-1 or Equation 290-2 of this section, as appropriate. Both of these equations equate emissions of cover gases or carrier gases to consumption of cover gases or carrier gases.

(1) To estimate emissions of cover gases or carrier gases by monitoring changes in container masses and inventories, emissions of each cover gas or carrier gas shall be estimated using Equation 290-1 of this section:

$$E_x = \left(I_{B,x} - I_{E,x} + A_x - D_x\right) \times 0.001$$

Equation 290-1

Where:

E_x	=	Emissions of each cover gas or carrier gas *x* over the reporting year (tonnes);
$I_{B,x}$	=	Inventory of each cover gas or carrier gas *x* stored in cylinders or other containers at the beginning of the year, including heels (kg);
$I_{E,x}$	=	Inventory of each cover gas or carrier gas *x* stored in cylinders or other containers at the end of the year, including heels (kg);
A_x	=	Acquisitions of each cover gas or carrier gas *x* during the year through purchases or other transactions, including heels in cylinders or other containers returned to the magnesium production or processing facility (kg);.
D_x	=	Disbursements of each cover gas or carrier gas *x* to sources and locations outside the facility through sales or other transactions during the year, including heels in cylinders or other containers returned by the magnesium production or processing facility to the gas supplier (kg);
0.001	=	Conversion factor from kg to tonnes; and
x	=	Each cover gas or carrier gas that is a GHG.

(2) To estimate emissions of cover gases or carrier gases by monitoring changes in the masses of individual containers as their contents are used, emissions of each cover gas or carrier gas shall be estimated using Equation 290-2 of this section:

$$E_x = \sum_{p=1}^{n} Q_p \times 0.001$$

Equation 290-2

Where:

E_x = Emissions of each cover gas or carrier gas *x* over the reporting year (tonnes);
Q_p = Mass of the cover or carrier gas consumed (kg) over the container-use period *p* as estimated using Equation 290-3;
n = Number of container-use periods in the year;
= Inventory of each cover gas or carrier gas *x* stored in cylinders or other containers at the beginning of the year, including heels (kg);
0.001 = Conversion factor from kg to tonnes; and
x = Each cover gas or carrier gas that is a GHG.

(b) For purposes of Equation 290-2 of this section, the mass of the cover gas used over the period *p* for an individual container shall be estimated by using Equation 290-3 of this section:

$$Q_p = M_B - M_E$$

Equation 290-3

Where:

Q_p = Mass of the cover or carrier gas consumed (kg) over the container-use period *p* (e.g., one month, etc.);
M_B = Mass of the container's contents (kg) at the beginning of period *p*; and
M_E = Mass of the container's contents (kg) at the end of period *p*.

(c) If a facility has mass flow controllers (MFC) and the capacity to track and record MFC measurements to estimate total gas usage, the mass of each cover or carrier gas monitored may be used as the mass of cover or carrier gas consumed (Q_p), in kg for period *p* in Equation 290-2 of this section.

§ WCI.294 Sampling, Analysis, and Measurement Requirements

Emissions (consumption) of cover gases and carrier gases may be estimated by monitoring as specified under paragraphs (a) through (c). Emissions must be estimated at least annually.

(a) Monitor the changes in container weights and inventories using Equation 290-1 of this subpart as follows:

(1) All quantities required by Equation 290-1 of this subpart must be measured using scales or load cells with an accuracy of 1 percent of full scale or better, accounting for the tare weights of the containers.

(2) Gas masses or weights provided by the gas supplier (e.g., for the contents of containers containing new gas or for the heels remaining in containers returned to the gas supplier) if the supplier provides documentation verifying that accuracy standards are met. However, the facility remains responsible for the accuracy of these masses or weights under this subpart.

(b) Monitor the changes in individual container weights as the contents of each container are used using Equations 290-2 and 290-3 of this subpart. The container identities and masses must be monitored and recorded as follows:

(1) Track the identities and masses of containers leaving and entering storage with check-out and check-in sheets and procedures. The masses of cylinders returning to storage shall be measured immediately before the cylinders are put back into storage.

(2) All the quantities required by Equations 290-2 and 290-3 of this subpart must be measured using scales or load cells with an accuracy of 1 percent of full scale or better, accounting for the tare weights of the containers.

(3) Gas masses or weights provided by the gas supplier (e.g., for the contents of cylinders containing new gas or for the heels remaining in cylinders returned to the gas supplier) if the supplier provides documentation verifying that accuracy standards are met. However, the facility remains responsible for the accuracy of these masses or weights under this subpart.

(c) Monitoring the mass flow of the pure cover gas or carrier gas into the gas distribution system. When estimating emissions by monitoring the mass flow of the pure cover gas or carrier gas into the gas distribution system, gas flow meters, or mass flow controllers, with an accuracy of 1 percent of full scale or better must be used.

All flow meters, scales, and load cells used to measure quantities that are to be reported under this subpart shall be calibrated using calibration procedures specified by the flow meter, scale, or load cell manufacturer. Calibration shall be performed prior to the first reporting year. After the initial calibration, recalibration shall be performed at the minimum frequency specified by the manufacturer.

§ WCI.295 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. Records must be documented and kept of the procedures used for all such estimates.

(a) A complete record of all measured parameters used in the GHG emission calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter will be used in the calculations as specified in paragraph (b) of this section.

(b) Replace missing data on the emissions of cover or carrier gases by multiplying magnesium production during the missing data period by the average cover or carrier gas usage rate from the most recent period when operating conditions were similar to those for the period for which the data are missing. Calculate the usage rate for each cover or carrier gas using Equation 290-4 of this section:

$$R_x = \left(\frac{C_x}{Mg}\right) \times 0.001$$

Equation 290-4

Where:

R_x	=	Usage rate of a particular cover gas or carrier gas *x* over the period of comparable operation (tonnes gas/tonne Mg);
C_x	=	Consumption of a particular cover gas or carrier gas *x* over the period of comparable operation (kg);
Mg	=	Magnesium produced or fed into the process over the period of comparable operation (tonnes);
0.001	=	Conversion factor from kg to tonnes; and
x	=	Each cover gas or carrier gas that is a GHG.

(c) If the precise before and after weights are not available, it should be assumed that the container was emptied in the process (i.e., quantity purchased should be used, less heel).

§ WCI.300 PETROCHEMICAL MANUFACTURING

§ WCI.301 Source Category Definition

(a) The petrochemical manufacturing source category consists of any facility that manufacturers petrochemicals, including acrylonitrile, carbon black, propylene, ethylene, ethylene dichloride, ethylene oxide, or methanol, from feedstocks derived from petroleum, or petroleum and natural gas liquids.

(b) A process that produces a petrochemical as a byproduct is not part of the petrochemical production source category.

(c) A facility that makes methanol, hydrogen, and/or ammonia from synthesis gas should report under this section if the annual mass of methanol produced exceeds the individual annual mass production levels of both hydrogen recovered as product and ammonia. The facility should report under WCI.130 (Hydrogen Production) if the annual mass of hydrogen recovered as product exceeds the individual annual mass production levels of both methanol and ammonia. The facility should report under WCI.80 (Ammonia Manufacturing) if the annual mass of ammonia produced exceeds the individual annual mass production levels of both hydrogen recovered as product and methanol.

(d) A direct chlorination process that is operated independently of an oxychlorination process to produce ethylene dichloride is not part of the petrochemical production source category.

(e) A process that produces a petrochemical from bio-based feedstock is not part of the petrochemical production source category.

§ WCI.302 Greenhouse Gas Reporting Requirements

In addition to the information required by the regulation, the annual emissions report must contain the following information:

(a) CO_2, N_2O, and CH_4 emissions from combustion of fuels in the stationary combustion units in tonnes, as specified in WCI.20.

(b) CO_2, N_2O, and CH_4 emissions from flares or other combustion devices in tonnes using methods WCI.303(a)(1), WCI.303(a)(2) or WCI.303(c).

(c) CO_2, N_2O, and CH_4 process emissions from vents in tonnes using method WCI.303(a)(3).

(d) CO_2, N_2O, and CH_4 process emissions from equipment leaks in tonnes using method WCI.303(a)(4).

(e) CO_2 process emissions in tonnes using method WCI.303(b).

(f) CO_2, N_2O, and CH_4 process emissions from ethylene production facilities in tonnes using WCI.303(c).

(g) Annual consumption of feedstock by type for all feedstocks that result in GHG emissions in standard cubic meters for gases, kilolitres for liquids, and tonnes for solid fuels.

§ WCI.303 Calculation of GHG Emissions

Calculate GHG emissions using one of the methods in paragraphs (a), (b), or (c):

(a) **Method 1:** Calculate the GHG emissions from petrochemical production processes using the methods specific in paragraphs (a)(1) through (a)(3) of this section.

(1) For flares, calculate CO_2, CH_4 and N_2O emissions using the methods specified in WCI.203(e).

(2) For combustion devices other than flares, calculate CO_2, CH_4 and N_2O emissions resulting from the combustion of fuels and process off-gas as specified in paragraphs (a)(2)(i) through (a)(2)(iii):

(i) Calculate CO_2 emissions from fuels and process off-gas in accordance with the methods in specified in WCI.20.

(ii) Calculate CH_4 and N_2O emissions from combustion of fuels using the applicable methods in WCI.24. Use the appropriate default emission factors for CH_4 and N_2O from Tables 20-2, 20-4, 20-6, and 20-7.

(iii) Calculate CH_4 and N_2O emissions from process off-gas using the applicable equation 20-12 in WCI.24, and the default emission factors of 2.8×10^{-3} kg/GJ for CH_4 and 5.7×10^{-4} kg/GJ for N_2O.

(3) Calculate the emissions from process vents using the method specified in WCI.203(b) for each process vent that can be reasonably expected to contain greater than 2 percent by volume CO_2 or greater than 0.5 percent by volume of CH_4 or greater than 0.01 percent by volume (100 parts per million) of N_2O.

(4) Calculate the emissions from equipment leaks using the method specified in WCI.203(i)(1).

(b) **Method 2:** Calculate the emissions of CO_2 from each process unit, for each calendar month as described in paragraphs (b)(1) through (b)(5) of this section.

(1) For each gaseous and liquid feedstock and product, measure the volume or mass used or produced each calendar month with a flow meter. Alternatively, for liquids, you may calculate the volume used or collected in each month based on measurements of the liquid level in a storage tank at least once per month (and just prior to each change in direction of the level of the liquid). Fuels used for combustion purposes are not considered to be feedstocks. The emissions from the combustion of fuels (other than process off-gas) in stationary combustion units must be calculated in accordance with the methods specified in WCI.23 for CO_2 and the methods specified in WCI.24 for CH_4 and N_2O.

(2) For each solid feedstock and product, measure the mass used or produced each calendar month.

(3) Collect a sample of each feedstock and product at least once per month and determine the carbon content of each sample. Alternatively, you may use the results of analyses conducted by a fuel or feedstock supplier, provided the sampling and analysis is

conducted at least once per month. If multiple valid carbon content measurements are made during the monthly measurement period, average them arithmetically.

(4) If you determine that the monthly average concentration of a specific compound in a feedstock or product is greater than 99.5 percent by volume (or mass for liquids and solids), then as an alternative to the sampling and analysis specified in paragraph (b)(3) of this section, you may calculate the carbon content assuming 100 percent of that feedstock or product is the specific compound during periods of normal operation. You must maintain records of any determination made in accordance with this paragraph (b)(4) along with all supporting data, calculations, and other information. This alternative may not be used for products during periods of operation when off-specification product is produced. You must reevaluate determinations made under this paragraph (b)(4) after any process change that affects the feedstock or product composition. You must keep records of the process change and the corresponding composition determinations. If the feedstock or product composition changes so that the average monthly concentration falls below 99.5 percent, you are no longer permitted to use this alternative method.

(5) Calculate the CO_2 mass emissions for each petrochemical process unit using Equations 300-1 through 300-4 of this section.

(i) <u>Gaseous feedstocks and products</u>. Use Equation 300-1 of this section to calculate the net annual carbon input or output from gaseous feedstocks and products. Note that the result will be a negative value if there are no gaseous feedstocks in the process but there are gaseous products.

$$C_g = \sum_{n=1}^{12} [\sum_{i=1}^{j\ or\ k} [(F_{gf})_{i,n} * (CC_{gf})_{i,n} * \frac{(MW_f)_i}{MVC} - (P_{gp})_{i,n} * (CC_{gp})_{i,n} * \frac{(MW_p)_i}{MVC}]]$$

Equation 300-1

Where:

C_g = Annual net contribution to calculated emissions from carbon (C) in gaseous materials (kg/yr).

$(F_{gf})_{i,n}$ = Volume of gaseous feedstock i introduced in month n (Rm^3) at reference temperature and pressure conditions as used by the facility. If a mass flow meter is used, measure the feedstock introduced in month n in kg and replace the term "$(MW_f)_i/MVC$" with "1".

$(CC_{gf})_{i,n}$ = Average carbon content of the gaseous feedstock i for month n (kg C per kg of feedstock).

$(MW_f)_i$ = Molecular weight of gaseous feedstock i (kg/kg-mole).

MVC = Molar volume conversion factor at the same reference conditions as the above $(F_{gf})_{i,n}$ (Rm^3/kg-mole).

= 8.3145 * [273.16 + reference temperature in °C] / [reference pressure in kilopascal]

$(P_{gp})_{i,n}$ = Volume of gaseous product i produced in month n (Rm^3) at the same reference conditions as the above $(F_{gf})_{i,n}$. If a mass flow meter is used, measure the gaseous product produced in month *n* in kg and replace the term "(MWp)i/MVC" with "1".

$(CC_{gp})_{i,n}$ = Average carbon content of gaseous product *i*, including streams containing CO_2 recovered for sale or use in another process, for month *n* (kg of C per m^3 of product when liquid product is measured in m^3, or kg of C per kg of product when product is measured in kg)

$(MW_p)_i$ = Molecular weight of gaseous product *i* (kg/kg-mole).

j = Number of feedstocks.

k = Number of products.

(ii) Liquid feedstocks and products. Use Equation 300-2 of this section to calculate the net carbon input or output from liquid feedstocks and products. Note that the result will be a negative value if there are no liquid feedstocks in the process but there are liquid products.

$$C_l = \sum_{n=1}^{12} [\sum_{i=1}^{j\ or\ k} [(F_{lf})_{i,n} * (CC_{lf})_{i,n} - (P_{lp})_{i,n} * (CC_{lp})_{i,n}]] \qquad \textbf{Equation 300-2}$$

Where:

C_l = Annual net contribution to calculated emissions from carbon in liquid materials, including liquid organic wastes (kg/yr).

$(F_{lf})_{i,n}$ = Volume or mass of liquid feedstock *i* introduced in month *n* (m^3 of feedstock). If a mass flow meter is used, measure the liquid feedstock in month *n* introduced in kg and measure the carbon content of feedstock in kg of C per kg of feedstock.

$(CC_{lf})_{i,n}$ = Average carbon content of liquid feedstock *i* for month *n* (kg C of C per m^3 of feedstock when feedstock usage is measured in m^3, or kg of C per kg of feedstock when feedstock usage is measured in kg).

$(P_{lp})_{i,n}$ = Volume or mass of liquid product i produced in month *n* (m^3). If a mass flow meter is used, measure the liquid product produced in kg and measure the carbon content of liquid product in kg of C per kg of product.

$(CC_{lp})_{i,n}$ = Average carbon content of liquid product *i*, including organic liquid wastes, for month *n* (kg C of C per m^3 of product when liquid product is measured in m^3, or kg of C per kg of product when product is measured in kg)

j = Number of feedstocks.

k = Number of products.

(iii) Solid feedstocks and products. Use Equation 300-3 of this section to calculate the net annual carbon input or output from solid feedstocks and products. Note that the result will be a negative value if there are no solid feedstocks in the process but there are solid products.

$$C_s = \sum_{n=1}^{12} \left\{ \sum_{i=1}^{j\ or\ k} \left[(F_{sf})_{i,n} * (CC_{sf})_{i,n} - (P_{sp})_{i,n} * (CC_{sp})_{i,n} \right] \right\} \qquad \textbf{Equation 300-3}$$

Where:

C_s = Annual net contribution to calculated emissions from carbon in solid materials (kg/yr).
$(F_{sf})_{i,n}$ = Mass of solid feedstock *i* introduced in month *n* (kg).
$(CC_{sf})_{i,n}$ = Average carbon content of solid feedstock *i* for month *n* (kg C per kg of feedstock).
$(P_{sp})_{i,n}$ = Mass of solid product *i* produced in month *n* (kg).
$(CC_{sp})_{i,n}$ = Average carbon content of solid product *i* in month *n* (kg C per kg of product).
j = Number of feedstocks.
k = Number of products.

(iv) Annual emissions. Use the results from Equations 300-1 through 300-3 of this section, as applicable, in Equation 300-4 of this section to calculate annual CO_2 emissions.

$$CO_2 = 0.001 * 3.664 * \left(C_g + C_l + C_s\right) \qquad \textbf{Equation 300-4}$$

Where:

CO_2 = Annual CO_2 mass emissions from process operations and process off-gas combustion (tonnes/year).
0.001 = Conversion factor from kg to tonnes.
3.664 = Ratio of molecular weight, carbon dioxide to carbon.

(c) **Method 3:** (Optional combustion methodology for ethylene production processes) For ethylene production processes, calculate CO_2, CH_4, and N_2O emissions as specified in paragraphs (c)(1) and (c)(2):

(1) For each flare, calculate CO_2, CH_4, and N_2O emissions using the methodology for flares specified in WCI.203(e).

(2) For all other combustion units, calculate the CO_2 emissions from combustion of fuel that contains ethylene process off-gas using either Calculation Methodology 3 or Calculation Methodogy 4 in WCI.23(c) and (d), respectively. Calculate CH_4 and N_2O emissions using the applicable method in WCI.24 and the emission factors of 2.8 x 10^{-3} kg/GJ for CH_4 and 5.7 x 10^{-4} kg/GJ for N_2O. You are not required to use the same calculation method for each stationary combustion unit that burns ethylene process off-gas.

§ WCI.304 Monitoring Requirements

(a) If you calculate emissions using the method specified in WCI.303(a):

(1) **Flares.** You must comply with the monitoring requirements for flares specified in WCI.204(e). The person may monitor the carbon content or the high heat value of the flares gas of flares in a petrochemical production facility on a quarterly basis.

(2) **Process Vents.** You must comply with the monitoring requirements for process vents specified in WCI.204(b).

(b) If you calculate emissions using the method specified in WCI.303(b):

(1) **Feedstock Consumption.** You must measure the feedstock consumption using the same plant instruments used for accounting purposes, such as weigh hoppers, belt weigh feeders, or flow meters.

(2) **Product Production.** You must measure the amount of product produced using the same plant instruments used for accounting purposes, such as weigh hoppers, belt weigh feeders, or flow meters.

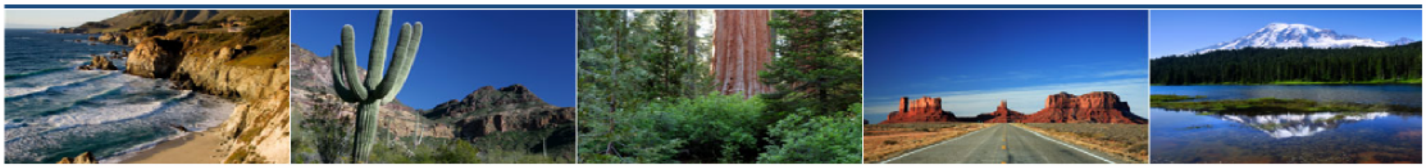
(3) **Carbon Content.** Except as allowed by WCI.303(b)(4), the carbon content of each feedstock and product must be measured at least once per month.

§ WCI.305 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. You must document and keep records of the procedures used for all such estimates.

(a) For each missing value of the carbon content and molecular weight, the substitute data value shall be the arithmetic average of the quality assured values of the parameter immediately preceding and immediately following the missing data incident. If no quality assured data are available prior to the missing data incident, the substitute data value shall be the first quality assured data value obtained after the missing data period.

(b) For missing feedstock and production values, the substitute data value shall be the best available estimate of the parameter, based on all available process data. You must document and retain records of the procedures used for all such estimates.



§ WCI.310 NITRIC ACID MANUFACTURING

§ WCI.311 Source Category Definition

A nitric acid production facility uses one or more trains to produce weak nitric acid (30 to 70 percent in strength). A nitric acid train produces weak nitric acid through the catalytic oxidation of ammonia.

§ WCI.312 Greenhouse Gas Reporting Requirements

For the purpose of the Regulation the annual emissions data report shall include the following information at the facility level calculated in accordance this method

(a) You must report facility wide N_2O process emissions as required by this method.

(b) Annual nitric acid production from the nitric acid facility (tonnes, 100 percent acid basis).

(c) You must report under WCI.20 (General Stationary Fuel Combustion Sources) the emissions of CO_2, CH_4, and N_2O from each stationary combustion unit by following the requirements of WCI.20.

§ WCI.313 Calculation of GHG emissions

(a) You must determine annual N_2O process emissions from each nitric acid train according to paragraphs (a)(1) or (a)(2) of this section.

(1) Use a site-specific emission factor and production data according to paragraphs (b) through (h) of this section.

(2) Request Director approval for an alternative method of determining N_2O emissions according to paragraphs.

(b) You must conduct an annual performance test according to paragraphs (b)(1) through (b)(3) of this section.

(1) You must measure N_2O emissions from the absorber tail gas vent for each nitric acid train using the methods specified in WCI.314(b) through (d).

(2) You must conduct the performance test under normal process operating conditions and without using N_2O abatement technology (if applicable).

(3) You must measure the production rate during the performance test and calculate the production rate for the test period in metric tons (100 percent acid basis) per hour.

(c) You must determine an N_2O emissions factor to use in Equation 310-3 of this section according to paragraphs (c)(1) or (c)(2) of this section.

(1) You may request Director approval for an alternative method of determining N_2O concentration according to the procedures in paragraphs (a)(2) of this section. Alternative methods include the use of N_2O CEMs.

(2) Using the results of the performance test in paragraph (b) of this section, you must calculate an average site-specific emission factor for each nitric acid train “t” according to Equation 310-1 of this section:

$$EF_{N2Ot} = \frac{\sum_{1}^{n} \frac{C_{N2O} * 1.828\times10^{-6} * Q}{P}}{n} \qquad \textbf{Equation 310-1}$$

Where:

EF_{N2Ot} = Average site-specific N_2O emissions factor for nitric acid train *t* (kg N_2O generated/tonne nitric acid produced, 100 percent acid basis).

C_{N2O} = N_2O concentration for each test run during the performance test (ppm N_2O).

1.828×10^{-6} = Conversion factor (kg/dsm^3-ppm N_2O).

Q = Volumetric flow rate of effluent gas for each test run during the performance test (dsm^3/hr).

P = Production rate for each test run during the performance test (tonnes nitric acid produced per hour, 100 percent acid basis).

n = Number of test runs.

(d) If applicable, you must determine the destruction efficiency for each N_2O abatement technology according to paragraphs (d)(1), (d)(2), or (d)(3) of this section.

(1) Use the manufacturer’s specified destruction efficiency.

(2) Estimate the destruction efficiency through process knowledge. Examples of information that could constitute process knowledge include calculations based on material balance, process stoichiometry, or previous test results provided the results are still relevant to the current vent stream conditions. You must document how process knowledge (if applicable) was used to determine the destruction efficiency.

(3) Calculate the destruction efficiency by conducting an additional performance test on the emissions stream following the N_2O abatement technology.

(e) If applicable, you must determine the abatement factor for each N_2O abatement technology. The abatement factor is calculated for each nitric acid train according to Equation 310-2 of this section.

$$AF_{N\,t} = \frac{P_{a\,t\,Abate}}{P_{a\,t}} \qquad \textbf{Equation 310-2}$$

Where:

$AF_{N\,t}$ = Abatement factor of N_2O abatement technology at nitric acid train *t* (fraction of annual production that abatement technology is operating).

$P_{a\,t}$ = Total annual nitric acid production from nitric acid train *t* (tonne acid produced, 100 percent acid basis).

$P_{a\,t\,Abate}$ = Annual nitric acid production from nitric acid train *t* during which N_2O abatement was used (tonne acid produced, 100 percent acid basis).

(f) You must determine the annual amount of nitric acid produced and the annual amount of nitric acid produced while each N_2O abatement technology is operating from each nitric acid train (100 percent basis).

(g) You must calculate N_2O emissions for each nitric acid train by multiplying the emissions factor (determined in Equation 310-1 of this section) by the annual nitric acid production and accounting for N_2O abatement, according to Equation 310-3 of this section:

$$E_{N_2Ot} = \sum_{N=1}^{z} \frac{EF_{N20t} * P_{a\,t} * (1 - (DF_{N\,t} * AF_{N\,t}))}{1000} \qquad \textbf{Equation 310-3}$$

Where:

E_{N2Ot} = N_2O mass emissions per year for nitric acid train *t* (tonnes).

EF_{N2Ot} = Average site-specific N_2O emissions factor for nitric acid train *t* (kg N_2O generated/tonne acid produced, 100 percent acid basis).

$P_{a\,t}$ = Annual nitric acid production from the train *t* (tonne acid produced, 100 percent acid basis).

$DF_{N\,t}$ = Destruction efficiency of N_2O abatement technology N that is used on nitric acid train *t* (percent of N_2O removed from air stream).

$AF_{N\,t}$ = Abatement factor of N_2O abatement technology for nitric acid train *t* (fraction of annual production that abatement technology is operating).

1000 = Conversion factor (kg/tonne).

z = Number of different N_2O abatement technologies.

(h) You must determine the annual nitric acid production emissions combined from all nitric acid trains at your facility using Equation 310-4 of this section:

$$N_2O = \sum_{t=1}^{m} E_{N2Ot} \qquad \textbf{Equation 310-4}$$

Where:

N_2O = Annual process N_2O emissions from nitric acid production facility (tonnes)

E_{N2Ot} = N_2O mass emissions per year for nitric acid train *t* (tonnes).

m = Number of nitric acid trains.

§ WCI.314 Sampling, Analysis, and Measurement Requirements

(a) You must conduct a new performance test and calculate a new site-specific emissions factor according to a test plan as specified in paragraphs (a)(1) through (a)(3) of this section.

(1) Conduct the performance test annually.

(2) Conduct the performance test when your nitric acid production process is changed, specifically when abatement equipment is installed.

(3) If you requested Director approval for an alternative method of determining N_2O concentration under WCI.313(a)(2), you must conduct the performance test if your request has not been approved by the Director within 150 days of the end of the reporting year in which it was submitted.

(b) You must measure the N_2O concentration during the performance test using one of the methods in paragraphs (b)(1) through (b)(3) of this section.

(1) EPA Method 320 at 40 CFR part 63, appendix A, Measurement of Vapor Phase Organic and Inorganic Emissions by Extractive Fourier Transform Infrared (FTIR) Spectroscopy.

(2) ASTM D6348-03 Standard Test Method for Determination of Gaseous Compounds by Extractive Direct Interface Fourier Transform Infrared (FTIR) Spectroscopy.

(3) An equivalent method, with Director approval.

(c) You must determine the production rate(s) (100 percent basis) from each nitric acid train during the performance test according to paragraphs (c)(1) or (c)(2) of this section.

(1) Direct measurement of production and concentration (such as using flow meters or weigh scales, for production and concentration measurements).

(2) Existing plant procedures used for accounting purposes (i.e. dedicated tank-level and acid concentration measurements).

(d) You must conduct all performance tests in conjunction with the applicable methods approved by the Director. For each test, the facility must prepare an emission factor determination report that must include the items in paragraphs (d)(1) through (d)(3) of this section.

(1) Analysis of samples, determination of emissions, and raw data.

(2) All information and data used to derive the emissions factor(s).

(3) The production rate during each test and how it was determined.

(e) You must determine the monthly nitric acid production and the monthly nitric acid production during which N_2O abatement technology is operating from each nitric acid train according to the methods in paragraphs (c)(1) or (c)(2) of this section.

(f) You must determine the annual nitric acid production and the annual nitric acid production during which N_2O abatement technology is operating for each train by summing the respective monthly nitric acid production quantities.

§ WCI.315 Procedures for Estimating Missing Data

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) and (b) of this section.

(a) For each missing value of nitric acid production, the substitute data shall be the best available estimate based on all available process data or data used for accounting purposes (such as sales records).

(b) For missing values related to the performance test, including emission factors, production rate, and N_2O concentration, you must conduct a new performance test according to the procedures in WCI.314 (a) through (d).

§ WCI.340 PHOSPHORIC ACID PRODUCTION

§ WCI.341 Source Category Definition

The phosphoric acid production source category consists of facilities that use a wet-process phosphoric acid process line to produce phosphoric acid by reacting phosphate rock with acid.

§ WCI.342 Greenhouse Gas Reporting Requirements

In addition to the information required by regulation, the annual emissions data report shall contain the following information:

(a) Annual CO_2 process emissions from all wet-process phosphoric acid production lines, as specified in WCI.343 (tonnes).

(b) CO_2, N_2O, and CH_4 emissions from stationary combustion units, as specified in WCI.20 (tonnes).

(c) Annual phosphoric acid production (tonnes).

(d) Annual phosphoric acid permitted production capacity (tonnes).

(e) Annual arithmetic average percent inorganic carbon in phosphate rock from monthly records (%).

(f) Annual phosphate rock consumption from monthly records (tonnes).

(g) Number of times missing data procedures were used to estimate phosphate rock consumption (months) and inorganic carbon contents of the phosphate rock (month).

§ WCI.343 Calculation of CO_2 Emissions

(a) Calculate CO_2 process emissions using Equation 340-1 and the measured inorganic carbon content and feedstock input of the phosphate rock.

$$CO_2 = \sum_{i=1}^{12} \frac{FS_i * CF_i * 3.664}{c} \qquad \textbf{Equation 340-1}$$

Where:

CO_2 = Annual carbon dioxide emitted (tonnes/year).
FS_i = Feedstock consumption in month *i* (tonnes/month).
CF_i = Carbonate content of feedstock (kg C/tonne feedstock) for month *i*.
3.664 = Ratio of molecular weights, CO_2 to carbon.
c = Conversion factor (1,000 kg/tonne).

§ WCI.344 Sampling, Analysis, and Measurement Requirements

The monthly mass of phosphate rock consumed shall be determined using either existing plant procedures that are used for accounting purposes (such as sales records) or data from existing monitoring equipment that is used to measure total mass flow of phosphorus-bearing feed.

The monthly inorganic carbon content shall be obtained as specified under paragraphs (a) and (b) of this section.

(a) Obtain a monthly grab sample of phosphate rock directly from the rock being fed to the process line according to the following requirements:

(1) Follow the applicable standard method in "Phosphate Mining States Methods Used and Adopted by the Association of Fertilizer and Phosphate Chemists AFPC Manual 10th Edition 2009 – Version 1.9".

(2) If phosphate rock is obtained from more than one origin in a month, a sample must be obtained from each origin of rock or a composite representative sample must be obtained.

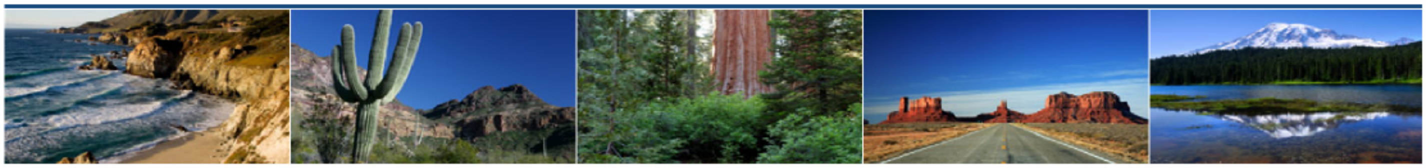
(b) Determine the inorganic carbon content of each monthly grab sample of phosphate rock (consumed in the production of phosphoric acid) using the applicable standard method in "Phosphate Mining States Methods Used and Adopted by the Association of Fertilizer and Phosphate Chemists AFPC Manual 10th Edition 2009 – Version 1.9".

§ WCI.345 Missing Data Procedures

A complete record of all measured parameters used in the GHG emissions calculations is required. Therefore, whenever a quality-assured value of a required parameter is unavailable, a substitute data value for the missing parameter shall be used in the calculations as specified in paragraphs (a) or (b) of this section. Records must be documented and kept of the procedures used for all such estimates.

(a) A substitute data value must be determined by calculated the arithmetic average of the quality-assured values of inorganic carbon contents of phosphate rock of origin *i* from samples immediately preceding and immediately following the missing data incident. If no quality-assured data on inorganic carbon contents of phosphate rock of origin *i* are available prior to the missing data incident, then the substitute data value shall be the first quality-assured value of inorganic carbon contents for phosphate rock of origin *i* obtained after the missing data period.

(b) For each missing value of monthly mass consumption of phosphate rock (by origin), the substitute data value shall be the best available estimate based on all available process data or data used for accounting purposes.



Due to the U.S. EPA finalizing publication of Part 98, Subpart W in November, 2010, the WCI has not yet performed detailed analyses on it for harmonization with cap and trade reporting. These analyses will be occurring in 2011. As such, for some specific emission sources identified in this quantification method option is given to facilities to report – for 2011 calendar year emissions only - using EPA equations and/or methods where these methods will give as or more accurate estimates of emissions than the otherwise prescribed methods.

§ WCI.350 NATURAL GAS TRANSMISSION AND DISTRIBUTION

§ WCI.351 Source Category Definition

This source category consists of the following:

(a) *Onshore natural gas transmission compression.* Onshore natural gas transmission compression means any stationary combination of compressors that move natural gas at elevated pressure from production fields or natural gas processing facilities in transmission pipelines to natural gas distribution pipelines or into storage. In addition, transmission compressor station may include equipment for liquids separation, natural gas dehydration, and tanks for the storage of water and hydrocarbon liquids. Residue (sales) gas compression operated by natural gas processing facilities are included in the onshore natural gas processing segment and are excluded from this segment.

(b) *Underground natural gas storage.* Underground natural gas storage means subsurface storage, including depleted gas or oil reservoirs and salt dome caverns that store natural gas that has been transferred from its original location for the primary purpose of load balancing (the process of equalizing the receipt and delivery of natural gas); natural gas underground storage processes and operations (including compression, dehydration and flow measurement, and excluding transmission pipelines); and all the wellheads connected to the compression units located at the facility that inject and recover natural gas into and from the underground reservoirs.

(c) *Liquefied natural gas (LNG) storage.* LNG storage means onshore LNG storage vessels located above ground, equipment for liquefying natural gas, compressors to capture and re-liquefy boil-off-gas, re-condensers, and vapourization units for re-gasification of the liquefied natural gas.

(d) *LNG import and export equipment.* LNG import equipment means all onshore or offshore equipment that receives imported LNG via ocean transport, stores LNG, re-gasifies LNG, and delivers re-gasified natural gas to a natural gas transmission or distribution system. LNG export equipment means all onshore or offshore equipment that receives natural gas, liquefies natural gas, stores LNG, and transfers the LNG via ocean transportation to any location, including locations in Canada.

(e) *Natural gas distribution.* Natural gas distribution consists of all natural gas equipment downstream of the station yard inlet shut-off valves of natural gas transmission pipelines at stations where pressure reduction and/or measuring first occurs for eventual delivery of natural gas to consumers.

(f) *Natural gas transmission pipelines.* Natural gas transmission pipelines means a high pressure pipeline (and associated equipment) transporting sellable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering and/or regulating stations before delivery to customers.

§ WCI.352 Greenhouse Gas Reporting Requirements

Where greenhouse gases are not emitted from a specific emission source identified in paragraphs (a) to (h) below, then the reported emissions for the specific source shall be reported as zero or "not applicable".

In addition to the information required by regulation, the annual emissions data report for both each individual facility over 10,000 tonnes, and the aggregate of facilities less than 10,000 tonnes (or as otherwise specified by regulation), must contain the following information:

(a) CO_2 and CH_4 (and N_2O, if applicable) emissions (in tonnes) from each industry segment specified in paragraph (b) through (f) of this section and from stationary and portable combustion equipment identified in paragraphs (g) and (h) of the section.

(b) For onshore natural gas transmission compression and natural gas transmission pipelines, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following sources:

(1) Compressor venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Blowdown vent stacks. *[WCI.353(c)]*

(iv) Natural gas pneumatic continuous high bleed devices and pumps. *[WCI.353(a)]*

(v) Natural gas pneumatic continuous low bleed and intermittent (low and high) bleed device venting. *[WCI.353(b)]*

(vi) Other venting emission sources.* *[WCI.353(l)]*

(2) Compressor fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves and meters. *[WCI.353(g)]*

(3) Compressor station flaring. *[WCI.353(d)]*

(4) Compressor other fugitive emission sources.**[WCI.353(l)]*

(5) Pipeline above ground meters and regulators at custody transfer city gate stations, including fugitive equipment leaks from connectors, block valves, control valves, pressure relief valves, orifice meters, regulators, and open ended lines. *[WCI.353(g)]*

(6) Above ground meters and regulators at non-custody transfer city gate stations, including station equipment leaks. Customer meters are excluded and instead are reported under WCI.352(f)(9). *[WCI.353(h)]*

(7) Pipeline flaring. *[WCI.353(d)]*

(8) Pipeline below ground meters and regulators and valve fugitives. *[WCI.353(h)]*

(9) Pipeline other fugitive emission sources not covered in (b)(5), (b)(6), (b)(7), or (b)(8) above (including, but not limited to, third party hits, farm taps, tubing systems less than one half inch diameter, pipe leaks, and customer meter sets).* *[WCI.353(l)]*

(10) Pipeline other venting emission sources.**[WCI.353(l)]*

(11) Transmission storage tanks [Reserved].

(c) For underground natural gas storage, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Natural gas pneumatic continuous high bleed devices and pumps. *[WCI.353(a)]*

(iv) Natural gas pneumatic continuous low bleed and intermittent (low and high) bleed devices. *[WCI.353(b)]*

(v) Other venting emission sources.* *[WCI.353(l)]*

(2) Fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves and meters. *[WCI.353(g)], [WCI.353(h)]*

(3) Flares. *[WCI.353(d)]*

(4) Other fugitive emission sources.* *[WCI.353(l)]*

(d) For LNG storage, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Other venting emission sources.* *[WCI.353(l)]*

(2) Fugitive equipment leaks from valves, pump seals, connectors, vapour recovery compressors, and other equipment leak sources. *[WCI.353(g)], [WCI.353(h)]*

(3) Flares. *[WCI.353(d)]*

(4) Other fugitive emission sources.* *[WCI.353(l)]*

(e) LNG import and export equipment, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Blowdown vent stacks. *[WCI.353(c)]*

(iv) Other venting emission sources.* *[WCI.353(l)]*

(2) Fugitive equipment leaks from valves, pump seals, connectors, vapour recovery compressors, and other equipment leak sources. *[WCI.353(g)], [WCI.353(h)]*

(3) Flares. *[WCI.353(d)]*

(4) Other fugitive emission sources.**[WCI.353(l)]*

(f) For natural gas distribution, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following sources:

(1) Above ground meters and regulators, at custody transfer city gate stations, including fugitive equipment leaks from connectors, block valves, control valves, pressure relief valves, orifice meters, regulators, and open ended lines. Customer meters are excluded and instead are reported under WCI.352(f)(9). *[WCI.353(g)]*

(2) Above ground meters and regulators at non-custody transfer city gate stations, including station equipment leaks. Customer meters are excluded and instead are reported under WCI.352(f)(9). *[WCI.353(h)]*

(3) Below ground meters and regulators and vault fugitives. *[WCI.353(h)]*

(4) Pipeline main fugitive equipment leaks. *[WCI.353(h)]*

(5) Service line fugitive equipment leaks. *[WCI.353(h)]*

(6) Pipeline flaring. *[WCI.353(d)]*

(7) Flares. *[WCI.353(d)]*

(8) Other venting emission sources.* *[WCI.353(l)]*

(9) Other fugitive emission sources (including but not limited to third party hits, farm taps, tubing systems less than one half inch diameter, and customer meter sets).* *[WCI.353(l)]*

(g) Report CO_2, CH_4, and N_2O emissions from each stationary fuel combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report stationary combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods.

(h) Report CO_2, CH_4, and N_2O emissions from each portable equipment combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report portable equipment combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods.

(i) Report data for each aggregated source type within paragraph (b) through (f) of this section as follows (for each individual facility or aggregate of facilities reported, as required by regulation):

(1) Where there is a choice of quantification method used for a source, the specific method(s) used and under what circumstances.

(2) Facility- and company-specific emission factors used in place of Tables 350-1 to 350-5.

(3) Count of natural gas pneumatic continuous high bleed devices.

(4) Count of natural gas pneumatic continuous low bleed devices.

(5) Count of natural gas pneumatic intermittent (low and high) bleed devices.

(6) Count of natural gas driven pneumatic pumps.

(7) Total pipeline length.

(8) For each dehydrator unit report the following:

(i) Glycol dehydrators:

(A) The number of glycol dehydrators less than and greater than or equal to 11,328 Sm^3/day operated

(ii) Desiccant dehydrators:

(A) The number of desiccant dehydrators operated.

(9) For each compressor report the following:

(i) Type of compressor whether reciprocating, centrifugal dry seal, or centrifugal wet seal.
(ii) Compressor capacity in horsepower.
(iii)Number of blowdowns per year.
(iv) Operating mode(s) during the year

(10) For fugitive equipment leaks and population count/emission factor sources using emission factors are used for estimating emissions in WCI.353(g) and (h), report the following:

(i) Component count for each source for which an emission factor is provided in this document. Approximate counts may be provided for the 2011 calendar year (reported in 2012) in preparation for full counts in the 2012 calendar year.

(ii) Total counts of leaks found in leak detection surveys by type of leak source for which an emission factor is provided.

(11) For natural gas distribution, report the following in addition to other requirements:
(i) Number of custody transfer gate stations.

(12) Number of non-custody transfer gate stations.

(13) Identification (including geographic coordinates) of any facility that was above 1,000 tonnes of greenhouse gas emissions in the previous year that was:
(i) Acquired during the reporting year;
(ii) Sold, decommissioned, or shut-in during the reporting year; and,
(iii) Greenhouse gas emissions for the facility in the previous year.

** other venting emission or other fugitive sources not specificially listed are not required to be reported if a specific other venting or other fugitive source type is reasonably estimated to be below 0.5% of total operation emissions and total emissions not reported under this clause do not exceed 1% of total operation emissions (if an individual facility is part of a larger reporting operation, the 0.5% or 1% should be interpreted as 0.5% or 1% of the reporting operation emissions, otherwise interpret as 0.5% or 1% of the facility emissions). The applicable regulator may, upon request and provision of sufficient information, provide a list of sources believed to be below these thresholds for all operations for which reporting and verification would not be required.*

§ WCI.353 Calculation of Greenhouse Gas Emissions

If greenhouse gases are not emitted from one or more of the following emission sources, the reporter will not need to calculate emissions from the emission source(s) in question and reported emissions for the emission source(s) will be zero or "not applicable". Where a quantification method is not provided for a specific source (such as for other venting and other fugitive sources), industry inventory practices must be used to estimate emissions. For ambient conditions, reporters must use average atmospheric conditions or typical operating conditions as applicable to the respective monitoring methods in this section.

(a) Natural gas pneumatic continuous high bleed device venting and natural gas driven pneumatic pump venting.

(1) Calculate emissions from a natural gas pneumatic continuous high bleed flow control device venting as follows:

(i) Estimate gas consumption for all continuous high bleed natural gas powered devices using statistically defensible emission factors that are reviewed every three to five years*. Factors should be developed using separate representative samples of the populations of high-bleed devices. Samples do not necessarily need to be repeated over time at a given location. Prior to 2013, Calculation Methodology 2 may be used.

(ii) Calculate CH_4 and CO_2 emissions from continuous high bleed pneumatic devices using Equation 350-1 of this section.

$$E_{GHGi} = V_{NG} \times M_i \times \left(\frac{MW_i}{MVC}\right) \times 0.001 \qquad \textbf{Equation 350-1}$$

Where:

E_{GHGi}	=	Emissions of GHG *i* (CH_4 or CO_2) (tonnes).
V_{NG}	=	Volume of natural gas consumed by continuous high bleed pneumatic devices (m^3/year).
M_i	=	Mole fraction of CH_4 or CO_2 in natural gas supply.
MW_i	=	Molecular weight of GHG_i.
MVC	=	Molar volume conversion factor.
0.001	=	Conversion factor from kg to tonnes

(2) For pneumatic pumps and if in 2011 or 2012 the statistically defensible emission factor is not available for continuous high bleed pneumatic devices, use the following method to estimate emissions from continuous high bleed devices and natural gas driven pneumatic pumps.

(i) For continuous high bleed devices, calculate vented emissions using manufacturer data.

(A) Obtain from the manufacturer specific pneumatic device model natural gas bleed rate during normal operation.

(B) Calculate the natural gas emissions for each continuous bleed device using Equation 350-2 of this section.

$$E_{s,n} = B_s \times t \qquad \textbf{Equation 350-2}$$

Where:

$E_{s,n}$	=	Annual natural gas emissions at standard conditions (m^3).
B_s	=	Natural gas driven pneumatic device bleed rate volume at standard conditions, as provided by the manufacturer (m^3/minute).
T	=	Amount of time that the pneumatic device has been operational through the reporting period (minutes).

(C) If manufacturer data for a specific device is not available, then use data for a similar device model, size and operational characteristics (or published default values) to estimate emissions.

(ii) Calculate emissions from natural gas driven pneumatic pump venting as follows:

(A) Obtain from the manufacturer specific pump model natural gas emission (or manufacturer "gas consumption") per unit volume of liquid circulation rate at pump speeds and operating pressures.

(B) Maintain a log of the amount of liquid pumped annually from individual pumps.

(C) Calculate the natural gas emissions for each pump using Equation 350-3 of this section.

$$E_{s,n} = F_s \times V \qquad \textbf{Equation 350-3}$$

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions (m^3/year).
F_s = Natural gas driven pneumatic pump gas emission in "emission per volume of liquid pumped at operating pressure" at standard conditions, as provided by the manufacturer (m^3/liter).
V = Volume of liquid pumped annually (liters/year).
.

(D) If manufacturer data for a specific pump in Equation 350-3 is not available, then use data for a similar pump model, size and operational characteristics (or published default values) to estimate emissions.

(iii) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section.

(3) Provide the total number of continuous high bleed natural gas pneumatic devices and pneumatic pumps of each type as follows:
(i) In the first calendar year, all continuous high bleed natural gas pneumatic devices and pneumatic pumps must be counted.
(ii) For the calendar year immediately following first calendar year, and for calendar years thereafter, facilities must update the total count of continuous high bleed pneumatic devices and pneumatic pumps and adjust accordingly to reflect any modifications due to changes in equipment.

* *[a phased in metering approach per that in WCI.364(a) is being considered for potential application for continuous high bleed devices covered by WCI.350 in place of the statistically defensible emission factor approach.]*

(b) <u>Natural gas pneumatic continuous low bleed and intermittent (low and high) bleed device venting</u>. Calculate emissions from natural gas pneumatic low continuous bleed, and intermittent (low and high) bleed device venting (separately) using Equation 350-4 of this section.

$$Mass_{s,i} = Count \times EF \times GHG_i \times t \times \rho_i \times 0.001 \qquad \textbf{Equation 350-4}$$

Where:

$Mass_{s,i}$	=	Annual total mass GHG emissions at standard conditions from all natural gas pneumatic continuous low bleed, and intermittent (low and high) bleed device venting, for GHG *i* (tonnes/year).
Count	=	Total number of natural gas pneumatic continuous low bleed, or intermittent (low and high) bleed devices.
EF	=	Population volumetric emission factors for natural gas pneumatic continuous low bleed, or intermittent (low and high) bleed device venting listed in Tables 350-1 and 350-2 of this section for onshore natural gas transmission and underground natural gas storage facilities, respectively.
GHG_i	=	For sources covered by WCI.350 (natural gas transmission), the value for GHG_i is 1.
t	=	Total time the continuous low bleed, or intermittent (low and high) bleed device was operating during the year (hours).
ρ_i	=	Density of GHG *i*, (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at STP of 15 ºC and 1 atmosphere).
0.001	=	Conversion factor from kilograms to tonnes.

(1) Provide the total number of continuous low bleed and intermittent (low and high) bleed natural gas pneumatic devices of each type as follows:
   (i) In the first calendar year, for the total number of each type, you may count the total of each type, or count any percentage number of each type plus an engineering estimate based on best available data of the number not counted.
   (ii) In the second calendar year, complete the count of all pneumatic devices, including any changes to equipment counted in prior years.
   (iii) For the calendar year immediately following the third consecutive calendar year, and for calendar years thereafter, facilities must update the total count of pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

(c) <u>Blowdown vent stacks</u>. Calculate blowdown vent stack emissions from depressurizing equipment to the atmosphere (excluding depressurizing to a flare, over-pressure relief, operating pressure control venting and blowdown of non-GHG gases) as follows:

(1) Calculate the total volume (including, but not limited to, pipelines, compressor case or cylinders, manifolds, suction and discharge bottles and vessels) between isolation valves determined by engineering estimates based on best available data.

(2) If the total volume between isolation valves is greater than or equal to 1.42 $Sm^{3,}$ retain logs of the number of blowdowns for each equipment type (including, but not limited to compressors, vessels, pipelines, headers, fractionators, and tanks). Blowdown volumes smaller than 1.42 $Sm^3$are exempt from reporting under paragraph (g) of this section

(3) Calculate the total annual venting emissions for each equipment type using Equation 350-5 of this section:

$$E_{s,n} = N \times \left(V_v \left[\frac{(273.15 + T_s)P_a}{(273.15 + T_a)P_s} \right] - V_v \times C \right)$$

Equation 350-5

Where:

$E_{s,n}$	=	Annual natural gas venting emissions at standard conditions from blowdowns (m^3).
N	=	Number of repetitive blowdowns for each equipment type of a unique volume in calendar year.
V_v	=	Total volume of blowdown equipment chambers (including, but not limited to, pipelines, compressors and vessels) between isolation valves (m^3).
C	=	Purge factor that is 1 if the equipment is not purged or zero if the equipment is purged using non-GHG gases.
T_s	=	Temperature at standard conditions (ºC).
T_a	=	Temperature at actual conditions in the blowdown equipment chamber (^oC).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at actual conditions in the blowdown equipment chamber (kPa).

(4) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section.

(5) Blowdowns that are directed to flares use the WCI.353(d) flare stacks calculation method rather than WCI.353(c) blowdown vent stacks calculation method.

(d) Flare stacks. Calculate CO_2, CH_4, and N_2O emissions from a flare stack as follows:

(1) If there is a continuous flow measurement device on the flare, measured flow volumes can be used to calculate the flare gas emissions. If all of the flare gas is not measured by the existing flow measurement device, then the flow not measured can be estimated using engineering calculations based on best available data or company records. If there is not a continuous flow measurement device on the flare, a flow measuring device can be installed on the flare or use engineering calculations based on process knowledge, company records, and best available data can be used.

(2) If there is a continuous gas composition analyzer on gas to the flare, these compositions must be used in calculating emissions. If there is not a continuous gas composition analyzer on gas to the flare, the appropriate gas compositions for each stream of hydrocarbons going to the flare must be used as follows:

(i) When the stream going to flare is natural gas, use the GHG mole percent in feed natural gas for all streams upstream of the de-methanizer or dew point control and GHG mole percent in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead or dew point control for onshore natural gas processing facilities.

(ii) When the stream going to the flare is a hydrocarbon product stream, such as ethane, butane, pentane-plus and mixed hydrocarbons, then use a representative composition from the source for the stream determined by engineering calculation based on process knowledge and best available data.

(3) Determine flare combustion efficiency from manufacturer. If not available, assume that flare combustion efficiency is 98 percent.

(4) Calculate GHG volumetric emissions at actual conditions using Equations 350-6, 350-7, 350-8, and 350-9 of this section.

$$E_{a,CH4} = V_a \times (1-\eta) \times X_{CH4}$$ **Equation 350-6**

$$E_{a,CO2}(noncombusted) = V_a \times X_{CO2}$$ **Equation 350-7**

$$E_{a,CO2}(combusted) = \sum_j \eta \times V_a \times Y_j \times R_j$$ **Equation 350-8**

$$E_{a,CO2}(total) = E_{a,CO2}(combusted) + E_{a,CO2}(noncombusted)$$ **Equation 350-9**

Where:

$E_{a,CH4}$	=	Contribution of annual noncombusted CH_4 emissions from flare stack under ambient conditions (m^3).
$E_{a,CO2}$ (noncombusted)	=	Contribution of annual CO_2 emissions from CO_2 in the inlet gas passing through the flare noncombusted under ambient conditions (m^3).
$E_{a,CO2}$ (combusted)	=	Contribution of annual emissions from combustion from flare stack under ambient conditions (m^3).
V_a	=	Volume of natural gas sent to flare during the year (m^3).
η	=	Percent of natural gas combusted by flare (default is 98 percent). For gas sent to an unlit flare, η is zero.
X_i	=	Mole fraction of GHG *i* in gas to the flare.
Y_j	=	Mole fraction of natural gas hydrocarbon constituents *j* (i.e., methane, ethane, propane, butane, and pentanes plus).
R_j	=	Number of carbon atoms in the natural gas hydrocarbon constituent *j*; 1 for methane, 2 for ethane, 3 for propane, 4 for butane, and 5 for pentanes plus).

(5) Calculate GHG volumetric emissions at standard conditions using calculations in paragraph (i) of this section.

(6) Calculate both CH_4 and CO_2 mass emissions from volumetric CH_4 and CO_2 emissions using calculation in paragraph (k) of this section.

(7) Calculate N_2O emissions using the Equation 350-10.

$$E_{N2O} = Fuel \times HHV \times EF \times 0.001$$

Equation 350-10

Where:

E_{N2O}	=	Annual N_2O emissions from the combustion of a particular type of fuel (tonnes).
Fuel	=	Mass or volume of the fuel combusted (mass or volume per year, choose appropriately to be consistent with the units of HHV).
HHV	=	High heat value of the fuel from paragraphs (d)(7)(i), (d)(7)(ii) or (d)(7)(iii) of this section (units must be consistent with Fuel).
EF	=	Use 9.52×10^{-5} kg N_2O/GJ.
0.001	=	Conversion factor from kilograms to tonnes.

(i) For fuels listed in Table 20-1, use the provided default HHV in the table.
(ii) For field gas or process vent gas, use 4.579×10^{-2} GJ/m^3 for HHV.
(iii) For fuels not listed in Table 20-1 and not field gas or process vent gas, you must use the methodology set forth in the Tier 2 methodology described in WCI.20 to determine HHV.

(8) To avoid double-counting, this emissions source excludes any emissions calculated under other emissions sources in this section. Where gas to be flared is manifolded from multiple sources in WCI.353 to a common flare, report all flaring emissions under WCI.353(d).

(e) Centrifugal compressor venting. Calculate emissions from centrifugal compressor vents as follows:*

(1) For each centrifugal compressor determine the volume of vapours from wet seal oil degassing tank sent to an atmospheric vent or flare using a temporary or permanent flow measurement meter such as, but not limited to, a vane anemometer according to methods set forth in WCI.354(b).

(2) Estimate annual emissions using meter flow measurement using Equation 350-11 of this section.

$$E_{a,i} = MT \times t \times M_i \times (1 - B)$$

Equation 350-11

Where:

$E_{a,i}$ = Annual GHG *i* (either CH_4 or CO_2) volumetric emissions at ambient conditions.
MT = Meter reading of gas emissions per unit time.
t = Total time the compressor associated with the wet seal(s) is operational in the reporting year.
M_i = Mole percent of GHG *i* in the degassing vent gas; use the appropriate gas compositions in paragraph (j)(2) of this section.
B = Percentage of centrifugal compressor vent gas sent to vapour recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapour recovery system and the amount of vent gas that is directed to the fuel gas system.

(3) An engineering estimate approach based on similar equipment specifications and operating conditions may be used to determine the MT variable in place of actual metered values for centrifugal compressors that are isolated for extended periods of time and used for peaking purposes in place of metered gas emissions if an applicable meter is not present on the compressor.

(4) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using paragraph (i) of this section.

(5) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (k) of this section.

(6) Calculate emissions from degassing vent vapours to flares as follows:

(i) Use the degassing vent vapour volume and gas composition as determined in paragraphs (e)(1) through (3) of this section.

(ii) Use the calculation methodology of flare stacks in paragraph (d) of this section to determine degassing vent vapour emissions from the flare.

(7) Emissions from dry seal centrifugal compressor vents, blow down valve leakage and unit isolation valve leakage to open ended vented are covered under WCI.353(l).

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(o) so long as the method is as accurate or more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(f) Reciprocating compressor venting. Calculate annual CH_4 and CO_2 emissions from all reciprocating compressor vents as follows.* Where venting emissions are sent to a common flare, calculate emissions using WCI.352(d).

(1) Estimate annual emissions using the flow measurement in (f)(2) or (f)(3) below and Equation 350-12.

$$E_{a,i,m} = MT \times t \times M_i$$

Equation 350-12

Where:

$E_{a,i,m}$ = Annual volumetric emissions of GHG *i* (either CH_4 or CO_2) at ambient conditions.

MT = Measured volumetric gas emissions (m^3/hour) under ambient conditions.

t = Total time the compressor is in the mode for which $E_{a,i,m}$ is being calculated, in the calendar year (hours).

M_i = Mole fraction of GHG *i* in the vent gas; use the appropriate gas compositions in paragraph (j)(2) of this section.

(2) If the reciprocating rod packing and blowdown vent is connected to an open ended vent line then use one of the following two methods to calculate emissions**.**

(i) Measure emissions from all vents (including emissions manifolded to common vents) including rod packing, unit isolation valves, and blowdown vents using either calibrated bagging or high volume sampler according to methods set forth in WCI.354(c) and (d).

(ii) Use a temporary meter such as a vane anemometer or a permanent meter such as an orifice meter to measure emissions from all vents (including emissions manifolded to a common vent) including rod packing vents, unit isolation valves, and blowdown valves according to methods set forth in WCI.354(b). If you do not have a permanent flow meter, you may install a port for insertion of a temporary meter or a permanent flow meter on the vents. For through-valve leakage to open ended vents, such as unit isolation valves on not operating, depressurized compressors and blowdown valves on pressurized compressors, you may use an acoustic detection device according to methods set forth in WCI.354(a).

(3) If the rod packing case is not equipped with a vent line use the following method to estimate emissions:

(i) Use the methods described in WCI.354(a) to conduct a progressive sample leak detection of fugitive equipment leaks from the packing case into an open distance piece, or from the compressor crank case breather cap or vent with a closed distance piece.

(ii) Measure emissions using a high flow sampler, or calibrated bag, or appropriate meter according to methods set forth in WCI.354(b), (c), or (d).

(4) Conduct an annual measurement for each compressor in the mode in which it is found during the annual measurement. Measure emissions from (including emissions manifolded to common vents) reciprocating rod packing vents, unit isolation valve vents, and blowdown valve vents.

(i) Operating or standby pressurized mode, blowdown vent leakage through the blowdown vent stack.

(ii) Operating mode, reciprocating rod packing emissions.

(iii) Not operating, depressurized mode, unit isolation valve leakage through the blowdown vent stack, without blind flanges.

(A) For the not operating, depressurized mode, each compressor must be measured at least once in any three consecutive calendar years if this mode is not found in the annual measurement. If a compressor is not operated and has blind flanges in place throughout the 3 year period, measurement is not required in this mode. If the compressor is in standby depressurized mode without blind flanges in place and is not operated throughout the 3 year period, it must be measured in the standby depressurized mode

(5) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using calculations in paragraph (i) of this section.

(6) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in paragraphs (j) and (k) of this section.

(7) Determine if the reciprocating compressor vent vapors are sent to a vapor recovery system.
   (i) Adjust the emissions estimated in paragraphs (f)(1) of this section downward by the magnitude of emissions recovered using a vapor recovery system as determined by engineering estimate based on best available data.

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(p) so long as the method is as accurate or more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(g) Leak detection and leaker emission factors. Existing legislative or regulatory requirements or progressive sampling methods described in WCI.354(a) must be used to conduct a leak detection of fugitive equipment leaks from all sources listed in WCI.352(b)(2), b(6), (c)(2), (d)(2), (e)(2), and (f)(1). This paragraph (g) applies to emissions sources in streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas content less than 10 percent CH_4 plus CO_2 by weight need to be reported instead under WCI.354(l). Tubing systems equal to or less than one half inch diameter are exempt from the requirements of this paragraph (g) need to be reported under WCI.354(l).

If fugitive equipment leaks are detected for sources listed in this paragraph, calculate emissions using Equation 350-13 (for volumetric emission factor [m^3/hour/component]) or Equation 350-14 (for mass emission factors [tonnes/hour/component]) of this section, as appropriate, for each source with fugitive equipment leaks.

$$E_{s,i} = Count \times EF_s \times GHG_i \times t_x \times \rho_i \times 0.001$$

Equation 350-13

$$E_{s,i} = Count \times EF_s \times GHG_i \times t_x$$

Equation 350-14

Where:

$E_{s,i}$	=	Annual total mass emissions of GHG *i* (CH_4 or CO_2) at standard conditions from each fugitive equipment leak source (tonnes/year).
Count	=	Total number of this type of emission source found to be leaking during t_x.
EF_s	=	Leaker emission factor for specific sources listed in Table 350-1 through Table 350-5 of this section or facility/company-specific emission factors used in place of Tables 350-1 to 350-5 (m^3/component/year for Equation 350-13 and tonnes/component/year for Equation 350-14).
GHG_i	=	For volumetric emissions in Equation 350-13, use 1 for CH_4 and 1.1×10^{-2} for CO_2. For mass emissions in Equation 350-14, use mass fractions of CH_4 and CO_2 from operation/facility specific data or the 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual.[1]
t_x	=	Total time the component was found leaking and operational, in hours. If one leak detection survey is conducted, assume the component was leaking from the start of the year until the leak was repaired and then zero for the remainder of the year. If the leak was not repaired, assume the component was leaking for the entire year. If multiple leak detection surveys are conducted, assume that the component found to be leaking has been leaking since the previous survey, or the beginning of the calendar year. For the last leak detection survey in the calendar year, assume that all leaking components continue to leak until the end of the calendar year or until the component was repaired and then zero until the end of the year.
ρ_i	=	Density of GHG *i* (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at STP of 15 ºC and 1 atmosphere*).
0.001	=	Conversion factor from kilograms to tonnes.

(1) Onshore natural gas transmission compression facilities shall use the appropriate default leaker emission factors listed in Table 350-1 of this section for fugitive equipment leaks detected from connectors, valves, pressure relief valves, meters, and open ended lines.

(2) Underground natural gas storage facilities for storage stations shall use the appropriate default leaker emission factors listed in Table 350-2 of this section for fugitive equipment leaks detected from connectors, valves, pressure relief valves, meters, and open ended lines.

(3) LNG storage facilities shall use the appropriate default leaker emission factors listed in Table 350-3 of this section for fugitive equipment leaks detected from valves, pump seals, connectors, and other equipment.

(4) LNG import and export facilities shall use the appropriate default leaker emission factors listed in Table 350-4 of this section for fugitive equipment leaks detected from valves; pump seals; connectors; and other.

[1] Clearstone Engineering Ltd. *Methodology Manual: Estimation of Air Emissions from the Canadian Natural Gas Transmission, Storage and Distribution System.* Prepared for Canadian Energy Partnership for Environmental Innovation (CEPEI). 2007

(5) Natural gas distribution facilities for above ground meters and regulators at city gate stations at custody transfer shall use the appropriate default leaker emission factors listed in Table 350-5 of this section for fugitive equipment leaks detected from connectors, block valves, control valves, pressure relief valves, orifice meters, regulators, and open ended lines.

(h) <u>Population count and emission factors</u>. This paragraph applies to emissions sources listed in WCI.352 b(7), b(9), (c)(2), (d)(2), (e)(2), (f)(2), (f)(3), (f)(4) and (f)(5) on streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas content less than 10 percent CH_4 plus CO_2 by weight do not need to be reported. Tubing systems equal or less than one half inch diameter are exempt from the requirements of paragraph (h) of this section and instead are to be reported under WCI.353(l).

Calculate emissions from all sources listed in this paragraph using Equation 350-15 (for volumetric emission factor [m^3/hour/component]) or Equation 350-16 (for mass emission factors [tonnes/hour/component]) of this section, as appropriate.

$$E_{s,i} = Count \times EF_s \times GHG_i \times t \times \rho_i \times 0.001$$

Equation 350-15

$$E_{s,i} = Count \times EF_s \times GHG_i \times t$$

Equation 350-16

Where:

$E_{s,i}$ = Annual total mass GHG emissions of GHG *i* (CH_4 or CO_2) at standard conditions from each fugitive source (tonnes/year).

Count = Total number of this type of emission source at the facility. Average component counts by major equipment pieces from the 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual (or other relevant Canadian Gas Association and/or Canadian Association of Petroleum Producers documentation) may be used as appropriate for operations and required by (h)(1) through (h)(5), below. If facility or company specific major equipment count data that meet or exceed the quality of the relevant CGA default count data are available, they must be used in its place.

EF_s = Population emission factor for specific sources listed in Table 350-1 through Table 350-5 of this section (m3/component/year for Equation 350-15 and tonnes/component/year for Equation 350-16). EF for non-custody transfer city gate stations is determined in Equation 350-17. The direction on the use of Tables 350-1 through 350-5 provided prior to the tables must be followed.

GHG_i = For volumetric emissions in Equation 350-15, use 1 for CH_4 and 1.1×10^{-2} for CO_2. For mass emissions in Equation 350-16, use mass fractions of CH_4 and CO_2 from operation/facility specific data or the 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual.

t	=	Total time the specific source associated with the fugitive equipment leak was operational in the reporting year (hours).
ρ_i	=	Density of GHG *i* (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at STP of 15 ºC and 1 atmosphere*).
0.001	=	Conversion factor from kilograms to tonnes.

(1) Underground natural gas storage facilities for storage wellheads shall use the appropriate default population emission factors listed in Table 350-2 of this section for fugitive equipment leaks from connectors, valves, pressure relief valves, and open ended lines.

(2) LNG storage facilities shall use the appropriate default population emission factors listed in Table 350-3 of this section for fugitive equipment leaks from vapour recovery compressors.

(3) LNG import and export facilities shall use the appropriate default population emission factor listed in Table 350-4 of this section for fugitive equipment leaks from vapour recovery compressors.

(4) Natural gas distribution facilities shall use the appropriate emission factors as described in paragraph (h)(5) of this section.

(i) Below grade meters and regulators; mains; and services, shall use the appropriate default population emission factors listed in Table 350-5 of this section.

(ii) Above grade meters and regulators at city gate stations not at custody transfer as listed WCI.352(f)(5), must use the total volumetric GHG emissions at standard conditions for all equipment leak sources calculated in paragraph (i)(6) of this section to develop facility emission factors using Equation 350-17 of this section. The calculated facility emission factor from Equation 350-17 of this section shall be used in Equations 350-15 and 350-16 of this section.

$$EF = \sum \frac{E_{s,i}}{Count}$$

Equation 350-17

Where:

EF	=	Facility emission factor for a meter at above grade M&R at city gate stations not at custody transfer in meters cubed per meter per year.
$E_{s,i}$	=	Annual volumetric GHG emissions at standard condition from all equipment leak sources at all above grade M&R city gate stations at custody transfer, from paragraph (i) of this section.
Count	=	Total number of meter runs at all above grade M&R city gate stations at custody transfer

(iii) To ensure proper calculation of emissions from pipeline main equipment leaks, Equations 350-15 and 350-16 and their inputs may be modified as necessary to meet 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual standards. For example, the length of the installed underground pipeline should be used in place of count and company specific leak data is permitted.

(i) Volumetric emissions. Calculate volumetric emissions at standard conditions as specified in paragraphs (i)(1) or (2) of this section determined by engineering estimate based on best available data unless otherwise specified.

(1) Calculate natural gas volumetric emissions at standard conditions by converting ambient temperature and pressure of natural gas emissions to standard temperature and pressure (15 ºC and 1 atmosphere in Canada) natural gas using Equation 350-18 of this section.

$$E_{s,n} = \frac{E_{a,n} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 350-18

Where:

$E_{s,n}$	=	Natural gas volumetric emissions at standard temperature and pressure (STP) conditions (m^3).
$E_{a,n}$	=	Natural gas volumetric emissions at ambient conditions (m^3).
T_s	=	Temperature at standard conditions (^oC).
T_a	=	Temperature at actual emission conditions (^oC).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at ambient conditions (kPa).

(2) Calculate GHG volumetric emissions at standard conditions by converting ambient temperature and pressure of GHG emissions to standard temperature and pressure using Equation 350-19 this section.

$$E_{s,i} = \frac{E_{a,i} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 350-19

Where:

$E_{s,i}$	=	GHG *i* volumetric emissions at standard temperature and pressure (STP) conditions (m^3).
$E_{a,i}$	=	GHG *i* volumetric emissions at actual conditions (m^3).
T_s	=	Temperature at standard conditions. (^oC).
T_a	=	Temperature at actual emission conditions. (^oC).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at ambient conditions (kPa).

(j) GHG volumetric emissions. Calculate GHG volumetric emissions at standard conditions as specified in paragraphs (j)(1) and (2) of this section determined by engineering estimate based on best available data unless otherwise specified.

(1) Estimate CH_4 and CO_2 emissions from natural gas emissions using Equation 350-20 of this section.

$$E_{s,i} = E_{s,n} \times M_i$$

Equation 350-20

Where:

$E_{s,i}$	=	GHG *i* (either CH_4 or CO_2) volumetric emissions at standard conditions.
$E_{s,n}$	=	Natural gas volumetric emissions at standard conditions.
M_i	=	Mole fraction of GHG *i* in the natural gas.

(2) For Equation 350-20 of this section, the mole fraction, M_i, shall be the annual average mole fraction for each facility, as specified in paragraphs (j)(2)(i) through (v) of this section.

(i) GHG mole fraction in transmission pipeline natural gas that passes through the facility for onshore natural gas transmission compression facilities.

(ii) GHG mole fraction in natural gas stored in underground natural gas storage facilities.

(iii) GHG mole fraction in natural gas stored in LNG storage facilities.

(iv) GHG mole fraction in natural gas stored in LNG import and export facilities.

(v) GHG mole fraction in local distribution pipeline natural gas that passes through the facility for natural gas distribution facilities.

(k) GHG mass emissions. Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions by converting the GHG volumetric emissions into mass emissions using Equation 350-21 of this section.

$$Mass_{s,i} = E_{s,i} \times \rho_i \times GWP \times 0.001$$

Equation 350-21

Where:

$Mass_{s,i}$	=	GHG *i* (either CH_4 or CO_2) mass emissions at standard conditions (tonnes CO_2e).
$E_{s,i}$	=	GHG *i* (either CH_4 or CO_2) volumetric emissions at standard conditions (m^3).
ρ_i	=	Density of GHG *i* (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at STP of 15 degrees celsius and 1 atmosphere*).
GWP	=	Global warming potential of GHG *i*, (1 for CO_2 and 21 for CH_4, and 310 for N_2O).

0.001 = Conversion factor from kilograms to tonnes.

* gas densities calculated using the 12th edition of the Gas Processors Suppliers Association Engineering Data Book.

(l) Other venting or fugitive emissions. All venting or fugitive emissions not covered by quantification methods in WCI.353 must be calculated by methodologies consistent with those presented here, in the 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual[2] (as amended from time to time), or in other relevant Canadian Gas Association documentation.

§ WCI.354 Sampling, Analysis, and Measurement Requirements

Instruments used for sampling, analysis and measurement must be operated and calibrated according to legislative, manufacturer's, or other written specifications or requirements. All sampling, analysis and measurement must be conducted only by, or under the direct supervision of individuals with demonstrated understanding and experience in the application (and principles related) of the specific sampling, analysis and measurement technique in use.

(a) (i) If a documented leak detection or integrity management standard or requirement that is required by legislation or regulation such as CSA Z662-07 Oil & Gas Pipeline Systems or similar standard Canadian Gas Association methodologies (as amended from time to time) is used, the documented standard or requirement must be followed – including service schedules for different components and/or facilities - with reporting as required for input to the calculation methods herein.

(ii) If there is no such legal requirement, then progressive sampling is required using one of the methods outlined below in combination with best industry practices for use of the method– including service schedules for different components - to determine the count of leaks (and time leaking) required in WCI.353(f), (g), and (h) as applicable. Progressive sampling means establishing a statistically valid baseline sample of leaks under normal operating conditions for the 2011 and 2012 calendar years, with subsequent sampling determined based random or spot sampling, modeling or measurement of leaks under normal operating conditions. A minimum of 18 months and a maximum of 36 months is allowed between surveys. This interval is determined based on whether there are indications of leaks. If a leak found and immediately repaired, the existing schedule may be maintained.

Leak detection for fugitive equipment leaks must be performed for all identified equipment in operation or on standby mode during a reporting period.

(1) Optical gas imaging instrument. Use an optical gas imaging instrument for fugitive equipment leaks detection in accordance with 40 CFR part 60, subpart A, §60.18(i)(1) and (2) *Alternative work practice for monitoring equipment leaks* (or per relevant

[2] Clearstone Engineering Ltd. *Methodology Manual: Estimation of Air Emissions from the Canadian Natural Gas Transmission, Storage and Distribution System.* Prepared for Canadian Energy Partnership for Environmental Innovation (CEPEI). 2007.

standard in Canada). In addition, the optical gas imaging instrument must be operated to image the source types required by this proposed reporting rule in accordance with the instrument manufacturer's operating parameters. The optical gas imaging instrument must comply with the following requirements:

(i) Provide the operator with an image of the potential leak points for each piece of equipment at both the detection sensitivity level and within the distance used in the daily instrument check described in the relevant best practices. The detection sensitivity level depends upon the frequency at which leak monitoring is to be performed.
(ii) Provide a date and time stamp for video records of every monitoring event.

(2) Bubble tests.

(3) Portable organic vapour analyzer. Use a portable organic vapour analyzer in accordance with US EPA Method 21 or as outlined in standard Canadian Gas Association methodologies or the CAPP Best Management Practices for Fugitive Emissions

(4) Other methods as outlined in standard Canadian Gas Association methodologies or the CAPP Best Management Practices for Fugitive Emissions may be used as necessary for operational circumstances. Other methods that are deemed to be technically sound based on an engineering assessment may also be used as necessary for operational circumstances provided that sufficient documentation as to the method used, results on tests, its reliability and accuracy is maintained and updated at regular intervals.

(b) All flow meters, composition analyzers and pressure gauges that are used to provide data for the GHG emissions calculations shall use measurement methods, maintenance practices, and calibration methods, prior to the first reporting year and in each subsequent reporting year using an appropriate standard method published by a consensus standards organization such as Canadian Standards Association (CSA), Canadian Gas Association, Canadian Energy Pipeline Association (CEPA), ASTM International, American National Standards Institute (ANSI), the relevant provincial or national oil and gas regulator, Measurement Canada, Canadian Association of Petroleum Producers (CAPP), American Petroleum Institute (API), American Society of Mechanical Engineers (ASME), and North American Energy Standards Board (NAESB). If a consensus based standard is not available, industry standard practices such as manufacturer instructions must be used.

(c) Use calibrated bags (also known as vent bags) only where the emissions are at near-atmospheric pressures and hydrogen sulphide levels are such that it is safe to handle and can capture all the emissions, below the maximum temperature specified by the vent bag manufacturer, and the entire emissions volume can be encompassed for measurement.

(1) Hold the bag in place enclosing the emissions source to capture the entire emissions and record the time required for completely filling the bag. If the bag inflates in less than one second, assume one second inflation time.

(2) Perform three measurements of the time required to fill the bag, report the emissions as the average of the three readings.

(3) Estimate natural gas volumetric emissions at standard conditions using calculations in WCI.353(i).

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.353(j) and (k).

(d) Use a high volume sampler to measure emissions within the capacity of the instrument.

(1) A technician following (and competent to follow) manufacturer instructions shall conduct measurements, including equipment manufacturer operating procedures and measurement methodologies relevant to using a high volume sampler, positioning the instrument for complete capture of the fugitive equipment leaks without creating backpressure on the source.

(2) If the high volume sampler, along with all attachments available from the manufacturer, is not able to capture all the emissions from the source then you shall use anti-static wraps or other aids to capture all emissions without violating operating requirements as provided in the instrument manufacturer's manual.

(3) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.353(j) and (k).

(4) Calibrate the instrument at 2.5 percent methane with 97.5 percent air and 100 percent CH_4 by using calibrated gas samples and by following manufacturer's instructions for calibration.

§ WCI.355 Procedures for Estimating Missing Data

A complete record of all estimated and/or measured parameters used in the GHG emissions calculations is required. If data are lost or an error occurs during annual emissions estimation or measurements, the estimation or measurement activity for those sources must be repeated as soon as possible, including in the subsequent reporting year if missing data are not discovered until after December 31 of the reporting year, until valid data for reporting is obtained. Data developed and/or collected in a subsequent reporting year to substitute for missing data cannot be used for that subsequent year's emissions estimation. Where missing data procedures are used for the previous year, at least 30 days must separate emissions estimation or measurements for the previous year and emissions estimation or meausrements for the current year of data collection. For missing data that are continuously monitored or measured (for example flow meters), or for missing temperature and pressure data, the reporter may use best available data for use in emissions determinations. The reporter must record and report the basis for the best available data in these cases.

§ WCI.356 Definitions

Blowdown vent stack emissions mean natural gas and/or CO_2 released due to maintenance and/or blowdown operations including compressor blowdown and emergency shut-down (ESD) system testing.

Calibrated bag means a flexible, non-elastic, anti-static bag of a calibrated volume that can be affixed to a emitting source such that the emissions inflate the bag to its calibrated volume.

Centrifugal compressor means any equipment that increases the pressure of a process natural gas or CO_2 by centrifugal action, employing rotating movement of the driven shaft.

Centrifugal compressor dry seals mean a series of rings around the compressor shaft where it exits the compressor case that operates mechanically under the opposing forces to prevent natural gas or CO_2 from escaping to the atmosphere.

Centrifugal compressor dry seals emissions mean natural gas or CO_2 released from a dry seal vent pipe and/or the seal face around the rotating shaft where it exits one or both ends of the compressor case.

Centrifugal compressor wet seal degassing venting emissions means emissions that occur when the high-pressure oil barriers for centrifugal compressors are depressurized to release absorbed natural gas or CO_2. High-pressure oil is used as a barrier against escaping gas in centrifugal compressor shafts. Very little gas escapes through the oil barrier, but under high pressure, considerably more gas is absorbed by the oil. The seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated. The separated gas is commonly vented to the atmosphere.

Component means each metal to metal joint or seal of non-welded connection separated by a compression gasket, screwed thread (with or without thread sealing compound), metal to metal compression, or fluid barrier through which natural gas or liquid can escape to the atmosphere.

Compressor means any machine for raising the pressure of a natural gas by drawing in low pressure natural gas and discharging significantly higher pressure natural gas.

Continuous bleed means a continuous flow of pneumatic supply gas to the process measurement device (e.g. level control, temperature control, pressure control) where the supply gas pressure is modulated by the process condition, and then flows to the valve controller where the signal is compared with the process set-point to adjust gas pressure in the valve actuator.

De-methanizer means the natural gas processing unit that separates methane rich residue gas from the heavier hydrocarbons (e.g., ethane, propane, butane, pentane-plus) in feed natural gas stream.

Equipment leak detection means the process of identifying emissions from equipment, components, and other point sources.

Engineering estimation, for the purposes of WCI.350 and WCI.360 means an estimate of emissions based on engineering principles applied to measured and/or approximated physical parameters such as dimensions of containment, actual pressures, actual temperatures, and compositions.

External combustion means fired combustion in which the flame and products of combustion are separated from contact with the process fluid to which the energy is delivered. Process fluids may be air, hot water, or hydrocarbons. External combustion equipment may include fired heaters, industrial boilers, and commercial and domestic combustion units.

Farm taps are pressure regulation stations that deliver gas directly from transmission pipelines to generally rural customers. The gas may or may not be metered, but always does not pass through a city gate station

Field gas means natural gas extracted from a production well prior to its entering the first stage of processing, such as dehydration.

Flare combustion efficiency means the fraction of natural gas, on a volume or mole basis, that is combusted at the flare burner tip.

Fugitive emissions means the unintended or incidental emissions of greenhouse gases from the transmission, processing, storage, use or transportation of fossil fuels, greenhouse gases, or other.

Fugitive equipment leak means the those fugitive emissions which could not reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening.

Gas conditions mean the actual temperature, volume, and pressure of a gas sample.

High-bleed pneumatic devices are automated continuous bleed control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate in excess of six standard cubic feet per hour.

Intermittent bleed pneumatic devices mean automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. These are snap-acting or throttling devices that discharge the full volume of the actuator intermittently when control action is necessary, but does not bleed continuously.

Internal combustion means the combustion of a fuel that occurs with an oxidizer (usually air) in a combustion chamber. In an internal combustion engine the expansion of the high-temperature and –pressure gases produced by combustion applies direct force to a component of the engine, such as pistons, turbine blades, or a nozzle. This force moves the component over a distance, generating useful mechanical energy. Internal combustion equipment may include gasoline and diesel industrial engines, natural gas-fired reciprocating engines, and gas turbines.

Liquefied natural gas (LNG) means natural gas (primarily methane) that has been liquefied by reducing its temperature to -162 degrees Celsius at atmospheric pressure.

LNG boiloff gas means natural gas in the gaseous phase that vents from LNG storage tanks due to ambient heat leakage through the tank insulation and heat energy dissipated in the LNG by internal pumps.

Low-bleed pneumatic devices mean automated control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate equal to or less than 0.17 standard cubic meters per hour.

Natural gas driven pneumatic pump means a pump that uses pressurized natural gas to move a piston or diaphragm, which pumps liquids on the opposite side of the piston or diaphragm.

Operating pressure means the containment pressure that characterizes the normal state of gas or liquid inside a particular process, pipeline, vessel or tank.

Pipeline quality natural gas means natural gas having a high heat value equal to or greater than 36.3 MJ/m3 or less than 40.98 MJ/m3, and which is at least ninety percent methane by volume, and which is less than five percent carbon dioxide by volume.

Portable means the same as defined in WCI.27 and WCI.361(a)(2)

Pump means a device used to raise pressure, drive, or increase flow of liquid streams in closed or open conduits.

Pump seals means any seal on a pump drive shaft used to keep methane and/or carbon dioxide containing light liquids from escaping the inside of a pump case to the atmosphere.

Pump seal emissions means hydrocarbon gas released from the seal face between the pump internal chamber and the atmosphere.

Reciprocating compressor means a piece of equipment that increases the pressure of a gas stream by positive displacement, employing linear movement of a shaft driving a piston in a cylinder.

Reciprocating compressor rod packing means a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of the compressed gas stream that escapes to the atmosphere.

Re-condenser means heat exchangers that cool compressed boil-off gas to a temperature that will condense natural gas to a liquid.

Reservoir means a porous and permeable underground natural formation containing significant quantities of hydrocarbon liquids and/or gases.

Transmission pipeline means high pressure cross country pipeline transporting saleable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering, regulating stations where the natural gas is typically odorized before delivery to customers.

Vapour recovery system means any equipment located at the source of potential gas emissions to the atmosphere or to a flare, that is composed of piping, connections, and, if necessary, flow-inducing devices, and that is used for routing the gas back into the process as a product and/or fuel.

Vapourization unit means a process unit that performs controlled heat input to vapourize LNG to supply transmission and distribution pipelines or consumers with natural gas.

Vented emissions means the same as defined in the relevant greenhouse gas reporting regulation, including process designed flow to the atmosphere through seals or vent pipes, equipment blowdown for maintenance, and direct venting of gas used to power equipment (such as pneumatic devices), but not including stationary combustion flue gas.

Directions for the use of Tables 350-1 to 350-5

(a) Starting with 2013 calendar year emissions, for each component listed in the Tables 350-1 to 350-5, or otherwise required by the quantification method referencing Tables 350-1 and 350-2:

(i) If statistically valid facility specific emission factors for a component type are available or can be safely or reasonably developed they must be used

(ii) If facility specific emissions factors for a component type are not available, an operator must use statistically valid company specific emission factors if they can be safely or reasonably developed.

(iii) If statistically valid facility or company specific emission factors for a specific component type cannot be safely and reasonably developed, estimates in the default Tables 350-1 to 350-5 may be used. Equipment or facilities that have low temporal utilization (e.g. equipment such as some booster stations used only sporadically during a year) may continue to use the default tables.

(b) For 2011 and 2012 calendar year emissions,

(i) An operator may use the default factors specified below, company or facility-specific emissions factors (if such emission factors are available). If the default factors in Tables 350-1 to 350-5 are used, an explanation as to why company or facility specific emission factors are cannot be used must be provided to the jurisdiction.

(c) If a facility-specific emission factor has been used in a previous reporting year, it must continue to be used until updated. If a company-specific emission factor has been used in a previous reporting year, it must continue to be used until updated or a facility-specific emission factor is used in its place

(d) Any changes from facility-specific factors to company-specific or table factors, or from company specific factors to the defaults in Tables 350-1 to 350-5 must be approved by the jurisdiction and substantiated by proof that the new approach is more accurate for the facility or facilities in question

(e) If an emission factor required by the quantification method referencing Tables 350-1 through 350-5 is not provided in the tables, emission factors from either the U.S. EPA 40 CFR Part 98.230 Tables W-3 through W-7 or the 2007 Canadian Gas Association Methodology Manual may be used (as converted for use in the relevant equation).

(f) Documentation on the method used to update the emission factors, input data, sampling methodology and other relevant information must be kept by the operator and provided to the jurisdiction or verifier upon request

(g) All emission factors or data collection for emission factors must be developed using Canadian Gas Association (CGA) standard methods, or other methods if CGA methods are not available or applicable. Facility and company-specific emission factors must be updated at a minimum on a three year cycle, with the first update to the original facility and company-specific emission factors for the 2016 reporting period, at the latest.

(h) Updated emission factors can only be incorporated for reporting purposes at the start of a reporting period and not during a calendar year.

(i) The default emission factors provided in Tables 350-1 to 350-5 below are industry average emission factors for Canada as of the 2010 calendar year. The factors will be updated every 3-5 years based on new data, methods and statistically valid samples of the entire industry and developed in collaboration with industry groups.

TABLE 350-1 –DEFAULT EMISSION FACTORS FOR TRANSMISSION

Transmission	Emission Factor (tonnes/hour/component) Direct conversion of EF's in CGA Manual[3] Table 6 (kg to tonnes)
Leaker Emission Factors - All Components, Gas Service	
Connector	4.471 E-7
Block valve	4.131 E-6
Control valve	1.650 E-2
Compressor blowdown valve	3.405 E-3
Pressure relief valve	1.620 E-4
Orifice meter	4.863 E-5
Other meter	9.942 E -6
Regulator	7.945 E-6
Open-ended line	9.183 E-5
Population Emission Factors - Other Components, Gas Service	**Emission Factor (Sm^3/hour/component) Direct conversion of EF's in EPA Subpart W Table W-3 (scf to Sm^3)**
Low-bleed pneumatic device vents	3.99 E-2
High continuous bleed pneumatic device vents	5.32 E-1
Intermittent (low and high) bleed pneumatic device vents	5.32 E-1

* The distribution emission factors in Table 350-5 should be used for equipment in odourized service and the transmission factors in Table 350-1 should be used for equipment in unodourized service, regardless of the actual classification or functionality of the facility

*Emission factors are conversions of those contained in the U.S. EPA Subpart W Table W-7.

** the distribution emission factors in Table 350-5 should be used for equipment in odourized service and the transmission factors in Table 350-1 should be used for equipment in unodourized service, regardless of the actual classification or functionality of the facility

Due to the U.S. EPA finalizing publication of Part 98, Subpart W in November, 2010, the WCI has not yet performed detailed analyses on it for harmonization with cap and trade reporting. These analyses will be occurring in 2011. As such, for some specific emission sources identified in this quantification method option is given to facilities to report – for 2011 calendar year emissions only - using EPA equations and/or methods where these methods will give as or more accurate estimates of emissions than the otherwise prescribed methods.

§WCI.360 PETROLEUM AND NATURAL GAS PRODUCTION AND GAS PROCESSING

§ WCI.361 Source Category Definition

(a) This source category consists of the following:

(1) *Offshore petroleum and natural gas production.* Offshore petroleum and natural gas production is any platform structure, affixed temporarily or permanently to offshore submerged lands, that houses equipment to extract hydrocarbons from the ocean or lake floor and that processes and/or transfers such hydrocarbons to storage, transport vessels, or onshore. In addition, offshore production includes secondary platform structures connected to the platform structure via walkways, storage tanks associated with the platform structure and floating production and storage offloading equipment (FPSO). This source category does not include reporting of emissions from offshore drilling and exploration that is not conducted on production platforms.

(2) *Onshore petroleum and natural gas production.* Onshore petroleum and natural gas production equipment means all structures associated with wells (including but not limited to compressors, generators, or storage facilities), piping (including but not limited to flowlines or intra-facility gathering lines), and portable non-self-propelled equipment (including but not limited to well drilling and completion equipment, workover equipment, gravity separation equipment, auxiliary non-transportation-related equipment, and leased, rented or contracted equipment) used in the production, extraction, recovery, lifting, stabilization, separation or treating of petroleum and/or natural gas (including condensate). This also includes associated storage or measurement and all systems engaged in gathering produced gas from multiple wells, all EOR operations using $CO_{2,}$ and all petroleum and natural gas production located on islands, artificial islands or structures connected by a causeway to land, an island, or artificial island.

(3) *Onshore natural gas processing.* Natural gas processing plants separates and/or recovers natural gas liquids (NGLs) and/or other non-methane gases and liquids from a stream of produced natural gas to meet onshore natural gas transmission pipeline quality specifications through equipment performing one or more of the following processes: oil and condensate removal, water removal, separation of natural gas liquids, sulphur and carbon dioxide removal, fractionation of NGLs, or other processes, and also the

capture of CO_2 separated from natural gas streams for delivery outside the facility. In addition, field gathering and/or boosting stations that gather and process natural gas from multiple wellheads, and compress and transport natural gas (including but not limited to flowlines or intra-facility gathering lines or compressors) as feed to the natural gas processing plants may be considered a part of the processing plant if emissions are not calculated under onshore petroleum and natural gas production. Gathering and boosting stations that send the natural gas to an onshore natural gas transmission compression facility, or natural gas distribution facility, or to an end user are also considered within onshore natural gas processing for the purposes of emissions calculation. All residue gas compression equipment operated by a processing plant, whether inside or outside the processing plant fence, are considered part of the natural gas processing plant.

(b) This source category does not include natural gas transmission and distribution (i.e., onshore natural gas transmission compression, underground natural gas storage, liquefied natural gas (LNG) storage, LNG import and export equipment, and natural gas distribution). These are included in WCI.350 (Natural Gas Transmission and Distribution).

§ WCI.362 Greenhouse Gas Reporting Requirements

Where greenhouse gases are not emitted from a specific emission source identified in paragraphs (a) to (f), below then the reported emissions for the specific source shall be reported as zero or "not applicable".

In addition to the information required by regulation, the annual emissions data report, for both each individual facility over 10,000 tonnes and the aggregate of facilities less than 10,000 tonnes (or as otherwise specified by regulation), must contain the following information:

(a) CO_2 and CH_4 (and N_2O, if applicable) emissions (in tonnes) from each industry segment specified in paragraph (b) through (d) of this section and from stationary and portable combustion equipment identified in paragraphs (e) and (f) of the section.

(b) For offshore petroleum and natural gas production, report CO_2, CH_4, and N_2O emissions from equipment leaks, vented emission, and flare emission source types as identified in the data collection and emissions estimation study conducted by BOEMRE in compliance with 30 CFR 250.302 through 304. Offshore platforms do not need to report portable emissions *[WCI.363(p), reserved]*

(c) For onshore petroleum and natural gas production, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following source types:

(1) Natural gas pneumatic continuous high bleed device venting. *[WCI.363(a)]*

(2) Natural gas driven pneumatic pump venting. *[WCI.363(a)]*

(3) Natural gas pneumatic continuous low bleed and intermittent (low and high) bleed device venting. *[WCI.363(b)]*

(4) Acid gas removal venting and incineration process. *[WCI.363(c)]*

(5) Dehydrator vents. *[WCI.363(d)]*

(6) Well venting for liquids unloading. *[WCI.363(e)]*

(7) Gas well venting during well completions or workovers with hydraulic fracturing, except where vent gas is sent to a flare. *[WCI.363(f)]*

(8) Gas well venting during well completions or workovers without hydraulic fracturing, except where vent gas is sent to a flare. *[WCI.363(f)]*

(9) Blowdown vent stacks. *[WCI.363(g)]*

(10) Storage tanks. *[WCI.363(h)]*

(11) Well testing venting and flaring. *[WCI.363(i)]*

(12) Associated gas venting and flaring. *[WCI.363(j)]*

(13) Flare stacks. *[WCI.363(k)]*

(14) Centrifugal compressor venting. *[WCI.363(l)]*

(15) Reciprocating compressor venting. *[WCI.363(m)]*

(16) Gathering pipeline fugitive equipment leaks. *[WCI.363(o) or WCI.363(x) for emission sources not covered by WCI.363(o)]*

(17) Fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves, pumps, flanges, and other fugitive equipment leak sources (such as instruments, loading arms, stuffing boxes, compressor seals, dump lever arms, and breather caps). *[WCI.363(o]*

(18) EOR injection pump blowdown. *[WCI.363(t)]*

(19) Hydrocarbon liquids dissolved CO_2 from flashing [Reserved]. *[WCI.363(u)]*

(20) Produced water dissolved CO_2 [Reserved]. *[WCI.363(v)]*

(21) Coal bed methane produced water emissions [Reserved]. *[WCI.363(v)]*

(22) Other venting emission sources.* *[WCI.363(x)]*

(23) Other fugitive emission sources.**[WCI.363(x)]*

(d) For onshore natural gas processing, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following sources:

(1) Acid gas removal venting or incineration. *[WCI.363(c)]*

(2) Dehydrator vents. *[WCI.363(d)]*

(3) Blowdown vent stacks. *[WCI.363(g)]*

(4) Storage tanks. *[WCI.363(h)]*

(5) Flare stacks. *[WCI.363(k)]*

(6) Centrifugal compressor venting. *[WCI.363(l)]*

(7) Reciprocating compressor venting. *[WCI.363(m)]*

(8) Gathering pipeline fugitive equipment leaks. *[WCI.363(o) or WCI.363(x) for emission sources not covered by WCI.363(o)]*

(9) Fugitive equipment leaks from: valves, connectors, open ended lines, pressure relief valves and meters. *[WCI.363(n)]*

(10) Other fugitive emission sources (including reciprocating compressor rod packing fugitives, centrifugal compressor dry and wet seals, etc).**[WCI.363(x)]*

(11) Other venting emission sources.**[WCI.363(x)]*

(e) Report CO_2, CH_4, and N_2O emissions from each stationary fuel combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report stationary combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods.**

(f) Report CO_2, CH_4, and N_2O emissions from each portable equipment combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report portable equipment combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods.**

(g) Report data for each aggregated source type within paragraph (b) through (d) of this section as follows (for each individual facility or aggregate of facilities reported, as required by regulation):

(1) Where there is a choice of quantification method used for a source, the specific method(s) used and under what circumstances.

(2) Facility and company-specific emission factors used in place of Tables 360-1 and 360-2.

(3) Count of natural gas pneumatic continuous high bleed devices.

(4) Count of natural gas pneumatic continuous low bleed devices.

(5) Count of natural gas intermittent (low and high) bleed devices.

(6) Count of natural gas driven pneumatic pumps.

(7) Total throughput of acid gas removal units.

(8) For each dehydrator unit report the following:
    (i) Glycol dehydrators:

        The number of glycol dehydrators less than and greater than or equal to 11,328 Sm^3/day operated.
    (ii) Desiccant dehydrators:
        (A) The number of desiccant dehydrators operated.

(9) Count of wells vented to the atmosphere for liquids unloading.

(10) Count of wells venting during well completions:
    (i) Number of conventional completions.
    (ii) Number of completions employing hydraulic fracturing.

(11) Count of wells venting during well workovers:
    (i) number well workovers involving well venting to the atmosphere.

(12) For each compressor report the following:
    (i) Type of compressor whether reciprocating, centrifugal dry seal, or centrifugal wet seal.
    (ii) Compressor capacity in horse powers (except for well site natural gas production compressors).
    (iii) Number of blowdowns per year (except for well site natural gas production compressors).
    (iv) Operating mode(s) during the year (except for well site natural gas production compressors).

(13) Number of EOR injection pump blowdowns per year.

(14) Count of wells tested in the reporting period.

(15) Count of wells venting or flaring associated natural gas in the reporting period.

(16) Count of wells being unloaded for liquids in the reporting year.

(17) Count of wells completed (worked over) in the reporting year.

(18) For fugitive equipment leaks and population count/emission factor sources where emission factors are used for estimating emissions in WCI.363(n) and (o), report the following:

(i) Component count for each source for which an emission factor is provided in this document. Approximate counts may be provided for the 2011 calendar year (reported in 2012) in preparation for full counts in the 2012 calendar year.
(ii) Total counts of fugitive equipment leaks found in leak detection surveys by type of leak source for which an emission factor is provided.

(19) Barrels of oil equivalent throughput/processed as determined by engineering estimate based on best available data.

(20) Identification (including geographic coordinates) of any facility that was above 1,000 tonnes of greenhouse gas emissions in the previous year that was:
(i) Acquired during the reporting year;
(ii) Sold, decommissioned or shut-in during the reporting year; and,
(iii) Greenhouse gas emissions for the facility in the previous year .

** Other venting emission or other fugitive sources not specifically listed are not required to be reported if a specific other venting or other fugitive source type is reasonably estimated to be below 0.5% of total operation emissions and total emissions not reported under this clause do not exceed 1% of total operation emissions (if an individual facility is part of a larger reporting operation, the 0.5% or 1% should be interpreted as 0.5% or 1% of the reporting operation emissions, otherwise interpret as 0.5% or 1% of the facility emissions). The applicable regulator may, upon request and provision of sufficient information, provide a list of sources believed to be below these thresholds for all operations for which reporting and verification would not be required.*

*** Portable equipment is portable fuel combustion equipment that cannot move on roadways under its own power and drive train, and that are located at an onshore production facility. Stationary or portable equipment include the following equipment which are integral to the extraction, processing or movement of oil or natural gas: well drilling and completion equipment, workover equipment, natural gas dehydrators, natural gas compressors, electrical generators, steam boilers, and process heaters*

§ WCI.363 Calculating GHG Emissions

If greenhouse gases are not emitted from one or more of the following emission sources, the reporter will not need to calculate emissions from the emission source(s) in question and reported emissions for the emission source(s) will be zero or "not applicable". Where a quantification method is not provided for a specific source (such as for other venting and other fugitive sources), industry inventory practices must be used to estimate emissions. For ambient conditions, reporters must use average atmospheric conditions or typical operating conditions as applicable to the respective monitoring methods in this section.

(a) <u>Natural gas pneumatic continuous high bleed device venting and natural gas driven pneumatic pump venting.</u> Calculate emissions from a natural gas pneumatic continuous high bleed flow control device venting and natural gas drived pneumatic pump venting as follows.

Natural gas driven pneumatic pumps covered in paragraph (d) of this section do not have to report emissions under paragraph (a) of this section:

(1) Calculation Methodology 1. Calculate vented emissions from a natural gas pneumatic continuous high bleed control devices or pneumatic pumps as follows:

(i) Measure gas consumption for all continuous high bleed natural gas powered devices (except pneumatic pumps not equipped with a meter) using a meter or meters that meet accuracy requirements specified by relevant oil and gas metering requirements in the jurisdiction (even if a meter is not prescribed for this circumstance in the relevant requirements). In 2013, reporters are required to meter gas consumption for at least 50% of all continuous high bleed devices. Metering of gas consumption for all continuous high bleed devices is required in 2014. Prior to 2013 and for up to 50% of continuous high bleed devices in 2013, Calculation Methodology 2 may be used. Common meters may be used where possible.

(ii) Calculate CH_4 and CO_2 emissions from continuous high bleed pneumatic devices and pumps using Equation 360-1.

$$E_{GHGi} = V_{NG} \times M_i \times \left(\frac{MW_i}{MVC}\right) \times 0.001$$ **Equation 360-1**

Where:

E_{GHGi}	=	Emissions of GHG *i* (CH_4 or CO_2) (tonnes)
V_{NG}	=	Volume of natural gas consumed by metered continuous high bleed pneumatic devices and pumps (m^3/year).
M_i	=	Mole fraction of CH_4 or CO_2 in natural gas supply.
MW_i	=	Molecular weight of GHG *i* .
MVC	=	Molar volume conversion factor.
0.001	=	Conversion factor from kg to tonnes.

(2) Calculation Methodology 2. Emissions from continuous high bleed devices and natural gas driven pneumatic pumps that are not equipped with meters must be calculated using the following methods.

(i) For continuous high bleed devices, calculate vented emissions using manufacturer data.

(A) Obtain from the manufacturer specific pneumatic device model natural gas bleed rates during normal operation.

(B) Calculate the natural gas emissions for each continuous bleed device using Equation 360-2.

$$E_{s,n} = B_s \times t$$ **Equation 360-2**

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions (m^3).
B_s = Natural gas driven pneumatic device bleed rate volume at standard conditions, as provided by the manufacturer (m^3/minute).
t = Amount of time that the pneumatic device has been operational through the reporting period (minutes).

If manufacturer data for a specific device is not available, then use data for a similar device model, size and operational characteristics to estimate emissions.

(ii) Calculate emissions from natural gas driven pneumatic pump venting as follows:

(A) Obtain from the manufacturer specific pump model natural gas emission (or manufacturer "gas consumption") per unit volume of liquid circulation rate at pump speeds and operating pressures.

(B) Maintain a log of the amount of liquid pumped annually from individual pumps.

(C) Calculate the natural gas emissions for each pump using Equation 360-3.

$$E_{s,n} = F_s \times V \qquad \textbf{Equation 360-3}$$

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions (m^3/year).
F_s = Natural gas driven pneumatic pump gas emission in "emission per volume of liquid pumped at operating pressure" at standard conditions, as provided by the manufacturer (m^3/liter).
V = Volume of liquid pumped annually (liters/year).

If manufacturer data for a specific pump is not available, then use data for a similar pump model, size and operational characteristics to estimate emissions.

(iii) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(3) Provide the total number of continuous high bleed natural gas pneumatic devices and pneumatic pumps of each type as follows:
(i) In the first calendar year, all continuous high bleed natural gas pneumatic devices and pneumatic pumps must be counted.
(ii) For the calendar year immediately following first calendar year, and for calendar years thereafter, facilities must update the total count of continuous high bleed

pneumatic devices and pneumatic pumps and adjust accordingly to reflect any modifications due to changes in equipment.

(b) Natural gas pneumatic continuous low bleed and intermittent (low and high) bleed device venting. Calculate emissions from natural gas pneumatic continuous low bleed and intermittent (low and high) bleed device venting (separately) using Equation 360-4 of this section.

$$Mass_{s,i} = Count \times EF \times GHG_i \times t$$

Equation 360-4

Where:

$Mass_{s,i}$	=	Annual total mass GHG emissions at standard conditions from all natural gas pneumatic continuous low bleed, and intermittent (low and high) bleed device venting, for GHG *i* (tonnes/year).
Count	=	Total number of natural gas pneumatic continuous low bleed, or intermittent (low and high) bleed devices.
EF	=	Population emission factors for natural gas pneumatic continuous low bleed, or intermittent (low and high) bleed device venting listed in Table 360-1 (tonnes of natural gas/component-hour).
GHG_i	=	Mass fraction of GHG *i* (CH_4 or CO_2), in produced natural gas (tonnes of GHG *i*/tonnes of natural gas).
t	=	Total time the continuous low bleed device, or intermittent (low and high) bleed device was operating during the year (hours).

(1) Provide the total number of continuous low bleed and intermittent (low and high) bleed natural gas pneumatic devices of each type as follows:
   (i) In the first calendar year, for the total number of each type, you may count the total of each type, or count any percentage number of each type plus an engineering estimate based on best available data of the number not counted.
   (ii) In the second calendar year, complete the count of all pneumatic devices, including any changes to equipment counted in prior years.
   (iii) For the calendar year immediately following the third consecutive calendar year, and for calendar years thereafter, facilities must update the total count of pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

(c) Acid gas removal (AGR) venting or incineration process. Except for AGRs where the acid gases are re-injected into the oil/gas field, calculate CO_2 emissions only (not CH_4) for AGR (including but not limited to processes such as amine, membrane, molecular sieve or other absorbents and adsorbents) using Equation 360-5.*

$$E_{a,CO2} = \left(V + \alpha \times \left(V \times \left(Vol_I - Vol_O\right)\right)\right) \times \left(Vol_I - Vol_O\right)$$ **Equation 360-5**

Where:

$E_{a,CO2}$	=	Annual volumetric CO_2 emissions at actual condition (m^3/year).
V	=	Metered total annual volume of natural gas flow into or out of AGR unit (m^3/year) as determined in paragraph (c)(1) of this section.
α	=	Factor is 1 if outlet stream flow is measured. Factor is 0 if inlet stream flow is measured.
Vol_I	=	Volume fraction of CO_2 in natural gas into the AGR unit as determined in paragraph (c)(2) of this section.
Vol_O	=	Volume fraction of CO_2 in natural gas out of the AGR unit as determined in paragraph (c)(3) of this section.

(1) Record the gas flow rate of the inlet and outlet natural gas stream of an AGR unit using a meter according to methods set forth in WCI.364(b).

(2) If a continuous gas analyzer is installed on the inlet gas stream, then the continuous gas analyzer results must be used. If a continuous gas analyzer is not available, either install a continuous gas analyzer or take monthly gas samples from the inlet gas stream to determine Vol_I according to methods set forth in WCI.364(b).

(3) Determine volume fraction of CO_2 content in natural gas out of the AGR units using one of the methods specified in paragraph (c)(3) of this section.

(i) If a continuous gas analyzer is installed on the outlet gas stream, then the continuous gas analyzer results must be used. If a continuous gas analyzer is not available, you may install a continuous gas analyzer.

(ii) If a continuous gas analyzer is not available or installed, monthly gas samples may be taken from the outlet gas stream to determine Vol_O according to methods set forth in WCI.364(b).

(4) Calculate CO_2 volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(5) Mass CO_2 emissions shall be calculated from volumetric CO_2 emissions using calculations in paragraphs (r) and (s) of this section.

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(d) so long as the method is as accurate or more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(d) Dehydrator vents. For dehydrator vents, calculate annual mass CH_4, CO_2 and N_2O (when flared) emissions at standard temperature and pressure (STP) conditions as follows*:

(1) Calculate annual mass emissions from dehydrator vents using a simulation software package of similar accuracy to GRI-GLYCalc Version 4.0 or AspenTech HYSYS®, that uses the Peng-Robinson equation of state to calculate the equilibrium coefficient, speciates CH_4 and CO_2 emissions from dehydrators, and has provisions to include regenerator control devises, a separator flash tank, stripping gas and a gas injection pump or gas assist pump. A minimum of the following parameters must be used for characterizing emissions from dehydrators:

(i) Feed natural gas flow rate.
(ii) Feed natural gas water content.
(iii) Outlet natural gas water content.
(iv) Absorbent circulation pump type (natural gas pneumatic/air pneumatic/electric).
(v) Absorbent circulation rate.
(vi) Absorbent type: including, but not limited to, triethylene glycol (TEG), diethylene glycol (DEG) or ethylene glycol (EG).
(vii) Use of stripping natural gas.
(viii) Use of flash tank separator (and disposition of recovered gas).
(ix) Hours operated.
(x) Wet natural gas temperature, pressure, and composition. Determine this parameter by selecting one of the methods described under paragraph (d)(1)(x) of this section.

(A) Use the wet natural gas composition as defined in paragraph (r)(2)(i) of this section.
(B) If wet natural gas composition cannot be determined using paragraph (r)(2)(i) of this section, select a representative analysis.
(C) You may use an appropriate standard method published by a consensus-based standards organization if such a method exists or you may use an industry standard practice as specified in WCI.364(b) to sample and analyze wet natural gas composition.
(D) If only composition data for dry natural gas is available, assume the wet natural gas is saturated.

(2) Determine if dehydrator unit has vapor recovery. Adjust the emissions estimated in paragraphs (d)(1) or (d)(2) of this section downward by the magnitude of emissions captured.

(3) Calculate annual emissions from dehydrator vents to flares or regenerator fire-box/fire tubes as follows:

(i) Use the dehydrator vent stack volume and gas composition as determined in paragraph (d)(1) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine dehydrator vent emissions from the flare or regenerator combustion gas vent.

(4) Dehydrators that use desiccant shall calculate emissions from the amount of gas vented from the vessel every time it is depressurized for the desiccant refilling process using Equation 360-6.

$$E_{s,n} = \left(\frac{H \times D^2 \times \pi \times P_2 \times \%G \times 365}{4 \times P_1 \times t} \right) \Big/ 100$$

Equation 360-6

Where:

$E_{s,n}$ = Annual natural gas emissions at standard conditions (m^3).
H = Height of the dehydrator vessel (m).
D = Inside diameter of the vessel (m).
P_1 = Atmospheric pressure (kPa).
P_2 = Pressure of the gas (kPa).
π = pi (3.14).
%G = Percent of packed vessel volume that is gas.
365 = Conversion from days to years.
t = Time between refilling (days).
100 = Conversion of %G to fraction.

(5) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(e) so long as the method is as accurate or more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(e) Well venting for liquids unloading. The CO_2 and CH_4 emissions for well venting for liquids unloading shall be determined using one of the following calculation methodologies:

(1) Calculation Methodology 1. For one well* of each well tubing diameter and producing horizon/formation combination in each gas producing field where gas wells are vented to the atmosphere to expel liquids accumulated in the tubing, a recording flow meter shall be installed on the vent line used to vent gas from the well (e.g. on the vent line off the wellhead separator or atmospheric storage tank) according to the methods set forth in the WCI.364(b). Calculate emission from well venting for liquids unloading using Equation 360-7.

$$E_{a,n} = \sum_h \sum_t t_{h,t} \times FR_{h,t}$$

Equation 360-7

Where:

$E_{a,n}$ = Annual natural gas emissions at actual conditions (m^3).
$t_{h,t}$ = Cumulative amount of time in hours of venting from all wells of the same tubing diameter (t) and producing horizon (h)/formation combination during the year.
$FR_{h,t}$ = Average flow rate (m^3) of the measured well venting for the duration of the liquids unloading, under actual conditions as determined in paragraph (e)(1)(i) of this section.

(i) Determine the well vent average flow rate as specified under paragraph (e)(1)(i) of this section.

(A) The average flow rate per hour of venting is calculated for each unique tubing diameter and producing horizon/formation combination in each producing field by averaging the recorded flow rates for the recorded for one well venting to the atmosphere.

(B) This average flow rate is applied to all wells in the field that have the same tubing diameter and producing horizon/formation combination, for the number of hours of venting these wells.

(C) A new average flow rate is calculated every other calendar year (if necessary) for each reporting field and horizon starting the first calendar year of data collection.

(ii) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(2) Calculation Methodology 2. Calculate emissions from each well venting for liquids unloading using Equation 360-8.

$$E_{a,n} = \left(\left[7.854 \times 10^{-5} \right] \times CD^2 \times WD \times \left[\frac{SP}{101.325} \right] \times N_V \right) + \left(SFR \times \left[HR - 1.0 \right] \times Z \right)$$

Equation 360-8

Where:

$E_{a,n}$ = Annual natural gas emissions at actual conditions (m^3/year).
7.854×10^{-5} = $(\pi/4)/(10000)$
CD = Casing diameter (cm).
WD = Well depth (m).
SP = Shut-in pressure (kPa-gage).
N_V = Number of vents per year.
SFR = Average sales flow rate of gas well (m^3/hr).
HR = Hours that the well was left open to the atmosphere during unloading.
1.0 = Hours for average well to blowdown casing volume at shut-in pressure.
Z = If HR is less than 1.0, then Z is equal to 0. If HR is greater than or equal to 1.0, then Z is equal to 1.

(i) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(3) Calculation Methodology 3. Calculate emissions from each well venting to the atmosphere for liquids unloading with plunger lift assist using Equation 360-9.

$$E_{a,n} = \left(\left[7.854 \times 10^{-5}\right] \times TD^2 \times WD \times \left[\frac{SP}{101.325}\right] \times N_V\right) + \left(SFR \times \left[HR - 0.5\right] \times Z\right)$$ **Equation 360-9**

Where:

$E_{a,n}$	=	Annual natural gas emissions at actual conditions (m^3/year).
7.854×10^{-5}	=	(π/4)/(10000)
TD	=	Tubing diameter (cm).
WD	=	Tubing depth to plunger bumper (meters).
SP	=	Sales line pressure (kPa-gage).
N_V	=	Number of vents per year.
SFR	=	Average sales flow rate of gas well (m^3/hr).
HR	=	Hours that the well was left open to the atmosphere during unloading.
0.5	=	Hours for average well to blowdown tubing volume at sales line pressure.
Z	=	If HR is less than 0.5 then Z is equal to 0. If HR is greater than or equal to 0.5 then Z is equal to 1.

(i) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(4) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

* the number of wells required to create an unbiased sample is being considered for future amendment

(f) Gas well venting during well completions and workovers with or without hydraulic fracturing. Calculate emissions from gas conventional or unconventional (from hydraulic fracturing) well venting during well completions and workovers using Equation 360-10. Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (r) of this section. Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.*

$$E_{a,n} = (t \times FR) - EnF - SG$$

Equation 360-10

Where:

$E_{a,n}$ = Annual natural gas vented emissions at ambient conditions (m^3).
t = Cumulative amount of time in hours of well venting during the year.
FR = Flow rate under ambient conditions, as required in paragraph (f)(1) of this section (m^3/hr).
EnF = Volume of CO_2 or N_2 injected gas (Sm^3) that was injected into the reservoir during an energized fracture job. If the fracture process did not inject gas into the reservoir, then EnF is 0. If injected gas is CO_2 then EnF is 0.
SG = Volume of natural gas (Sm^3) that was recovered into a sales pipeline. If no gas was recovered for sales, SG is 0.

(1) The flow rate for gas well venting during well completions and workovers from hydraulic fracturing shall be determined using either of the calculation methodologies described in this paragraph (f)(1). The same calculation methodology must be used for the entire volume for the reporting year.
   (i) Calculation Methodology 1. For a statistically valid sample of well completions and well workovers, a recording flow meter shall be installed on the vent line during each well unloading event according to methods set forth in WCI.364(b). The average flow rate for each well in the field (m^3/minute of venting) is calculated based on the statistically valid sample of well completions and well workovers.
   (ii) Calculation Methodology 2. For a statistically valid sample of well completions and well workovers, record the pressures measured before and after the well choke according to methods set forth in WCI.364(b). The average flow rate across the choke (m^3/minute of venting) is calculated for each well completion and each well workover.
   (iii) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.
   (iv) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(2) Calculate annual emissions from gas well venting during well completions and workovers to flares as follows:
   (i) Use the gas well venting volume during well completions and workovers as determined in paragraph (f)(1) of this section.
   (ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine gas well venting during well completions and workovers emissions from the flare.

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(g) so long as the method is as accurate or more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(f.1) Gas well venting during well completions and workovers without hydraulic fracturing. Reserved *[paragraph (f) indicated to be appropriate for use in Canada for gas wells without hydraulic fracturing]*

(g) Blowdown vent stacks. Calculate blowdown vent stack emissions from depressurizing equipment to the atmosphere (excluding depressurizing to a flare, over-pressure relief, operating pressure control venting and blowdown of non-GHG gases; desiccant dehydrator blowdown venting before reloading is covered in paragraph (d)(4) of this section) as follows:

(1) Calculate the total volume (including, but not limited to, pipelines, compressor case or cylinders, manifolds, suction and discharge bottles and vessels) between isolation valves determined by engineering estimates based on best available data.

(2) If the total volume between isolation valves is greater than or equal to 1.42 Sm^3, retain logs of the number of blowdowns for each equipment type (including, but not limited to compressors, vessels, pipelines, headers, fractionators, and tanks). Blowdown volumes smaller than 1.42 Sm^3 are exempt from reporting under paragraph (g) of this section.

(3) Calculate the total annual venting emissions for each equipment type using Equation 360-11:

$$E_{s,n} = N \times \left(V_v \left[\frac{(273.15 + T_s) P_a}{(273.15 + T_a) P_s} \right] - V_v \times C \right)$$

Equation 360-11

Where:

$E_{s,n}$	=	Annual natural gas venting emissions at standard conditions from blowdowns (m^3).
N	=	Number of repetitive blowdowns for each equipment type of a unique volume in calendar year.
V_v	=	Total volume of blowdown equipment chambers (including, but not limited to, pipelines, compressors and vessels) between isolation valves (m^3).
C	=	Purge factor that is 1 if the equipment is not purged or zero if the equipment is purged using non-GHG gases.
T_s	=	Temperature at standard conditions (ºC).
T_a	=	Temperature at actual conditions in the blowdown equipment chamber (ºC).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at actual conditions in the blowdown equipment chamber (kPa).

(4) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(5) Blowdowns that are directed to flares use the WCI.363(k) Flare stacks calculation method rather than WCI.363(g) Blowdown vent stacks calculation method.

(h) <u>Onshore production and processing storage tanks</u>. For emissions from atmospheric pressure fixed roof storage tanks receiving hydrocarbon produced liquids from onshore petroleum and natural gas production facilities and onshore natural gas processing facilities, calculate annual CH_4 and CO_2 emissions as specified in paragraphs (h)(1) or (h)(2). For atmospheric storage tanks vented to flares, use the calculation methodology for flare stacks in paragraph (k) of this section. Storage tanks equipped with vapour recovery units (VRU) are exempt from the requirements of this paragraph.

(1) CH_4 and CO_2 emissions at storage tank batteries where the oil production rate is 10 barrels per day or greater shall be calculated using Equation 360-12.

$$E_{GHGi} = GOR \times PR \times \left(\frac{1}{MVC}\right) \times MW_g \times MF_i \times 0.001$$

Equation 360-12

Where:

E_{GHGi}	=	Annual emissions of greenhouse gas *i* (CO_2 or CH_4) (tonnes/year).
GOR	=	Gas Oil Ratio (m^3 gas/m^3 oil).
PR	=	Oil production rate (m^3/measurement period).
MVC	=	Molar volume conversion.
MW_g	=	Molecular weight of the gas (kg/kg-mole).
MF_i	=	Mass fraction of greenhouse gas *i* (CO_2 or CH_4) in gas (kg *i* /kg gas).
0.01	=	Conversion factor (tonnes/kg).

(2) Methane and carbon dioxide emissions at storage tank batteries where the oil production rate is less than 10 barrels per day shall calculate methane emissions using the latest software package for E&P Tank. A minimum of the following parameters must be used to characterize emissions from liquid transfer to atmospheric pressure storage tanks.
(i) Separator oil composition.
(ii) Separator temperature.
(iii) Separator pressure.
(iv) Sales oil API gravity.
(v) Sales oil production rate.
(vi) Sales oil Reid vapour pressure.
(vii) Ambient air temperature.
(viii) Ambient air pressure.

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(j) so long as the method is as accurate or

more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(i) Well testing venting and flaring. Calculate CH_4, CO_2, and N_2O (when flared) well testing venting and flaring emissions as follows:

(1) Determine the gas to oil ratio (GOR) of the hydrocarbon production from each well tested.

(2) If GOR cannot be determined from your available data, then use one of the two procedures in paragraph (i)(2) of this section to determine GOR:
(i) You may use an appropriate standard method published by a consensus-based standards organization if such a method exists.
(ii) Or you may use an industry standard practice as described in WCI.364(b).

(3) Estimate venting emissions using Equation 360-13.

$$E_{a,n} = GOR \times FR \times D$$

Equation 360-13

Where:

$E_{a,n}$	=	Annual volumetric natural gas emissions from well testing ambient conditions (m^3).
GOR	=	Gas to oil ratio (m^3 gas/m^3 oil); oil here refers to hydrocarbon liquids produced of all API gravities.
FR	=	Flow rate (m^3 oil/day) for the well being tested.
D	=	Number of days during the year the well is tested.

(4) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(5) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(6) Calculate emissions from well testing to flares as follows:
(i) Use the well testing emissions volume and gas composition as determined in paragraphs (i)(1) through (3) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine well testing emissions from the flare.

(j) Associated gas venting and flaring. Calculate associated gas venting and flaring emissions not in conjunction with well testing (refer to section (i): Well testing venting and flaring) as follows:

(1) Determine the GOR ratio of the hydrocarbon production from each well whose associated natural gas is vented or flared. If GOR from each well is not available, the GOR from a cluster of wells in the same field shall be used.

(2) If GOR cannot be determined from your available data, then use one of the two procedures in paragraph (j)(2) of this section to determine GOR:
   (i) You may use an appropriate standard method published by a consensus-based standards organization if such a method exists.
   (ii) Or you may use an industry standard practice as described in WCI.364(b).

(3) Estimate venting emissions using the Equation 360-14.

$$E_{a,n} = GOR \times V$$

Equation 360-14

Where:

$E_{a,n}$	=	Annual volumetric natural gas emissions from associated gas venting under ambient conditions (m^3).
GOR	=	Gas to oil ratio (m^3 gas/m^3 oil); oil here refers to hydrocarbon liquids produced of all API gravities.
V	=	Total volume of oil produced for the calendar year during which associated gas was flared or vented (m^3 oil/year)..

(4) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(5) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(6) Calculate emissions from associated natural gas to flares as follows:
   (i) Use the associated natural gas volume and gas composition as determined in paragraph (j)(1) through (4) of this section.
   (ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine associated gas emissions from the flare.

(k) Flare stacks. Calculate CO_2, CH_4, and N_2O emissions from a flare stack as follows:

(1) If there is a continuous flow measurement device on the flare, measured flow volumes must be used to calculate the flare gas emissions. If all of the flare gas is not measured by the existing flow measurement device, then the flow not measured can be estimated using engineering calculations based on best available data or company records. If there is not a continuous flow measurement device on the flare, a flow measuring device can be installed on the flare or engineering calculations based on process knowledge, company records, and best available data can be used.

(2) If there is a continuous gas composition analyzer on the gas to the flare, these compositions must be used in calculating emissions. If there is not a continuous gas

composition analyzer on the gas to the flare, the appropriate gas compositions for each stream of hydrocarbons going to the flare must be used as follows:

(i) For onshore natural gas production, determine natural gas composition using (r)(2)(i) of this section.

(ii) For onshore natural gas processing, when the stream going to flare is natural gas, use the GHG mole percent in feed natural gas for all streams upstream of the de-methanizer or dew point control and GHG mole percent in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead or dew point control for onshore natural gas processing facilities.

(iii) When the stream going to the flare is a hydrocarbon product stream, such as ethane, butane, pentane-plus, and mixed light hydrocarbons then use a representative composition from the source for the stream determined by engineering calculation based on process knowledge and best available data.

(3) Determine flare combustion efficiency from manufacturer. If not available, assume that flare combustion efficiency is 98 percent.

(4) Calculate GHG volumetric emissions at actual conditions using Equations 360-15, 360-16, 360-17, and 360-18.

$$E_{a,CH4} = V_a \times (1-\eta) \times X_{CH4}$$ **Equation 360-15**

$$E_{a,CO2}(noncombusted) = V_a \times X_{CO2}$$ **Equation 360-16**

$$E_{a,CO2}(combusted) = \sum_j \eta \times V_a \times Y_j \times R_j$$ **Equation 360-17**

$$E_{a,CO2}(total) = E_{a,CO2}(combusted) + E_{a,CO2}(noncombusted)$$ **Equation 360-18**

Where:

$E_{a,CH4}$	=	Contribution of annual noncombusted CH_4 emissions from flare stack under ambient conditions (m^3).
$E_{a,CO2}$ (noncombusted)	=	Contribution of annual CO_2 emissions from CO_2 in the inlet gas passing through the flare noncombusted under ambient conditions (m^3).
$E_{a,CO2}$ (combusted)	=	Contribution of annual CO_2 emissions from combustion from flare stack under ambient conditions (m^3).
V_a	=	Volume of natural gas sent to flare during the year (m^3).
η	=	Percent of natural gas combusted by flare (default is 98 percent). For gas sent to an unlit flare, η is zero.
X_i	=	Mole fraction of GHG *i* in gas to the flare.

Y_j = Mole fraction of natural gas hydrocarbon constituents *j* (i.e., methane, ethane, propane, butane, and pentanes plus).

R_j = Number of carbon atoms in the natural gas hydrocarbon constituent *j* (i.e., 1 for methane, 2 for ethane, 3 for propane, 4 for butane, and 5 for pentanes plus).

(5) Calculate GHG volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(6) Calculate both CH_4 and CO_2 mass emissions from volumetric CH_4 and CO_2 emissions using calculation in paragraph (s) of this section.

(7) Calculate N_2O emissions using Equation 360-19.

$$E_{N2O} = Fuel \times HHV \times EF \times 0.001$$

Equation 360-19

Where:

E_{N2O} = Annual N_2O emissions from the combustion of a particular type of fuel (tonnes).

Fuel = Mass or volume of the fuel combusted (mass or volume per year, choose appropriately to be consistent with the units of HHV).

HHV = High heat value of the fuel from paragraphs (k)(7)(i), (k)(7)(ii) or (k)(7)(iii) of this section (units must be consistent with Fuel).

EF = Use 9.52×10^{-5} kg N_2O/GJ.

0.001 = Conversion factor from kilograms to tonnes.

(i) For fuels listed in Table 20-1, use the provided default HHV in the table.

(ii) For field gas or process vent gas, use 4.579×10^{-2} GJ/m^3 for HHV.

(iii) For fuels not listed in Table 20-1 and not field gas or process vent gas, you must use the methodology set forth in the Tier 2 methodology described in WCI.20 to determine HHV.

(8) To avoid double-counting, this emissions source excludes any emissions calculated under other emissions sources in WCI.363. Where gas to be flared is manifolded from multiple sources in WCI.363 to a common flare, report all flaring emissions under WCI.363(k).

(l) Centrifugal compressor venting. Calculate emissions from centrifugal compressor venting as follows:*

(1) For each centrifugal compressor determine the volume of vapours from wet seal oil degassing tank sent to an atmospheric vent or flare using a temporary or permanent flow measurement meter such as, but not limited to, a vane anemometer according to methods set forth in WCI.364(b).

(2) Estimate annual emissions using meter flow measurement using Equation 360-20.

$$E_{a,i} = MT \times t \times M_i \times (1 - B)$$

.

Equation 360-20

Where:

$E_{a,i}$	=	Annual volumetric emissions of GHG *i* (either CH_4 or CO_2) at ambient conditions.
MT	=	Meter reading of gas emissions per unit time.
t	=	Total time the compressor associated with the wet seal(s) is operational in the reporting year.
M_i	=	Mole percent of GHG *i* in the degassing vent gas; use the appropriate gas compositions in paragraph (r)(2) of this section.
B	=	Percentage of centrifugal compressor vent gas sent to vapour recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapour recovery system and the amount of vent gas that is directed to the fuel gas system.

(3) An engineering estimate approach based on similar equipment specifications and operating conditions may be used to determine the MT variable in place of actual metered values for centrifugal compressors that are isolated for extended periods of time and used for peaking purposes in place of metered gas emissions if an applicable meter is not present on the compressor.

(4) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using paragraph (q) of this section.

(5) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (s) of this section.

(6) Calculate emissions from degassing vent vapours to flares as follows:
(i) Use the degassing vent vapour volume and gas composition as determined in paragraphs (l)(1) through (3) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine degassing vent vapour emissions from the flare.

(7) Emissions from dry seal centrifugal compressor vents, blow down valve leakage and unit isolation valve leakage to open ended vented are covered under WCI.353(x).

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(o) so long as the method is as accurate or more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(m) Reciprocating compressor venting. Calculate annual CH_4 and CO_2 emissions from all reciprocating compressor vents as follows, except as specified in paragraph (m)(8), following*. Where venting emissions are sent to a common flare, calculate emissions using WCI.362(k).

(1) Estimate annual emissions using the flow measurement in (m)(2) or (m)(3) below and Equation 360-21.

$$E_{a,i,m} = MT \times t \times M_i$$

Equation 360-21

Where:

$E_{a,i,m}$	=	Annual volumetric emissions of GHG *i* (either CH_4 or CO_2) at ambient conditions.
MT	=	Measured volumetric gas emissions (m^3/hour) under ambient conditions.
t	=	Total time the compressor is in the mode for which $E_{a,i,m}$ is being calculated, in the calendar year (hours).
M_i	=	Mole fraction of GHG *i* in the vent gas; use the appropriate gas compositions in paragraph (r)(2) of this section.

(2) If the reciprocating rod packing and blowdown vent is connected to an open ended vent line then use one of the following two methods to calculate emissions.

(i) Measure emissions from all vents (including emissions manifolded to common vents) including rod packing, unit isolation valves, and blowdown vents using either calibrated bagging or high volume sampler according to methods set forth in WCI.364(c) and (d).

(ii) Use a temporary meter such as a vane anemometer or a permanent meter such as an orifice meter to measure emissions from all vents (including emissions manifolded to a common vent) including rod packing vents, unit isolation valves, and blowdown valves according to methods set forth in WCI.364(b). If you do not have a permanent flow meter, you may install a port for insertion of a temporary meter or a permanent flow meter on the vents. For through-valve leakage to open ended vents, such as unit isolation valves on not operating, depressurized compressors and blowdown valves on pressurized compressors, you may use an acoustic detection device according to methods set forth in WCI.364(a).

(3) If the rod packing case is not equipped with a vent line use the following method to estimate emissions:

(i) Use the methods described in WCI.364(a) to conduct a progressive sample leak detection of fugitive equipment leaks from the packing case into an open distance piece, or from the compressor crank case breather cap or vent with a closed distance piece.

(ii) Measure emissions using a high flow sampler, or calibrated bag, or appropriate meter according to methods set forth in WCI.364(b), (c), or (d).

(4) Conduct an annual measurement for each compressor in the mode in which it is found during the annual measurement, except as specified in paragraph (m)(8) of this section. Measure emissions from (including emissions manifolded to common vents) reciprocating rod packing vents, unit isolation valve vents, and blowdown valve vents.

(i) Operating or standby pressurized mode, blowdown vent leakage through the blowdown vent stack.

(ii) Operating mode, reciprocating rod packing emissions.

(iii) Not operating, depressurized mode, unit isolation valve leakage through the blowdown vent stack, without blind flanges.

(A) For the not operating, depressurized mode, each compressor must be measured at least once in any three consecutive calendar years if this mode is not found in the annual measurement. If a compressor is not operated and has blind flanges in place throughout the 3 year period, measurement is not required in this mode. If the compressor is in standby depressurized mode without blind flanges in place and is not operated throughout the 3 year period, it must be measured in the standby depressurized mode

(5) Calculate CH_4 and CO_2 volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(6) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in paragraphs (r) and (s) of this section.

(7) Determine if the reciprocating compressor vent vapors are sent to a vapor recovery system.

(i) Adjust the emissions estimated in paragraphs (f)(1) of this section downward by the magnitude of emissions recovered using a vapor recovery system as determined by engineering estimate based on best available data.

(8) Onshore petroleum and natural gas production shall calculate emissions from well-site reciprocating compressors as follows using Equation 360-22:

$$E_{s,i} = Count \times EF_i$$

Equation 360-22

Where:

$E_{s,i}$	=	Annual total volumetric GHG emissions at standard conditions from reciprocating compressors (m^3/year).
Count	=	Total number of well-site reciprocating compressors for the reporter.

EF_i	=	Emission factor for GHG *i* (either CH_4 or O_2). Use 272.7 Sm^3/year per compressor for CH_4 and 15.2 Sm^3/year per compressor for CO_2 at 20 °C and 1 atmosphere or 268.5 Sm^3/year per compressor for CH_4 and 14.9 Sm^3/year per compressor for CO_2. at 15.6 °C and 1 atmosphere, or as adjusted for different temperatures.

* For 2011 calendar year emissions only, an operator may use other equations and methods as presented by the EPA in 40 CFR Part 98.233(p) so long as the method is as accurate or more accurate as that presented here for the specific emission source in question and the appropriate regulator is notified of the choice.

(n) Leak detection and leaker emission factors. Existing legislative or regulatory requirements or progressive sampling methods described in WCI.364(a) must be used to conduct a leak detection of fugitive equipment leaks from all sources listed in §WCI.362(d)(9). This paragraph (n) applies to emissions sources in streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas content less than 10 percent CH_4 plus CO_2 by weight need to be reported instead under WCI.364(x). Tubing systems equal to or less than one half inch diameter are exempt from the requirements of this paragraph (n) and need to be reported under WCI.364(x).

If fugitive equipment leaks are detected for sources listed in this paragraph, calculate emissions using Equation 360-23 for each source with fugitive equipment leaks.

$$E_{s,i} = Count \times EF_s \times GHG_i \times t_x$$

Equation 360-23

Where:

$E_{s,i}$	=	Annual total volumetric emissions of GHG *i* (either CH_4 or CO_2),at standard conditions from each fugitive equipment leak source (m^3).
Count	=	Total number of this type of emission source found to be leaking during time t_x.
EF_s	=	Leaker volumetric emission factor for specific sources listed in 40 CFR Part 98 Table W-2, relevant Canadian Association of Petroleum Producers (CAPP) methodology manuals, if available or facility/company-specific emission factors used (as converted for use in Equation 360-23).
GHG_i	=	For onshore natural gas processing facilities, concentration of GHG *i* (either CH_4 or CO_2) in the total hydrocarbon of the feed natural gas.
t_x	=	Total time the component was found leaking and operational (hours). If one leak detection survey is conducted, assume the component was leaking from the start of the year until the leak was repaired and then zero for the remainder of the year. If the leak was not repaired, assume the component was leaking for the entire year. If multiple leak detection surveys are conducted, assume that the component found to be leaking has been leaking since the previous survey, or the beginning of the calendar year. For the last leak detection

survey in the calendar year, assume that all leaking components continue to leak until the end of the calendar year or until the component was repaired and then zero until the end of the year.

(1) Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions using calculations in paragraph (s) of this section.

(2) Onshore natural gas processing facilities shall use the appropriate default volumetric leaker emission factors listed in 40 CFR Part 98 Table W-2 (as converted to metric) or relevant Canadian Association of Petroleum Producer methodology manuals, if available for fugitive equipment leaks detected from valves; connectors; open ended lines; pressure relief valves; and meters.

(o) Population count and emission factors. This paragraph applies to emissions sources listed in §WCI.362(c)(3), (c)(16), (c)(17), (c)(21), and (d)(8) on streams with gas content greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas content less than 10 percent CH_4 plus CO_2 by weight do not need to be reported. Tubing systems equal or less than one half inch diameter are exempt from the requirements of paragraph (o) of this section and instead need to be reported under WCI.363(x). Calculate emissions from all sources listed in this paragraph using Equation 360-24.

$$E_{s,i} = Count \times EF_s \times GHG_i \times t$$

Equation 360-24

Where:

$E_{s,i}$	=	Annual total mass emissions of GHG *i* (CH_4 or CO_2) at standard conditions from each fugitive source (tonnes/year).
Count	=	Total number of this type of emission source at the facility. Average component counts by major equipment pieces for Canada from Table 360-3 may be used as appropriate. If facility or company specific major equipment count data that meet or exceed the quality of the relevant default count data are available, they must be used instead. To ensure proper use of kg/km units in emission factors for underground gathering pipelines, the length of the installed underground pipeline should be used in place of count.
EF_s	=	Population mass emission factor for specific major equipment sources listed in Table 360-1 or Table 360-2. The direction on the use of Tables 360-1 and 360-2 provided prior to these tables must be followed.
GHG_i	=	Mass fraction of GHG *i* (CH_4 or CO_2) in produced natural gas or feed natural gas.
t	=	Total time the specific source associated with the fugitive equipment leak was operational in the reporting year (hours).

(1) Onshore petroleum and natural gas production facilities shall use the appropriate default population emission factors listed in Table 360-1 or 360-2 for fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves, pump, flanges, and other equipment. Where facilities conduct EOR operations the emissions factors listed in Table 360-1 or Table 360-2 shall be used to estimate all streams of gases, including the recycle CO_2 stream. The component count can be determined using either of the methodologies described in this paragraph (o)(1). The same methodology must be used for the entire calendar year..

(i) *Component Count Methodology 1*. For all onshore petroleum and natural gas production operations in the facility perform the following activities:

(A) Count all major equipment listed in Table 360-3 of this section.

(B) Multiply major equipment counts by the average component counts listed in Table 360-3 of this section for onshore natural gas production and onshore oil production, respectively. Use the appropriate factor in Table 360-1 or Table 360-2 of this section or from CAPP methodology manuals, if the appropriate factor is not provided in Tables 360-1 or 360-2.

(ii) *Component Count Methodology 2*. Count each component individually for the facility. Use the appropriate factor Table 360-1 or Table 360-2 of this section or from CAPP methodology manuals, if the appropriate factor is not provided in Tables 360-1 or 360-2.

(2) Onshore natural gas processing facilities shall use the appropriate default population emission factor listed in Table 360-1, Table 360-2 or from CAPP methodology manuals for fugitive equipment leaks from gathering pipelines.

(p) <u>Offshore petroleum and natural gas production facilities in both provincial and federal waters.</u>
[reserved]

(q) <u>Volumetric emissions</u>. Calculate volumetric emissions at standard conditions as specified in paragraphs (q)(1) or (2) determined by engineering estimate based on best available data unless otherwise specified.

(1) Calculate natural gas volumetric emissions at standard conditions by converting ambient temperature and pressure of natural gas emissions to standard temperature and pressure (15 ºC and 1 atmosphere in Canada) natural gas using Equation 360-25 of this section.

$$E_{s,n} = \frac{E_{a,n} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 360-25

Where:

$E_{s,n}$ = Natural gas volumetric emissions at standard temperature and pressure (STP) conditions (m^3).
$E_{a,n}$ = Natural gas volumetric emissions at ambient conditions (m^3).
T_s = Temperature at standard conditions (^oC).
T_a = Temperature at actual emission conditions (^oC).
P_s = Absolute pressure at standard conditions (kPa).
P_a = Absolute pressure at ambient conditions (kPa).

(2) Calculate GHG volumetric emissions at standard conditions by converting ambient temperature and pressure of GHG emissions to standard temperature and pressure using Equation 360-26.

$$E_{s,i} = \frac{E_{a,i} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 360-26

Where:

$E_{s,i}$ = GHG *i* volumetric emissions at standard temperature and pressure (STP) conditions (m^3).
$E_{a,i}$ = GHG *i* volumetric emissions at actual conditions (m^3).
T_s = Temperature at standard conditions (^oC).
T_a = Temperature at actual emission conditions (^oC).
P_s = Absolute pressure at standard conditions (kPa).
P_a = Absolute pressure at ambient conditions (kPa).

(r) GHG volumetric emissions. Calculate GHG volumetric emissions at standard conditions as specified in paragraphs (r)(1) and (2) of this section determined by engineering estimate based on best available data unless otherwise specified.

(1) Estimate CH_4 and CO_2 emissions from natural gas emissions using Equation 360-27.

$$E_{s,i} = E_{s,n} \times M_i$$

Equation 360-27

Where:

$E_{s,i}$ = GHG *i* (CH_4 or CO_2) volumetric emissions at standard conditions.
$E_{s,n}$ = Natural gas volumetric emissions at standard conditions.

M_i = Mole fraction of GHG *i* in the natural gas.

(2) For Equation 360-27 of this section, the mole fraction, M_i, shall be the annual average mole fraction for each facility, as specified in paragraphs (r)(2)(i) and (ii) of this section.

(i) GHG mole fraction in produced natural gas for onshore petroleum and natural gas production facilities. If you have a continuous gas composition analyzer for produced natural gas, you must use these values in calculating emissions. If you do not have a continuous gas composition analyzer, then either the known composition for the company or operator for the specific field from Table 360-4 (or as referenced in Table 360-4 (as Table 360-4 is under development)), or the methods set forth in WCI.364(b) must be used.

(ii) GHG mole fraction in feed natural gas for all emissions sources upstream of the de-methanizer or dew point control and GHG mole fraction in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead or dew point control for onshore natural gas processing facilities. If you have a continuous gas composition analyzer on feed natural gas, you must use these values in calculating emissions. If you have a continuous gas composition analyzer on feed natural gas, you must use these values for determining the mole percent. If you do not have a continuous gas composition analyzer, then the known composition for the company or operator for the specific field must be used as taken according to methods set forth in WCI.364(b).

(s) <u>GHG mass emissions</u>. Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions by converting the GHG volumetric emissions into mass emissions using Equation 360-28.

$$Mass_{s,i} = E_{s,i} \times \rho_i \times GWP_i \times 0.001$$

Equation 360-28

Where:

$Mass_{s,i}$ = GHG *i* (either CH_4 or CO_2) mass emissions at standard conditions (tonnes CO_2e).

$E_{s,i}$ = GHG *i* (either CH_4 or CO_2) volumetric emissions at standard conditions (m^3).

ρ_i = Density of GHG *i*, (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4)*.

GWP_i = Global warming potential of GHG *i* (1 for CO_2 and 21 for CH_4, and 310 for N_2O).0.001 = Conversion factor from kilograms to tonnes.

* gas densities calculated using the 12th edition of the Gas Processors Suppliers Association Engineering Data Book.

(t) <u>EOR injection pump blowdown</u>. Calculate pump blowdown emissions as follows:

(1) Calculate the total volume in cubic meters (including, but not limited to, pipelines, manifolds and vessels) between isolation valves.

(2) Retain logs of the number of blowdowns per reporting period.

(3) Calculate the total annual venting emissions using Equation 360-29.

$$Mass_{c,i} = N \times V_v \times R_c \times GHG_i \times 0.001$$

Equation 360-29

Where:

$Mass_{c,i}$	=	Annual EOR injection gas venting emissions at critical conditions *c* from blowdowns (tonnes).
N	=	Number of blowdowns for the equipment in reporting year.
V_v	=	Total volume of blowdown equipment chambers (including, but not limited to, pipelines, manifolds and vessels) between isolation valves (m^3).
R_c	=	Density of critical phase EOR injection gas (kg/m^3). Use an appropriate standard method published by a consensus-based standards organization if such a method exists or otherwise an industry standard to determine density of super critical EOR injection gas.
GHG_i	=	Mass fraction of GHG_i in critical phase injection gas.
0.001	=	Conversion factor from kilograms to tonnes.

(u) [Reserved]

(v) [Reserved]

(w) Field gas or process vent gas combustion. For combustion units that combust field gas or process vent gas or any blend of field gas and process vent gas, you must comply with following requirements:

(1) Measure the higher heating value of the field gas or process vent gas annually.

(2) If the measured higher heating value is equal to or greater than 36.3 MJ/m^3 and less than 40.98 MJ/m^3, then calculate the CO_2, CH_4, and N_2O emissions using the methods in WCI.20 (General Stationary Combustion Sources) following the methods required for pipeline quality natural gas.

(3) If the measured higher heating value is less than 36.3 MJ/m^3 or greater than 40.98 MJ/m^3, then calculate the CO_2 and CH_4 emissions using either the Tier 3 or Tier 4 methodology in WCI.20 (General Stationary Combustion Sources). Sampling, analysis

and measurement requirements (including for gas composition) required for WCI.360 in WCI.025(f) apply in place of those indicated for Equation 20-7. For N_2O, use 4.579×10^{-2} GJ/m^3 for HHV.

(x) Other venting or fugitive emissions. All venting or fugitive emissions not covered by quantification methods in WCI.363 must be calculated by methodologies consistent with those presented here, the 2009 API Compendium[1], or other similar resource documents.

§ WCI.364 Sampling, Analysis, and Measurement Requirements

Instruments used for sampling, analysis and measurement must be operated and calibrated according to legislative, manufacturer's, or other written specifications or requirements. All sampling, analysis and measurement must be conducted only by, or under the direct supervision of individuals with demonstrated understanding and experience in the application (and principles related) of the specific sampling, analysis and measurement technique in use.

(a) (i) If a documented leak detection or integrity management standard or requirement that is required by legislation or regulation such as CSA Z662-07 Oil & Gas Pipeline Systems or the CAPP Best Management Practices for Fugitive Emissions or similar standard CAPP Methodologies (as amended from time to time) is used, the documented standard or requirement must be followed – including service schedules for different components and/or facilities - with reporting as required for input to the calculation methods herein.

(ii) If there is no such legal requirement, then progressive sampling is required using one of the methods outlined below in combination with best industry practices for use of the method– including service schedules for different components - to determine the count of leaks (and time leaking) required in WCI.363(m), (n), and (o), as applicable. Progressive sampling means establishing a statistically valid baseline sample of leaks under normal operating conditions for the 2011 and 2012 calendar years, with subsequent sampling determined based random or spot sampling modelling or measurement of leaks under normal operating conditions. A minimum of 18 months and a maximum of 36 months is allowed between surveys. This interval is determined based on whether there are indications of leaks. If a leak found and immediately repaired, the existing schedule may be maintained.

Leak detection for fugitive equipment leaks must be performed for all identified equipment in operation or on standby mode during a reporting period.

(1) Optical gas imaging instrument. Use an optical gas imaging instrument for fugitive equipment leaks detection in accordance with 40 CFR part 60, subpart A, §60.18(i)(1) and (2) *Alternative work practice for monitoring equipment leaks* (or per relevant standard in Canada). In addition, the optical gas imaging instrument must be operated to image the source types required by this proposed reporting rule in accordance with

[1] American Petroleum Institute. *Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Natural Gas Industr*y. August 2009. Table 6-22 (from Clearstone Engineering Ltd.. *A National Inventory of Greenhouse Gas (GHG), Criteria Air Contaminant (CAC) and Hydrogen Sulphide (H2S) Emissions by the Upstream Oil and Gas Industry*, Volume 5, September 2004.)

the instrument manufacturer's operating parameters. The optical gas imaging instrument must comply with the following requirements:

(i) Provide the operator with an image of the potential leak points for each piece of equipment at both the detection sensitivity level and within the distance used in the daily instrument check described in the relevant best practices. The detection sensitivity level depends upon the frequency at which leak monitoring is to be performed.

(ii) Provide a date and time stamp for video records of every monitoring event.

(2) Bubble tests

(3) Portable organic vapour analyzer. Use a portable organic vapour analyzer in accordance with US EPA Method 21 or as outlined in the CAPP Best Management Practices for Fugitive Emisisons

(4) Other methods as outlined in the CAPP Best Management Practices for Fugitive Emissions or similar standard CAPP Methodologies (as amended from time to time) may be used as necessary for operational circumstances. Other methods that are deemed to be technically sound based on an engineering assessment may also be used as necessary provided that sufficient documentation as to the method used, test results, its reliability, and accuracy is maintained and updated at regular intervals.

(b) All flow meters, composition analyzers and pressure gauges that are used to provide data for the GHG emissions calculations shall use measurement methods, maintenance practices, and calibration methods, prior to the first reporting year and in each subsequent reporting year using an appropriate standard method published by a consensus standards organization such as ASTM International, Canadian Standards Assocation (CSA), American National Standards Institute (ANSI), the relevant provincial or national oil and gas regulator, Measurement Canada, Canadian Association of Petroleum Producers (CAPP), Canadian Gas Association (CGA), American Petroleum Institute (API), American Society of Mechanical Engineers (ASME), and North American Energy Standards Board (NAESB). If a consensus based standard is not available, industry standard practices such as manufacturer instructions must be used.

(c) Use calibrated bags (also known as vent bags) only where the emissions are at near-atmospheric pressures and hydrogen sulphide levels are such that it is safe to handle and can capture all the emissions, below the maximum temperature specified by the vent bag manufacturer, and the entire emissions volume can be encompassed for measurement.

(1) Hold the bag in place enclosing the emissions source to capture the entire emissions and record the time required for completely filling the bag. If the bag inflates in less than one second, assume one second inflation time.

(2) Perform three measurements of the time required to fill the bag, report the emissions as the average of the three readings.

(3) Estimate natural gas volumetric emissions at standard conditions using calculations in WCI.363(q).

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.363(r) and (s).

(d) Use a high volume sampler to measure emissions within the capacity of the instrument.

(1) A technician following manufacturer instructions shall conduct measurements, including equipment manufacturer operating procedures and measurement methodologies relevant to using a high volume sampler, including, positioning the instrument for complete capture of the fugitive equipment leaks without creating backpressure on the source.

(2) If the high volume sampler, along with all attachments available from the manufacturer, is not able to capture all the emissions from the source, then anti-static wraps or other aids must be used to capture all emissions without violating operating requirements as provided in the instrument manufacturer's manual.

(3) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.363(r) and (s).

(4) Calibrate the instrument at 2.5 percent methane with 97.5 percent air and 100 percent CH_4 by using calibrated gas samples and by following manufacturer's instructions for calibration.

(e) Peng Robinson Equation of State means the equation of state defined by Equation 360-30 of this section.

$$p = \frac{RT}{V_m - b} - \frac{a\alpha}{V_m^2 + 2bV_m - b^2} \qquad \textbf{Equation 360-30}$$

Where:

p = Absolute pressure.
R = Universal gas constant.
T = Absolute temperature.
V_m = Molar volume.

$$a = \frac{0.45724 R^2 T_c^2}{p_c}$$

$$b = \frac{0.7780 RT_c}{p_c}$$

$$\alpha = \left(1 + \left(0.37464 + 1.54226\omega - 0.26992\omega^2\right)\left(1 - \sqrt{\frac{T}{T_c}}\right)\right)^2$$

Where:

ω	=	Acentric factor of the species.
T_c	=	Critical temperature.
P_c	=	Critical pressure.

(f) Onshore Production and Processing Storage Tanks.

(1) A pressurized sample of produced liquids shall be collected from the separator at a location upstream of the storage tank. This point would typically be at the final separation device before produced oil transitions from separator outlet pressure to atmospheric pressure and enters a production storage tank. This may require the installation of a sampling valve at the appropriate location. Sampling protocol specific to the collection of separator liquid can be found in the following publications:

(i) Appendix C Sampling Protocol section (page 33) of the *E&P TANK Version 2.0 User's Manual*.

(ii) Wyoming Department of Environmental Quality Air Quality Division guidance document *Oil and Gas Production Facilities, Chapter 6, Section 2 Permitting Guidance (revised August 2001), Appendix D Sampling and Analysis of Hydrocarbon Liquids and Natural Gas.*

(iii) Gas Processors Association (GPA) Standard 2174-93, *Obtaining Liquid Hydrocarbon Samples for Analysis by Gas Chromatography*.

(2) The sample collection pressure shall be determined at the time of collection and again prior to processing in the laboratory to insure that sample integrity has been maintained. Liquid temperature should also be determined and recorded at the time of collection.

(3) Sampling and laboratory based determination of the gas to oil ratio GOR shall be conducted at prescribed intervals and at a time when operational parameters of the storage tank battery are representative and consistent with normal operating conditions. Sampling shall be annual for oil production rates between 1.75 and 15.9 m^3/day, semi-annual for oil production rates between15.9 and 79.5 m^3/day, and quarterly for oil production rates greater than 79.5 m^3/day.

(4) An additional sample shall be collected and analyzed if:

(i) The oil production rate at the storage tank battery changes more than 20 percent for time periods in excess of one week (e.g., in cases where a well or wells feeding the storage tank battery stop or start production).

(ii) The separator operating pressures change by more than 10 percent.

(5) The volume (barrels) of liquid produced during the sampling interval shall be determined using a calibrated liquid meter or industry standard method to an accuracy of ±5%.

§ WCI.365 *Procedures for Estimating Missing Data*

A complete record of all estimated and/or measured parameters used in the GHG emissions calculations is required. If data are lost or an error occurs during annual emissions estimation or measurements, the estimation or measurement activity for those sources must be repeated as soon as possible, including in the subsequent reporting year if missing data are not discovered until after December 31 of the reporting year, until valid data for reporting is obtained. Data developed and/or collected in a subsequent reporting year to substitute for missing data cannot be used for that subsequent year's emissions estimation. Where missing data procedures are used for the previous year, at least 30 days must separate emissions estimation or measurements for the previous year and emissions estimation or meausrements for the current year of data collection. For missing data that are continuously monitored or measured (for example flow meters), or for missing temperature and pressure data, the reporter may use best available data for use in emissions determinations. The reporter must record and report the basis for the best available data in these cases.

§ WCI.366 Definitions

Absorbent circulation pump means a pump commonly powered by natural gas pressure that circulates the absorbent liquid between the absorbent regenerator and natural gas contactor.

Acid gas means hydrogen sulphide (H_2S) and carbon dioxide (CO_2) contaminants that are separated from sour natural gas by an acid gas removal unit.

Acid gas removal (AGR) unit means a process unit that separates hydrogen sulphide and/or carbon dioxide from sour natural gas using liquid or solid absorbents or membrane separators.

Acid gas removal vent stack emissions mean the acid gas separated from the acid gas absorbing medium (e.g., an amine solution) and released with methane and other light hydrocarbons to the atmosphere or a flare.

Blowdown vent stack emissions mean natural gas and/or CO_2 released due to maintenance and/or blowdown operations including compressor blowdown and emergency shut-down (ESD) system testing.

Calibrated bag means a flexible, non-elastic, anti-static bag of a calibrated volume that can be affixed to a emitting source such that the emissions inflate the bag to its calibrated volume.

Centrifugal compressor means any equipment that increases the pressure of a process natural gas or CO_2 by centrifugal action, employing rotating movement of the driven shaft.

Centrifugal compressor dry seals mean a series of rings around the compressor shaft where it exits the compressor case that operates mechanically under the opposing forces to prevent natural gas or CO_2 from escaping to the atmosphere.

Centrifugal compressor dry seals emissions mean natural gas or CO_2 released from a dry seal vent pipe and/or the seal face around the rotating shaft where it exits one or both ends of the compressor case.

Centrifugal compressor venting emissions means emissions that occur when the high-pressure oil barriers for centrifugal compressors are depressurized to release absorbed natural gas or CO_2. High-pressure oil is used as a barrier against escaping gas in centrifugal compressor shafts. Very little gas escapes through the oil barrier, but under high pressure, considerably more gas is absorbed by the oil. The seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated. The separated gas is commonly vented to the atmosphere.

Coal bed methane (CBM) means natural gas which is extracted from underground coal deposits or "beds."

Component means each metal to metal joint or seal of non-welded connection separated by a compression gasket, screwed thread (with or without thread sealing compound), metal to metal compression, or fluid barrier through which natural gas or liquid can escape to the atmosphere.

Compressor means any machine for raising the pressure of a natural gas or CO_2 by drawing in low pressure natural gas or CO_2 and discharging significantly higher pressure natural gas or CO_2.

Condensate means hydrocarbon and other liquid separated from natural gas that condenses due to changes in the temperature, pressure, or both, and remains liquid at storage conditions..

Continuous bleed means a continuous flow of pneumatic supply gas to the process measurement device (e.g. level control, temperature control, pressure control) where the supply gas pressure is modulated by the process condition, and then flows to the valve controller where the signal is compared with the process set-point to adjust gas pressure in the valve actuator

Dehydrator means a device in which a liquid absorbent (including desiccant, ethylene glycol, diethylene glycol, or triethylene glycol) directly contacts a natural gas stream to absorb water vapor.

Dehydrator vent emissions means natural gas and CO_2 released from a natural gas dehydrator system absorbent (typically glycol) reboiler or regenerator, including stripping natural gas and motive natural gas used in absorbent circulation pumps.

De-methanizer means the natural gas processing unit that separates methane rich residue gas from the heavier hydrocarbons (e.g., ethane, propane, butane, pentane-plus) in feed natural gas stream.

Desiccant means a material used in solid-bed dehydrators to remove water from raw natural gas by adsorption. Desiccants include activated alumina, pelletized calcium chloride, lithium chloride and granular silica gel material. Wet natural gas is passed through a bed of the granular or pelletized solid adsorbent in these dehydrators. As the wet gas contacts the surface of the particles of desiccant material, water is adsorbed on the surface of these desiccant particles. Passing through the entire desiccant bed, almost all of the water is adsorbed onto the desiccant material, leaving the dry gas to exit the contactor.

E&P Tank means the most current version of an exploration and production field tank emissions equilibrium program that estimates flashing, working and standing losses of hydrocarbons, including methane, from produced crude oil and gas condensate. Equal or successors to E&P Tank Version 2.0 for Windows Software. Copyright (C) 1996-1999 by The American Petroleum Institute and The Gas Research Institute.

Engineering estimation, for the purposes of WCI.350 and WCI.360 means an estimate of emissions based on engineering principles applied to measured and/or approximated physical parameters such as dimensions of containment, actual pressures, actual temperatures, and compositions.

Enhanced oil recovery (EOR) means the use of certain methods such as water flooding or gas injection into existing wells to increase the recovery of crude oil from a reservoir. In the context of this rule, EOR applies to injection of critical phase carbon dioxide into a crude oil reservoir to enhance the recovery of oil.

Equipment leak detection means the process of identifying emissions from equipment, components, and other point sources.

External combustion means fired combustion in which the flame and products of combustion are separated from contact with the process fluid to which the energy is delivered. Process fluids may be air, hot water, or hydrocarbons. External combustion equipment may include fired heaters, industrial boilers, and commercial and domestic combustion units.

Field means the surface area underlaid or appearing to be underlaid by one or more pools, and the subsurface regions vertically beneath that surface area;

Field gas means natural gas extracted from a production well prior to its entering the first stage of processing, such as dehydration.

Flare combustion efficiency means the fraction of natural gas, on a volume or mole basis, that is combusted at the flare burner tip.

Fugitive emissions means the unintended or incidental emissions of greenhouse gases from the transmission, processing, storage, use or transportation of fossil fuels, greenhouse gases, or other.

Fugitive equipment leak means the those fugitive emissions which could not reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening.

Gas conditions mean the actual temperature, volume, and pressure of a gas sample.

Gas gathering/booster stations mean centralized stations where produced natural gas from individual wells is co-mingled, compressed for transport to processing plants, transmission and distribution systems, and other gathering/booster stations which co-mingle gas from multiple production gathering/booster stations. Such stations may include gas dehydration, gravity separation of liquids (both hydrocarbon and water), pipeline pig launchers and receivers, and gas powered pneumatic devices.

Gas to oil ratio (GOR) means the ratio of the volume of gas at standard temperature and pressure that is produced from a volume of oil when depressurized to standard temperature and pressure.

Gas well means a well completed for production of natural gas from one or more gas zones or reservoirs. Such wells contain no completions for the production of crude oil.

High-bleed pneumatic devices are automated control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate in excess of six standard cubic feet per hour.

Intermittent bleed pneumatic devices mean automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. These are snap-acting or throttling devices that discharge the full volume of the actuator intermittently when control action is necessary, but does not bleed continuously.

Internal combustion means the combustion of a fuel that occurs with an oxidizer (usually air) in a combustion chamber. In an internal combustion engine the expansion of the high-temperature and –pressure gases produced by combustion applies direct force to a component of the engine, such as pistons, turbine blades, or a nozzle. This force moves the component over a distance, generating useful mechanical energy. Internal combustion equipment may include gasoline and diesel industrial engines, natural gas-fired reciprocating engines, and gas turbines.

Liquefied natural gas (LNG) means natural gas (primarily methane) that has been liquefied by reducing its temperature to -162 degrees Celsius at atmospheric pressure.

LNG boiloff gas means natural gas in the gaseous phase that vents from LNG storage tanks due to ambient heat leakage through the tank insulation and heat energy dissipated in the LNG by internal pumps.

Low-bleed pneumatic devices mean automated control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate equal to or less than 0.17 standard cubic meters per hour.

Natural gas driven pneumatic pump means a pump that uses pressurized natural gas to move a piston or diaphragm, which pumps liquids on the opposite side of the piston or diaphragm.

Offshore means seaward of the terrestrial borders of the Canada, including waters subject to the ebb and flow of the tide, as well as adjacent bays, lakes or other normally standing waters, and extending to the outer boundaries of the jurisdiction and control of Canada.

Oil well means a well completed for the production of crude oil from at least one oil zone or reservoir.

Operating pressure means the containment pressure that characterizes the normal state of gas or liquid inside a particular process, pipeline, vessel or tank.

Pump means a device used to raise pressure, drive, or increase flow of liquid streams in closed or open conduits.

Pump seals means any seal on a pump drive shaft used to keep methane and/or carbon dioxide containing light liquids from escaping the inside of a pump case to the atmosphere.

Pump seal emissions means hydrocarbon gas released from the seal face between the pump internal chamber and the atmosphere.

Reciprocating compressor means a piece of equipment that increases the pressure of a gas stream by positive displacement, employing linear movement of a shaft driving a piston in a cylinder.

Reciprocating compressor rod packing means a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of the compressed gas stream that escapes to the atmosphere.

Re-condenser means heat exchangers that cool compressed boil-off gas to a temperature that will condense natural gas to a liquid.

Reservoir means a porous and permeable underground natural formation containing significant quantities of hydrocarbon liquids and/or gases.

Residue gas and residue gas compression mean, respectively, production lease natural gas from which gas liquid products and, in some cases, non-hydrocarbon components have been extracted such that it meets the specifications set by a pipeline transmission company, and/or a distribution company; and the compressors operated by the processing facility, whether inside the processing facility boundary fence or outside the fence-line, that deliver the residue gas from the processing facility to a transmission pipeline.

Sales oil means produced crude oil or condensate measured at the production lease automatic custody transfer (LACT) meter or custody transfer meter tank gauge.

Separator means a vessel in which streams of multiple phases are gravity separated into individual streams of single phase.

Sour natural gas means natural gas that contains significant concentrations of hydrogen sulphide and/or carbon dioxide that exceed the concentrations specified for commercially saleable natural gas delivered from transmission and distribution pipelines.

Sweet gas is natural gas with low concentrations of hydrogen sulphide (H_2S) and/or carbon dioxide (CO_2) that does not require (or has already had) acid gas treatment to meet pipeline corrosion-prevention specifications for transmission and distribution.

Transmission pipeline means high pressure cross country pipeline transporting saleable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering, regulating stations where the natural gas is typically odorized before delivery to customers.

Turbine meter means a flow meter in which a gas or liquid flow rate through the calibrated tube spins a turbine from which the spin rate is detected and calibrated to measure the fluid flow rate.

Vapour recovery system means any equipment located at the source of potential gas emissions to the atmosphere or to a flare, that is composed of piping, connections, and, if necessary, flow-inducing devices, and that is used for routing the gas back into the process as a product and/or fuel.

Vapourization unit means a process unit that performs controlled heat input to vapourize LNG to supply transmission and distribution pipelines or consumers with natural gas.

Vented emissions means the same as defined in the relevant greenhouse gas reporting regulation, including but not limited to process designed flow to the atmosphere through seals or vent pipes, equipment blowdown for maintenance, and direct venting of gas used to power equipment (such as pneumatic devices), but not including stationary combustion flue gas.

Well completions means a process that allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and test the reservoir flow characteristics, steps which may vent produced gas to the atmosphere via an open pit or tank. Well completion also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packer(s), or lifting equipment, steps that do not significantly vent natural gas to the atmosphere. This process may also include high-rate flowback of injected gas, water, oil, and proppant used to fracture or re-fracture and prop open new fractures in existing lower permeability gas reservoirs, steps that may vent large quantities of produced gas to the atmosphere.

Well workover means the process(es) of performing of one or more of a variety of remedial operations on producing petroleum and natural gas wells to try to increase production. This process also includes high-rate flowback of injected gas, water, oil, proppant and sand used to re-fracture and prop-open new fractures in existing low permeability gas reservoirs, steps that may vent large quantities of produced gas to the atmosphere.

Wellhead means the piping, casing, tubing and connected valves protruding above the Earth's surface for an oil and/or natural gas well. The wellhead ends where the flow line connects to a wellhead valve. Wellhead equipment includes all equipment, permanent and portable, located on the improved land area (i.e. well pad) surrounding one or multiple wellheads.

Wet natural gas means natural gas in which water vapour exceeds the concentration specified for commercially saleable natural gas delivered from transmission and distribution pipelines. This input stream to a natural gas dehydrator is referred to as "wet gas".

Directions for the use of Tables 360-1 to 360-2

(a) Starting with 2013 calendar year emissions, for each component listed in the Tables 360-1 to 360-2 or otherwise required by the quantification method referencing Tables 360-1 and 360-2:

(i) If statistically valid facility specific emission factors for a component type are available or can safely or reasonably developed, they must be used.

(ii) If facility specific emissions factors for a component type are not available, an operator must use statistically valid company specific emission factors, if they can be safely or reasonably developed.

If statistically valid facility or company specific emission factors for a specific component type cannot be safely and reasonably developed, estimates in the default tables 360-1 to 360-2 may be used. Equipment or facilities that have low temporal utilization (e.g. equipment such as booster stations used only sporadically during a year) may continue to use the default tables.

(b) For 2011 and 2012 calendar year emissions:

(i) An operator may use the default factors specified below, company or facility-specific emissions factors (if such emission factors are available). If the default factors in Tables 360-1 to 360-2 are used, an explanation as to why company or facility specific emission factors are cannot be used must be provided to the jurisdiction.

(c) If a facility-specific emission factor has been used in a previous reporting year, it must continue to be used until updated. If a company-specific emission factor has been used in a previous reporting year, it must continue to be used until updated or a facility-specific emission factor is used in its place

(d) Any changes from facility-specific factors to company-specific or the defaults in Tables 360-1 to 360-2, or from company specific factors to the defaults in Tables 360-1 to 360-2 must be approved by the jurisdiction and substantiated by evidence that the new approach is more accurate for the facility or facilities in question.

(e) If an emission factor required by the quantification method referencing Tables 360-1 and 360-2 is not provided in the tables, emission factors from either the U.S. EPA 40 CFR Part 98.230 Tables W-1A or W-2 or the Clearstone Engineering Ltd.. *A National Inventory of Greenhouse Gas (GHG), Criteria Air Contaminant (CAC) and Hydrogen Sulphide (H2S) Emissions by the Upstream Oil and Gas Industry*, Volume 5, September 2004 may be used (as converted for use in the relevant equation).

(f) Documentation on the method used to update the emission factors, input data, sampling methodology and other relevant information must be kept by the operator and provided to the jurisdiction or verifier upon request.

(g) All emission factors or data collection for emission factors must be developed using CAPP (CAPP) or Canadian Gas Association (CGA) standard methods, or other methods if CAPP or CGA methods are not available or applicable. Facility and company-specific emission factors must be updated at a minimum on a three year cycle, with the first update to the original facility and company-specific emission factors for the 2016 reporting period, at the latest.

(h) Updated emission factors can only be incorporated for reporting purposes at the start of a reporting period and not during a calendar year.

(i) The default emission factors provided in Tables 360-1 to 360-2 below are published emission factors for Canada as of the 2010 calendar year. The factors will be updated every 3-5 years based on new data, methods and statistically valid samples of the entire industry and developed in collaboration with industry groups.

Table 360-1. Additional Natural Gas Facility Average Emission Factors

Component – Service	Emission Factor, tonnes THC/component-hr
Valves - fuel gas	2.81E-06
Valves - light liquid	3.52E-06
Valves - gas/vapor - all	2.46E-06
Valves - gas/vapor - sour	1.16E-06
Valves - gas/vapor - sweet	2.81E-06
Connectors - fuel gas	8.18E-07
Connectors - light liquid	5.51E-07

Western Climate Initiative

WCI Regional Emissions Trading Program Status Update

WCI Stakeholder Meeting
Hollywood, CA
April 13, 2011

WCI Regional Emissions Trading Program

- Comprehensive strategy to reduce regional greenhouse gas emissions and spur a clean-energy economy
- Detailed Program Design released July 2010

  http://westernclimateinitiative.org/the-wci-cap-and-trade-program/program-design

  - Provides a roadmap to inform Partners in their development of implementing regulations
  - Based on extensive analysis and stakeholder consultation

Program Benefits

- Reduces costly impacts that climate change will have on water resources, natural ecosystems, air quality, and environment-dependent industries like agriculture and tourism
- Provides incentives for clean-energy technologies
- Creates green jobs
- Increases energy security
- Protects public health

Progress Implementing the Program

- WCI Partner jurisdictions have made significant progress on key elements of a linked regional program, including:
  - Emissions reporting
  - Offset protocols
  - Infrastructure requirements
  - Regional administrative organization
- WCI Partner jurisdictions also continue to work closely with federal governments and other North American climate initiatives to promote national and international action and ensure coordination

Implementation Schedule

- The WCI Detailed Program Design accommodates alternative schedules for implementation
- As each jurisdiction assesses its options for moving forward, CA, BC, and QC are working towards a 2012 start date
- ON and MB will join after the program starts
- Additional jurisdictions will be able to join

Other Approaches to Climate Action

- All 11 WCI Partner jurisdictions continue to work together, and with states and provinces in other North American climate initiatives
- Portfolio approach to climate action
  - Includes a range of strategies and policies to grow the low-carbon, clean energy economy in North America
  - Information on next steps will be released in the coming months

Emissions Reporting

- WCI Partner jurisdictions have been phasing-in new reporting requirements
  - A rigorous reporting system and high-quality emissions data achieves environmental and economic objectives and supports program design
  - ON is still phasing-in reporting and so will join after 2012
- WCI is also working with federal counterparts to develop common systems
  - This would minimize duplication and reduce the reporting burden for industry

Offset Protocols

- WCI Partner jurisdictions are continuing to design an offset system that produces high-quality offsets
  - Goal is to ensure cost-effective compliance options through a broad range of emission reduction strategies
  - Final recommendations for the WCI offset definition and quality criteria were released in July 2010
  - Draft recommendations for the process of offset project approval will be released this week
- WCI Partner jurisdictions are also evaluating an initial set of protocols to meet the WCI quality criteria

Infrastructure – Tracking System

- WCI Partner jurisdictions are working to establish a compliance instrument tracking system
  - System needed to ensure accurate accounting of the issuance, holding, transfer, and retirement of emission allowances and offset credits
  - The system will be accessible, secure, and scalable and will meet the jurisdictions' transparency objectives through public reporting

Infrastructure – Auction Platform

- WCI Partner jurisdictions are working to define requirements for a platform to support a regionally coordinated auction
  - The platform will support a process to ensure fairness and transparency, promote price discovery, and maximize efficiency in the allowance market while being consistent with applicable state and provincial laws

Auction Design

- WCI Partner jurisdictions are finalizing recommendations on:
  - Setting a reserve price and purchase limit
  - Addressing currency exchange issues
  - Settling tied bids
  - Evaluating options for a non-competitive component of the auction and for consignment of allowances

Market Monitoring and Oversight

- WCI Partner jurisdictions are committed to ensuring a well-functioning allowance market
  - Comprehensive market oversight, including market monitoring, to ensure that market participants are protected from fraudulent activities
- Program design includes specific policies to ensure:
  - Fair and equal access to the market
  - Transparent operations
  - Timely public disclosure of information
  - Safeguards to prevent market manipulation

Coordinating Program Administration

- WCI Partner jurisdictions are considering setting up a regional administrative organization (RAO)
  - An RAO (like RGGI Inc.) is one way to support coordinated implementation and ensure integrity, efficiency, and consistency in the administration of the emissions trading program
  - WCI Partners are specifying the function and structure of a RAO for the WCI program

Next Steps

- Continue working together to complete design
- Finalize regulations
- Put in place administrative systems and infrastructure
- Review each jurisdiction's program to assess consistency and to facilitate linkage
- WCI will continue to provide stakeholders with periodic updates

Western Climate Initiative

Draft Recommendations
Offset System Process
(Offset Committee Task 1.3)
June 7, 2011

An efficient offset system, consistent across WCI Partner Jurisdictions, will help ensure an adequate supply of high-quality offsets.

The Western Climate Initiative (WCI) Offsets Committee today releases draft recommendations for the requirements and process of offset project review and approval and credit creation for the regional emissions trading program.

The WCI Design Recommendations (2008) recommended the establishment of a rigorous offset system to support the WCI cap-and-trade program. The Design for the WCI Regional Program (2010) recommended essential criteria for credible offsets and that standards and processes for approving offset projects be developed in an open and transparent manner in advance of the start of the cap-and-trade program. The draft recommendations in this paper support these objectives.

The draft recommendations identify the critical elements of offset project approval that WCI Partner Jurisdictions believe will lead to high-quality offset credits that can be exchangeable across the region. Consistent, transparent processes are expected to lower project development costs and support learning and sharing of experience among Partner Jurisdictions and offset project developers. Stakeholder engagement, third party involvement, and regulatory oversight combine to ensure the environmental integrity of the program.

The Draft Recommendations are available on the WCI website. The WCI Offsets Committee will hold a stakeholder conference call to present the draft recommendations on **Wednesday, June 15, 2011, from 12:30 – 2:00 p.m. Pacific Daylight Time**. To join the call dial **1-800-868-1837** and enter participant code **753491#.** A PowerPoint presentation will be posted to the WCI website at the time of the call. Written comments should be submitted here via the WCI website by **Friday, July 8, 2011**.

1 Executive Summary

This paper is the fourth paper issued by the WCI Offsets Committee as part of its efforts to offer design recommendations for the WCI offset system to the WCI Partner jurisdictions. This paper describes the draft recommendations for the WCI offset system process steps. The three previous papers provided recommendations for the WCI offset definition and essential criteria.

In the WCI's workplan, this paper is part of the Offset Committee's Task 1.3 to identify the specific requirements for registration, validation, monitoring, quantification, reporting, verification, certification and issuance of offsets. For each of these steps, this paper presents draft recommendations which are summarized in Table 1.0 below and depicted in Figure 1.

As WCI Partner jurisdictions will recognize the offsets issued by other Partners, it is important for the Partner jurisdictions to have processes in their offset systems that ensure the rigor and interchangeability of offsets across the WCI Partner jurisdictions. These draft recommendations propose processes to help ensure the necessary level of rigor across WCI Partner jurisdictions. The WCI Partner jurisdictions recognize that Partner jurisdictions have labeled the steps with varying terms, and in some cases have combined steps in their proposed programs. These draft recommendations acknowledge that such variations that result in the same or greater level of rigor being achieved are acceptable.

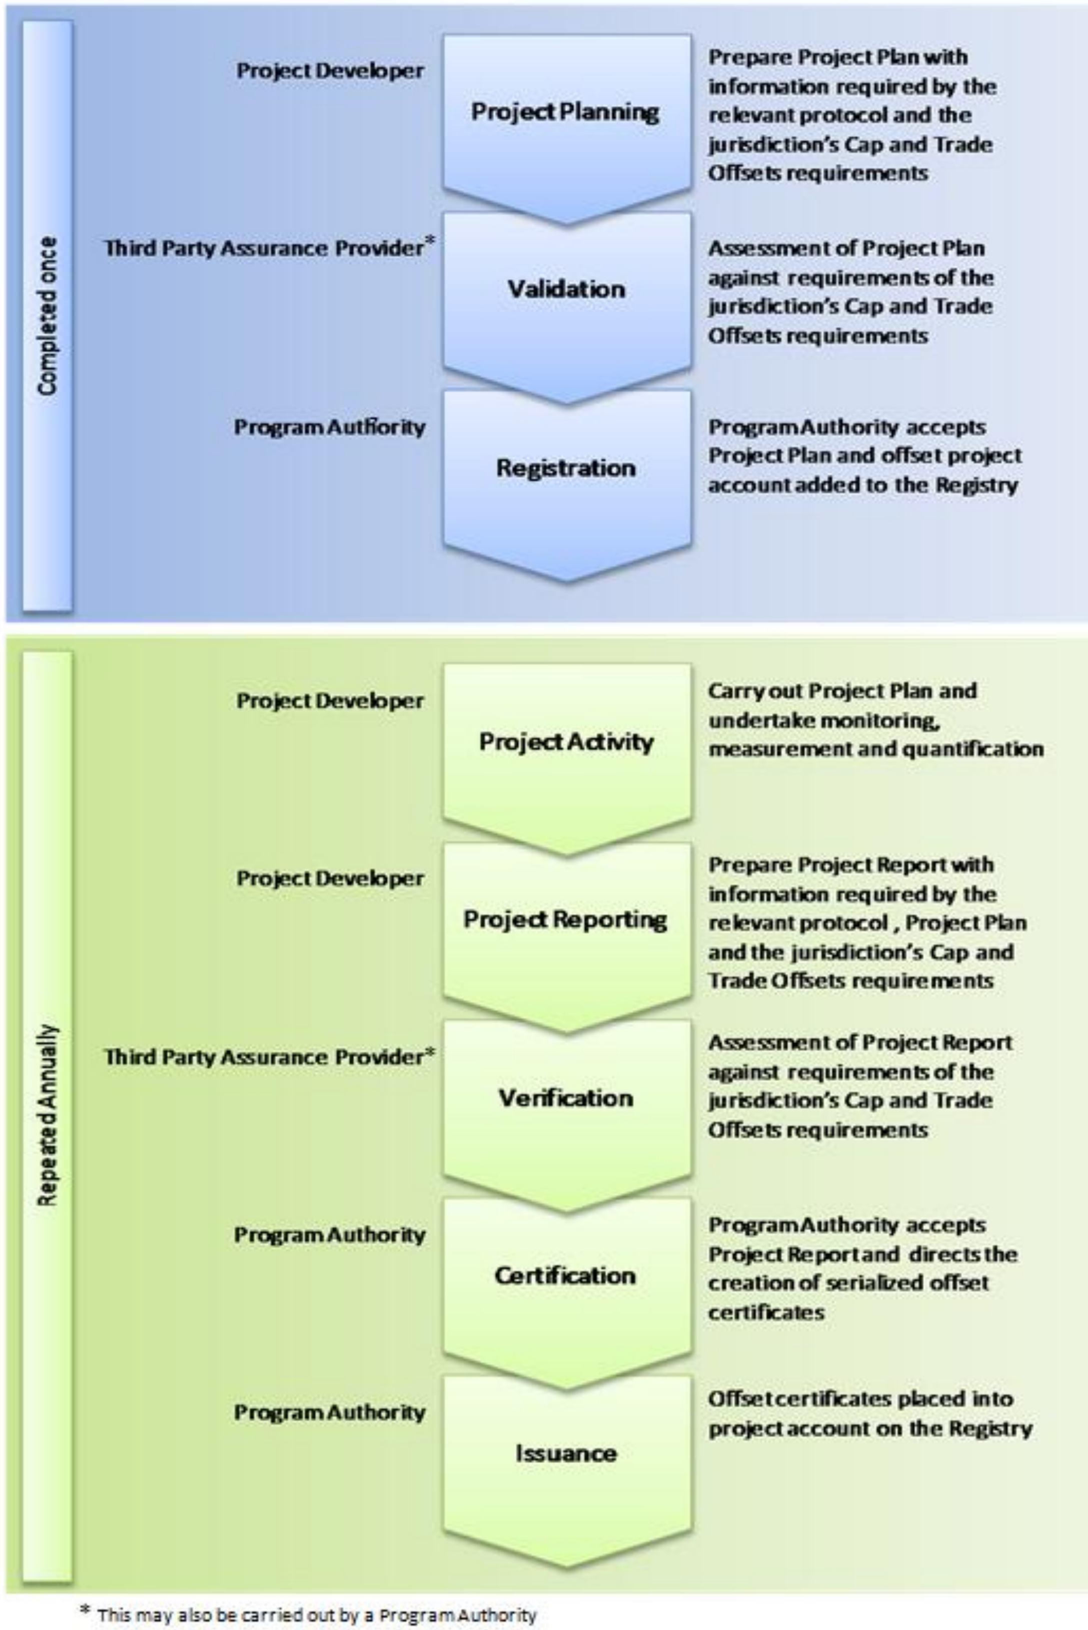

Figure 1. Recommended Western Climate Initiative offset system process flow

Table 1. Draft Recommendations

Section	Criteria	Draft Recommendation
3.1	Validation	Validation will initiate a relationship between the proposed project and the relevant authority. Each WCI Partner jurisdiction will be responsible for evaluating offset projects within its respective jurisdiction and may also evaluate and register offset projects in non-WCI jurisdictions throughout Canada, the United States and Mexico. Therefore, whether performed by a WCI Partner jurisdiction or a validation body, validation will be conducted with the expectation that the project will be considered under a specific jurisdiction's offset system. An offset project proponent initiates the process by submitting information on their proposed project required by the WCI Partner jurisdiction or an accredited third-party validation body to effectively perform their validation activities. The required information may be defined by the relevant protocol and may be in the form of a project plan providing basic contact information, describing the project, referring to the appropriate WCI protocol, baseline scenario (where appropriate) or performance standard, and identifying all project-specific monitoring requirements. The WCI Partner jurisdiction or the validation body will assess whether the project meets the requirements of the WCI offsets system and is in conformance with an appropriate protocol. The validation step must be completed prior to verification of the offset project's first project report. A project must be validated as part of each renewed crediting period. If validation is performed by an accredited third-party validation body, the validation body must issue a positive validation statement before the project can be registered. Subject to activity (validation/verification) and sectoral scope (project type) requirements, third-party validation bodies must conduct validation in accordance with ISO 14064-3 and must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction's required statutory or

		regulatory process that is at least as stringent as the process defined in ISO 17011.
3.2	Registration	Project registration requires the submission of information for each project to the responsible WCI Partner jurisdiction. The required information may be defined by the relevant protocol and may be in the form of a project plan. Registration information will be posted for public review and comment to provide transparency. The project developer must identify a potential offset project and determine if it is conformant to WCI offset criteria and an accepted WCI protocol. For aggregation of small projects, unless otherwise specified in the protocol, a single request for registration can be submitted for the entire aggregation although it must include the required information on each project. The Project Developer must implement the project per the information provided as part of registration. If the proponent changes any aspect of the project compared to the project plan at the time of registration, the change will need to be approved by the relevant WCI Partner jurisdiction and a revised project plan reflecting the change posted for public review. The WCI Offsets Committee is not recommending a preferred approach among the options presented above for Registration. WCI Partner jurisdictions will retain the flexibility to select the Registration approach most appropriate for their jurisdiction. However, for all WCI Partner jurisdictions, no offset certificates will be issued until the project is validated, registered and has verified emission reductions.
3.3	Monitoring and Quantification	Each offset project shall follow the monitoring and quantification requirements specified in the applicable protocol. Monitoring and quantification requirements for offsets will be harmonized, to the extent practicable, with WCI Mandatory Reporting Requirements.
3.4	Reporting	Reporting frequency will be annual unless otherwise specified in a recommended protocol. A WCI Partner jurisdiction will have two options for assigning the annual reporting date for a project:

		• the month and day of the project start date (as determined by the first day for which a reduction is claimed); or • a common calendar date for all projects each year. Reporting requirements will be harmonized, to the extent possible, with the WCI Mandatory Reporting Requirements. Aggregated small projects may submit a single report for the entire aggregation of projects, unless otherwise specified in protocol, although the report must include required information on each project’s reductions.
3.5	Verification	Emission reductions or removals must be verified by an accredited third-party verification body and submitted to the relevant WCI Partner jurisdiction prior to the issuance of offset certificates. Subject to activity (validation/verification) and sectoral scope (project type) requirements, verification bodies must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction’s required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011. The verification must also be conducted in accordance with ISO 14064-3 to a reasonable level of assurance. A third party assurance provider which validated the registered project plan may not perform third-party verification of a project report for that project within the same crediting period. Verification statements will be posted publicly. Unless otherwise specified in protocol, for aggregation of small projects, a single verification report can be submitted for the entire aggregation, although it must include verification for each project’s reductions.
3.6	Certification	The certification step involves the WCI Partner jurisdiction or its agent/recognized body reviewing project documentation presented as evidence and accepting that evidence into the system through the assignment or creation of an offset certificate when they are satisfied all conditions of the Partner Jurisdiction have been or will be met. The committee

		recommends certification take place at the point of issuing an offset certificate, so that certificates are not issued prior to successful completion of certification.
3.7	Issuance	Following certification, the WCI Partner jurisdiction will proceed with offset issuance. The jurisdiction will complete the administrative steps of serializing the units and issuing to the appropriate account(s) in the tracking system. Issuance does not require the project proponent to submit any additional information nor require the WCI Partner jurisdiction to conduct any further review of the project.
3.8	Post-Issuance Activities	Project protocols and the offset systems of the WCI Partner jurisdictions will ensure permanence, including mechanisms that will replace offsets from sequestration projects lost to unintentional and intentional reversal. No draft recommendation is made at this time regarding the ability to revoke or require the replacement of offset certificates. Comment is solicited regarding three potential options for consideration: • Offset certificates are not revocable by any WCI Partner jurisdiction and the remedies for fraud and error include replacement. • Any offset certificate is revocable by the WCI Partner jurisdiction that issued it upon discovery of fraud or error. • WCI Partner Jurisdictions choose to issue, at their discretion, offset certificates that are either revocable or non-revocable. This option would support some jurisdictions issuing offset certificates that may be revoked, and others issuing offset certificates that may not be revoked. WCI Partner jurisdictions would appreciate comments on potential implications of these options for: offset supply; trading of offset certificates; program administration requirements; and environmental integrity.

2 Purpose and Background

The July 2010 Design for the WCI Regional Program includes provisions for a rigorous offset system. The primary role of the offset system is to reduce the compliance costs associated with the cap-and-trade program while maintaining the environmental integrity of the cap. The design of the offset system should encourage emission reductions, innovation, and technology development in sectors and at sources not covered by the cap-and-trade program.

The purpose of the WCI Offset Committee is to make recommendations to the WCI Partner jurisdictions on the design and operation of the offset system as part of the WCI cap-and-trade program. The committee divided its work into three tasks. Task 1 is recommendations for essential elements and infrastructure to create and operate the WCI offset system. Task 2 will provide recommendations for accepting offsets and allowances from other greenhouse gas trading programs. Task 3 is the review and recommendation of protocols for the WCI offset system.

This paper is part of the Offset Committee's Task 1 Essential Element work, specifically Task 1.3 to identify the specific requirements for registration, validation, monitoring, quantification, reporting, verification, certification and issuance of offsets. This paper presents draft recommendations for those elements. Since WCI Partner jurisdictions will recognize the offsets issued by other Partners, it is important for the Partner jurisdictions to have processes in their offset systems that ensure the rigor and interchangeability of offsets across the WCI Partner jurisdictions. These draft recommendations propose processes to ensure the necessary level of rigor across WCI Partner jurisdictions. Figure 1 identifies the process steps from project design and project implementation to project performance. The WCI Partner jurisdictions recognize that Partner jurisdictions have labeled the steps with varying terms, and in some cases have combined steps, in the processes proposed for their programs. While offering these draft recommendations, the WCI Partner jurisdictions acknowledge that such variations that result in the same or greater level of rigor being achieved are acceptable.

As part of their effort to design an offset system that encourages emission reductions from sources not covered by the cap-and-trade program, WCI Partner jurisdictions aim to facilitate participation of small projects by implementing a process that readily accommodates the aggregation of small projects. The draft recommendations for some process steps include specific elements related to the aggregation of small projects in order to streamline the process for these projects while ensuring the same high quality standards are met for all offset projects.

3 Process Options and Draft Recommendations

3.1 Validation

Validation is the assessment of a proposed offset project against the offset system requirements. Validation includes review and assessment of project information for conformance with system criteria, alignment with an appropriate protocol[1] and review of quantification methodologies, baselines, standards, calculations, assumptions, factors, forecasts and assertions. Validation is intended to provide the project developer and the WCI Partner jurisdiction with assurance that the project, when implemented, is likely to meet all of the WCI criteria and is likely result in emission reductions qualifying under the WCI offset system. More detailed information on the validation step can be found in ISO 14064-3.

3.1.1 Options

Validation could be conducted by staff of the WCI Partner jurisdiction registering the project, a commissioned service provider or an independent third party. Each option presents some key concerns for consideration:

- Would WCI Partner jurisdictions ensure a staff approach was adequately resourced, trained and experienced to ensure an efficient and effective review and validation process in each jurisdiction and would institutional capacity be consistent across the WCI region?
- Would a commissioned service provider be capable of maintaining independence and incorporating direction from all of the WCI Partner jurisdictions?
- Would there be adequate third party verifiers and at what potential cost to project developers?

Each option brings unique benefits that must be weighed against these considerations:

- A staff approach would allow direct regulatory control over the initial project review and approval step and would provide the project developer with comfort that the regulator will register their project once they pass the validation step.
- A commissioned service provider could provide a similar level of comfort to the WCI Partner jurisdiction while providing access to a pool of validation capacity that can be shaped to accommodate the changing level of demand for validation services.
- Third party validation provides less direct control to the WCI Partner jurisdiction while delivering the variable capacity of a commissioned service provider and requires the validator place their reputation on each validation service performed to ensure a high level of integrity and reliability in services provided.

[1] By "appropriate protocol," the WCI Offset Committee is referring to a protocol which has been recommended by the WCI Partners and which is appropriate to the project activity.

Validation could occur at any of a variety of times along the project cycle including prior to registration, at registration, before or concurrent with verification or at certification. Each option presents a different cost/benefit to the project developer and the WCI Partner jurisdiction. Earlier in the process may mean more up-front cost for the project developer with an accompanying increase in certainty of being accepted by the program. Later in the process aligns validation effort and cost with successful project activities and claims for offset, reducing up front cost and possibly lessening certainty for project developers.

Information required to complete the validation step could include contact and other project details, information about the project operation and expected emission reductions, protocol selection, baseline selection, applicability and project eligibility. The validation process could follow an established standard such as ISO 14064 part 3.

Validation could provide assurance that information has been reviewed for completeness and consistency, could go deeper to provide assurance the information is well founded in evidence and fact or could include a thorough review of all project documentation, testing of assumptions and field inspection of project assertions. Increasing levels of assurance usually require additional time and cost to achieve and provide increasing levels of comfort to the WCI Partner jurisdiction that the criteria for inclusion in the offset system are met.

3.1.2 Draft recommendation

As the first step in the process, validation will initiate a relationship between the proposed project and the relevant authority. Each WCI Partner jurisdiction will be responsible for evaluating offset projects within its respective jurisdiction and may also evaluate and register offset projects in non-WCI jurisdictions throughout Canada, the United States and Mexico.[2] Therefore, whether performed by a WCI Partner jurisdiction or a validation body, validation will be conducted with the expectation that the project will be considered under a specific jurisdiction's offset system.

An offset project proponent initiates the process by submitting information on their proposed project required by the WCI Partner jurisdiction or an accredited third-party validation body to effectively perform their validation activities. The required information may be defined by the relevant protocol[3] and may be in the form of a project plan providing basic contact information,

[2] The program design in one jurisdiction, New Mexico, does not include the implementation of an offset system to issue offset certificates. As part of linking, New Mexico could agree with another WCI Partner jurisdiction that the other jurisdiction will issue offset certificates for projects in New Mexico.

[3] The protocols included in California's cap-and-trade program refer to this information as "listing information."

describing the project, referring to the appropriate WCI protocol, baseline scenario (where appropriate) or performance standard, and identifying all project-specific monitoring requirements. The WCI Partner jurisdiction or the validation body will assess whether the project meets the requirements of the WCI offsets system and is in conformance with an appropriate protocol. The validation step must be completed prior to verification of the offset project's first project report. A project must be validated as part of each renewed crediting period. If validation is performed by an accredited third-party validation body, the validation body must issue a positive validation statement before the project can be registered. Subject to activity (validation/verification) and sectoral scope (project type) requirements, third-party validation bodies must conduct validation in accordance with ISO 14064-3 and must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction's required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011.

3.1.3 Explanation of draft recommendation

This draft recommendation meets the WCI Offset System Essential Elements Final Recommendation (July 2010) that, "validation is a required review by an accredited independent third party of the WCI Partner jurisdiction to assess the likely result of reduction or sequestration from a proposed project that would use a WCI offset protocol."

Validation serves as the initial review of a proposed project. In order to ensure a complete and efficient verification of emission reductions, the draft recommendation proposes that validation be conducted prior to verification of the first project report for a given offset project. At the start of a new crediting period some project information reviewed as part of the validation process is unlikely to change. However, information regarding applicable regulatory requirements, as well as performance standard thresholds to assess additionality, may change over time. Each project must be validated prior to each crediting period to assure that the project meets the current requirements of the appropriate protocol. To the degree possible, the validation process for project renewal will be streamlined.

Information submitted on the proposed project will serve as the basis for the validation review. Submitted information will include identification and description of the project, an assertion of the projection's additionality, and copies of other legal documentation required for the project (e.g., permits, environmental impact assessment).

The draft recommendation does not require at the system-wide level site visits as part of the project review process for validation. The WCI Offsets Committee recognizes that requiring a site visit presents a potentially unnecessary cost to project developers, particularly given the

WCI Partners' preference for standardized offset protocols. However, if required for particular protocols, project types or technologies a site visit could be included as part of the validation process.

The accreditation requirement for third-party validators is designed to mirror as closely as possible the accreditation requirement for third-party verifiers providing services for mandatory reporting and offset projects.

Following a validation review, a third-party validator may issue a positive validation statement if they determine the project to be in conformance with offset system requirements and the appropriate protocol. As discussed later in this paper, a verifier would then verify a project against the validation statement.

3.2 Registration

The registration process is the mechanism for project developers to record offset project information with the WCI Partner jurisdiction evaluating the project. Project registration requires the submittal of forms and information on each project to the applicable WCI Partner jurisdiction to help ensure that projects meet the requirements of the offsets system. For the WCI Partner jurisdictions, a registration system for recording and managing project information will be especially important to ensure proper oversight for a regulatory compliance program and effective communication across multiple jurisdictions. Posting registration information for public review provides transparency to the offset system.

3.2.1 Options for Registration

The WCI Offsets Committee evaluated several approaches for project registration. Under all of the options considered, no offset certificates would be issued by a WCI Partner jurisdiction until the project is validated, registered, and has verified emission reductions. If validation is performed by an accredited third-party validation body, the validation body must issue a positive validation statement before the project can be registered. The options present different approaches for the timing for completing the validation, registration and verification step, but for all projects each step would be required.

Option A

- Project proponent submits registration information to the WCI Partner jurisdiction as specified in the appropriate protocol. The Partner jurisdiction reviews the information for consistency with eligibility criteria and completeness of information. The project would be considered "listed" in the program registry and not yet registered if the information is complete. The project would not be registered until a project is validated and a verified project report is submitted which demonstrates that real emissions reductions have occurred. This approach is similar to the process of the Climate Action Reserve.

Option B

- As part of validation step, the WCI Partner jurisdiction could have the project proponent submit detailed registration information as specified in the appropriate protocol. The WCI Partner jurisdiction or an accredited third-party assurance provider would undertake a detailed review of the information and assess the project against system requirements as part of a both the validation and registration process steps. Upon successful completion of the WCI Partner jurisdiction review, the project would be registered. This approach resembles the initial review and registration process under the RGGI program.

Option C

- Project proponents would wait to submit documentation for validation and registration until just prior to verification. A project proponent would not be required to submit any information until the first project report is due. At that time, a project would complete the validation, registration and verification steps in succession. Under this approach, validation and registration could occur after the project has already begun operation. This approach is similar to the process used by the Voluntary Carbon Standard.

Option D

- A hybrid approach informed by the approach best suited to a project type. The project developer is allowed to choose one of several approaches based on their experience and risk tolerance. If validation is performed by an accredited third-party validation body, the validation body must issue a positive validation statement before the project can be registered.

3.2.2 Draft recommendation

Project registration requires the submission of information for each project to the responsible WCI Partner jurisdiction. The required information may be defined by the relevant protocol and may be in the form of a project plan. Registration information will be posted for public review and comment to provide transparency.

The project developer must identify a potential offset project and determine if it is conformant to the jurisdiction’s offset criteria and the jurisdiction’s adopted protocol. For aggregation of small projects, unless otherwise specified in the protocol, a single request for registration can be submitted for the entire aggregation although it must include the required information on each project. The Project Developer must implement the project per the information provided as part of registration. If the proponent changes any aspect of the project compared to the project plan at the time of registration, the change will need to be approved by the relevant WCI Partner jurisdiction and a revised project plan reflecting the change posted for public review.

The WCI Offsets Committee is not recommending a preferred approach among the options presented above for Registration. WCI Partner jurisdictions will retain the flexibility to select the Registration approach most appropriate for their jurisdiction. However, for all WCI Partner jurisdictions, no offset certificates will be issued until the project is validated, registered and has verified emission reductions.

3.2.3 Explanation of draft recommendation

The WCI Offsets Committee recommends the priority for ensuring the integrity of offsets across the WCI Partner jurisdictions is for requirements to be consistently met and documented in all WCI Partner jurisdictions prior to the issuance of offset certificates. The timing of when requirements and process steps for registration, as well as with validation presented above, occur may vary based on circumstances specific to each WCI Partner jurisdiction.

3.3 Monitoring and Quantification

Monitoring is the process of collecting project activity data essential for quantifying GHG reductions or removals and also the process of validating assumptions used in quantification. Monitoring includes what project activities need to be measured, how often measurements should be taken, what methods are acceptable, what instrumentation should be used for data collection, how the data is stored and how data quality is maintained. Monitoring of an offset project is intended to allow for the complete and transparent quantification of GHG reductions or removals.

Essential elements of monitoring procedures and monitoring reports often include the following:

- GHG data and information for all sources and sinks to be monitored, including units of measurement.
- Source information for all data and information included.
- Monitoring methodology identified, including description of the approach used (e.g., estimation, modeling, measurement or calculation) and description of all relevant assumptions, constants, mathematical relationships and formulas.
- Measurement collection techniques identified including technical information regarding location and specifications of metering equipment, procedures for meter reading, calibration and maintenance, and length of measurement periods.
- Level of uncertainty associated with measurement and estimation of data.
- Roles and responsibilities for monitoring procedures.

- QA/QC measures including data management systems, procedures for managing poor quality or lost data and data archive procedures.

Quantification is the process of estimating emissions reductions achieved from project activity data collected through monitoring. Requirements for quantification will be included in offset protocols recommended by the WCI Partner jurisdictions. The process for developing recommended offset protocols, including quantification requirements, will be addressed through the work under Task 3 of the WCI Offset Committee.

3.3.1 Options for Monitoring and Quantification

Several options for developing monitoring requirements are available and different approaches reflect the desired level of standardization at the protocol and program levels.

Protocols may specify the monitoring requirements for all projects of a specific type using the same recommended protocol. Protocol monitoring requirements could include options that project proponents could choose from in order to best tailor the requirements to the individual project activity. Program-level requirements, in addition to protocol-specific requirements, could specify required elements of monitoring that would need to be incorporated into all protocols and/or projects.

Allowing alternative monitoring approaches provides flexibility to tailor monitoring requirements to individual project circumstances while maintaining the integrity of the system. This could be especially relevant to projects with pre-existing systems in place or for carbon sequestration projects where preferred measurement approaches may vary based on the project conditions.

3.3.2 Draft recommendation

Each offset project shall follow the monitoring and quantification requirements specified in the applicable protocol and offset system rules of the WCI Partner jurisdiction. Monitoring and quantification requirements for offsets will be harmonized, to the extent practicable, with WCI Mandatory Reporting Requirements.

3.3.3 Explanation of draft recommendation

Protocol-specific monitoring requirements will provide consistency across projects using the same protocol and allow WCI Partner jurisdictions to tailor monitoring requirements to each project type. Under this approach, monitoring guidance requirements will be included as part of each WCI recommended protocol for a given project type. Since waiting until verification to have the monitoring plan approved could increase risk to project developers, project proponents will be required to submit a monitoring plan as part of the validation review that demonstrates how the project will meet the monitoring guidance requirements of the WCI recommended protocol being used. During the reporting and verification process steps, submitted monitoring data will be reviewed to ensure it meets the procedures outlined in the approved monitoring plan.

Consistency of monitored data is important for quantification, reporting and verification. Requiring all project developers for each project type to follow the same monitoring requirements helps ensure the consistency of monitored data. However, under certain circumstances a WCI Partner jurisdiction may allow a project proponent to use an alternative monitoring approach or to propose alternative monitoring approaches with approval from WCI Partner jurisdictions. For a proponent to propose an alternative monitoring approach, the proponent must be unable to implement the monitoring approach in the protocol, and the proponent must propose an approach that will achieve a similar level of accuracy to the approach in the protocol.

3.4 Reporting

Reporting refers to the process of summarizing project monitoring data, quantifying the GHG reduction achieved in the applicable period according to the calculation methodology in the project plan, and documenting that information in a project report. Periodic reporting on the performance of GHG reduction projects is a step required by most offsets systems and a necessary step before offsets can be issued. The required content and level of detail required in project reports vary between systems and by project type. A complete project report in the WCI offset system might include the following components:

- Summarized monitoring data.
- Calculations supporting the GHG reductions achieved (in accordance with the quantification methodologies of the appropriate WCI protocol).
- Proponent's assertion of the GHG reduction.
- A signed verification statement.

The WCI Partner jurisdictions will establish overall reporting requirements to ensure adequate oversight of the offset system. These requirements are intended to serve the needs of project proponents, assurance providers, and ultimately the wider WCI market by establishing what information must be documented before an offset certificate may be issued. Clear reporting requirements should allow for reports to be submitted and verified without undue delay.

3.4.1 Options for Reporting

Within the WCI offset system it may be beneficial to define a minimum level of monitoring data detail that proponents must be provided in a project report. The minimum level could be to provide the total GHG emissions or removals for each source and sink within the project boundary. A further layer of detail could be to require, at the level of source and sink and/or in aggregate, project emissions and removals by type of greenhouse gas.

Quantification methodologies should be well established by protocol. The project report should identify the extent to which any missing data was replaced and how it was replaced.

Reporting templates may be established. Standardizing the template for reporting could facilitate the verification process through clear identification of basic data requirements and assertions that will be necessary for the assurance provider to assess the project report. In addition, establishing a reporting template could facilitate consistency between offset project reporting requirements and the essential requirements for WCI reporting.

Reporting is an ongoing activity in active offsets projects. It is a necessary step in having GHG reductions verified and recognized as offsets and also provides a level of review and oversight. A reasonable reporting frequency needs to be established which balances adequate review and oversight with the recognition that reporting represents a project cost due to the resources required to prepare and subsequently verify project reports. Based on the approved reporting frequency, the project proponent would submit a periodic report to the verification body, which will review and issue a verification statement. The final report, including the verification statement would be provided to the program authority for review.

3.4.2 Draft recommendation

Reporting frequency will be annual unless otherwise specified in a recommended protocol. A WCI Partner jurisdiction will have two options for assigning the annual reporting date for a project:

- the month and day of the project start date (as determined by the first day for which a reduction is claimed); or
- a common calendar date for all projects each year.

Reporting requirements will be harmonized, to the extent possible, with the WCI Mandatory Reporting Requirements. Aggregated small projects may submit a single report for the entire aggregation of projects, unless otherwise specified in protocol, although the report must include required information on each project's reductions.

3.4.3 Explanation of draft recommendation

The WCI Offsets Committee recommends annual reporting to ensure ongoing oversight of project activities. For particular project types (e.g., long-term sequestration projects), less frequent reporting may be appropriate.

The WCI Offsets Committee discussed the merits of having common or staggered reporting dates for offset projects. The advantage of the common date was that offsets reporting would thus be more similarly aligned with mandatory reporting which also has a common date. Staggered reporting dates according to a project's start date allow the workload placed on verifiers to be more constant throughout the year instead of focused in one quarter of the year. Staggered dates are also consistent with other notable offset mechanisms. The Offsets Committee believes that both approaches are valid and recommends that WCI Partner jurisdictions be allowed to follow either approach, as this should not adversely affect the rigor or fungibility of offsets across the WCI region.

Harmonization of reporting requirements with the WCI Mandatory Reporting Requirements and aggregation of small projects into a single reporting report, are recommendations aimed at reducing the administrative burden and improving efficiency for project developers.

3.5 Verification

Verification is the process of reviewing offset project information to ensure that claimed emissions reductions have been achieved in accordance with the appropriate offset protocol and project plan.

3.5.1 Options for Verification

At verification, the verification body will review project documents and facilities, and produce a verification report and statement, which includes the verification body's assessment of the proponent's GHG assertion. The verification report should contain the following types of information:

- Verification plan, verification objective, criteria, scope, materiality and schedules.
- Sampling plan which would include amount and type of evidence necessary to achieve the agreed level of assurance, methodologies for determining samples, risks of potential errors, omissions or misrepresentations.
- Assessment of the GHG information systems and controls for sources of potential errors, omissions and misrepresentations.
- Assessment of the GHG data and information.
- Assessment against the appropriate protocol and system requirements.
- Evaluation of the GHG assertion.
- Issuance of the verification statement which will describe: the level of assurance of the verification statement, the objective scope and criteria, whether the data supporting the GHG assertion was historical, and will provide the verifier's conclusion on the GHG assertion including any limitations.
- Site visits as required for review.

The verification report will be submitted with the project report to the WCI Partner jurisdiction for review and consideration for certification and issuance.

3.5.2 Draft recommendation

Emission reductions or removals must be verified by an accredited third-party verification body and submitted to the relevant WCI Partner jurisdiction prior to the issuance of offset certificates. Subject to activity (validation/verification) and sectoral scope (project type) requirements, verification bodies must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction's required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011. The verification must also be conducted in accordance with ISO 14064-3 to a reasonable level of assurance. A third party assurance provider which validated the registered project plan may not perform third-party verification of a project report within the same crediting period. Verification statements will be posted publicly. Unless otherwise specified in protocol, for aggregation of small projects, a single verification report can be submitted for the entire aggregation, although it must include verification for each project's reductions.

3.5.3 Explanation of draft recommendation

The draft recommendation for the verification process steps is based on the final recommendation for verification established in the WCI Offsets System Essential Elements Final Recommendations Paper (July 2010). The final recommendation stated, "verifiers for WCI offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner jurisdiction in which the project is registered." The process steps draft recommendation presents accreditation requirements for third-party verifiers. The recommended accreditation requirements, accreditation for entities verifying offsets are consistent with the WCI mandatory reporting recommendations requirements.

Since a third-party body may have a conflict of interest if it verifies a project which it also validated, the Offsets Committee recommends that a third-party which validated a project's project plan may not also verify a project's emissions reductions or removals for the crediting period covered by the validation. As validation is necessary for a renewed crediting period, an entity which validated a project for its first but not its second compliance period would be allowed to verify a project's reductions or removals during the second compliance period.

3.6 Certification

At some point in the creation of an offset compliance instrument a WCI Partner Jurisdiction has to "accept" that the documentation provided and reviewed indicates that the reduction upon which the offset certificate may be based is real, additional, permanent and verifiable. At this step in the process, the WCI Partner Jurisdiction must have the ability to enforce these requirements through its review of the documentation and its assessment of whether it supports a determination that the reduction is real, additional, permanent, and verifiable. By performing this step, other jurisdictions in a regional trading system would be assured that the offset and underlying project meet all of the offset criteria and would be able to accept the offset for compliance. It is not essential that the WCI Partner Jurisdiction perform all of the certification steps directly and may assign certain roles, tasks and decisions to a third party. The tasks or steps involved in certification can take place at different times in the offset cycle and may be separated for convenience or functional efficiency.

The successful completion of the certification step is expected to lead to the Partner jurisdiction creating a tradable unit with a unique serial number within the tracking system of the WCI Partner jurisdictions. A partner jurisdiction may choose not to issue offsets and would therefore not have a certification step in their offset process and may not have an offset process at all.

3.6.1 Options for Certification

Two options have been identified for certification: (1) certification could be performed following successful completion of the verification step and prior to issuance; or (2) certification could be conducted after issuance, for example, when the offset is used for compliance. Under both options, certification would involve review of project documentation.

One approach would be for a WCI Partner Jurisdiction to certify an offset following successful completion of verification and prior to issuing the certificate. Under this approach, the certificate will likely be treated in a similar fashion to an allowance by market actors and compliance entities in the trading system. As one component of the full process, this approach provides a measure of certainty regarding the acceptable nature of the offset for the market and the jurisdictions accepting the offset certificate for compliance. This approach requires the commitment of resources needed to process all requests for certification (with associated administrative costs) before a certificate is issued.

An alternative approach is to conduct certification after issuance of an offset certificate. In this case, the offset instrument would be created based on the results of the verification, enabling offset certificates to be issued more quickly. The offset could be traded before certification is performed. Under this option, certification could be triggered when an offset is used for compliance. At that time, the jurisdiction that issued the offset certificate would review the project documentation to determine whether it supports a determination that the reduction is real, additional, permanent, and verifiable. The resources required for certification would be driven by the rate at which offsets were used for compliance, rather than the rate at which they were created.

If offset certificates are issued prior to certification, there will be more uncertainty regarding the reliability of the offset certificates in circulation. Using a certificate for compliance that has not yet been certified could entail risks if there is a chance that a subsequent unsuccessful certification would lead to the disqualification of the offset certificate for compliance. Consequently, if WCI Partner jurisdictions use differing approaches to the timing of certification, some occurring before and some occurring after issuance, the reliability and value of the two groups of offset certificates may be viewed differently in the marketplace.

Additional uncertainty is also created for the regulatory authority that accepts for compliance an offset certificate that has not been certified. Following the use of the offset for compliance, the jurisdiction would need to wait for the issuing jurisdiction to complete its certification prior to knowing whether the offset met all the necessary criteria.

3.6.2 Draft recommendation

The certification step involves the WCI Partner jurisdiction or its agent/recognized body reviewing project documentation presented as evidence and accepting that evidence into the system through the assignment or creation of an offset certificate when they are satisfied all conditions of the Partner Jurisdiction have been or will be met. The committee recommends certification take place at the point of issuing an offset certificate, so that certificates are not issued prior to successful completion of certification.

3.6.3 Explanation of draft recommendation

The draft recommendation for the certification process is based on WCI Partner Jurisdictions preferring to avoid adding uncertainty to the reliability of offset certificates and preferring not to add complexity to compliance procedures for little or no benefit. Completing certification prior to issuance ensures that the full set of reviews and evaluations are conducted prior to the offset certificate being issued, so that the quality and reliability of the offset instrument are less uncertain. In making this recommendation the WCI Partner jurisdictions recognize that the full set of criteria and processes recommended for offset systems collectively contribute to the quality and reliability of offset certificates. Certification is identified as one component of the overall process at which a final evaluation ensures that the emission reduction on which the offset is based is real, additional, permanent, and verifiable.

3.7 Issuance

After an emissions reduction or removal has been verified and certified in accordance with all requirements and a project proponent has submitted all required reports, the WCI Partner jurisdiction will issue offsets in an amount equal to the reductions credited to the projects, with each issued offset representing one metric tonne CO_2e reduced or removed. Issued offsets will be assigned a unique serial number and issued to the proponent's registry account or a registry account designated by the proponent. For sequestration projects, some offsets may also be retained in a contingency account or buffer pool as required by WCI Partner jurisdictions.

The unique serial number allows each issued offset to be linked to all supporting documents for the offset project. It also allows tracking of an offset from issuance until retirement, enhancing transparency and assisting with any enforcement activities that may be required. Once issued and deposited in an account, offsets can be traded, sold, or used to meet a compliance obligation.

3.7.1 Options for Issuance

Two approaches to issuance have been evaluated for this recommendation:

A. Offsets are issued following certification of reductions or removals.

   If WCI Partner jurisdiction staff review project documentation during the certification process, it may be duplicative to require additional submittals or project review prior to issuance.

B. Project proponents must submit additional documentation to request issuance of offsets following certification of reductions or removal.

   Some programs, most notably the CDM, require project proponents to apply for credit issuance following certification. The application for issuance is accompanied by verification and monitoring documents. Each WCI Partner jurisdiction would then review all documents prior to credit issuance. Requiring a separate application for credit issuance could potentially give project proponents more control over the timing of credit issuance. In addition, requiring a separate application for issuance could provide an opportunity for public review and consultation between offset certification and issuance. Additional review prior to credit issuance is most suited to programs where certification is conducted by a third-party. If WCI Partner jurisdictions review projects during certification, requiring additional submittals and review prior to issuance will probably duplicate efforts and increase the burden on project proponents.

3.7.2 Draft recommendation

Following certification, the WCI Partner jurisdiction will proceed with offset certificate issuance. The jurisdiction will complete the administrative steps of serializing the units and issuing to the appropriate account(s) in the tracking system. Issuance does not require the project proponent to submit any additional information nor require the WCI Partner jurisdiction to conduct any further review of the project.

3.7.3 Explanation of draft recommendation

The comprehensive due diligence process recommended in this paper combines the rigor of direct WCI Partner jurisdiction oversight and accreditation with the efficient aspects of third-party service providers, allowing project developers the maximum flexibility in scheduling and arranging for assurance services and providing jurisdictions with maximum assurance and control. The issuance of an offset certificate culminates the due diligence cycle, delivering a high quality, reliable product into the marketplace.

3.8 Post-Issuance Activities

Following issuance of offset certificates, the ownership of the certificates will be tracked in the tracking system used by the WCI Partner jurisdictions. Offset certificates may be traded and used for compliance within the rules of the WCI Partner jurisdiction programs. Offset certificates could also be retired by their owners for reasons other than compliance if desired.

The offset criteria and processes recommended by the WCI Partner jurisdictions are designed to ensure that all offset certificates are based on well-documented emission reductions. Nevertheless, situations may arise that require action by regulatory authorities regarding specific offset certificates in order to maintain the environmental integrity of the offset system and as a consequence the cap-and-trade program.

It is well recognized that carbon sequestration projects (such as some forestry projects) are vulnerable to reversal in which carbon that was verified as sequestered is released into the atmosphere. To ensure that carbon sequestration achieves the level of permanence described in the offset criteria, protocols and the offset system must include procedures for addressing both unintentional and intentional project reversals. Following issuance, regulatory authorities that issue the offset must have the ability to enforce these procedures and requirements.

In addition to permanence risk, there is a risk that following issuance the basis for issuing an offset certificate for a specific project could be found to be fraudulent or in error. The recommended documentation and independent review requirements are designed to detect such conditions prior to issuance, so that post-issuance discovery of such conditions is expected to be rare. Nevertheless, procedures are required to respond to such circumstances when they arise.

3.8.1 Options for Post Issuance Activities

The approach to post-issuance activities has been divided into two parts for this recommendation, one part for project reversals and one part for fraud and error. For projects that have a risk of reversal the project protocol must be designed with features that provide a mechanism for ensuring permanence. Mechanisms may include, for example, a buffer pool of offsets that is used to replace reductions that are unintentionally reversed. For this approach to be effective, the regulatory authority must have the ability to require that the buffer pool be maintained in adequate quantity to address risks of unintentional reversal, must have the ability to detect when unintentional reversals occur, and must be able to access the pool when needed to replace the carbon lost to unintentional reversal. Through these procedures, the offset certificate that is in circulation (or that may have been used for compliance) remains in circulation and the reduction underlying the certificate is replaced by a reduction from the buffer pool.

Mechanisms for addressing intentional reversals may vary from those for unintentional reversals. The WCI Partner jurisdictions expect that an enforceable relationship between the regulatory authority and the project proponent will require that the project proponent provide a valid instrument to replace the reduction reversed through an intentional reversal.[4] The regulatory authority must have the ability to enforce this requirement. Through this procedure, the offset certificate that is in circulation (or that may have been used for compliance) remains in circulation and the reduction underlying the certificate is replaced with another valid instrument.

Although expected to be rare, fraud or error could affect the validity of an offset from any type of project. Information regarding potential fraud or error could become available in several ways, including from a third-party verifier hired to verify emission reductions at an ongoing project, from public comment, or from Partner jurisdiction audit. Regulatory authorities must have the resources to respond to such information and determine whether the new information changes the conclusion that the project meets the requirements for the offset system. If the regulatory agency finds that the project does not meet the requirements, it must take action to ensure that the environmental integrity of the offset system is maintained.

Two approaches have been identified for taking action.

---

[4] The WCI Offset System Essential Elements Final Recommendation (July 2010) includes replacement as part of the criteria for permanence.

- The regulatory authority is expected to have the ability to enforce requirements placed on project proponents and verifiers. The regulatory authority could require that those entities replace the offsets. While the regulatory authority pursues its remedies with the responsible parties, the offset certificate that is in circulation (or that may have been used for compliance) remains in circulation and the reduction underlying the certificate is replaced by project proponents.

- The regulatory authority could revoke offsets in the tracking system, removing them from any account. If the offsets have been used for compliance, the entity that used the offsets would be required by the jurisdiction in which it submitted the offset for compliance to replace it. The owner of the offset that was revoked could choose to pursue those responsible for the error or fraud to remedy their loss. The regulatory authority could pursue cases of fraud, but would not seek recovery of the offset itself, as that would be left to the offset owner.

In both approaches, the regulatory authorities have the ability to pursue remedies from those responsible for the error or fraud. The first approach puts the responsibility of ensuring that the offset is replaced on the regulatory authority. The current owner has no exposure to the risks of fraud or error in this first approach. The second approach puts the risk on the offset owner. If fraud or error is found to undermine an offset, the offset certificate is revoked and the offset owner may seek a remedy from the responsible party.

Both approaches can also encounter situations in which the mechanisms or those responsible for replacing the offset are unable to replace an offset. For example, a project proponent may have inadequate resources to replace offsets as directed by regulatory authorities. Consequently, under both approaches the regulatory authorities issuing the offsets must be able to take responsibility to ensure the environmental integrity of the program when those required to replace offsets cannot be compelled to do so.

The value of taking the first approach is that it allows offset certificates to be traded without concern that the certificate may be revoked. Offset buyers would not need to assess the risk of fraud or error that could potentially lead to an offset certificate being revoked. To maintain the environmental integrity of the program, the regulatory authorities would need to have sufficient resources to obtain remedies from the responsible parties that include replacing the offsets. If the responsible parties are unable to replace the offsets, the responsibility falls to the issuing regulatory authority.

The value of taking the second approach is that it puts the risk of revocation on the market participants (buyers and sellers) who are able to manage the risk through pricing and contracting. Facing these risks, the buyers and sellers may conduct more due diligence on the offsets and offset suppliers. Mechanisms for spreading the risk, such as through insurance, may develop to provide low cost security to compliance entities. The cost of bearing the risk of fraud and error would be expected to be internalized into the prices for offset certificates. However, the environmental integrity of the program may be maintained more easily under the second approach because offsets that have not been used for compliance are removed from the system immediately: environmental integrity does not rely on being able to get project proponents to replace the offsets. If the revoked offsets have been used for compliance, burden for replacement falls to the compliance entity.

3.8.2 Draft recommendation

Project protocols and the offset systems of the WCI Partner jurisdictions will have mechanisms in place to ensure permanence, including provisions to address unintentional and intentional reversals.

The offset systems of the WCI Partner jurisdictions will establish rules which enable action to be taken where fraud or error has been discovered. The outcomes of such action will include maintaining the environmental integrity of the program by ensuring every certificate in the system is supported by an emission reduction that is real, additional, permanent and verifiable.

No draft recommendation is made at this time regarding the ability to revoke or require the replacement of offset certificates. Comment is solicited regarding three potential options for consideration:

- Offset certificates are not revocable by any WCI Partner jurisdiction and the remedies for fraud and error include replacement.
- Any offset certificate is revocable by the WCI Partner jurisdiction that issued it upon discovery of fraud or error.
- WCI Partner Jurisdictions choose to issue, at their discretion, offset certificates that are either revocable or non-revocable. This option would support some jurisdictions issuing offset certificates that may be revoked, and others issuing offset certificates that may not be revoked.

WCI Partner jurisdictions would appreciate comments on potential implications of these options for: offset supply; trading of offset certificates; program administration requirements; and environmental integrity.

3.8.3 Explanation of draft recommendation

The draft recommendation regarding unintentional and intentional reversals is designed to ensure that sequestration projects and the offset system have built-in mechanisms to ensure permanence. These mechanisms should be used to deliver the promised performance of the offset projects.

No draft recommendation is made at this time regarding the ability to revoke or require the replacement of offset certificates. Partner jurisdictions have received and are continuing to receive stakeholder comments on this topic.

4 Consultation

The WCI Offsets Committee will receive stakeholder comment on this paper and its recommendations before making its final recommendations to WCI Partner Jurisdictions for consideration. Written comments may be submitted here via the WCI website through Friday, July 8, 2011. The WCI Offsets Committee will also host a stakeholder call on Wednesday, June 15, 2011 from 12:30 – 2:00 p.m. Pacific Daylight Time. To join the call, dial 1-800-868-1837 toll free in the US and Canada (1-404-920-6440 outside the US and Canada) and enter participant code 753491#. A PowerPoint presentation will be posted to the WCI website at the time of the call.

WCI Stakeholder Call

June 15, 2011

To join the call, dial **1-800-868-1837** toll free in the US and Canada (1-404-920-6440 outside the US and Canada) and enter participant code **753491#.**

Background

- The WCI's detailed Design for a Regional Program included recommended criteria for offsets
- Today, the Committee is introducing draft recommendations for the requirements and process of offsets project review and approval and credit creation for the regional emissions trading program
- The Committee is now examining options for the review and recommendation process for offset protocols

Offset System Process

- This paper identifies the specific requirements for validation, registration, monitoring, quantification, reporting, verification, certification and issuance of offsets
- The recommended process is designed to lead to high quality offset credits that can be exchangeable across the region
- The WCI Partner jurisdictions recognize that Partner jurisdictions have labeled the steps with varying terms, and in some cases have combined steps, in the processes proposed for their programs. While offering these draft recommendations, the WCI Partner jurisdictions acknowledge that such variations that result in the same or greater level of rigor being achieved are acceptable

Validation

- Will initiate a relationship between the proposed project and the relevant authority
- Project proponent submits project information for validation by Partner Jurisdiction or third-party validation body
- This must be completed prior to verification of the project's first project report

Registration

- Requires that submission of information for each project to the responsible Partner Jurisdictions
- Registration information will be posted for public review and comment to provide transparency
- The Project Developer must implement the project per the information provided as part of registration

Monitoring and Quantification

- Each offset project shall follow the monitoring and quantification requirements specified in the applicable protocol
- Monitoring and quantification requirements for offsets will be harmonized, to the extent practicable, with WCI Mandatory Reporting Requirements

Reporting

- Reporting frequency will be annual unless otherwise specified in a recommended protocol
- Partner Jurisdictions will have two options for assigning the annual reporting date for the project:
  - the month and day of the project start date; or
  - a common calendar date for all projects each year

Verification

- Emission reductions or removals must be verified by an accredited third-party verification body and submitted to the relevant WCI Partner jurisdiction prior to the issuance of offset certificates
- The verification must be conducted in accordance with ISO 14064-3 to a reasonable level of assurance
- Verification statements will be publicly posted

Certification

- Reviewing project documentation presented as evidence and accepting that evidence into the system through the assignment or creation of an offset certificate when all conditions of the Partner Jurisdiction have been met
- The committee recommends certification take place at the point of issuing an offset certificate, so that certificates are not issued prior to successful completion of certification

Issuance

- Offset issuance follows certification
- The jurisdiction will complete the administrative steps of serializing the units and issuing to the appropriate account(s) in the tracking system

Post-Issuance Activities

- Project protocols and the offset systems of the Partner jurisdictions will ensure permanence, including mechanisms that will replace offsets from sequestration projects lost to unintentional and intentional reversal
- There is no draft recommendation at this time regarding revocation of offset certifications; however there are three potential options:
  - Offset certificates are not revocable
  - Offset certificates are revocable
  - Offsets certificates are issued as either revocable or non-revocable as per the jurisdictions discretion

Next steps

- The WCI Offsets Committee will receive stakeholder comment on this paper and its recommendations before making its final recommendations to WCI Partner Jurisdictions for consideration.
- Written comments may be submitted via the WCI website through Friday, July 8, 2011.

Note: Business requirements discovery is on-going with WCI Partner jurisdictions.

This content is focused on the business processes that will become part of the Compliance Instrument Tracking System Service, required to support the administration of the cap and trade program.

Purpose

The purpose of the Compliance Instrument Tracking System Service (CITSS) Draft Business Requirements is to provide our stakeholders and the public with an overview of the work completed to date in defining business processes and design requirements for the administrative tracking system, CITSS, that will support the Western Climate Initiative (WCI) cap and trade program. This is not a request for proposals and will not be used to pre-qualify or screen vendors for a subsequent competitive bidding process, if any.

These requirements are 'generic' to indicate that they are tracking system requirements that are applicable to all participating jurisdictions and do not include jurisdiction-specific customizations or service requirements.

This document incorporates information contained in the Western Climate Initiative's "Design for the WCI Regional Program" published July, 2010, as well as other previously published WCI documents. It also incorporates publicly available information contained within the California Air Resources Board's May 24, 2010, Market Tracking System Request for Information (RFI) and discussions with representatives of other cap and trade programs.

Introduction

The WCI has designed business requirements for a common system service that could be applied across all participating WCI Partner jurisdictions. Although this system service may be common across the region, each participating jurisdiction will retain authority over its own covered sources and compliance instruments. Beyond the common functions, the form and service of CITSS is left to the discretion of the WCI Partner jurisdictions.

CITSS is an integral component in the administration of the WCI Partner jurisdictions' cap and trade programs. In particular, CITSS is the record of ownership of compliance instruments; will record information related to accounts; enable and record compliance instrument transfers; facilitate compliance verification; and support market oversight through the collection of relevant information.

In addition to the CITSS system service, there are requirements to interface with several other systems and services, to maintain the efficiency and integrity of the cap and trade program.

Background

The Western Climate Initiative (WCI) is a collaboration of seven US states (Arizona, California, Montana, New Mexico, Oregon, Utah, and Washington) and four Canadian provinces (British Columbia, Manitoba, Ontario, and Quebec) to reduce greenhouse gas emissions (GHG). Several WCI partner jurisdictions have signaled their intent to implement greenhouse gas cap and trade programs and link them to form a regional market for compliance instruments. Several WCI participating jurisdictions continue to work towards a 2012 start date for regional emissions trading. The WCI Partner jurisdictions also recognize that alternative schedules for implementation can be accommodated and will continue to encourage additional jurisdictions to join the program after 2012.

As the name implies, the program puts a cap on the total amount of GHG that can be emitted by covered sources under the program by issuing a limited number of emission allowances, or permits to emit one metric ton of carbon dioxide equivalent (CO_2e). Once the cap is set, the program will enable allowances to be allocated (directly, or available for purchase at auction), bought and sold, and banked for future use.

To reduce compliance costs and encourage emissions reductions, WCI Partner jurisdictions will issue credits for certified offset projects that induce a reduction or removal of CO_2e and meet all recommended offset criteria. Offset credits, each representing one metric ton of CO_2e, provide a flexible mechanism that reduces the cost of a cap and trade program by introducing a broader range of reduction opportunities, and incentivize emissions reductions in sectors such as forestry and agriculture that are not covered by the cap and trade program. Allowances and offset credits are collectively called "compliance instruments."

Sources subject to a jurisdiction's cap and trade requirements (covered sources) will be required to submit allowances and/or offset credits on a certain date to the jurisdiction in which they operate in a number equal to their emissions over a compliance period. Because the number of allowances in the program is fixed, the cap and trade approach provides a measure of environmental certainty about the total quantity of GHG emissions attributable to the covered sources.

To successfully administer a regional cap and trade program, the WCI Partner jurisdictions are working on the development of a number of information services. These services include: an offsets information system service, auction services, one or more databases for covered source emissions and a Compliance Instrument Tracking System Service (CITSS). The CITSS is the focus of this document.

WCI Cap and Trade Cycle

For a comprehensive description of the Western Climate Initiative cap and trade recommendations, please refer to the WCI website.

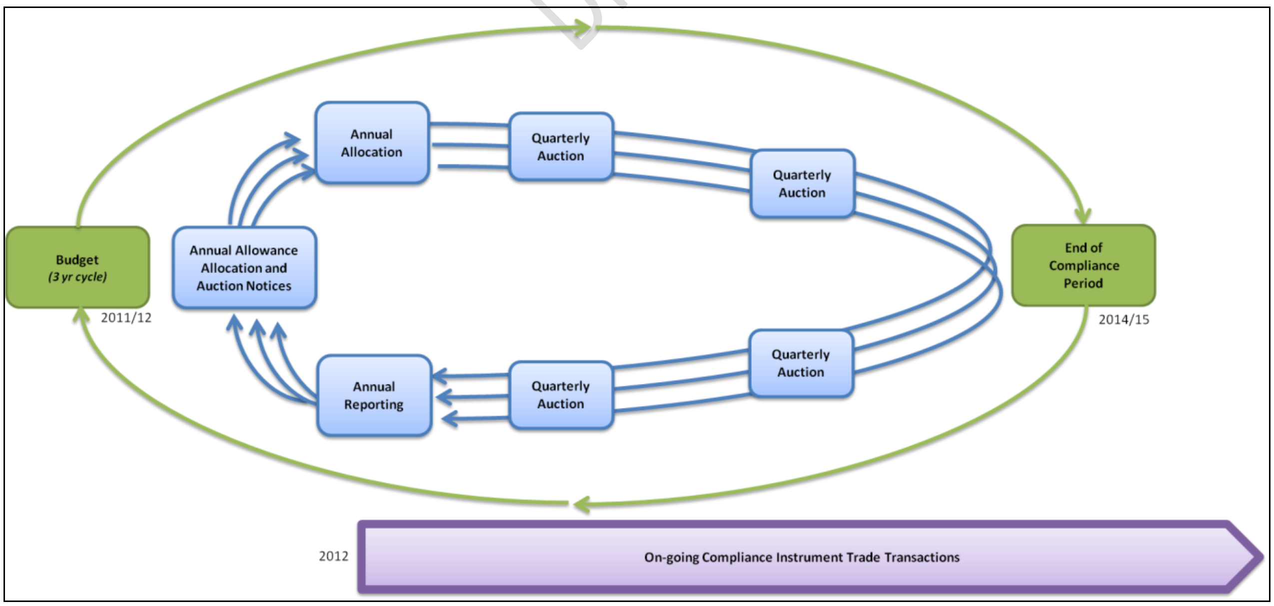
WCI Participating jurisdictions (states and provinces) will set budgets for greenhouse gas levels (emission allowance caps) for a given period. The goal is to lower emissions annually and to regulate compliance in successive three-year compliance periods.

Jurisdictions will control the amount of allowable emissions by issuing allowances in limited amounts. Each jurisdiction may, at its discretion, directly allocate a number of emission allowances to its covered sources (large greenhouse gas emitters) at or near the start of the compliance period and at other times during the compliance period as it sees fit. Jurisdictions will also hold regular auctions of allowances, expected to be quarterly.

Covered sources may meet their obligations by surrendering compliance instruments in the form of allowances and offset credits in amounts equal to their verified emissions for the three year compliance period. By a specified deadline following the end of the compliance period, those not having met their commitments will be subject to compliance enforcement.

In 2015, a subsequent three year compliance period commences.

Figure 1: Cap and trade three year cycle



CITSS Actors

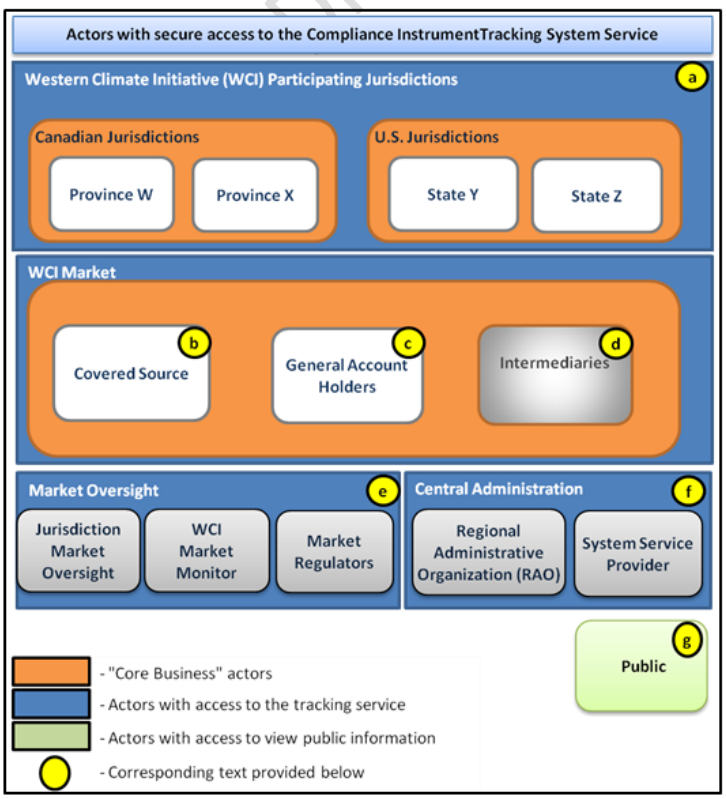
Participants in a cap and trade program include the following core actors who are actively involved in the issuance, acquisition, transfer and retirement of compliance instruments:

1. Participating jurisdictions (i.e., states and provinces)
2. Covered sources, including sources that emit greenhouse gases in a participating jurisdiction in excess of a threshold; sources voluntarily electing to opt into the program, as defined in their jurisdiction's regulations; first jurisdictional deliverers of electricity; and distributors of transportation fuels and residential and commercial fuels
3. Other general account holders, such as developers who undertake offset projects to reduce greenhouse gases and other market participants.

Other parties involved in the cap and trade system may have specific roles, such as providing market monitoring services or brokering trades in compliance instruments on behalf of clients. As an environmental program, the system must also have an element of transparency for the public.

Figure 2 is a conceptual depiction of the WCI cap and trade program actors. It is not meant to infer a hierarchy or tracking system account structure. Regardless of their access to the tracking system, all actors play significant roles in the success of the cap and trade program.

Figure 2: CITSS Actors



The following section provides a brief description of each of the proposed CITSS actors and lists its actions in the process. The descriptions in this document are clarifying descriptions for the purposes of system requirements. If any conflicts exist between definitions, the jurisdiction requirements take precedence.

a. Jurisdictions

Jurisdictions are participating states and provinces responsible for issuance of compliance instruments and general administration of the cap and trade program.

Jurisdiction:

- Defines its budget (sets emission caps) and issues allowances
- Approves the creation of compliance accounts and general accounts in its jurisdiction
- Allocates allowances to covered sources and other market participants, as defined by each jurisdiction
- Issues offset credits in respect of offset projects
- Coordinates auction timing with other jurisdictions and sets the quantity of allowances to be auctioned
- Retires compliance instruments at the end of each compliance period
- Has the authority to suspend all transfers in its jurisdiction (similar to halt in financial trading)

b. Covered Sources

Covered sources include: sources that emit greenhouse gases in a participating jurisdiction in excess of a threshold; sources voluntarily electing to opt into the program, as defined in their jurisdiction's regulations; first jurisdictional deliverers of electricity; and distributors of transportation fuels and residential and commercial fuels.

Covered entities are the legal entities that operate a business, a facility or an establishment that is covered by a jurisdiction's cap and trade law and regulations (covered sources). It has not yet been defined for all jurisdictions whether compliance will be assessed at the covered source or covered entity level. For simplicity, this requirements document has been written as having compliance accounts and compliance activities being the responsibility of the covered source. It may be necessary for CITSS to support compliance at either the covered source or covered entity level.

Covered Sources:

- Must register in CITSS for their business, facility or establishment that is covered by a jurisdiction's cap and trade law and regulations.
- Must report corporate affiliates that also have compliance instrument ownership interest.
- Must report any changes concerning the covered source, such as ownership, closure, corporate affiliation, and beneficial ownership in a timely manner, as specified by each Partner jurisdiction
- Must report covered emissions annually to the jurisdiction, which are imported into CITSS
- Must surrender allowances to their jurisdiction to meet their compliance obligations according to their jurisdictions' regulatory requirements and deadlines.
- May take any of the actions of a "general account holder" (section c. next page)

c. General Account Holders

An individual (natural person) or entity (including covered sources) that acquires, holds and trades compliance instruments in the market.

General Account Holders:

- Must register to open a general account, subject to authentication and approval by a jurisdiction
- May hold compliance instruments in the account
- May receive offset credits upon issuance by a jurisdiction
- May transfer compliance instruments between accounts
- Must declare beneficial ownership and corporate affiliations and changes to these in a timely manner, as specified by each Partner jurisdiction
- May transfer compliance instruments through an intermediary, such as a registered broker

d. Intermediaries

Intermediaries may include brokerage houses (registered brokers), banks, clearing houses, and market exchanges. All references to intermediaries and brokers are still under review.

- May hold compliance instruments on behalf of others, while maintaining records of beneficial ownership of the compliance instruments
- May hold compliance instruments on its own behalf as a "general account holder" (see section c.)

e. Market Monitors

Market monitoring is a key element of market oversight. Effective monitoring will contribute to market integrity through the deterrence and detection of fraud and manipulation. Market monitors support jurisdictions with investigation and enforcement matters. A market monitor:

- May view details of any transfer
- View all compliance instrument holdings and transfer activity of an account holder and its affiliates at any point in time (query or report)
- Review all transfers related to given compliance instruments

f. Central Administrator

The WCI partner jurisdictions may establish a central administrator either in the form of a regional administrative organization (RAO) and/or a system service provider, yet to be determined. The central administrator will be authorized to manage administrative tasks associated with the day-to-day operations across the regional cap and trade program. This is a role that would be defined and monitored by the partner jurisdictions, and would work to benefit the jurisdictions.

g. Public

The partner jurisdictions are committed to transparency. Public access to information is anticipated to include reports and basic queries of non-confidential information. All information access will be subject to legislation regarding privacy protection, and will be respectful of business-sensitive information.

CITSS Processes

The following sections describe the business processes designed to support compliance instrument tracking, as well as how CITSS will fit together with the other related systems.

Process sections 1 to 6 focus on the business (administrative) processes required to support the tracking of compliance instruments from issuance to retirement or cancellation, as depicted in the following overview diagram. Sections 7 and 8 of the document examine system interfaces and reports, while the last section (9) describes the known "non-functional" requirements. CITSS is expected to support the functionality described.

1. Accounts

For clarity, this document uses the term "user identification" or "user i.d." rather than "user account", to avoid confusion with accounts that hold compliance instruments.

CITSS User Identification

A user i.d. and role are needed for anyone to act upon or view any data in CITSS. A user i.d. is required for logging into the system and ties the access to an identifiable person, not to a position. A role defines the general access and authority in the system. A user may be assigned more than one role (for instance, a user may be an Authorized Account Representative on one account and be an Electronic Submission Agent on a different account).

System users that are not related to the jurisdiction will apply for user i.d.'s as part of the account creation process, as described later in this section[1]. Roles-based security will be defined by the jurisdiction for each user and will limit user access to data, as appropriate. More is written on this topic in the security section. These are the anticipated user roles required in CITSS:

At the jurisdiction level:

- **Jurisdiction Authority and Alternate**, who have sign-off authority in the jurisdiction
- **Jurisdiction Administrator**, who must be granted security access to jurisdiction functions and accounts by the Jurisdiction Authority(ies), which provides a separation of duties to suit the given jurisdiction
- **Jurisdiction Security Administrator** who will verify applications for new users of the tracking system

At the market participant and covered entity/covered source level:

- **Authorized Account Representative and Alternate Account Representative**
- **Electronic Submission Agent**

[1] System users may also be added to accounts after the accounts are created, and as approved by the jurisdiction.

At the market oversight and monitoring level:

- Market oversight system users **-** yet to be fully defined, anticipating the need to have a class that can query within a jurisdiction and some that may query data across WCI

At the system level:

- Possible regional administrative organization (RAO) administrators
- Service-operator roles with limited access to administrative or technical duties across all jurisdictions.

CITSS Accounts

Every account in CITSS must be opened through a participating jurisdiction. Each account that holds compliance instruments:

- Must name an Account Holder - a legal entity[2] ultimately responsible for the account
- Must name only one Authorized Account Representative and, optionally, one or more Alternate Authorized Account Representative - persons who will act in the account on behalf of the Account Holder and are the only managers of an account. In the case of accounts of a covered entity or a covered source, an Alternate Account Representative is mandatory.
- May optionally have one or more Electronic Submission Agents who are authorized to act in the account for specific purposes by the Authorized Account Representative(s). To authorize an Electronic Submission Agent, the Authorized Account Representatives must first submit a certificate of delegation to the appropriate jurisdiction.

The jurisdiction will decide whether to issue the CITSS user i.d.'s and compliance instrument accounts upon review of applications with certificate(s) of representation and all necessary information for authentication and security purposes.

1.1 Accounts for a Jurisdiction

1.1.1 Creating a new Jurisdiction in the system

On-boarding of new jurisdictions will require CITSS to create the initial foundation and access. This is a secure technical duty that will not be accessible to CITSS users at any level. When a jurisdiction is new to CITSS:

[2] Legal entities include government organizations, non-governmental organizations, corporate entities, and natural persons.

- A Jurisdiction Authority and Alternate Authority must be identified who will authorize and manage the accounts and system users in the jurisdiction.
- A Jurisdiction Security Administrator must be identified who will administer the creation of new users for authority approval.

1.1.2 Creating/Updating Jurisdiction Users

The Jurisdiction Authority and Security Administrator together must be able to update and remove all jurisdiction system users (authorities, administrators, and security administrators), appointing new users as jobs change. Each change will create an audit record in CITSS.

1.1.3 Creating/Updating Jurisdiction Compliance Instrument Accounts

The Jurisdiction Authorities must be able to create jurisdiction compliance instrument accounts according to their needs, including at minimum a jurisdiction general account, an issuance account, and a retirement account.

1.1.4 Jurisdiction Security

The Jurisdiction Authority and Alternate Authority will approve security access to the jurisdiction's compliance instrument accounts. This will be accomplished by defining roles and role access to system functions and accounts, and assigning users to the specific roles.

1.2 Accounts for Covered Sources

A source becomes "covered" under the cap and trade program as prescribed by a jurisdiction's regulations requiring mandatory compliance or when its entity[3] (operator) chooses to register it as part of the cap and trade program ("opt-in"), if this is permitted in their jurisdiction. Covered sources that are "opt-ins" will not be tracked differently in the system from covered sources with mandatory requirements. Once a source has been opted in, it will fall under the same rules and requirements as all other covered sources in the tracking system.

Prior to creating accounts related to a covered source, the jurisdiction must obtain the required information on the covered entity, the covered source, and the people who will be responsible

[3] A covered entity is a legal entity that operates a business, a facility or an establishment that is covered by a jurisdiction's cap and trade law and regulations.

for the related accounts in CITSS. The data collection will be done using an "account certificate of representation", as per the Design for the WCI Regional Program[4].

1.2.1 Processing an Account Certificate of Representation for a New Covered Source

1. A designated official from the covered entity will submit an account certificate of representation to create a new covered source presence in CITSS. The form will contain the following information[5]. :
   a) Covered Entity Data:
      - Legal and Operating names of the covered entity
      - Physical and mailing addresses
      - Telephone, facsimile numbers, cell phone, and email address
      - Web site address, if any
      - Contact name and position
      - Contact's direct telephone, facsimile, cell phone, and email address
      - Corporate Ownership (parent companies and subsidiaries) and Affiliation relationships (partnerships), including contact name and position, addresses, and full contact information, as above
      - Jurisdiction corporate number and other identifiers, as required by jurisdictions (multiple identifiers per entity)

   b) Covered Source Data must be provided for each covered source that is new to the system operated by the same covered entity:
      - Name of Covered Source
      - Type of source: NAICS / SCIAN code
      - Geographical location(s), which will dictate the relevant jurisdiction responsible and be used for reporting compliance by geographic area
        - Latitude and longitude of a specific location or
        - General area of a geographically dispersed operation
      - Covered Source Identifiers connecting it to the emissions database

   c) Certificate(s) of representation, as defined in the DPD, designating the Authorized Account Representative and Alternate Authorized Account Representative, and Electronic Submission Agents, if applicable

   d) Electronic signature confirming that the above information is complete and accurate (legal wording to be inserted). Paper signature and physical verification of documents may be needed to conduct the verification required (the method is still under review for parties outside all jurisdictions)

2. The relevant jurisdiction administrator will verify the accuracy of the covered entity, covered source, and prospective user information provided. It may ask for more information if required.

[4] http://westernclimateinitiative.org/the-wci-cap-and-trade-program/program-design

[5] There will likely be hardcopy submission requirements for verification of new CITSS users.

3. Once the documentation for each of the users has been reviewed and approved, the jurisdiction security administrator will generate an invitation to the prospective new users to create their CITSS user i.d.'s and passwords using a secure online form. Method subject to security standards.
4. The prospective users will complete a request for CITSS user i.d. form online with terms and conditions of use and communicate with the jurisdiction once their user i.d.'s have been confirmed to enable the completion of the account set up.
5. Once the users have been verified, the jurisdiction creates the covered source in the tracking system by entering:
    a. the covered entity (if it has not been registered in the system previously)
    b. the covered source tombstone data (i.e. identifying data, contacts, etc.),
    c. the covered source general and compliance accounts, and using the confirmed user i.d.'s, the Authorized Account Representatives and the Alternate Authorized Account Representative for the accounts.
6. The Authorized Account Representatives of the covered source accounts will provide access to Electronic Submission Agents, as applicable.

1.2.2 Updating the account of an existing covered source

Authorized Account Representatives of covered entity and covered source accounts may:

- Update basic covered entity/covered source contact information in CITSS, such as addresses, telephone numbers, email addresses, and web sites.
- Change the security access of Electronic Submission Agents in accounts over which they have authority.
- Notify the Jurisdiction of a change to any other secured data under their area of responsibility, such as their covered entity, covered source, Electronic Submission Agents, any other Authorized Account Representatives or themselves.
- Notify the jurisdiction of a change of corporate ownership (parent companies and subsidiaries) and affiliations.

Jurisdictions governing covered entity and covered source accounts may:

- Update data that is critical to the identification or classification of covered entities and covered sources (e.g., NAICS code, legal name, etc.).
- Change the ownership or structure of an account. There are many situations that may require a change of account ownership or restructuring of covered source accounts, such as sale of a facility or jurisdictional reassessment resulting in a merger with an adjacent or related covered source. The system needs to support the administrative records for these types of transactions, including providing linkages to past related accounts in the case of a transfer or split.
- Change the Authorized Account Representative or Electronic Submission Agents of a covered entity/covered source and any of the related core data.

- Update the records of association of a covered entity.

1.3 Accounts for General Account Holders (Market Participants)

This section deals with accounts for general account holders – individuals or entities who wish to open a general account not related to compliance.

Each account is opened in a single jurisdiction, and each system user obtains their user i.d. through a single jurisdiction. However, users may have roles in multiple accounts, and in more than one WCI jurisdiction (as Authorized Account Representative or Electronic Submission Agent) – for example, if their business or covered sources span the WCI region.

1.3.1 Creating new general account holder in the system

In order to register as a general account holder, an account certificate(s) of representation must be completed online in CITSS, with hard-copy identity documentation submitted to the jurisdiction for verification:

1. The individual (natural person) or designated official of an organization will use an online application form in CITSS to open an account by providing the following information, in general, with jurisdictional variances:

   a) Information on the general account holder:
      Account Holder information will be collected in two slightly different formats depending whether the applicant is an individual or an organization (may require separate versions of a form)

      Individual (data still subject to privacy impact assessment)
      - Legal and Common names
      - Identifying data (e.g., government issued id, etc)
      - Whether acting as a broker
      - Physical and mailing addresses
      - Telephone, facsimile numbers, cell phone, and email address
      - Employer, for conflict of interest
      - Any other relevant relationships (partnerships, holding positions in companies involved in WCIS cap and trade). For each affiliation, include full personal or organization contact information.

      Organization
      - Legal and Operating names of the organization responsible, as per jurisdiction's rules
      - Type of organization (e.g., NGO, Corporate, etc.)
      - Whether acting in the account as a broker
      - Organization physical and mailing addresses

- Organization telephone, facsimile numbers, cell phone, and email address
- Organization Web site address, if any
- Contact name and position
- Contact's direct telephone, facsimile, cell phone, and email address
- Corporate Ownership (parent companies and subsidiaries) and Affiliation relationships (partnerships), to be determined by the Market Oversight Committee

b) Certificate(s) of representation, as defined in the DPD, designating the Authorized Account Representative and Alternate Authorized Account Representative, and Electronic Submission Agents, if applicable

c) Electronic signature confirming that the above information is complete and accurate (legal wording to be inserted). Paper signature may also be required.

2. The relevant jurisdiction administrator or authority will verify the accuracy of the information provided, and ask for more information if required.
3. Once the documentation for each of the prospective users has been reviewed and approved, the jurisdiction security administrator will generate an invitation to the prospective new users to create their CITSS user i.d.'s and passwords using a secure online form (method subject to security standards).
4. The prospective users will complete a CITSS user i.d. request form online with terms and conditions of use. They must notify the jurisdiction of their user i.d. once it's been confirmed to enable the completion of the account set up.
5. Once the users are verified, the jurisdiction creates the general account in the tracking system and assigns the Authorized Account Representative(s) and Electronic Submission Agents, if applicable.

1.3.2 Updating an existing general account

Authorized Account Representatives of general accounts may:

- Update their own basic contact information, such as addresses, telephone numbers, email addresses, and web sites.
- Change the security access of Electronic Submission Agents in accounts over which they have authority.
- Notify the Jurisdiction of a change to any other secured data under their area of responsibility, Electronic Submission Agents, any other Authorized Account Representatives or themselves.
- Notify the jurisdiction of any change to Corporate Ownership (parent companies and subsidiaries) or Affiliation relationships.

Jurisdiction governing a general account holder may:

- Update data that is critical to the identification or classification of general account holders, Authorized Account Representatives, and Electronic Submission Agents.
- Change the ownership or structure of an account. There are many situations that may require a change of account ownership or restructuring of general accounts, such as sale of a company or jurisdictional reassessment resulting in a merger with or split from another general account. The system needs to support the proper administrative records for these types of transactions, including providing linkages to past related accounts in the case of a transfer or split.

1.4 Account Status, Restrictions, and Closure

Jurisdictions will have the authority to change the status of any of the jurisdiction-controlled accounts in CITSS. Account status can be open, suspended, inactive, or closed.

The jurisdictions may impose different types of suspensions on accounts, depending on the reason. In some cases the suspension is complete and the account is essentially frozen, allowing no activity by the account holder until the jurisdiction lifts the suspension and returns the account to “open”. In other cases, the jurisdiction may suspend the account to prevent the deposit of compliance instruments. For example, if an account has reached a threshold of compliance instruments, the jurisdiction may choose to suspend the account until the number of compliance instruments has been lowered to an acceptable level. Yet another type of account suspension may occur when a covered source is not in compliance. In this case, the jurisdiction may allow deposits into the account and limit transfers out to only specific accounts (e.g., the covered source may be permitted to deposit compliance instruments into its general account, but only transfer compliance instruments into its compliance account for the purpose of meeting a compliance obligation or an excess emissions obligation).

Accounts will be identified by the jurisdiction after a period of inactivity. To provide the jurisdictions with the flexibility to manage their own house-keeping, a report or query is required that will allow administrators to find accounts that have not be accessed for a period of time. The query or report would allow jurisdictions to request a listing of accounts with a period of inactivity longer than a specified timeframe, and ideally would allow the jurisdiction to choose to change their status to inactive. No process will be allowed from inactive accounts.

The jurisdiction may choose to close an account and an account holder may request that their account be closed. Compliance instruments in the account would be transferred out of the account before it is closed. Closed accounts cannot be re-opened, and no activity may be generated from a closed account

The system must allow the jurisdiction to include a comment, such as a reason, for changing the status of accounts.

1.5 Confidentiality of Data

The jurisdiction administrator may identify any data, including personal data, which CITSS must keep confidential; that information may only be accessible by specific users, such as the administrator and the relevant user. CITSS must have the ability to support field-level security, to provide the ability to restrict viewing sensitive data to specific roles.

2. Jurisdiction Budget

Each jurisdiction will provide a budget set out by calendar years, which are linked to compliance periods. The following table is intended to provide an example of the type of data that may be required for budgets. It is not intended to be a prescriptive design:

Jurisdiction - XX	**Period**	**Year**	**Number of Allowances**
Version: current	Compliance Period 1	2012	999,999,999
Effective Date: 2011-DEC-05		2013	999,999,999
Updated by: J. Doe		2014	999,999,999
Notes: Changed the xxx due to xx decision to ...	Compliance Period 2	2015	999,999,999
		2016	999,999,999
		2017	999,999,999
	Compliance Period 3	2018	999,999,999
		2019	999,999,999
		2020	999,999,999
	...	...	...

Entering budgets in CITSS will provide jurisdictions with control over the number of allowances that can be issued within a given year. This will mitigate potential administrative errors and maintain the integrity of the emissions cap. It is recommended that security for the entry of budgets be limited to the Jurisdiction Authority, with confirmation by an Alternate Jurisdiction Authority. The dual authority within a jurisdiction to change the budget is recommended as security control.

3. Issue Compliance Instruments

Compliance instruments are generated in the tracking system through a process termed "issuance". A compliance instrument is issued with a unique identifier that follows the WCI Compliance Instrument Serialization System (CISerS) (details in Section 3.4). This highly secure and controlled process requires a separation of duties between two CITSS users within a jurisdiction with the authority to a) enter a proposed compliance instrument issuance transaction, and b) approve the transaction.

3.1 Types of Compliance Instruments

At an upper level, all compliance instruments are classified either as allowances or offset credits. The tracking system must allow for the definition of new compliance instrument types in the future, such as compliance instruments from other approved cap and trade programs. Certain business rules are applicable based on the type of compliance instrument.

3.1.1 Allowances

Allowances are issued by jurisdictions as per the WCI Compliance Instrument Serialization System. Allowance issuance may not exceed the jurisdiction's budget.

3.1.2 Offset Credits

Compliance instruments created as a result of an offset project will also use the WCI Compliance Instrument Serialization System and will have a project code to allow the instrument to be referenced to its project. That code will enable the holder of the offset to identify the project and project type[6] for which it was issued.

3.2 Steps for Issuing Compliance Instruments

STEP 1. A Jurisdiction Administrator with the security privilege to do so will enter the proposed compliance instrument issuance, specifying the appropriate data depending on the type of instrument (see section 3.3) and the account(s) to which the compliance instruments will be deposited.

It may be beneficial to have all newly issued compliance instruments deposited initially into jurisdiction issuance accounts (separate accounts for allowances and offsets) for ease of consistent reporting across the region, and then transferred automatically to their ultimate destinations in the final stage of the issuance process. Note that jurisdictions are still considering their account requirements. It is up to the jurisdiction

[6] Projects will be categorized by the offset protocol used.

to decide their account structure and into which account issued compliance instruments are deposited.

Allowances

In the case of issuing new allowances, jurisdictions may use a distribution form, specifying the total number of allowances to issue and the intended method of distribution, such as:

a. Percentage or number of compliance instruments to auction

b. Percentage or number of compliance instruments to hold in reserve (e.g., for future allocation, auction or any other purpose, at the discretion of the jurisdiction)

c. Percentage or number of compliance instruments to transfer to other jurisdiction accounts, as determined by each jurisdiction.

d. Number to distribute to each account-holder (if known at the time of issuance).

e. Ability for jurisdiction to opt to issue to a single account (e.g., allowance issuance account) and transfer the issued allowances into other accounts as a separate system action.

Offsets

In the case of issuing new jurisdiction offsets, jurisdictions will complete an offset issuance form, specifying the total number of offset credits to issue, the offset project name and link to the offset information system, and the ultimate account in which to deposit the offset credits after issuance (usually that of the offset developer).

STEP 2. The system will present the Jurisdiction Administrator or Authority with a confirmation page, allowing them to verify the proposed issuance and distribution and change any items before continuing. The confirmation will result in a notice to a second Jurisdiction Authority (approver) for segregation of duties.

STEP 3. The second Jurisdiction Authority will receive a notice of the request for approval and can choose either to return the request to the Jurisdiction Administrator if it needs to be changed (prefer that this function include the ability for the authority to include a note why) or to approve the issuance.

STEP 4. On the final approval, the instruments will automatically be serialized and deposited into the jurisdiction issuance account, and from there will be transferred to any destination account(s). In the case of an offset project, it may go to a jurisdiction issuance account and then to the account of the offset developer.

STEP 5. Following the issuance of allowances, CITSS will enable the jurisdiction to report on compliance instrument issuance.

3.3 Compliance Instrument Serialization

When each compliance instrument is issued, it will be assigned an identification number by the system that is unique across the WCI region and cannot be re-used in the future.

The compliance instrument identification number will link the compliance instrument to a record of issuance, which will hold the following information associated with the origin of each compliance instrument:

a. Issuing jurisdiction
b. Vintage
c. Instrument Type, e.g.:
    i. Allowance
        a) WCI Allowance
        b) Early reduction allowance (ERA)
        c) Price containment reserve allowance
        d) Consignment allowance
        e) Recognized allowance from another cap and trade program
    ii. Offset credit
        a) WCI Offset
        b) Recognized offset from another cap and trade program
d. Offset project code (when offset credit)
e. Number of Compliance Instruments in the Issuance
f. Serial block start (first compliance instrument identifier in the series, as determined by CITSS)
g. Serial block end (last compliance instrument identifier in the series, as determined by CITSS)
h. Approving authority (user id)
i. Date and time of issuance

The potential number of compliance instruments that will be may reach the low billions over the next 20 years. Jurisdictions would prefer to restart the number portion of the serial code at zero annually, which would keep the number much smaller. However, conventional data standards require that the number should be unique throughout the years, regardless of other qualifiers.

4. Transfer Compliance Instruments

All transfers conducted within CITSS must conform to the jurisdictions' requirements when developed. This section outlines a general process by which compliance instruments will be transferred in CITSS.

There are several types of transfer transactions:

Transfers Initiated by Jurisdictions

Multiple Transfers by Jurisdictions

The system needs to support the entry of balanced, multiple entry transfers, for functions such as allowance allocations, auction results, and retirements. This type of entry serves to reduce data entry/accounting errors by incorporating a verification step that shows the total effect of the transfers prior to their approval and commitment to the database. On approval, each of the multiple entries will still represent a transfer between two accounts. Multiple transfers can be entered manually online or may be submitted through a batch interface. These are the most common jurisdiction examples of multiple transfers:

1. Distribution plan transfers (online transfer from jurisdiction account to multiple general accounts)
2. Auction result transfers (batch transfers from jurisdiction to multiple general accounts)
3. Retirement transfers (from multiple covered source compliance accounts to a jurisdiction retirement account)

Single Transfers by Jurisdictions

The most common data transfers will be single transfers with the transferor as the debit account and the acquirer as the credit account. Examples include:

4. Transfers between accounts held by the same jurisdiction
5. Transfers from jurisdiction accounts to general accounts (of covered sources, general account holders or other jurisdictions)

Transfers Initiated by General Account Holders

6. Transfers between general accounts held by the same account holder[7]
7. Transfers between general accounts held by different account holders
8. Transfers involving intermediaries[8]

[7] This may be necessary when an account holder has both a general account at a corporate level and a general account related to a covered source. The system needs to accommodate jurisdictions limiting account holders to one general 'non-covered source' account. The system also needs to be able to accommodate additional ownership in client/broker accounts.

Initiated by Covered Source Account Holders to meet Compliance Obligations

Covered Sources may also act as General Account Holders (see items 6-8 above). However, transfer type 9 is specific to accounts related to covered sources.

9. Transfers from covered source general account to covered source compliance account

Initiated by Account Holders for Voluntary Retirement

10. Transfers from any General Account to the Jurisdiction Retirement Account, for voluntary retirement purposes.

4.1 Jurisdiction Transfers

Jurisdictions have sole authority to transfer compliance instruments out of their own accounts, whether to another of their own jurisdiction accounts or to other accounts. Only users with the security to transfer compliance instruments out of an account may do so. The Jurisdiction Authority sets this privilege for jurisdiction accounts and may name any number of Jurisdiction Administrators. Jurisdiction Administrators may have variable access levels (e.g. view only access) to jurisdiction accounts as enabled by the Jurisdiction Authority.

Functions resulting in multiple transfers are highly secure and controlled processes, requiring a separation of duties between two jurisdiction system users; one user has the privilege to a) enter data or download a proposed multiple-transfer form, and the second user has the ability to b) approve the completed multiple-transfer form.

The Jurisdiction Administrator and Authority are both required to enter and approve any changes to high-level control transactions and multi-transfer forms, such as the budget plan or the allowance distribution plan. Jurisdictions will not have access to the budget or allowance distribution plan table of other jurisdictions. In the case of retirement transfers, the jurisdiction will decide on a date and time to run the retirement process (entered as a parameter in CITSS) and once the initial transfers are proposed, the Jurisdiction Authority will have an opportunity to review and accept the transfers.

Jurisdictions also have authority to enter and approve single transfers from jurisdiction accounts to general account holders, such as transferring issued offset credits.

[8] WCI may structure broker accounts such that the account holder is the owner and the broker is an electronic agent on the account or a trust account is created for every broker/client relationship.

4.2 General Account Holder Transfers

Content throughout this section is subject to final decision on market transfer protocol. The 'push' model would have the transfer completed by the transferor only; the 'push/pull' model requires initiation by the transferor and confirmation from the acquirer; and in the 'push, pull, match' model, both parties submit their sides of the transaction and a match happens in CITSS to confirm the completion. Until a final decision is made, the assumption in this document is that a "push" protocol will be used.

4.2.1 Transfers between two accounts held by the same General Account Holder

Compliance instrument transfers between two accounts that have the same account holder are considered administrative transfers and do not require a reported price[9].

4.2.2 Transfers between general accounts held by two different account holders

An assumption has been made that the transferring account holder will be solely responsible for reporting transfers between general account holders in CITSS (see above). Transfers between general accounts may require that price is reported[10].

4.2.3 Transfers involving intermediaries

For the purpose of this document, accounts will be structured such that the account holder is the owner of the compliance instruments held in the account, and that limited access may be provided to a broker (electronic submission agent) to act on his/her client's behalf.

4.2.4 Transfers Covered Sources use to meet their Compliance Obligations

Transfers from a covered source's general account to its compliance account are handled like any other transfer between accounts held by the same account holder (see 4.2.1). The only difference is the permanence of that action, because compliance instruments cannot be transferred back to the covered source general account.

[9] This applies if the accounts are held by single owners, but is difficult if accounts have multiple (beneficial) owners. The WCI is still investigating the structuring of brokerage accounts.

[10] Transfers between general accounts may require that price is reported.

4.3 Steps for Transferring Compliance Instruments

1. An account user with the security privilege to do so will enter the proposed compliance instrument transfer, specifying the transferring account that will be debited, the acquiring account and name (for verification), the type of compliance instrument, vintage, project i.d., when applicable, quantity of instruments to transfer, and price and currency, if applicable.

2. If the proposed transfer exceeds the amount of compliance instruments held in the transferor's account, CITSS will request a modification to the entry and not allow the transfer to proceed.

3. Depending on the approval process for the specific transfer, CITSS may require that the Alternate Account Representative of the transferring account and/or the Account Representative of the receiving account confirm the transaction. If this is the case, the system must present the Alternate Account Representative of the transferring account and/or the Account Representative of the receiving account with a notification and a confirmation page, allowing them to verify the proposed transfer or change any items before continuing. Completion of the confirmation may result in a notice to the user who initiated the transfer.

4. After all required approvals:

    a. There will be a final system check of any transfer rules prior to committing the transfer to the database, such as holding limits and accountability limits. If a limit is reached, a review, warning or error process will go into effect.

    b. If the transfer proceeds, the instruments will be debited from the transferring account and credited to the acquiring account. In addition to the transfer data defined in step 1, for audit purposes, the system will store the following audit data on the transfer record:

        - Date and time stamp of update
        - User i.d. of the user(s) who transferred or authorized the transfer from the transferring account
        - User i.d. of the person who confirmed the transfer from the acquiring account, if applicable.

5. Following the transfer of compliance instruments, any account representative who is directly affected by the transfer but was a passive participant will be notified by CITSS to

check their account for the change in balance. For example, in the “push” transfer model where the transferor initiates the transfer, the acquiring party would receive a notification.

4.4 Transfer Reversal

If a transfer is made in error, CITSS requires a transfer reversal to “undo” the transfer made in error. A transfer reversal links the ’correction’ transfer to the original transfer in error, and requests a reason for the reversal. A reference to the original transfer in error (A) will be stored in the transfer reversal log for (B), and vice versa for accounting and audit integrity.

For transfers between two account holders, the transfer must be proposed by one of the two original parties and approved by the other. The system function must clearly state that the action can only be used to reverse a transfer that was completed in error. Jurisdictions of both account holders will be notified of the transfer reversal in a daily activity summary and in any other reports that may be of interest to the market monitor.

Transfer reversals will be excluded from transfer volume statistics.

5. Compliance

All registered program participants must conform to their jurisdiction's requirements. This section outlines the compliance process as it will be facilitated by CITSS.

Key terms[11] for this section are:

- Annual verified emissions: The annual verified emissions of a given covered source. This figure is determined on a calendar year basis and is entered/imported from the jurisdiction's emissions database.

- Compliance obligation ('true-up value'): The sum of the annual verified emissions for all three calendar years within a compliance period.

5.1 The Compliance Obligation ('True-up") value

Each year, annual verified emissions per covered source are recorded in each jurisdiction's emissions database. The annual verified emissions per covered source will be imported into CITSS from the various jurisdiction emissions databases. The jurisdictions also need the ability to enter verified emissions manually in CITSS, without the import interface. The deadline of emissions entry varies by jurisdiction and will not be managed by CITSS. At its discretion, a jurisdiction can run an exception report to check if any of the verified emissions are missing for its covered sources for a given year or compliance period[12].

When the jurisdiction decides that its emissions data is complete for a compliance period, the jurisdiction has two options to identify the compliance obligation value: [Option A] enter the compliance obligation value manually or [Option B] initiate a function for CITSS to determine the compliance obligation value for each covered source by adding together its annual verified emissions for each year of the 3-year compliance period. The compliance obligation and annual verified emissions values for a given covered source will be standard data featured in the covered source account to enable covered sources and covered entities to clearly see the data that will constitute their compliance obligation at any time in the compliance period.

[11] Actual terms used by each jurisdiction may vary.

[12] A covered source will not have annual verified emissions submitted in CITSS for years prior to being "covered". If a source becomes covered part-way through a compliance period, there may be legitimate emissions data gaps at the start of the period.

CITSS will notify the covered source's account representative once the compliance obligation values have been recorded in CITSS. The notification[13] will advise the account representative to log in to CITSS for instructions on how to surrender their compliance instruments to meet the covered source compliance obligation by the compliance date. In addition to the notification, account representatives of covered source accounts will have the ability to view or query the compliance obligation value of the current, or previous compliance period(s).

5.2 Surrendering Compliance Instruments

To satisfy a compliance obligation, compliance instruments must be surrendered by the account representative of the covered source's compliance account in an amount equal to or greater than the compliance obligation by the deadline. The compliance deadline will be the set by the jurisdictions.

Account representatives may transfer compliance instruments into a covered source's compliance account at any time prior to the deadline. Once compliance instruments are in a compliance account, they cannot be transferred out by the covered source. Only the jurisdiction may approve the transfer of compliance instruments out of a covered source's compliance account.

There is no limit to the number of compliance instruments that can be transferred into a compliance account. Instruments held in compliance accounts are exempt from holding limits up to an amount equal to the emissions reported or estimated in a positive or qualified positive verification statement covering the previous annual verified emissions in a calendar year.

The jurisdictions are considering allowing the covered source account representative to choose to specify (flag) which of its compliance instruments it prefers to have the jurisdiction retire first. This functionality is still being discussed. Priority would only be considered in the case where a compliance account contains more compliance instruments than is needed for the impending obligation. On the compliance deadline, CITSS will automatically transfer compliance instruments from the covered source compliance account to the jurisdiction retirement account, based on the order outlined in section 5.3. The mix of compliance instruments retired will not exceed the maximum percentage of offset credits nor the overall compliance obligation value for a given covered source, and will not include future vintages.

[13] Notifications have two components 1) an email message sent to each account representative stating the type of notification and to log into CITSS for details, and 2) notification details in a secure notification area, available through secure sign-on to CITSS. Emails may not be used to transmit confidential data.

5.3 Retiring Compliance Instruments

Final retirement of compliance instruments occurs once the compliance instruments are transferred to the jurisdictions' retirement account.   Compliance instruments transferred to the retirement account are permanently removed from circulation (end of compliance instrument life-cycle).

At the compliance deadline, compliance instrument retirement will be initiated automatically by CITSS on behalf of each jurisdiction, transferring compliance instruments from covered source compliance accounts to the appropriate jurisdiction retirement accounts. Compliance instruments that are of a vintage within the compliance period or earlier will be retired in the following order[14]:

1. Offset credits flagged by the account representative, taking the oldest first and adhering to the maximum offset limit
2. Allowances instruments flagged by the account representative, taking the oldest first to the maximum of the remaining obligation.
3. Oldest offset credits **not** flagged by the account representative, to the maximum offset limit and remaining obligation
4. Oldest allowances **not** flagged by the account representative, to the maximum of the remaining obligation.

The covered source status will be updated to either "in compliance" or "out of compliance" depending whether it meets its compliance obligation. If there are more compliance instruments in the compliance account than required, the excess compliance instruments will remain in the compliance account.

[14] The order may be amended if policy changes. Recognised compliance instruments from other cap and trade programs are not included here. Further policy direction and refinement is needed for this instance, which is not anticipated in the first year(s) of the WCI regional cap and trade program operation.

A compliance report will be produced for each jurisdiction, based on selected compliance period:

Displaying and sorted by:

- compliance status
- covered entity
- covered source
- contact information for the covered source

Specifying:

- original compliance obligation
- number of compliance instruments retired (separated into offsets, allowances and total)
- excess emissions (described in section 5.4)
- excess emissions obligation (described in section 5.4)
- relevant balances in the covered source compliance account and general account

5.4 Non-Compliance (Excess Emissions)

For any covered source that has not met its compliance liability (has excess emissions[15]):

1. The status of the covered source and of the covered entity will be changed to “not in compliance”.
2. All accounts of the covered source and its covered entity may have their status updated to “suspended”, suspending the ability for the account representative to transfer compliance instruments to any other account than the compliance account.
3. CITSS will calculate the excess emissions obligation that the covered source must meet. The program design specifies that an excess emission obligation of three times the excess emissions (i.e. outstanding compliance obligation) must be applied to the covered source. The original outstanding compliance obligation is still required to be met by the covered source.
4. The Jurisdictions may transfer compliance instruments from the covered source’s or the covered entity’s accounts to the jurisdiction’s retirement account to cover the outstanding compliance obligation and excess emissions obligation[16]. Excess emissions obligations may be met with later vintages.

[15] “Excess emissions” is the difference between the compliance obligation and the number of compliance instruments retired.

[16] The DPD indicates that as a first course of action, the jurisdiction will deduct allowances, regardless of vintage, from the compliance account. It also indicates that offset credits will not be use (pre-supposes that the offset credit usage limit has been reached?)

5. If there are insufficient compliance instruments to meet the outstanding compliance obligation and the excess emissions obligation, the account representative of the covered source will have a period of time (i.e., 30 days) to meet its requirements.

CITSS must have the functionality to support a jurisdiction in taking any of the following administrative actions, at the jurisdiction's discretion:

- Appending notes/instructions/official document reference codes on specified accounts
- Transferring compliance instruments from the covered source's or covered entity's general account(s) into the covered source's compliance account (referred to as "deductions" in the DPD; recommend two jurisdiction e-signatures)
- Suspending the transfer out of compliance instruments from specified accounts
- Suspending the complete use of specified accounts

CITSS may also be required to hold information or notations appended to each account that will list the date and jurisdiction reference number of any previous compliance, verification or enforcement action by a jurisdiction.

5.6 Close the Compliance Period

At the end of the retirement process for a compliance period, any compliance instruments remaining in the covered source accounts can continue to be held for use in a future compliance period, regardless of vintage; they do not expire. This applies equally to compliance instruments in general accounts and compliance accounts.

Closing the compliance period is not a formal system process, but a time to produce reports of various types (to be determined), especially to summarize compliance and support reconciliation.

One suggested compliance report would summarize all retired compliance instruments at the jurisdiction level, listing the type of instrument, jurisdiction of origin, vintage, and in the case of offsets, project, with total amounts for each. This type of report will assist in reconciliation of compliance instruments across the WCI.

6. Voluntary Retirement and Cancellation of Compliance Instruments

Though mandatory compliance is the primary way in which compliance instruments will be removed from circulation, jurisdictions may also need to process voluntary retirements and may need to cancel / retire issued compliance instruments on infrequent occasions. It is important to distinguish between mandatory retirement, voluntary retirement and cancellation for administrative purposes (e.g., remedies offset invalidation, cancel excess compliance instruments). Each 'end of compliance instrument lifecycle' process has a distinct purpose, and this purpose needs to be documented to enable necessary reporting and reconciliation of issued and retired/cancelled compliance instruments. This section describes processes for ending compliance instrument circulation that are not related to compliance.

Action to permanently remove compliance instruments from circulation	Applicable to Account Types
Retirement - Mandatory	Covered Source
Retirement - Voluntary	General Market Participant
Cancellation for Administrative Purposes (e.g., administrative error or offset invalidation)	Jurisdiction

6.1 Voluntary Retirement of Compliance Instruments

Account holders may choose to retire compliance instruments voluntarily at any time. This is a different process than the retirement which occurs as part of the compliance process in that the retirement of units is not to meet a compliance obligation. The system must make the distinction very clear to avoid user confusion between selecting voluntary over mandatory retirement and vice versa.

Steps for voluntary retirement:

1. Account authorized representative selects a "Voluntary Retirement" transfer, specifying which compliance instruments to retire.
   a. It is recommended that the system interface provide a means to easily distinguish this function from regular transfers and from compliance-related retirements to minimize its selection by mistake, due to the final nature of this

function and the different outcomes between it and that of mandatory retirement (i.e. to meet a compliance obligation).

2. A confirmation page will be displayed, listing the compliance instruments to be retired, informing the authorized account representative that once the voluntary retirement has taken place, these compliance instruments will be taken out of circulation and cannot be returned and that as a voluntary retirement, the compliance instruments will not be used towards any compliance obligation.
3. Once confirmed, the compliance instruments will be transferred to the voluntary retirement account of the jurisdiction governing the account from which they are being transferred[17].
4. A notification of the transfer will be sent to the authorized account representative and to the jurisdiction.

Voluntary retirements may be reported as a separate class of data than compliance retirements and cancellations for reporting purposes.

6.2 Cancellation of Compliance Instruments for Administrative Purposes

Cancellations of compliance instruments for administrative purposes are likely to be for exceptional events. However, from an accounting and administrative perspective, it's important to have the ability to cancel compliance instruments appropriately. The following are examples where cancellation of compliance instruments may be required:

- Allowance over-issuance within budget - a jurisdiction has made an administrative error, issuing too many allowances.
- Reducing issued allowances and budget - a jurisdiction has either made an administrative error at the budget level or has chosen to reduce allowances in circulation.
- Offset invalidation - a jurisdiction may (a) reverse all or a portion of an offset project's issued offset credits or (b) the jurisdiction may cancel an equivalent number of compliance instruments to restore the environmental integrity of issued offset credits that are subject to invalidation.

Cancellations will be reported as a separate class of data than retirements, as cancellations are not accounted in compliance.

[17] Assumption that in Voluntary Retirement, account holders will not have a choice which jurisdiction will be the recipient of the voluntary retirement – it will go to the jurisdiction with authority over the account. This also assumes that the compliance instruments' jurisdiction of origin is irrelevant.

6.2.1 Allowance Over-Issuance within Budget (Budget Unaffected)

If a jurisdiction has made an error by issuing more allowances than it had planned for a single issuance but is still within its overall budget, the following steps are taken:

1. Jurisdiction administrator or authority verifies that the excess allowances are still in the jurisdiction's accounts.[18]

2. The jurisdiction authority selects a transfer that indicates this is a cancellation due to over-issuance and specifies which instruments to cancel and any further notes regarding the reason for cancellation.

3. A second jurisdiction authority will be notified of a requirement to complete a confirmation page, which lists the compliance instruments to be cancelled (including vintage), and notes that once the cancellation has taken place, these compliance instruments will be taken out of circulation permanently.

4. Upon second authority approval, the system will move the compliance instruments from the jurisdiction's general or issuance account to the jurisdiction's cancellation account with the recorded reason.

6.2.2 Reducing Issued Allowances and Budget (Budget Affected)

If a jurisdiction must reduce the budget and corresponding number of issued allowances in circulation:

1. Jurisdiction authority verifies that the jurisdiction holds the amount of available allowances to be reduced in the right vintage in either the issuance or general account as per the jurisdiction's design (i.e., not retired or cancelled, not pending for use in an auction or held in an account with a specific and defined purpose, such as an offset contingency account). If allowances are already in circulation, the jurisdiction may choose to reduce planned (future) issuances.

2. The jurisdiction administrator/authority proposes a reduction in the allowance budget for the given period, noting the reason. The appropriate amount of allowances of the right vintage is held for transfer to the cancellation account, pending approval.

3. A second jurisdiction administrator/authority will be notified of a requirement to complete a confirmation page, which lists the allowances to be cancelled, and notes that

[18] For control purposes, it may be best to always cancel from only one jurisdiction account, e.g., general or issuance.

once the cancellation has taken place, these allowances will be taken out of circulation permanently.

4. Upon authority approval, the system will move the allowances from the jurisdiction's account to the jurisdiction's cancellation account with the recorded reason and will record a new version of the budget.

6.2.3 Offset Invalidation/Reversals

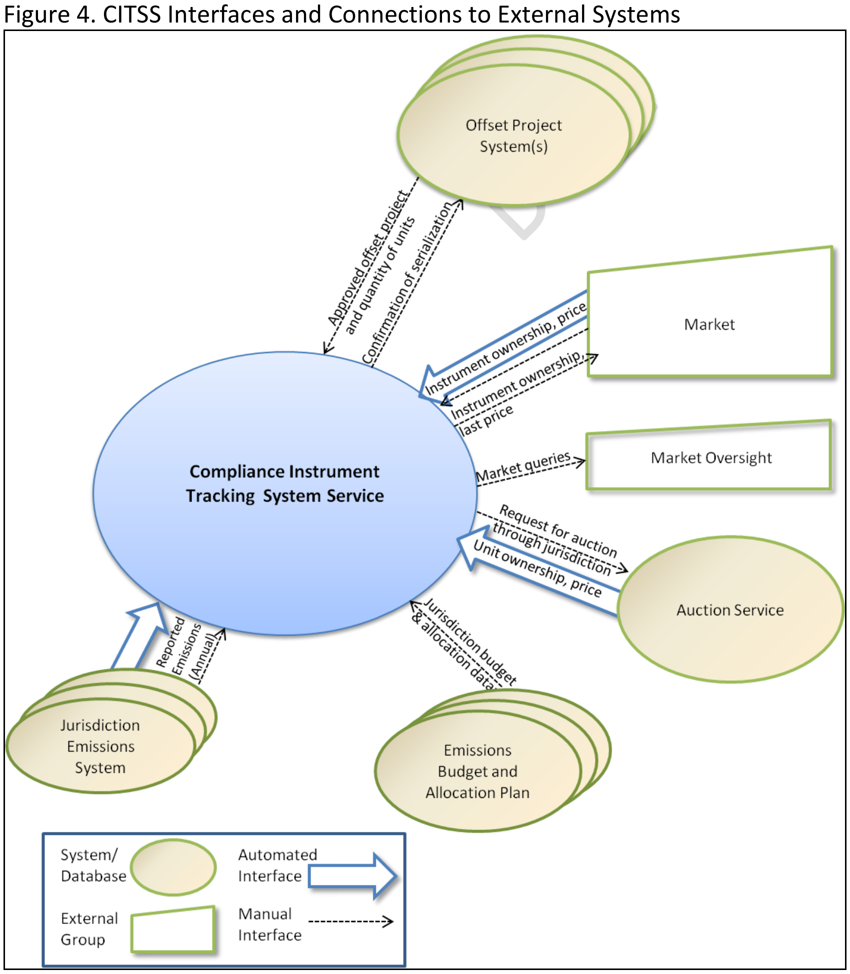
To support possible actions related to offset invalidation / reversals, CITSS must provide the capability of reporting all accounts holding offset credits from a particular offset project, including accounts that are closed or restricted (e.g. compliance accounts, retirement account of another jurisdiction, etc.). There must also be a means of extracting data to enable communication with the account holders.

7. Interfaces

Further to the processes defined in sections 1 to 6, this section provides a consolidated overview of the interface requirements of CITSS with respect to its connection to external systems. Export interfaces will be files generated in CITSS to send to other systems, while import interfaces will be files generated by external systems for input into CITSS. In some cases, the interface will not require a file – only that both systems share common key data to provide the ability to look up information (e.g., offset project number).

In the following diagram, CITSS is represented in blue and other related systems as ovals. Markets and Market Oversight have been included as external groups that may require automated interfaces but they are not defined systems. The arrows represent interfaces. Data best suited to be entered into CITSS through automated interfaces are identified by large blue arrows and data that can be entered manually or viewed by an external source without creating a file exchange are identified by black, dotted arrows. In some cases, like emissions reporting, both automated and manual interfaces are anticipated. Details of the interfaces follow in sub-sections 7.1 to 7.5.

Figure 4. CITSS Interfaces and Connections to External Systems



7.1 Auction Interfaces

Allowance auctions will be carried out through an auction service provider four times per year as coordinated among jurisdictions.

This section discusses, from the perspective of CITSS, the processes required to provide necessary data to support the auctions and to receive auction results data for input into CITSS. The auction service provider will receive data about registered bidders from the tracking system in a suitable and secure electronic format prior to the auction. The auction service provider will prepare and send post-auction results to the tracking system in a suitable and secure electronic format.

7.1.1 Process to Prepare for Auction and Auction Export Interface

The following CITSS-related process steps will be taken in preparation for an auction:

1. Jurisdictions will identify the number of allowances they intend to auction at a given time and transfer these into a separate account or as a separate entry in the jurisdiction auction account. (Note: This entry will be the control number used to verify the completeness of auction results imported back into CITSS via the results interface.)

2. In advance of the auction, prospective auction participants must qualify and indicate their intent to bid with the auction service provider. As part of auction qualification, prospective participants must provide their CITSS user i.d. and CITSS general account name and number to which their auction acquisitions will be deposited. Any party interested in participating in an auction that does not yet have a CITSS user i.d. and general account must first obtain them before their registration form may be submitted.

3. The auction service provider will require limited access to data in CITSS to:
   - Confirm that the prospective bidder exists in CITSS
   - Confirm that the account provided in the auction registration form either belongs to the applicant or that the applicant has authority to purchase allowances on the owner's behalf
   - Confirm that the general account provided is in good standing

Export Interface to Auction Service Provider

Selected bidder information from CITSS will be sent via export file to the auction service provider to support the auction (may include account numbers, purchase limits, etc.). This transfer of information will need to be consistent with jurisdictions' privacy and security requirements.

7.1.2 Process for Inputting Auction Results and Auction Import Interface

After the auction has been closed, auction results have been approved and payments have been processed, the following CITSS-related process steps will be taken to process the auction results and reflect the change of ownership of the allowances in CITSS:

1. The auction service provider will create encrypted auction results files for each jurisdiction.

2. The auction service provider will use a secure file transfer protocol to transmit the auction result data to the CITSS platform.

3. The import program will check the totals in the import file against the jurisdiction control amount for the auction.

4. The regular check of any holding limits will be conducted as part of the update.

5. For entries that meet all rules and any limits, CITSS will update individual accounts with the winning auction bids by transferring allowances to the general account designated by the winning bidder.

Import Results Interface from Auction Service Provider
The auction service provider will send a separate file to each jurisdiction with only its own auction results, listing for each winning bid, CITSS i.d., CITSS general account number, number of allowances purchased, price, and currency.

7.2 Offset Information System Interfaces

Service requirements for offset information system(s) are in development. An offset information system records integral offset project data and relevant documentation associated with an offset project: from validation and registration of a project to monitoring and quantification, reporting, verification, certification, and proposed issuance of offsets.

7.2.1 Input of Offset Project Data from the Offset Information System

It is anticipated that at the initial implementation of CITSS, input of information from the Offset Information System for the purpose of offset credit issuance will be managed manually through simple data entry. The anticipated volume of approved offset projects does not warrant an automated interface.

Once an offset project is certified by a jurisdiction in the Offset Information System, to receive issued offset credits the offset project developer must apply for a CITSS account (if it does not already have one), identifying account representatives, including CITSS user i.d.s, as per Section 1 - Accounts.

Once the offset project developer has specified an account for deposit, the CITSS administrator will issue serialized offset credits to the jurisdiction issuance account and transfer them to the offset project developer's account.

7.2.2 Enabling Look-ups on the Offset Information System

The issuance record will hold relevant project data in CITSS to enable a link with the Offset Project Information system. This will allow market participants to research offset project information associated with any issued offset credit.

Ideally, it would be "nice to have" the ability to mouse click on an offset project code in CITSS and to get a new browser instance with a public page for the project on the Offset Information System.

It is important to note that CITSS will only contain basic offset project information such as the unique project identification code – the Offset Information System contains the detailed information about offset project history, validation, verification etc.

7.3 Market Interface

While inbound data in the form of transfers of compliance instruments is a known requirement, market processes could take different forms such as over-the-counter transactions or transactions stemming from an exchange. CITSS must allow for batch entry of transfers from trusted market sources.

7.4 Market Oversight Access

In order to monitor the marketplace effectively, one or more market monitors may require direct online access, or request all relevant data from a jurisdiction(s). Some of this data will include confidential personal information and would therefore need to be handled according to jurisdictional privacy requirements. Market oversight will require an outbound interface (streaming, export or other form of file transfer) from CITSS as well as the ability for the monitor to perform queries.

7.5 Emissions Information System Interfaces

Each jurisdiction has an emissions reporting system or database used to record the annual reportable emissions of sources. Jurisdictions will use this data to determine which sources must be covered under the cap and trade program (‘covered sources’) based on the rules/regulations of the jurisdiction (e.g., sources above an emissions threshold are subject to the cap and trade regulation).

While the jurisdictions’ systems do not share a common data structure or platform, regional data standards are in place for measurement of emissions and key identifiers (e.g., industry codes), which makes data sharing possible with a regional system like CITSS.

At this time, there is no need for data transfers from CITSS to the emissions databases. However, there are two times that data from the emissions databases may be needed for reference in CITSS: (1) covered source account opening, (2) entry of annual verified emissions, and any changes (e.g., in the event of a revised verification).

7.5.1 Input of Covered Source data into CITSS

When a new covered source account is created in CITSS the basic ‘tombstone’ data identifying the covered source must be the same as that data in the jurisdiction emissions database. This may mean that a CITSS Jurisdiction Administrator needs to do a simple look up on the emissions database or refer to a report. Covered source data needs to be synchronized between the systems when changes occur to identifying data such as its operator, the operator’s representative, contact information, associations and affiliations.

Data to reference in emissions systems:

- Covered Source identifier (for entry into CITSS for future cross reference)
- Covered Entity identifier (for entry into CITSS for future cross-reference)
- Covered Entity legal name
- Covered Entity contact name, address, phone numbers, etc.
- Covered Entity associations (e.g. parent company, subsidiaries, etc.)
- Industry Code (NAICS)

7.5.2 Input of Emissions data into CITSS

The second interface from the emissions systems is required to enter annual verified into CITSS to ensure covered sources will cover their compliance obligation fully. While this can be accomplished through direct data entry into CITSS, an interface file to transfer (upload) emissions data into CITSS is preferred, both for security and accuracy.

Data required in the emissions interface file:

- Jurisdiction
- Period Ending (annual)

- Covered entity identifier
- Covered entity legal name
- Covered Source identifier
- Annual verified emissions (tCO2e)

8. Reports

Reports are needed to serve a number of purposes, from transactional and ad hoc administrative reports to management, public, and executive reports.

CITSS will need to deliver some reports on-screen, like notifications and confirmations, and other more traditional reports both on-screen and in pdf format. On-screen reports that are formatted as lists with columns should have a feature to allow sorting by clicking on most column headings.

It is expected that selected reports will have accompanying selection and parameter screens to allow the user to tailor the report request.

Reports listed in this section do not include extract files listed in the Interface section.

The reports listed here are not yet comprehensive. At this point, report planning is still at a conceptual stage and will be further developed with the final completion of requirements.

8.1 Administrative Reports and Notifications

Administrative reports are required to ensure the flow of day-to-day business. Most of these reports and notifications are referenced in the process sections of this document and are issued as part of a system function.

8.1.1 Jurisdiction Administrative Reports and Notifications

- Confirmation of Budget – a one-page summary of a jurisdiction's budget entry awaiting approval
- Confirmation of Issuance – a one-page confirmation of an issuance awaiting approval
- Confirmation of Allocation – a confirmation page of a jurisdiction's proposed allocations awaiting approval
- Confirmation of Compliance Results – a confirmation page of a jurisdiction's compliance results for a compliance period

8.1.2 Account Holder Reports and Notifications

- Notification of compliance instrument acquisition – sent to the acquiring account representative when the transferor completes the transfer
- Notification of compliance instrument transfer - would only be required if the completion of the transfer depends on confirmation from another party. If the model is "push" only, the transferor will receive confirmation on-screen as a result of his/her actions.

- Account summaries (ad hoc requests available to account representatives and electronic submission agents with access)
    - All acquisitions and transfers over a time period
    - Acquisitions over a time period
    - Transfers over a time period
        - To general accounts within portfolio (group of accounts)
        - To other account holders
        - Surrenders for compliance
        - Retirements from compliance accounts
        - Voluntary Retirements and Cancellations

8.2 Management Reports

Management reports are required so that a jurisdiction's work is managed effectively (assists in environmental compliance, work planning, financial and resource management, etc). Reports under this section would be generated exclusively for individual jurisdictions and would not be viewable by other CITSS users.

8.2.1 Work Flow and Management Reports

- Summarized balance of holdings of covered source and general participant accounts tied to a jurisdiction, with breakdown by type of compliance instrument (one page)
- Summary of transfers by compliance instrument type over a time period (one page).
- For any year / compliance period, allocations, annual emissions, true-up (compliance obligation) amount and compliance instruments surrendered for each compliance account or for all compliance accounts.
- Preliminary compliance status reports after true-up date and a final compliance status reports 30 day after the true-up date (including outstanding obligation and excess emissions obligation if applicable).
- Daily transaction summary for a period of time (e.g. option to select per day summary or daily average, reporting over a period of time [week , month, quarter, year], reporting daily volume and value by transfer type, with optional breakdown by user group [jurisdiction, covered source, general account holder])
- Number of new accounts created per day in a given time period.
- Summary of offset credit issuances in a given time period.
- Covered entity/general account holder listing of associations and affiliations.

8.2.2 Financial, Reconciliation and Audit Reports

- Jurisdiction compliance instrument summary at a point-in-time, with balances of each jurisdiction account (e.g. issuance, auction, reserve, holding, retirement, voluntary retirement, cancellation), and balance of jurisdiction allowances and offset credits in circulation (in accounts governed by jurisdiction and in accounts outside jurisdiction).
- Summary of origin of holdings in the jurisdiction accounts and jurisdiction governed accounts (i.e. which jurisdiction compliances instruments originated)
- Listing of covered entity/covered source accounts at a point in time (end of business day): balance, number of allowances, number of offset credits, number of transfers (credits, debits)
- Number of transfer reversals in a time period with summary of reasons.

8.3 Market Monitor Reports

Market monitoring reports are required to ensure that the independent market monitor has access to the information in CITSS. Reports under this section would be generated exclusively for the market monitor and would span every jurisdiction in CITSS. The information below is an example of the information CITSS would need to report to the market monitor. It is anticipated that additional information may be requested by the independent market monitor.

- Summarized balance of holdings of accounts
- Summary of transfers by compliance instrument type over a time period.
- Detailed and up-to-date information for each account in CITSS, including covered entity/general account holder information, current compliance instrument ownership, beneficial ownership information, and listing of associations and affiliation.
- Detailed transaction information for a period of time (e.g. option to select per day summary or daily average, reporting over a period of time [week , month, quarter, year]) which includes: counter-parties, daily volume, price, date and time-stamp,

8.3 Public Reports

Information released to the public in online reports is dependent on what information jurisdictions can publicly release, depending on jurisdiction privacy laws and privacy impact assessment. This is a preliminary list of proposed reports for consideration that may be posted publicly on the CITSS unsecured website.

- Allocation Plan and History of Changes (per jurisdiction and across WCI)
- Compliance Summary
- Accounts Search
    - Lists: Jurisdiction, account name, account type, account holder, authorized representative.
- Covered Source Search
    - Lists: Jurisdiction, account holder, covered source name and number, account type, NAICS code, compliance status, link to view compliance details of current and past compliance periods.

8.4 Executive/Business Intelligence

Additional reports may be required that would assist WCI jurisdictions in assessing operational or policy issues. An extract file may be needed to provide the foundation for an external business intelligence database, which would support WCI jurisdictions in policy planning and future directions.

9. Non-functional Requirements

This section focuses on the non-functional requirements of the Compliance Instruments Tracking System of the WCI cap and trade program, with particular attention to the user interface, technical, security, and financial service related requirements for CITSS.

9.1 User Interface

These basic user requirements are over-arching and must be kept in mind throughout the system design process.

9.1.1 Usability

The tracking system must be designed with its intended users in mind so that actions can be performed easily and without making errors. The tracking system must provide user-friendly interfaces for its customization and operation.

9.1.2 Multi-language

The tracking system must be fully multilingual and must be available at least in English and in French from the beginning. Support for other languages might be required later on.

9.2 Technical Requirements

9.2.1 Extensibility

9.2.1.1 Compatibility

The tracking system must be able to share data easily with various internal and external systems, particularly any required external databases, such as existing emissions reporting.

It is important to keep in mind that any “live” link between the CITSS and an external system may be expensive and take considerable time to implement; asynchronous transfers such as batch XML files imports tend to be simpler and cheaper to develop.

9.2.1.2 Customization

Within certain boundaries specified in the functional requirements document, the overall look and feel (skin) of the system and reports (wrapper), language, the

CITSS registration forms, the accounts naming scheme, and various transaction rule parameters must be customizable.

9.2.1.3 Flexibility

The tracking system shall be developed with possible future integration in mind, in particular with other cap-and-trade programs in Canada, the U.S. or the E.U.

9.3 Security Requirements

9.3.1 Standards Compliance

Critical systems such as CITSS are subject to security standards compliance. For example, any system dealing with credit card numbers is required to abide by the PCI-DSS standard (Payment Card Industry). Even though the tracking system will not deal directly with credit cards and money, it will be the record of ownership of compliance instruments, which have value. Strong security standards are required to prevent theft and illegal manipulation of the instruments and accounts.

Another widespread security standard, ISO 27001, describes thoroughly the best practices for the information security field. One can formally certify its information security management system against the ISO 27001 standard by commissioning an independent auditor to perform a fully documented audit on a regular basis.

If the WCI members prefer not to impose PCI-DSS compliance to the service provider of the tracking system because of its tight coupling with the credit cards industry, requiring the service provider to demonstrate ISO 27001 compliance with complete documentation disclosure could be a valuable alternative.

CITSS must also be designed considering relevant best practices and recent developments in tracking system operations to mitigate security risks. For example, CITSS design should consider the relevance of the "Proposal to change rules on EU ETS registry infrastructure" http://ec.europa.eu/clima/news/articles/news_2011050501_en.htm

Some questions related to this topic are:

- Is there government regulation in any of the WCI jurisdictions stating which standards must be followed for a sensitive financial information system?
- If not, what would be a minimum acceptable requirement for each jurisdiction?

9.3.2 Confidentiality

Confidentiality means to prevent the disclosure of information to unauthorized individuals or systems. For example, filling a tracking system application form on the Internet requires personal information to be transmitted from the user's computer to the CITSS servers. The system should enforce confidentiality by encrypting the user information during transmission, by limiting the places where it might appear (in databases, log files, backups, printed receipts, and so on), and by restricting access to the places where it is stored. If an unauthorized party obtains personal information in any way, a breach of confidentiality has occurred.

A thorough analysis of which information assets are considered personal or sensitive should be conducted to ensure confidentiality is properly addressed. Confidentiality is necessary (but not sufficient in itself) for maintaining the privacy of the people and corporations whose personal or confidential information is held in CITSS.

9.3.3 Integrity

Transaction integrity means that data cannot be modified undetectably. All system actions should be audit stamped with the user name and date of the action (transaction).

Data integrity in a quasi-financial system is achieved with accountability of the units of value, in this case, compliance instruments. It is important that every compliance instrument be serialized with a unique number that is traceable such that the status of the instrument is known and that it can only exist in one account at a time.

A jurisdiction should be able to prove ownership of specific instruments at any given time in the system's history through the CITSS data. It is critical (i.e., zero tolerance for errors) that at any given time, the system holds the right amount of instruments in the correct accounts.

9.3.4 Non-repudiation

Non-repudiation is a method by which the sender of data is provided with proof of delivery and the recipient is assured of the sender's identity, so that neither can later deny having processed the data. It is a way to avoid denial of transactions.

In law, non-repudiation implies one's intention to fulfill their obligations to a contract. It also implies that one party of a transaction cannot deny having received a transaction nor can the other party deny having sent a transaction.

Electronic commerce uses technology such as digital signatures and encryption to establish authenticity and non-repudiation.

For CITSS, here are a few examples of requirements that could lead to satisfactory non-repudiation:

- Strong user authentification mechanism in place. This likely means that more is required than the usual username/password strategy. Examples of potential strategies are multi-factor authentification, digital signatures and SecurIDs
- Strong encryption of all data transmitted over the network
- Pro-active “approval” of any transfer by both parties involved
- Complete logs of everything that occurs in the system
- Management and operational processes that guarantee the integrity and non-repudiation of the logs themselves.

9.3.5 Authentication

In computing, e-Business and information security it is necessary to ensure that the data, transactions, communications or documents (electronic or physical) are genuine. It is also important for authenticity to validate that both parties involved are who they claim they are.

9.3.6 Personal Information Protection[19]

Protection of personal information is a high priority for WCI Partner jurisdictions. CITSS will be designed to ensure information is managed in accordance with WCI Partner jurisdiction requirements and legislation.

[19] Please refer to a Canadian federal government document: “Guidance Document: Taking Privacy into Account Before Making Contracting Decisions” (http://www.tbs-sct.gc.ca/atip-aiprp/tpa-pcp/tpa-pcp01-eng.asp)

Western Climate Initiative

Draft Offset Protocol Review and Recommendation Process

July 14, 2011

The Western Climate Initiative (WCI) Partner Jurisdictions have recommended the establishment of a robust and transparent process to review and recommend offset protocols that meet the requirements for the regional emissions trading and offset program. This paper presents draft recommendations for the: 1) identification of candidate protocols, 2) evaluation of protocols by expert task teams, 3) public consultation on candidate protocols and 4) recommendation of candidate protocols for adoption by WCI Partner Jurisdictions.

The WCI Partner Jurisdictions will build on the extensive work of other individuals and organizations, sound science, and standard greenhouse gas accounting practices to revise and update existing protocols to meet the geographic, regulatory, technological and sectoral scope of the WCI regional emissions trading and offset program. WCI Partner Jurisdictions will consider protocols recommended by this WCI protocol review process for incorporation or inclusion in their state or provincial approaches to implement the regional emissions trading and offset program. Issues regarding intellectual rights related to existing protocols will be examined on a case-by-case basis.

The preference of the WCI Partner Jurisdictions is to recommend a single protocol for each project type and the WCI Partner Jurisdictions recognize this may not be feasible or practical in all applications.

The WCI Offsets Committee (Committee) will carry out the review and recommendation process based on the prioritization of project types and protocols determined by the WCI Partners.

Four main steps are recommended in the process to allow Partner Jurisdictions to demonstrate to the market and public that their process is rigorous and transparent.

1. Identification of a candidate protocol
2. Evaluation of a candidate protocol
3. Public consultation
4. Recommendation of a candidate protocol

1. Identification of a candidate protocol

In order to be considered for review, a candidate offset protocol must be nominated by a WCI Partner Jurisdiction. The WCI Partner Jurisdictions will establish a list of candidate protocols under review and scheduled for review, and make that list known to stakeholders. Partner Jurisdictions will agree on the scheduling of reviews and any additions to the established list of project types over time.

When jurisdictions nominate an additional candidate protocol, it will be added to the established list in a priority agreed by Partner Jurisdictions. When more than one candidate protocol for a project type is nominated they will be evaluated simultaneously. When there is more than one candidate protocol with different geographic coverage the committee may recommend multiple candidate protocols providing there is no overlapping geographic coverage and the methodologies (baseline, monitoring, quantification, additionality, etc…) are compatible. The Committee work will proceed on direction of the WCI Partner Jurisdictions and as time and resources allow.

2. Evaluation of candidate Protocol

After a candidate protocol is identified, it will be evaluated in regards to its alignment to the WCI design. A task team will be established consisting of relevant staff from each WCI Partner Jurisdiction. There will be an initial review of legislation and common practice in each Partner Jurisdiction to determine suitability of the protocol across the WCI region. At this step, WCI Partner Jurisdictions will assign whatever resources are required to complete the work.

At any point in the evaluation process the task team may consider seeking additional technical advice from expert advisors to inform the candidate protocol evaluation process and may develop white papers, hold webinars or workshops to seek broader stakeholder input on aspects of interest to the team or the WCI Partner Jurisdictions. A project manager will be assigned or hired for each candidate protocol evaluation process and the task team may draw on administrative support when necessary throughout the protocol evaluation process.

Once the task team is established they will evaluate the candidate protocol. The candidate protocol will initially be evaluated against the high level criteria in the WCI design:

- Definition of project scope
- Eligibility /additionality requirements
- GHG quantification method
- GHG emissions reduction method
- Monitoring and verification method
- Permanence
- Leakage

The candidate protocol will be further evaluated against the more detailed criteria recommended by the WCI Partner Jurisdictions within the high level criteria listed above. This two phase evaluation will be customized to the specific characteristics of each project type. This evaluation will deliver a gap analysis identifying where the candidate protocol aligns with WCI design and where it does not align.

At the end of the evaluation the task team will reach a consensus opinion based on the results of the work and the gap analysis and will make one of the following recommendations to WCI Partner Jurisdictions for consideration:

A. Recommend
   The task team can demonstrate that the candidate protocol meets all the requirements of the WCI design and that it can be applied in all WCI Partner Jurisdictions. The candidate protocol should Proceed with Public Consultation (Step 3).

B. Reject
   The task team cannot demonstrate that the protocol meets all the requirements of the WCI design and that it can be applied in all WCI Partner Jurisdictions. The candidate protocol should not proceed. Reasons for rejection may include:
   - not within the scope of the WCI offset system,
   - lack of necessary scientific or technical information,
   - unable to manage leakage or permanence,
   - Extremely low potential for offset creation,
   - There is already a recommended protocol of the same type.

C. Revise
   The task team can demonstrate that the candidate protocol could meet all the requirements of the WCI design and that it could be applied in all WCI Partner Jurisdictions with reasonable revision. The task team will identify the gaps in the protocol and propose how to resolve those gaps including resources required in a proposed work plan for revisions. This could include consolidating a number of protocols using the elements that best fit WCI design standards. The proposal will include a timeline and budget for resources required to complete the revisions. The task team will be as detailed as possible in describing the work that is required to produce a revised candidate protocol. The proposed workplan will be provided to the WCI Partner Jurisdictions for approval.

   After WCI Partner approval of the recommended approach to revise the protocol the task team will begin the revision process. The revision may include options papers, workshops, working groups, webinars or consultations on certain areas of the protocol. Consultations may include discussions with expert advisors, integration of public comment and stakeholder feedback. The result of this process will be a revised candidate protocol to WCI Partners for approval to move on to public consultation. The revised candidate protocol may include options in specific sections where an approach is not agreed upon by all WCI Partner Jurisdictions.

3. WCI Public Consultation

When WCI Partner Jurisdictions receive a recommended candidate protocol or revised candidate protocol, the WCI Partner Jurisdictions will post the document for public consultation. The candidate protocol will be posted to the WCI website and a joint WCI webinar will take place within 2 weeks of posting. There will be minimum 30 day consultation period where stakeholders may submit comments on the document. This public consultation will serve to provide input in the development of a WCI recommended Protocol and each WCI Partner Jurisdiction may carry out stakeholder engagement within their jurisdiction at any time during or after the WCI joint engagement process.

The task team will summarize stakeholder comments and integrate relevant proposed changes into a revised candidate protocol.

4. Recommendation of a candidate protocol

The WCI Partner Jurisdictions will review a revised candidate protocol incorporating stakeholder comments and will consider recommending it for use by WCI Partner Jurisdictions in the regional emissions trading and offsets program. The recommended protocol will be posted on the WCI website.

The recommended protocol will be available for adoption into the rules and regulations of individual WCI Partner Jurisdictions. Each WCI Partner Jurisdiction will follow its own procedures to incorporate the recommended protocol into its rules or regulations including the public comment process requirements of their own jurisdictions. Jurisdictions may need to make revisions to the recommended protocol to incorporate it into their respective rules or regulations and to maintain transparency, each WCI Partner Jurisdiction will keep other jurisdictions informed of revisions. As needed, WCI Partners will address concerns regarding revisions made by individual jurisdictions.

DRAFT Offset Protocol Review and Recommendation Process

WCI Stakeholder Call

July 20, 2011

To join the call, dial **1-800-868-1837** toll free in the US and Canada (1-404-920-6440 outside the US and Canada) and enter participant code **753491#.**

DRAFT process

1. Identification of a candidate protocol
2. Evaluation of a candidate protocol
3. Public consultation
4. Recommendation of a candidate protocol

Identification of a candidate protocol

- Candidate protocol nominated by a WCI Partner Jurisdiction
- Candidate protocol added to established list of protocols in agreed priority
- Offsets Committee works through established list as time and resources allow

Identification of a candidate protocol

- When more than one candidate protocol is nominated they will be evaluated simultaneously
  - Offsets Committee may recommend multiple protocols providing there is no overlapping geographic coverage and the methodologies (baseline, monitoring, quantification, additionality, etc…) are compatible

Evaluation of a candidate protocol

- Offset Committee will establish a task team of WCI Partner Jurisdiction staff for each protocol
- Assign task team lead and project manager
- Carry out cross-jurisdictional regulatory analysis
- Review protocol against design criteria
  - may include options papers, workshops, webinars
- Consult expert advisors as necessary
- Provide recommendation to WCI Partner Jurisdictions

Evaluation of a candidate protocol

- Offset Committee may:
  - Recommend
    - candidate protocol moves forward to public consultation
  - Reject
    - candidate protocol does not move forward
  - Revise
    - task team proposes gap analysis and work plan
    - may propose options papers, workshops, webinars for specific candidate protocol components
    - revised candidate protocol moves forward to public consultation

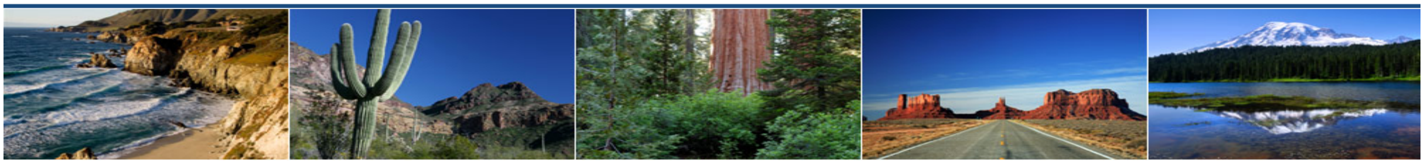
Public consultation

- WCI Partner Jurisdictions receive candidate or revised candidate protocol with recommendation to post for public consultation
- Public posting for minimum of 30 days
  - available on central website (WCI Partner Jurisdictions optional)
  - joint webinar (WCI Partner Jurisdictions may run simultaneous consultations)
- Summary of public comments
- Task team revises candidate protocol to reflect relevant comments

Recommendation of a candidate protocol

- WCI Partner Jurisdictions consider recommending revised candidate protocol for use by all WCI Partner Jurisdictions
- Protocol available on central website
  - WCI Partner Jurisdictions may post individually
- Recommended protocol considered for adoption into rules and regulations of WCI Partner Jurisdictions
- Individual WCI Partner Jurisdictions inform each other of any protocol modifications necessary during adoption into rules and regulations

Western Climate Initiative



Final Offset Protocol Review and Recommendation Process

December 19, 2011

An efficient offset system consistent across WCI Partner Jurisdictions will ensure an adequate supply of low cost, high quality offsets for the region.

The Partner jurisdictions of the Western Climate Initiative (WCI) today release the final process to review and recommend offset protocols for adoption by WCI Partner jurisdictions. Working together, the Partner jurisdictions that comprise the WCI have forged a comprehensive strategy to mitigate climate change that will spur investment in clean-energy technologies, create green jobs and reduce independence on import oil. When fully implemented, the plan will reduce GHG emissions to 15 percent below 2005 levels by 2020.

The Western Climate Initiative (WCI) Partner jurisdictions have recommended the establishment of a robust and transparent process to review and recommend offset protocols that meet the requirements for the regional emissions trading and offset program. This paper presents final recommendations for the: 1) identification of candidate protocols, 2) evaluation of protocols by expert task teams, 3) public consultation on candidate protocols and 4) recommendation of candidate protocols for adoption by WCI Partner jurisdictions.

The WCI Partner jurisdictions will build on the extensive work of other individuals and organizations, sound science, and standard greenhouse gas accounting practices to revise and update existing protocols to meet the geographic, regulatory, technological and sectoral scope of the WCI regional emissions trading and offset program. WCI Partner jurisdictions will consider protocols recommended by this WCI protocol review process for incorporation or inclusion in their state or provincial approaches to implement a regional emissions trading and offset program.

The preference of the WCI Partner jurisdictions is to recommend a single protocol for each project type and the WCI Partner Jurisdictions recognize this may not be feasible or practical in all applications. The WCI Offsets Committee will carry out the review and recommendation process based on the prioritization of project types and protocols determined by the WCI Partner jurisdictions. The four main steps recommended in the process allow Partner Jurisdictions to demonstrate to the market and public that their process is rigorous and transparent.

The final process reflects input from stakeholders and is available on the WCI website. There were no significant change to the content of the paper. There were small editorial changes throughout the document for clarity and Step 3 was revised for readability.

1. Identification of a candidate protocol

In order to be considered for review, a candidate offset protocol must be nominated by a WCI Partner jurisdiction. The WCI Partner jurisdictions will establish a list of candidate protocols under review and scheduled for review, and make that list known to stakeholders. WCI Partner jurisdictions will agree on the scheduling of reviews and any additions to the established list of project types over time.

When WCI Partner jurisdictions nominate an additional candidate protocol, it will be added to the established list in a priority agreed by WCI Partner jurisdictions. When more than one candidate protocol for a project type is nominated they will be evaluated simultaneously. When there is more than one candidate protocol with different geographic coverage, the committee may recommend multiple candidate protocols providing there is no overlapping geographic coverage and the methodologies (baseline, monitoring, quantification, additionality, etc.) are compatible. The WCI Offsets Committee work will proceed on direction of the WCI Partner jurisdictions and as time and resources allow.

2. Evaluation of candidate protocol

After a candidate protocol is identified, it will be evaluated in regards to its alignment to the WCI design. A task team will be established consisting of relevant staff from each WCI Partner jurisdiction. There will be an initial review of legislation and common practice in each WCI Partner jurisdiction to determine suitability of the protocol across the WCI region. At this step, WCI Partner jurisdictions will assign whatever resources are required to complete the work.

At any point in the evaluation process the task team may consider seeking additional technical advice from expert advisors to inform the candidate protocol evaluation process and may develop white papers and hold webinars or workshops to seek broader stakeholder input on aspects of interest to the team or the WCI Partner jurisdictions. A project manager will be assigned or hired by the WCI for each candidate protocol evaluation process and the task team will draw on administrative support when necessary throughout the protocol evaluation process. The task team lead, similar to the chair of the WCI Offsets Committee, will serve as the primary point of contact for providing input on the task team's work.

Once the task team is established, the candidate protocol will be evaluated. The candidate protocol will initially be evaluated against the WCI criteria as defined in the WCI *Offset System Essential Elements Final Recommendations Paper* and the WCI *Detailed Design*:

- Definition of project scope
- Eligibility/additionality requirements
- GHG quantification method
- GHG emissions reduction method
- Monitoring and verification method
- Permanence
- Leakage

The candidate protocol will be further evaluated against the more detailed criteria recommended by the WCI Partner jurisdictions within the high level criteria listed above. This two phase evaluation will be customized to the specific characteristics of each project type. This evaluation will deliver a gap analysis identifying where the candidate protocol aligns and does not align with WCI design.

At the end of the evaluation, the task team will reach a consensus opinion based on the results of the work and the gap analysis and **will make one of the following recommendations to WCI Partner** jurisdictions for consideration:

A. Recommend
   The task team concludes that the candidate protocol meets all the requirements of the WCI design and that it can be applied in all WCI Partner jurisdictions. The candidate protocol should proceed with public consultation (Step 3).

B. Reject
   The task team concludes that the protocol does not meet the requirements of the WCI design and/or that it is not appropriate for WCI Partner jurisdictions. The candidate protocol would not proceed further. Reasons for rejection may include:
   - not within the scope of the WCI offset system,
   - lack of necessary scientific or technical information,
   - unable to manage leakage or permanence,
   - extremely low potential for offset creation,
   - a protocol for the same project type already recommended.

C. Revise
   The task team concludes that the candidate protocol, with reasonable revision, could meet all the requirements of the WCI design and that it could be applied in all WCI Partner jurisdictions. The task team will identify the gaps in the protocol and propose how to resolve those gaps including resources required in a proposed work plan for revisions. This could include consolidating multiple protocols using the elements that best fit WCI design standards. The proposal will include a timeline and budget for resources required to complete the revision. The task team will be as detailed as possible in describing the work that is required to produce a revised candidate protocol. The proposed workplan will be provided to the WCI Partner jurisdictions for approval.

   After WCI Partner approval of the recommended approach to revise the protocol, the task team will begin the revision process. The revision may include options papers, workshops, working groups, webinars or consultations on certain areas of the protocol. Consultations may include discussions with expert advisors, integration of public comment and stakeholder feedback. The result of this process will be a revised candidate protocol to WCI Partner jurisdictions for approval to move on to public consultation. The revised candidate protocol may include options in specific sections where an approach is not agreed upon by all WCI Partner jurisdictions.

3. WCI public consultation

As noted above, as part of the task team's evaluation of the protocol, public input in the form of webinars and written comments may be sought during the evaluation and revision process. Following the evaluation of a candidate protocol (Step 2), once WCI Partner jurisdictions receive a recommended candidate protocol or revised candidate protocol, the WCI Partner jurisdictions will post the document for public consultation. The candidate protocol will be posted to the WCI website, and a WCI webinar will take place within two weeks of posting. There will be a minimum 30-day consultation period during which stakeholders may submit comments on the protocol. The task team will summarize stakeholder comments and may integrate relevant proposed changes into a revised candidate protocol. This WCI public consultation process wil help harmonize WCI recommended protocols that are subsequently adopted by WCI Partner jurisdictions by gathering input from stakeholders across the WCI Partner jurisdictions prior to recommendation of a protocol. WCI Partner jurisdictions may hold further public consultation as required as part of their process to adopt a recommended protocol into its rule or regulation.

4. Recommendation of a candidate protocol

The WCI Partner jurisdictions will review a revised candidate protocol incorporating stakeholder comments and will consider recommending it for use by WCI Partner jurisdictions in the regional emissions trading and offsets program. The recommended protocol will be posted on the WCI website.

The recommended protocol will be available for adoption into the rules and regulations of individual WCI Partner jurisdictions. Each WCI Partner jurisdiction will follow its own procedures to incorporate the recommended protocol into its rules or regulations including the public comment process requirements of their own jurisdictions. Jurisdictions may need to make revisions to the recommended protocol to incorporate it into their respective rules or regulations and to maintain transparency. Each WCI Partner jurisdiction will keep other jurisdictions informed of revisions. As needed, WCI Partners will address concerns regarding revisions made by individual jurisdictions.

A process will be developed for the revision and update of recommended protocols.

Western Climate Initiative

Final Essential Requirements of Mandatory Reporting

2011 Amendments for Harmonization of Reporting in Canadian Jurisdictions

December 21, 2011

Amended February 10, 2012 to include #7 in the list of errata changes

1 Introduction 2

2 Harmonization Principles 3

2.1 For U.S. Jurisdictions 3

2.2 For Canadian Jurisdictions 3

3 Harmonization Approach 4

3.1 For U.S. Jurisdictions 4

3.2 For Canadian Jurisdictions 4

3.3 Verification 5

3.4 Missing Data Procedures 5

4 Summary of Changes to the Quantification Methods 5

5 Errata Changes to Quantification Methods 9

1 Introduction

This document and the attachments provide an overview of the 2011 amendments made to WCI Final Essential Requirements of Mandatory Reporting for harmonization of reporting for Canadian jurisdictions (referred to as the 2011 Canadian ERs).

The WCI Essential Requirements for Mandatory Reporting (ERs) were first published on July 15, 2009 and then amended in 2010 to create U.S. (published November 12, 2010) and Canadian versions (published December 17, 2010). The 2010 amendments were a result of WCI partners being concerned that the existence of two different reporting systems in a WCI state could result in the imposition of duplicative or conflicting reporting obligations on facilities subject to both programs. The Partners therefore directed the WCI Reporting Committee to develop amended ERs that are harmonized with the EPA rule. The November 12, 2010 U.S. ERs took the form of a mark-up of the U.S. Environmental Protection Agency (EPA) rule showing the changes to the EPA program that are needed to support a cap-and-trade program.

To ensure consistency and harmonization with the U.S. ERs in Canadian Partner jurisdictions, on December 17, 2010, the WCI published the "Final Essential Requirements for Mandatory Reporting – Canadian Harmonization Version" (the "2010 Canadian ERs"). The 2010 Canadian ERs adopted consistent quantification methods for use in Canadian Partner jurisdictions for all source categories. Significant updates were made to a number of quantification sections and the two oil and gas methods were published for the first time.

Quantification methods for the oil and gas sector are evolving in the U.S. and some technical elements of the U.S. EPA November 8, 2010 Subpart W (Petroleum and Natural Gas Systems) publication were not reflected in the 2010 Canadian ERs. WCI's Reporting Committee has worked through 2011, with the help of technical experts, to develop cap and trade quality reporting requirements for sources covered by Subpart W for use in both Canadian and U.S. jurisdictions. In addition, WCI also retained a technical expert to refine the biomass emission factors.

Stakeholder comments on proposed changes to the ERs were sought by the WCI Partner jurisdictions using informal means. This included communications on technical issues about the methods, consultation with individual companies and consultation with industry groups.

The 2011 Canadian ERs make both minor amendments and broader harmonization updates to the two oil and gas quantification sections. No changes are made to the general provisions of the ERs. The updates replace specific sections or clauses of the 2010 Canadian ERs and have been designed to be adopted for use by Canadian jurisdictions at the earliest point feasible in the jurisdiction. For those jurisdictions with direct references to the WCI Canadian ERs, adoption would be for 2012 calendar year emissions, as reported in 2013.

Further work within WCI is expected in 2012 given that the U.S. EPA released a revised Subpart W on December 2, 2011. WCI plans to review the latest Subpart W revisions and may consult with stakeholders on further potential updates (though less extensive) to the two oil and gas quantification sections in 2012.

Further evaluation of "reporting only" sources within the scope of the methods in the ERs, particularly for specific oil and gas sources, will be occurring, along with analysis and incorporation of further changes needed to include such sources within a cap and trade system.

This document and the attachments provide an overview of the 2011 amendments made to WCI Final Essential Requirements of Mandatory Reporting for harmonization of reporting for Canadian jurisdictions. Only those quantification methods where there are significant changes are re-published in full in this package. Where only a few modifications were made to a method, errata changes made are listed in Section 5 below.

2 Harmonization Principles

2.1 For U.S. Jurisdictions

The harmonization principles for U.S. jurisdictions are outlined in the "Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule"[1].

2.2 For Canadian Jurisdictions

In developing harmonized ERs that modify the existing ERs for use in Canadian Partner jurisdictions, the WCI Reporting Committee adhered to the following principles:

1. A Canadian facility should apply the equivalent functions, equations, sampling protocols and measurement criteria as U.S. facilities subject to the U.S. version of the harmonized ERs. This means that the harmonized ERs will achieve the same level of reporting accuracy for Canadian and U.S. facilities, but the U.S. version may require more data elements to be reported to harmonize with the EPA rule.
2. The quantification methods included in the harmonized ERs must remain sufficiently reliable and accurate to be employed in a GHG cap-and-trade program.

[1] http://www.westernclimateinitiative.org/news-and-updates/125-harmonization-of-essential-requirements-for-mandatory-reporting-in-us-jurisdictions-with-epa-mandatory-reporting-rule

3. The WCI reporting system must remain suitable for use in Canadian Partner jurisdictions. For example, it must allow reporting in metric as well as English units and must where necessary include Canada-specific emission factors.
4. The harmonized ERs should facilitate harmonization with Canadian federal reporting. Some Canadian Partner jurisdictions are working with Environment Canada to develop a one-window reporting tool for provincial and national GHG reporting requirements.

WCI intends to follow the same principles with regard to future additions or amendments to the EPA rule, such as the recently finalized Subpart W for the oil and gas industry, and the recently proposed revisions to Subpart A (general provisions) and several source category subparts.[2] WCI will review each proposed revision to assess its suitability for cap-and-trade before incorporating it into the harmonized ERs.

3 Harmonization Approach

3.1 For U.S. Jurisdictions

The harmonization approach for U.S. jurisdictions is outlined in the "Harmonization of Essential Requirements for Mandatory Reporting in U.S. Jurisdictions with EPA Mandatory Reporting Rule"[3].

3.2 For Canadian Jurisdictions

For the Canadian jurisdictions, the key requirement is that the WCI reporting system as a whole require the use of comparable methodologies and produce comparable results for facilities of the same type, so that "a tonne is a tonne" in both the U.S. and Canada. For Canadian jurisdictions it is not nearly as important to avoid small differences between the ERs and the EPA rule as it is for the U.S. jurisdictions, where such differences could create a risk of inadvertent non-compliance.

Canadian Partners have developed Canadian ERs that can be applied within the provincial legal frameworks. U.S. states also work within their legal framework by referencing the EPA rules and making the specific amendments needed to ensure cap and trade quality data. This latest Canadian ERs conforms in substance with reporting requirements adopted by the US WCI Partners (e.g., California). In addition, the Canadian ERs facilitate harmonization with Environment Canada and the use of Canada-specific reporting metrics and factors.

---

[2] Pre-publication version posted on July 20, 2010 at: http://www.epa.gov/climatechange/emissions/technical-corrections.html#revisions

[3] http://www.westernclimateinitiative.org/news-and-updates/125-harmonization-of-essential-requirements-for-mandatory-reporting-in-us-jurisdictions-with-epa-mandatory-reporting-rule

3.3 Verification

Consistent with the Design Recommendations for the WCI Regional Cap-and-Trade Program, the harmonized U.S. and Canadian ERs require third party verification of emission reports for entities and facilities with emissions equal to or greater than 25,000 tonnes CO_2e. No revisions to the verification rule are made in the 2011 amendments to the Canadian ERs.

The amount of data to be reported for Canadian jurisdictions has been keep at a reduced level compared to that which is required to be reported to the EPA. This reflects the WCI third party verification requirements for emissions reports instead of the reliance on internal verification.

3.4 Missing Data Procedures

The Canadian harmonized ERs incorporate the EPA missing data procedures. During initial implementation of the cap-and-trade program, however, the WCI intends to revisit this issue. The WCI is investigating how the EPA missing data procedures can be modified to be more consistent with the needs of a cap-and-trade program while adhering to the harmonization principles and intends to propose and implement the necessary modifications in time for the 2013 reporting year.

4 Summary of Changes to the Quantification Methods

The following table summarizes the changes to the quantification methods that the WCI is publishing for Canadian jurisdictions. The specific language for the amendments is made in Section 5 and the attached amended quantification methods.

Section	Change to WCI Rule	Rationale
WCI.023	Updates to CO2 equations and parameters	Clarification of biomass and solid waste reporting, other clarifications
WCI.024	Updates to CH4 and N20 equations, creation of new coal-specific equations.	Simplification and clarification of equations
WCI.025	Refinement to sampling, analysis and measurement procedures, including calibration.	Simplification and clarification

Section	Change to WCI Rule	Rationale
WCI.027	Updated biomass emission factors	Review of differences between various published biomass emission factors 2010 sample data.
WCI.020 / WCI.040 and WCI.210	Clarification of where to report black liquor emissions	Avoidance of double-counting
WCI.160 and WCI.240	Errata changes Addition of method for sampling waste-based fuels	Clarification Technical review
WCI.040 and WCI.090	Errata changes	Clarification
WCI.352 WCI.362	Clarified and updated application of different quantification methods Updated information to be reported	Clarification and updates Updates
WCI.353 WCI.363 (throughout)	Simplification of equations to most basic form	Simplification and clarification
WCI.353(a), (a.1), (b), (b.1) WCI.363(a), (a.1), (b), (b.1)	Split pneumatic devices to four categories Extended phase-in and clarified language for metering of high bleed devices and pumps Clarified reporting of compressor starters	Rule clarity Extension of phase-in, rule clarity Clarification
WCI.363(c)	Incorporated EPA 98.233(d) methods 1 and 2 and revised existing WCI equation	Addition of options, reduced error in main acid gas removal equation, harmonization within WCI.

Section	Change to WCI Rule	Rationale
WCI.363(f)	Incorporated EPA 98.233(g) methods	Harmonization within WCI
WCI.353 (c) WCI.363(g)	Updated equation to be consistent with EPA	Harmonization within WCI
WCI.353 (c.1) WCI.363 (g.1)	Added third party line hit method	Completeness of reporting
WCI.363 (h)	Removed limitation on choice of method	Ease of use
WCI.353 (m) WCI.363(h.1)	Added transmission storage tank method from EPA 98.233(k)	Harmonization within WCI / correction of oversight
WCI.353(e) WCI.363(l)	Identified wet and dry gas seals Allowed application of emission factor for units (in aggregate) <250 hp (WCI.363 only) Added detail of operating modes per EPA language	Clarification, harmonization within WCI Reduced burden for small compressors Harmonization within WCI
WCI.353(f) WCI.363(m)	Added control factor to account for seal gas used as fuel Allowed application of emission factor for units (in aggregate) <250 hp (WCI.363 only)	Accuracy Reduced burden for small compressors

Section	Change to WCI Rule	Rationale
WCI.353(g) and WCI.353(h) WCI.363(n) and WCI.363(o)	Cross-checked and corrected references to WCI.352 and WCI.362 sections for application of leak detection and population count methods Clarified requirements for leak detection at small compressor stations	Accuracy Harmonization within WCI, reduced burden
WCI.363(o)	Correct equation to account for THC factors and multiple service types	Technical correction
WCI.353(j)	Clarified use of known gas composition for transmission and distribution	Clarification, reduced burden
WCI.363(w)	Required use of actual compositions where known. Indicated that same methodology must be used in subsequent year	Accuracy, use of existing data Accuracy
WCI.357 WCI.367 Tables	Added table of pneumatic manufacturer average bleed rates Revised pneumatic emission factors Revised reference from Clearstone Methodology Manual Table 6 to Table 9	Reduced burden Harmonization within WCI Technical correction
WCI.356 WCI.366 Definitions	Revised use of “city gate station” to “metering-regulation station” Clarified split between custody transfer and non-custody transfer Other updates	Clarification and technical corrections

5 Errata Changes to Quantification Methods

The following is a list of the errata changes made to quantification methods other than WCI.020 (General Stationary Combustion), WCI.350 (Natural Gas Transmission and Distribution) and WCI.360 (Petroleum and Natural Gas Production and Natural Gas Processing in the Final Essential Requirements of Mandatory Reporting (for harmonization of reporting for Canadian jurisdictions). No changes are made to the general provisions (WCI.1 to WCI.9) as published by the WCI on July 15, 2009 and updated on December 17, 2010. Errata changes are effective immediately and are meant to clarify issues for 2011 calendar year reporting and into the future.

1. **Cement Manufacturing:** WCI.094(j) is amended by adding "**, and or material balances.**" at the end of the provision.
2. **Electricity Generation:** WCI.043(a)(1)(A) is modified to read "… the results of fuel sampling and analysis for the fuel heat value **or carbon content, as applicable,** from the fuel supplier…".
3. **Electricity Generation and Pulp and Paper Manufacturing**. The following note is placed at the top of the WCI.040 and WCI.210 quantification methods:

   "*Note: CO_2, CH_4, and N_2O emissions from spent/pulping liquor combusted to produce electricity in the process of pulp and paper manufacturing should be reported under WCI.210, starting with the 2011 reporting year. Additional reporting requirements that are present in the two quantification methods are maintained independent on the direction of where to report the emissions."*
4. **Lead Production and Zinc Production**: WCI.164(a)(4) and WCI.244(a)(4) are struck and replaced with the following:

   (4) For waste-based carbon-containing material, determine the carbon content by either:

   i. Operating the smelting furnace both with and without the waste-reducing agents while keeping the composition of other material introduced constant.

   A. To ensure representativeness of waste-based carbon containing material variability, the specific testing plan (e.g. number of test runs, other process variable to keep constant, timing of runs) for these trials must be approved by the jurisdiction.

   ii. By using the theoretical carbon content of the waste-based carbon containing material as derived using engineering estimation techniques.
5. **Lead Production**: WCI.164(a) is amended by adding the following:

   (5) A facility may use an appropriate analytical method for determining the carbon content of ore
6. **Lead Production and Zinc Production**: WCI.162(c) and WCI.242(c) are modified to read "… (tonnes C/tonne input material)"
7. Updates to the WCI.28 Tables are applicable starting with 2011 calendar year emissions as they correct emission factors that were in error or had substantive uncertainty.

§ WCI.20 GENERAL STATIONARY COMBUSTION

§ WCI.21 Source Category Definition

Stationary fuel combustion sources are devices that combust solid, liquid, or gaseous fuel generally for the purpose of producing electricity, generating steam or providing useful heat or energy for industrial, commercial, or institutional use; or reducing the volume of waste by removing combustible matter. Stationary fuel combustion sources are boilers, simple and combined cycle combustion turbines, engines, incinerators (including units that combust hazardous waste), process heaters, and any other stationary combustion device that is not specifically addressed under the methods for another source category. This source category does not include portable equipment, emergency generators, and emergency equipment (including emergency flares).

§ WCI.22 Greenhouse Gas Reporting Requirements

Note: CO_2, CH_4, and N_2O emissions from spent/pulping liquor combusted in the process of pulp and paper manufacturing should be reported under WCI.210, starting with the 2011 reporting year.

Except as noted in the previous paragraph, the emissions data report shall include the following information at the facility level:

(a) Annual greenhouse gas emissions in tonnes, reported as follows:

(1) Total CO_2 emissions for fossil fuels, reported by fuel type.

(2) Total CO_2 emissions for biomass, reported by fuel type.

(3) Total CH_4 emissions, reported by fuel type.

(4) Total N_2O emissions, reported by fuel type.

(b) Annual fuel consumption:

(1) For gases, report in units of standard cubic meters.

(2) For liquids, report in units of kilolitres.

(3) For non-biomass solids, report in units of tonnes.

(4) For biomass solid fuels, report in units of bone dry tonnes.

(c) Annual weighted average carbon content of each fuel, if used to compute CO_2 emissions.

(d) Annual weighted average high heat value of each fuel, if used to compute CO_2 emissions.

(e) Annual steam in kilograms, for units that burn biomass fuels or municipal solid waste and generate steam.

§ WCI.23 Calculation of CO_2 Emissions

For each fuel, calculate CO_2 mass emissions using one of the four calculation methodologies specified in this section, subject to the restrictions in WCI.23(e). If a fuel or fuels is not listed in all of Tables 20-1 through 20-7, or in Table C-1 or C-2 of U.S. EPA 40 CFR Part 98, Subpart C, then emissions from such fuels do not need to be reported so long as the sum of emissions from these fuels does not exceed 0.5% of total facility emissions. If the sum of emissions from these fuels exceeds 0.5% of total facility emissions, then report emissions from one or more of these fuels as needed so that the sum of emissions from the remaining unlisted fuels does not exceed 0.5% of total facility emissions.

(a) Calculation Methodology 1. Calculate the annual CO_2 mass emissions for each type of fuel by substituting a fuel-specific default CO_2 emission factor, a default high heat value, and the annual fuel consumption into Equation 20-1 or 20-1a:

$$CO_2 = Fuel \times HHV \times EF \times 0.001$$ **Equation 20-1**

$$CO_2 = Fuel \times EF_c \times 0.001$$ **Equation 20-1a**

Where:

CO_2 = Annual CO_2 mass emissions for the specific fuel type (tonnes).
Fuel = Mass or volume of fuel combusted per year (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).
HHV = Default high heat value of the fuel, from Table 20-1 and 20-1a (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).
EF = Fuel-specific default CO_2 emission factor, from Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable (kg CO_2/GJ).
EFc = Fuel-specific default CO_2 emission factor, from Tables 20-2 or 20-5 (kg CO_2 per tonne for solid fuel, kg CO_2 per kilolitre for liquid fuel, or kg CO_2 per cubic meter for gaseous fuel)
0.001 = Conversion factor from kilograms to tonnes.

(b) Calculation Methodology 2. Calculate the annual CO_2 mass emissions using a default fuel-specific CO_2 emission factor, a high heat value provided by the supplier or measured by the operator, using Equation 20-2, except for emissions from the combustion of biomass fuels, for which the operator may instead elect to use the method shown in Equation 20-3. For use of Calculation Methodology 2 for municipal solid waste, Equation 20-3 must be used.

(1) For any type of fuel for which an emission factor is provided in Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable, except biomass fuels when the operator elects to use the method in WCI.23(b)(2), use Equation 20-2:

$$CO_2 = \sum_{p=1}^{n} Fuel_p \times HHV_p \times EF \times 0.001$$ **Equation 20-2**

Where:

CO_2	=	Annual CO_2 mass emissions for a specific fuel type (tonnes).
n	=	Number of required heat content measurements for the year as specified in WCI.25.
$Fuel_p$	=	Mass or volume of the fuel combusted during the measurement period *p* (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).
HHV_p	=	High heat value of the fuel for the measurement period *p* (GJ per tonne for solid fuel, GJ per bone-dry tonne biomass solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).
EF	=	Fuel-specific default CO_2 emission factor, from Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable (kg CO_2/GJ).
0.001	=	Conversion factor from kilograms to tonnes.

(2) For units that combust municipal solid waste and produce steam, use Equation 20-3. Equation 20-3 of this section may also be used for any solid biomass fuel listed in Table 20-2 of this subpart provided that steam is generated by the unit.

$$CO_2 = Steam \times B \times EF \times 0.001$$ **Equation 20-3**

Where:

CO_2	=	Annual CO_2 mass emissions from biomass solid fuel or municipal solid waste combustion (tonnes).
Steam	=	Total mass of steam generated by biomass solid fuel or municipal solid waste combustion during the reporting year (tonnes steam).
B	=	Ratio of the boiler's design rated heat input capacity to its design rated steam output capacity (GJ/tonne steam).
EF	=	Default emission factor for biomass solid fuel or municipal solid waste, from Table 20-2 or Table 20-7, as applicable (kg CO_2/GJ),[1] Site-specific emission factor determined through measurements may be used if updated no less often than every third year as provided in WCI.25(a)(7)(B).
0.001	=	Conversion factor from kilograms to tonnes.

(c) Calculation Methodology 3. Calculate the annual CO_2 mass emissions for each fuel by using measurements of fuel carbon content or molar fraction (for gaseous fuels only), conducted by the operator or provided by the fuel supplier, and the quantity of fuel combusted.

(1) For a solid fuel, except for the combustion of municipal solid waste, use Equation 20-4 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i$$ **Equation 20-4**

[1] The ER required development of a site-specific emission factor for MSW. For harmonization with Part 98, Subpart C, this requirement was deleted. However, jurisdictions may allow or require testing to develop a site-specific emission factor as an alternative to the default emission factors in Subpart C, Table C-1.

Where:

CO_2 = Annual CO_2 mass emissions from the combustion of the specific solid fuel (tonnes).
n = Number of carbon content determinations for the year.
$Fuel_i$ = Mass of the solid fuel combusted in measurement period *i* (tonnes).
CC_i = Carbon content of the solid fuel, from the fuel analysis results for measurement period *i* (percent by weight, expressed as a decimal fraction, e.g., 95% = 0.95).
3.664 = Ratio of molecular weights, CO_2 to carbon.

(2) For biomass fuels and municipal solid waste, which is combusted in units for producing steam, either use 20-5 or Equation 20-3 in WCI.23(b)(2) above. Equation 20-5 of this section may also be used for any solid biomass fuel listed in Table 20-2 provided that steam is generated by the unit.

$$CO_2 = Steam \times EF \times 0.001$$

Equation 20-5

Where:

CO_2 = Annual CO_2 mass emissions from biomass solid fuel or municipal solid waste combustion (tonnes).
Steam = Total mass of steam generated by biomass solid fuel or municipal solid waste combustion during the reporting year (tonnes steam).
EF = Measured emission factor for biomass solid fuel or municipal solid waste, as applicable (kg CO_2/tonne steam), adjusted no less often than every third year.
0.001 = Conversion factor from kilograms to tonnes.

(3) For a liquid fuel, use Equation 20-6 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i$$

Equation 20-6

Where:

CO_2 = Annual CO_2 mass emissions from the combustion of the specific liquid fuel (tonnes).
n = Number of required carbon content determinations for the year, as specified in WCI.25.
$Fuel_i$ = Volume of the liquid fuel combusted in measurement period *i* (kilolitres).

CC_i	=	Carbon content of the liquid fuel, from the fuel analysis results for measurement period *i* (tonne C per kilolitre of fuel).
3.664	=	Ratio of molecular weights, CO_2 to carbon.

(4) For a gaseous fuel, use Equation 20-7 of this section:

$$CO_2 = \sum_{i=1}^{n} 3.664 \times Fuel_i \times CC_i \times 0.001 \qquad \textbf{Equation 20-7}$$

Where:

CO_2	=	Annual CO_2 mass emissions from combustion of the specific gaseous fuel (tonnes).
n	=	Number of required carbon content determinations for the year, as specified in WCI.25.
$Fuel_i$	=	Fuel combusted in period "i" (a day or month, as applicable) (volume of the gaseous fuel in Rm^3 at reference temperature and pressure conditions as used by the facility, or mass of the gaseous fuel in kg if a mass flow meter is used)
CC_i	=	Average carbon content of the gaseous fuel, from the fuel analysis results for the period *i* (day or month, as applicable) (kg C per Rm^3 or kg C per kg of fuel if a mass flow meter is used).
3.664	=	Ratio of molecular weights, CO_2 to carbon.
0.001	=	Conversion factor from kg to tonnes.

(d) Calculation Methodology 4. Calculate the annual CO_2 mass emissions from all fuels combusted in a unit, by using data from continuous emission monitoring systems (CEMS) as specified in (d)(1) through (d)(7). This methodology requires a CO_2 monitor and a flow monitoring subsystem except as otherwise provided in paragraph (d)(3) of this section. CEMS shall use methodologies provided in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7) (Revised December 2005) (or by other document that supersedes it).

(1) For a facility that operates CEMS in response to federal, state, provincial, or local regulation, use CO_2 or O_2 concentrations and flue gas flow measurements to determine hourly CO_2 mass emissions using methodologies provided in Report EPS 1/PG/7 (Revised December 2005) (or by other relevant document, if superseded).

(2) The operator shall report CO_2 emissions for the reporting year in tonnes based on the sum of hourly CO_2 mass emissions over the year, converted to tonnes.

(3) An oxygen (O_2) concentration monitor may be used in lieu of a CO_2 concentration monitor in a CEMS installed before January 1, 2012, to determine the hourly CO_2 concentrations, if the effluent gas stream monitored by the CEMS consists solely of combustion products (i.e., no process CO_2 emissions or CO_2 emissions from acid gas control are mixed with the combustion products) and if only the following fuels are

combusted in the unit: coal, petroleum coke, oil, natural gas, propane, butane, wood bark, or wood residue.

(A) If the unit combusts waste-derived fuels (as defined in the General Provisions and including municipal solid waste), emissions calculations shall not be based on O_2 concentrations.

(B) If the operator of a facility that combusts biomass fuels uses O_2 concentrations to calculate CO_2 concentrations, annual source testing must demonstrate that the calculated CO_2 concentrations, when compared to measured CO_2 concentrations, meet the Relative Accuracy Test Audit (RATA) requirements in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded).

(4) If both biomass fuel (including fuels that are partially biomass) and fossil fuel are combusted during the year, determine and report the biogenic CO_2 mass emissions separately, as described in paragraph (f) of this section.

(5) For any units for which CO_2 emissions are reported using CEMS data, the operator is relieved of the requirement to separately report process emissions from combustion emissions for that unit or to report emissions separately for different fossil fuels for that unit when only fossil fuels are co-fired. In this circumstance, operators shall still report fuel use by fuel type as otherwise required.

(6) If a facility is subject to requirements for continuous monitoring of gaseous emissions, and the operator chooses to add devices to an existing CEMS for the purpose of measuring CO_2 concentrations or flue gas flow, the operator shall select and operate the added devices pursuant to the appropriate requirements for the facility as applicable in Canada.

(7) If a facility does not have a CEMS and the operator chooses to add one in order to measure CO_2 concentrations, the operator shall select and operate the CEMS pursuant to the appropriate requirements or equivalent requirements as applicable in Canada. Operators who add CEMS under this paragraph are subject to the specifications in paragraphs (d)(1) through (d)(5), if applicable.

(e) Use of the Four CO_2 Calculation Methodologies. Use of the four CO_2 emissions calculation methodologies described in paragraphs (a) through (d) of this section is subject to the following requirements and restrictions:

(1) Calculation Methodology 1 (Equations 20-1 and 20-1a).

(A) May be used by a facility that is not subject to the verification requirements by regulation for any type of fuel for which a default high heat value (Table 20-1 and 20-1a) and a default CO_2 emission factor (Tables 20-1a, 20-2, 20-3, or 20-5, as applicable) is specified.

(B) May be used for a facility emitting at any level for the combustion of natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter, and for the combustion of any of the fuels listed in Table 20-1a.

(C) May be used for a facility emitting at any level from the combustion of municipal solid waste in a unit that does not generate steam.

(D) May be used for the combustion of biomass listed in Table 20-2 that is exempted from verification requirements by the jurisdiction, unless it is specifically addressed under the provisions for another source category (e.g., spent pulping liquor from pulp and paper facilities).

(E) May not be used at a facility emitting at any level from a fuel for which you routinely perform fuel sampling and analysis for the fuel's high heat value or can obtain the results (i.e. high heat value) of fuel sampling and analysis from the fuel supplier at the minimum frequency specified in WCI.25(a), or at a greater frequency. In such cases, Calculation Method 2, 3 or 4 shall be used for those fuels.

(2) Calculation Methodology 2 (Equations 20-2 and 20-3).

(A) Calculation Methodology 2 may not be used by a facility that is subject to the verification requirements by regulation, except as specified in paragraphs (e)(2)(B) through (E) of this section. Otherwise, Calculation Methodology 2 may be used for any type of fuel combusted for which a default CO_2 emission factor for the fuel is specified in Tables 20-1a, 20-2, 20-3, 20-5, or 20-7, as applicable.

(B) Calculation Methodology 2 may be used for the combustion of natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter at a facility emitting at any level. Notwithstanding the provisions in paragraph (e)(1) of this section, Calculation Methodology 2, 3, or 4 shall be used for combustion in any unit with a rated heat input capacity greater than 264 GJ/hr (250mmBtu/hr) and that has operated for more than 1,000 hours in any of the past three years, when the fuel is natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter.

(C) Calculation Methodology 2 may be used at a facility emitting at any level for the combustion of any of the fuels listed in Table 20-1a, and for biomass that has been determined by [the jurisdiction] not to be subject to a compliance obligation under the cap-and-trade program.

(D) Equation 20-3 may be used for the combustion of municipal solid waste only at facilities that are not subject to verification by regulation.

(E) Equation 20-2 may not be used for the combustion of municipal solid waste.

(3) Calculation Methodology 3 (Equations 20-4 through 20-7) may be used for the combustion of any type of fuel, except as specified in paragraph (e)(3)(A) through (E) of this section.

(A) Notwithstanding the provisions in paragraph (e)(1) and (e)(2) of this section, Calculation Methodology 3 or 4 must be used at a facility subject to verification for all combustion in any unit with a rated heat input capacity greater than 264 GJ/hr (250mmBtu/hr) and that has operated for more than 1,000 hours in any of the past three years, except when the fuel is natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter, the fuel is listed in Table 20-1a, or the fuel is biomass that has been determined by [the jurisdiction] not to be subject to a compliance obligation under the cap-and-trade program.

(B) Must be used for all other combustion at a facility subject to verification, except for combustion of fuels for which Calculation Methodology 1 or 2 is permitted, as described in paragraphs (e)(1) and (e)(2) of this section.

(C) May not be used when the use of Calculation Methodology 4 is required.

(D) Equation 20-4 may not be used for the calculation of emissions from combustion of municipal solid waste.

(E) Equation 20-5 may be used for the combustion of municipal solid waste at a facility emitting at any level; however, it must be used for the combustion of municipal solid waste if the facility is subject to verification by regulation, unless Calculation Methodology 4 is required.

(4) Calculation Methodology 4 may be used for a unit combusting any type of fuel. Notwithstanding the provisions in paragraphs (e)(1) through (3) of this section, Calculation Methodology 4 must be used for a combustion unit with a CEMS that is required by any federal, provincial, or local regulation and that includes both a stack gas volumetric flow rate monitor and a CO_2 concentration monitor.

(5) You may elect to use any applicable higher calculation methodology for one or more of the fuels combusted in a unit. For example, if a unit combusts natural gas and distillate fuel oil, you may elect to use Calculation Methodology 1 for natural gas and Calculation Methodology 2 for the fuel oil, even though Calculation Methodology 1 could have been used for both fuels. However, for units that use Calculation Methodology 4, CO_2 emissions from the combustion of all fuels shall be based solely on CEMS measurements.

(f) CO_2 emissions from combustion of mixtures of biomass or biomass fuel and fossil fuel. Use the procedures of this paragraph (f) to estimate biogenic CO_2 emissions from units that combust a combination of biomass and fossil fuels, including combustion of waste-derived fuels (e.g., municipal solid waste, tires, etc,) that are partially biomass.

(1) If CEMS are not used to measure CO_2 and the facility combusts biomass fuels that do not include waste-derived fuels (e.g., municipal solid waste and tires), use Calculation Methodology 1, 2, or 3, as applicable, to calculate the annual biogenic CO_2 mass emissions from the combustion of biomass fuels. Determine the mass of biomass combusted using either company records, or, for premixed fuels that contain biomass and fossil fuels (e.g., mixtures containing biodiesel), use best available information to determine the mass of biomass fuels and document the procedure.

(2) If a CEMS is used to measure CO_2 (or O_2 as a surrogate) and the facility combusts biomass fuels that do not include waste-derived fuels (as defined in the General Provisions), use Calculation Methodology 1, 2, or 3 to calculate the annual CO_2 mass emissions from the combustion of fossil fuels. Calculate biomass fuel emissions by subtracting the fossil fuel-related emissions from the total CO_2 emissions determined from the CEMS-based methodology.

(3) If the owner or operator that combusts fuels or fuel mixtures for which the biomass fraction is unknown or cannot be documented (e.g., municipal solid waste, tire-derived fuel, etc.), or if the owner or operator combusts a biomass fuel for which a CO_2

emission factor is not provided in Table 20-2, use the following to estimate biogenic CO_2 emissions:

(A) Use Calculation Methodology 1, 2, 3, or 4 to calculate the total annual CO_2 mass emissions, as applicable.

(B) Determine the biogenic portion of the CO_2 emissions using ASTM D6866-08 “Standard Test Methods for Determining the Biobased Content of Solid, Liquid, and Gaseous Samples Using Radiocarbon Analysis”, as specified in this paragraph. This procedure is not required for fuels that contain less than 5 percent biomass by weight or for waste-derived fuels that are less than 30 percent by weight of total fuels combusted in the year for which emissions are being reported, except where the operator wishes to report a biomass fuel fraction of CO_2 emissions.

(C) The operator shall conduct ASTM D6866-08 analysis on a representative fuel or exhaust gas sample at least every three months. The exhaust gas samples shall be collected over at least 24 consecutive hours following the standard practice specified by ASTM D7459-08 “Standard Practice for Collection of Integrated Samples for the Speciation of Biomass (Biogenic) and Fossil-Derived Carbon Dioxide Emitted from Stationary Emissions Sources.” If municipal solid waste is combusted, the ASTM D6866-08 analysis must be performed on the exhaust gas stream.

(D) The operator shall divide total CO_2 emissions between biomass fuel emissions and non-biomass fuel emissions using the average proportions of the samples analyzed for the year for which emissions are being reported.

(E) If there is a common fuel source to multiple units at the facility, the operator may elect to conduct ASTM D6866-06a testing for only one of the units sharing the common fuel source.

(4) If Equations 20-1 or 20-1a of this section is selected to calculate the annual biogenic mass emissions for wood, wood waste, or other solid biomass-derived fuel, Equation 20-8 of this section may be used to quantify biogenic fuel consumption, provided that all of the required input parameters are accurately quantified. Similar equations and calculation methodologies based on steam generation and boiler efficiency may be used, provided that they are documented.

$$\left(Fuel\right)_p = \frac{\left[H \times S\right] - \left(HI\right)_{nb}}{\left(HHV\right)_{bio} \times \left(Eff\right)_{bio}} \qquad \textbf{Equation 20-8}$$

Where:

$(Fuel)_p$	=	Quantity of biomass consumed during the measurement period *p* (tonnes/year or tonnes/month, as applicable).
H	=	Average enthalpy of the boiler steam for the measurement period (GJ/tonne).
S	=	Total boiler steam production for the measurement period (tonne/month or tonne/year, as applicable).

$(HI)_{nb}$ = Heat input from co-fired fossil fuels and non-biomass-derived fuels for the measurement period, based on company records of fuel usage and default or measured HHV values (GJ/month or GJ/year, as applicable).

$(HHV)_{bio}$ = Default or measured high heat value of the biomass fuel (GJ/tonne).

$(Eff)_{bio}$ = Efficiency of biomass-to-energy conversion, expressed as a decimal fraction.

(g) Calculation of CO_2 from sorbent.

(1) When a unit is a fluidized bed boiler, is equipped with a wet flue gas desulfurization system, or uses other acid gas emission controls with sorbent injection, use Equation 20-9 of this section to calculate the CO_2 emissions from the sorbent, if those CO_2 emissions are not monitored by CEMS:

$$CO_2 = S \times R \times \left(\frac{MW_{CO2}}{MW_S} \right)$$ **Equation 20-9**

Where:

CO_2 = CO_2 emitted from sorbent for the reporting year (tonnes).

S = Limestone or other sorbent used in the reporting year, from company records (tonnes).

R = 1.00, the calcium-to-sulphur stoichiometric ratio, or determined based on the actual absorbent used.

MW_{CO2} = Molecular weight of carbon dioxide.

MW_S = Molecular weight of sorbent.

(2) The annual CO_2 mass emissions for the unit shall be the sum of the CO_2 emissions from the combustion process and the CO_2 emissions from the sorbent.

§ WCI.24 Calculation of CH_4 and N_2O Emissions

Calculate the annual CH_4 and N_2O mass emissions from stationary fuel combustion sources using the procedures in paragraph (a), (b), or (c), as appropriate. You are not required to calculate the annual CH_4 and N_2O emissions for fuels that are not listed in Tables 20-2, 20-3, 20-4 and 20-6. However, you may use engineering estimates to calculate the annual CH_4 and N_2O emissions for fuels that are not listed in Tables 20-2, 20-3, 20-4 and 20-6.

(a) ***For fuel(s) other than coal***: If the High Heat Value (HHV) for fuels is not measured directly, use Equation 20-10 to calculate the emissions for each fuel type:

$$CH_4 \text{ or } N_2O = \sum_{i=1}^{n} Fuel_i \times HHV_{D\_i} \times EF_i \times 0.000001$$ **Equation 20-10**

(a.2) ***For coal***: If the emissions factors are not measured directly or provided by suppliers, use Equation 20-11 to calculate the emissions for each type of coal :

$$CH_4 \text{ or } N_2O = \sum_{i=1}^{n} Fuel_i \times EF_{c,i} \times 0.001 \qquad \textbf{Equation 20-11}$$

Where:

CH_4 or N_2O	=	Combustion emissions from specific fuel type (tonnes CH_4 or N_2O per year).
$Fuel_i$	=	Mass or volume of fuel type combusted during measurement period "i" (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).
$HHV_{D,i}$	=	Default high heat value specified by fuel type during measurement period "i" provided in Table 20-1, (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).
EF_i	=	Default CH_4 or N_2O emission factor for each fuel type during measurement period "i" provided in Tables 20-2 or 20-4, as applicable, grams CH_4 or N_2O per GJ. The facility may also use equipment specific factors from U.S. EPA AP-42 for the specific equipment as appropriate.
$EF_{c,i}$	=	Default CH_4 or N_2O emission factor for each coal type during measurement period "i" provided in Table 20-6 (grams CH_4 or N_2O per kg of coal). The facility may also use equipment specific factors from U.S. EPA AP-42 for the specific equipment as appropriate.
0.000001	=	Factor to convert grams to tonnes in Equation 20-10 .
0.001	=	Factor to convert kg to tonne in Equation 20-11.

(b) ***For fuels other than coal:*** If the HHVs for fuels are measured directly or provided by suppliers then use Equation 20-12 to calculate the emissions for each type of fuels:

$$CH_4 \text{ or } N_2O = \sum_{i=1}^{n} Fuel_i \times HHV_{P,i} \times EF_i \times 0.000001 \qquad \textbf{Equation 20-12}$$

(b.2) ***For coal only:*** If the emission factors are measured directly or provided by suppliers then use Equation 20-13 to calculate the emissions for each coal type:

$$CH_4 \text{ or } N_2O = \sum_{i=1}^{n} Fuel_i \times EF_{c,i} \times 0.001 \qquad \textbf{Equation 20-13}$$

Where:

CH_4 or N_2O	=	Combustion emissions from specific fuel type (tonnes CH_4 or N_2O per year).
$Fuel_i$	=	Mass or volume of fuel type during measurement period "i" (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).
$HHV_{P,i}$	=	High heat value of the specific fuel during measurement period "i" measured

directly or provided by supplier(s) (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).

EF_i = Default CH_4 or N_2O emission factor for fuel "i" other than coal or during measurement period "i" provided in Tables 20-2 or 20-4, as applicable, grams CH_4 or N_2O per GJ. The facility may also use equipment specific factors from U.S. EPA AP-42 for the specific equipment as appropriate.

$EF_{c,i}$ = CH_4 or N_2O emission factor for each coal type during measurement "i" measured directly or provided by supplier(s) (kg CH_4 or N_2O per tonne of coal).

0.000001 = Factor to convert grams to tonnes in Equation 20-12.

0.001 = Factor to convert kg to tonne in Equation 20-13.

(c) For biomass and municipal solid waste combustion where Equation 20-3 or -5 or 20-4 is used to calculate CO_2 emissions, use Equation 20-14 of this section to estimate CH_4 and N_2O emissions:

$$CH_4 \ or \ N_2O = Steam \times B \times EF \times 0.000001 \qquad \textbf{Equation 20-14}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a biomass or municipal solid waste (tonnes).

Steam = Total mass of steam generated by biomass or municipal solid waste combustion during the reporting year (tonnes steam).

B = Ratio of the boiler's design rated heat input capacity to its design rated steam output (GJ/tonne steam).

EF = Fuel-specific emission factor for CH_4 or N_2O, from Tables 20-2, 20-4, 20-6, or 20-7 as applicable (grams per GJ).

0.000001 = Conversion factor from grams to tonnes.

(d) Use Equation 20-15 of this section for units that use Calculation Methodology 4 and for which heat input is monitored on a year round basis.

$$CH_4 \ or \ N_2O = (HI)_A \times EF \times 0.000001 \qquad \textbf{Equation 20-15}$$

Where:

CH_4 or N_2O = Annual CH_4 or N_2O emissions from the combustion of a particular type of fuel (tonnes).

$(HI)_A$ = Cumulative annual heat input from the fuel (GJ), derived from the electronic data reports or estimated from the best available information used for accounting purposes (e.g., fuel feed rate measurements, fuel heating values, engineering analysis, etc.). For coal cumulative mass of coal (kilograms)

		from the best available information (e.g., fuel feed rate measurements, cumulative heat input, fuel heating values, engineering analysis).
EF	=	Fuel-specific emission factor for CH_4 or N_2O, from Tables 20-2, 20-4, or 20-6, as applicable (grams per GJ or grams per kilogram for coal).
0.000001	=	Conversion factor from grams to tonnes.

(1) If only one type of fuel is combusted during normal operation, substitute the cumulative annual heat input from combustion of the fuel into Equation 20-15 of this section to calculate the annual CH_4 or N_2O emissions.

(2) If more than one type of fuel listed is combusted during normal operation, use Equation 20-15 of this section separately for each type of fuel.

(e) When multiple fuels are combusted during the reporting year, sum the fuel-specific results from Equations 20-10/ 20-11, 20-12/13 and 20-14 or 20-15 of this section (as applicable) to obtain the total annual CH_4 and N_2O emissions, in tonnes.

(f) The operator may elect to calculate CH_4 or N_2O emissions using source-specific emission factors derived from source tests conducted at least annually under the supervision of the regulator. Upon approval of a source test plan, the source test procedures in that plan shall be repeated in each future year to update the source specific emission factors annually.

(g) Use of the four CH_4 and N_2O Calculation Methodologies. Use of the four CH_4 and N_2O emissions calculation methodologies described in paragraphs (a) through (d) of this section is subject to the following requirements and restrictions:

(1) WCI.24(a) may not be used by a facility that is subject to the verification requirements of WCI.8, except for stationary combustion units that combust natural gas with a high heat value between 36.3 and 40.98 MJ per cubic meter. Otherwise, WCI.24(a) may be used for any type of fuel for which a default CH_4 or N_2O emission factor (Tables 20-2, 20-4, 20-6, and 20-7) and a default high heat value (Table 20-1 and 20-1a) is specified.

(2) WCI.24(b) may be used for a unit of any size combusting any type of fuel.

(3) WCI.24(c) may only be used for biomass or municipal solid waste combustion. WCI.24(c) must be used instead of WCI.24(a) for any unit combusting municipal solid waste that generates steam.

(3) (4) WCI.24(d) may be used for a unit of any size combusting any type of fuel, and must be used for any units for which Calculation Methodology 4 is used to estimate CO_2 emissions and heat input is monitored on a year round basis.

§ WCI.25 Sampling, Analysis, and Measurement Requirements

(a) Fuel Sampling Requirements. Fuel sampling must be conducted or fuel sampling results must be received from the fuel supplier at the minimum frequency specified in paragraphs (a)(1) through (a)(7) of this section, subject to the requirements of WCI.23(e) and WCI.24(g). All fuel samples shall be taken at a location in the fuel handling system that provides a representative of the fuel combusted.

(1) Once for each new fuel shipment or delivery for coal.

(2) Once for each new fuel shipment or delivery of fuels, or quarterly for each of the fuels listed in Table 20-1a (when required).

(3) Semiannually for natural gas (when required and except as noted in WCI.025(f) and (g)).

(4) Quarterly for liquid fuels and fossil fuel-derived gaseous fuels other than fuels listed in Table 20-1a (when Table 20-1a is used).

(5) Quarterly for gases derived from biomass including landfill gas and biogas from wastewater treatment or agricultural processes.

(6) For gaseous fuels other than natural gas, gases derived from biomass, and biogas, daily sampling and analysis to determine the carbon content and molecular weight of the fuel is required if the necessary equipment is in place to make these measurements. If the necessary equipment is not in place to make the measurements, weekly sampling and analysis shall be performed. If on-line instrumentation is to be used, the equipment necessary to perform daily sampling and analysis of carbon content and molecular weight must determine fuel carbon content accurate to ±5 percent.

(7) Monthly for solid fuels other than coal and waste-derived fuels (including municipal solid waste), as specified below:

(A) The monthly solid fuel sample shall be a composite sample of weekly samples.

(B) The solid fuel shall be sampled at a location after all fuel treatment operations but before fuel combustion, and the samples shall be representative of the fuel chemical and physical characteristics immediately prior to combustion.

(C) Each weekly sub-sample shall be collected at a time (day and hour) of the week when the fuel consumption rate is representative and unbiased.

(D) Four weekly samples (or a sample collected during each week of operation during the month) of equal mass shall be combined to form the monthly composite sample.

(E) The monthly composite sample shall be homogenized and well mixed prior to withdrawal of a sample for analysis.

(F) One in twelve composite samples shall be randomly selected for additional analysis of its discrete constituent samples. This information will be used to monitor the homogeneity of the composite.

(8) For biomass fuels and waste-derived fuels (including municipal solid waste), the following may apply in lieu of WCI.25(a)(5):

(A) If CO_2 emissions are calculated using Equation 20-3 in WCI.23(b)(2) or Equation 20-4 in WCI.23(c)(1), the fuel-specific high heat value or carbon content is determined annually. If CO_2 emissions are calculated using Equation 20-5 in WCI.23(c)(2) (biomass fuels and municipal solid waste only), the operator shall adjust the emission factor, in kg CO_2/GJ not less frequently than every third year, through a stack test measurement of CO_2 and use of the applicable ASME

Performance Test Code to determine heat input from all heat outputs, including the steam, flue gases, ash and losses.

(b) Fuel Consumption Monitoring Requirements.

(1) Facilities may determine fuel consumption on the basis of direct measurement or recorded fuel purchase or sales invoices measuring any stock change (measured in MJ, litres, million standard cubic meters, tonnes or bone dry tonnes) using Equation 20-16. For facilities that are covered by WCI.360 (Petroleum and Natural Gas Production and Gas Processing), an operator may calculate fuel consumption for gasoline, propane and diesel using Equation 20-16 without correcting for the difference in inventory at the beginning and end of the year or using Equation 20-16a

Fuel Consumption in the Report Year = Total Fuel Purchases – Total Fuel Sales + Amount Stored (or reading) at Beginning of Year – Amount Stored (or reading) at Year End

Equation 20-16

$$Fuel = \sum_{j=1}^{n} \frac{P_{rated\ j}}{\eta_j} \times \frac{LD_j}{HHV_j} \times OH_j \times 0.0036$$

Equation 20-16a

Where:

Fuel	= Annual theoretical volume of liquid fuel combusted by fired equipment *j* (m^3/year).
$P_{rated\ j}$	= Maximum rated power for fired equipment *j* (kW).
LD_j	= Load for fired equipment *j* (load fraction).
OH_j	= Annual operating hours for fired equipment *j* (hours/year).
η_j	= Thermal efficiency for fired equipment *j*.
HHV_j	= High heat value of the liquid fuel combusted by fired equipment *j* (GJ/m^3).
n	= quantity of fired equipment units,
0.0036	= conversion factor between kWh and GJ.

(2) Fuel consumption measured in MJ values shall be converted to the required metrics of mass or volume using heat content values that are either provided by the supplier, measured by the facility, or provided in Table 20-1.

(3) All fuel oil and gas flow meters (except for gas billing meters) shall be calibrated prior to the first year for which GHG emissions are reported under this rule, using calibration procedures specified by the flow meter manufacturer[2]. Fuel flow meters shall be recalibrated once every three years, upon replacement of a previously calibrated meter or at the minimum frequency specified by the manufacturer. For orifice, nozzle,

[2] California's requirements in s. 95103(k) are being considered.

and venturi flow meters, the calibration shall consists of in-situ calibration of the differential pressure (delta-P), total pressure, and temperature transmitters. For flow meters used for natural gas, the facilities may follow the requirements under the laws and regulation of Measurement Canada for electricity and gas. For clarity, this provision also applies to flow meters used in upstream oil and gas, and natural gas transmission and distribution applications.

(4) For fuel oil, tank drop measurements may also be used.

(5) Fuel flow meters that measure mass flow rates may be used for liquid fuels, provided that the fuel density is used to convert the readings to volumetric flow rates. The density shall be measured at the same frequency as the carbon content, using ASTM D1298-99 (Reapproved 2005) "Standard Test Method for Density, Relative Density (Specific Gravity), or API Gravity of Crude Petroleum and Liquid Petroleum Products by Hydrometer Method."

(6) Facilities using Calculation Methods 1 or 2 for CO_2 emissions may use the following (Table 20-8) default density values for fuel oil, in lieu of using the ASTM method in paragraph (b)(5) of this section. These default densities may not be used for facilities using Calculation Method 3.

Table 20-8 Fuel Oil Default Density Values

Fuel Oil	No.1 Oil	No.2 Oil	No.6 Oil
Default Density, kg/litre	0.81	0.86	0.97

(c) Fuel Heat Content Monitoring Requirements. High heat values shall be based on the results of fuel sampling and analysis received from the fuel supplier or determined by the operator, using an applicable analytical method listed by regulation. For fuel heat content monitoring of natural gas, the facilities may follow the requirements under the laws and regulation of Measurement Canada for electricity and gas.

(1) For gases, use the most appropriate method published by a consensus-based standards organization, if such a method exists. Specific test procedures that may be required to be used include ASTM D1826 "Standard Test Method for Calorific (Heating) Value of Gases in Natural Gas Range by Continuous Recording Calorimeter", ASTM D3588 "Standard Practice for Calculating Heat Value, Compressibility Factor, and Relative Density of Gaseous Fuels", or ASTM D4891-, GPA Standard 2261 "Analysis for Natural Gas and Similar Gaseous Mixtures by Gas Chromatography." If no appropriate method is published by a consensus-based standards organization, use industry standard methods, noting where such methods are used and what methods are used. The operator may alternatively elect to use on-line instrumentation that determines heating value accurate to within ±5.0 percent. Where existing on-line instrumentation provides only low heat value, the operator shall convert the low heat value to high heat value as follows:

$$HHV = LHV \times CF \qquad \textbf{Equation 20-17}$$

Where:

HHV	= fuel or fuel mixture high heat value (MJ/scm).
LHV	= fuel or fuel mixture low heat value (MJ/scm).
CF	= conversion factor.

For natural gas, a CF of 1.11 shall be used. For refinery fuel gas and mixtures of refinery fuel gas, a weekly average fuel system-specific CF shall be derived as follows:

(A) By concurrent LHV and HHV measurements determined by on-line instrumentation or laboratory analysis as part of the daily carbon content determination; or,

(B) By the HHV/LHV ratio obtained from the laboratory analysis of the daily samples.

(2) For middle distillates and oil, or liquid waste-derived fuels, use the most appropriate method published by consensus-based standards organization. Specific test procedures that may be required to use include ASTM D240 “Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter” or ASTM D4809 “Standard Test Method for Heat of Combustion of Liquid Hydrocarbon Fuels by Bomb Calorimeter (Precision Method).” If no appropriate method is published by a consensus-based standards organization, use industry standard methods, noting where such methods are used and what methods are used.

(3) For solid biomass-derived fuels, use the most appropriate method published by a consensus-based standards organization. Specific test procedures that may be required to use include ASTM D5865 “Standard Test Method for Gross Calorific Value of Coal and Coke.” If no appropriate method is published by a consensus-based standards organization, use industry standard methods, noting where such methods are used and what methods are used.

(4) For waste-derived fuels, use the most appropriate method published by a consensus-based standards organization. Specific test procedures that may be required to use include ASTM D5865 and ASTM D5468 “Standard Test Method for Gross Calorific and Ash Value of Waste Materials.” Operators who combust waste-derived fuels that are not pure biomass fuels shall determine the biomass fuel portion of CO_2 emissions using the method specified in WCI.23(f), if applicable. If no appropriate method is published by a consensus-based standards organization, use industry standard methods, noting where such methods are used and what methods are used.

(5) Use Equation 20-18 to calculate the weighted annual average heat content of the fuel, if the measured heat content is used to calculate CO_2 emissions.

$$(HHV)_{annual} = \frac{\sum_{p=1}^{n} (HHV)_p \times (Fuel)_p}{\sum_{p=1}^{n} (Fuel)_p} \qquad \textbf{Equation 20-18}$$

Where:

$(HHV)_{annual}$ = Weighted annual average high heat value of the fuel (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).

$(HHV)_p$ = High heat value of the fuel, for measurement period *p* (GJ per tonne for solid fuel, GJ per kilolitre for liquid fuel, or GJ per cubic meter for gaseous fuel).

$(Fuel)_p$ = Mass or volume of the fuel combusted during measurement period *p* (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).

n = Number of measurement periods in the year that fuel is burned in the unit.

(d) Fuel Carbon Content Monitoring Requirements. The determination of fuel carbon content and either molecular weight or molar fraction for gaseous fuels shall be based on the results of fuel sampling and analysis received from the fuel supplier or determined by the operator, using an applicable analytical method listed by regulation. For carbon content monitoring of natural gas, the facilities may follow the requirements under the laws and regulation of Measurement Canada for electricity and gas .

(1) For coal and coke, solid biomass fuels, and waste-derived fuels, use the most appropriate method published by a consensus-based standards organization. Specific test procedures that may be required to use include ASTM 5373“Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Laboratory Samples of Coal”. If no appropriate method is published by a consensus-based standards organization, use industry standard methods, noting where such methods are used and what methods are used.

(2) For liquid fuels, use the most appropriate method published by a consensus-based standards organization. Specific test procedures that may be required to use include the following ASTM methods: For petroleum-based liquid fuels and liquid waste-derived fuels, use ASTM D5291“Standard Test Methods for Instrumental Determination of Carbon, Hydrogen, and Nitrogen in Petroleum Products and Lubricants,” ultimate analysis of oil or computations based on ASTM D3238, and either ASTM D2502“Standard Test Method for Estimation of Mean Relative Molecular Mass of Petroleum Oils From Viscosity Measurements” or ASTM D2503 “Standard Test Method for Relative Molecular Mass (Molecular Weight) of Hydrocarbons by Thermoelectric Measurement of Vapor Pressure.” If no appropriate method is published by a consensus-based standards organization, use industry standard methods, noting where such methods are used and what methods are used.

(3) For gaseous fuels, use the most appropriate method published by a consensus-based standards organization. Specific test procedures that may be required to used include use ASTM D1945 “Standard Test Method for Analysis of Natural Gas by Gas Chromatography” or ASTM D1946 “Standard Practice for Analysis of Reformed Gas by Gas Chromatography.” If no appropriate method is published by a consensus-based standards organization, use industry standard methods, noting where such methods are used and what methods are used.

(4) Use Equation 20-19 to calculate the weighted annual average carbon content of the fuel, if the measured carbon content is used to calculate CO_2 emissions.

$$(CC)_{annual} = \frac{\sum_{p=1}^{n} (CC)_p \times (Fuel)_p}{\sum_{p=1}^{n} (Fuel)_p} \qquad \textbf{Equation 20-19}$$

Where:

$(CC)_{annual}$ = Weighted annual average carbon content of the fuel (percent C by weight for solid fuel, tonne C per kilolitre for liquid fuel, or kg C per kg fuel for gaseous fuel).

$(CC)_p$ = Carbon content of the fuel, for measurement period *p* (percent C by weight for solid fuel, tonne C per kilolitre for liquid fuel, or kg C per kg fuel for gaseous fuel).

$(Fuel)_p$ = Mass or volume of the fuel combusted during measurement period *p* (express mass in tonnes for solid fuel, volume in standard cubic meters for gaseous fuel, or volume in kilolitres for liquid fuel).

n = Number of measurement periods in the years that fuel is burned in the unit.

(e) Fuel Analytical Data Capture. When the applicable emissions estimation methodologies in WCI.23 and WCI.24 require periodic collection of fuel analytical data for an emissions source, the operator shall demonstrate every reasonable effort to obtain a fuel analytical data capture rate of 100 percent for each report year.

(1) If the operator is unable to obtain fuel analytical data such that more than 20 percent of emissions from a source cannot be directly accounted for, the emissions from that source shall be considered unverifiable for the report year.

(2) If the fuel analytical data capture rate is at least 80 percent but less than 100 percent for any emissions source identified in WCI.23 and WCI.24, the operator shall use the methods in WCI.26(b) to substitute for the missing values for the period of missing data.

(f) Specific Requirements for Petroleum and Natural Gas Production and Gas Processing. For field or process gas combustion or general stationary combustion of natural gas within facilities covered by WCI.360, legislative or regulatory requirements, such as those required by the Petroleum and Natural Gas Act of British Columbia are sufficient for the points of measurement that are metered. For British Columbia, combustion sources specifically covered by the Petroleum and Natural Gas Act are to be metered, sampled and analyzed in the manner prescribed by the Act and its regulations, guidelines, and policies. Calibration for all meters used in emissions quantification (whether covered by legislative or regulatory requirements, or not) must be conducted annually, or at the minimum frequency specified by the manufacturer, if appropriate for emissions quantification. Combustion sources not specifically covered by the legislative or regulatory requirements must be measured according to the following requirements:

(1) For combustion emissions sources where meters are not required by legislation or regulation, a calculated shrinkage value is sufficient but must be assigned using engineering estimation techniques to the various sources, if required for reporting.

(2) For field, pipeline quality natural gas as defined in WCI.350, or process gas combustion emissions sources where metering is not required by law or regulation and shrinkage is not calculated, engineering estimation techniques that consolidate to common meter points such as that at the input to a processing plant used for financial purposes are sufficient. As required, fuel use must be allocated (using equipment specifications, operating hours, and flow rates) to specific emissions sources.

(3) For upstream sources, a meter is required at each installation or at a point where fuel use can be allocated to multiple combustion sources such that the aggregate of all combustion sources are metered.

All combustion estimates must be calculated in a manner that ensures that fugitive, flaring, and venting emissions as calculated under WCI.360 are uniquely reported and that no double-counting of emissions in one or more categories occurs.

Carbon content and molecular weight of the field or process gas determined annually by a facility following paragraphs (c)(1) and (d)(3) of this section for operational and regulatory purposes must be used as inputs to Equation 20-7. When this data is not available, the generic gas composition (as covered into the required format) provided in Table 360-4(or as provided by the jurisdiction) must be used by a company or operator for the specific gas field in question.

(g) Specific Requirements for Natural Gas Transmission and Distribution. Weights and Measures Act of Canada standards (or other appropriate standards if the Weights and Measures Act is not applicable) are deemed to be sufficiently rigorous for the sampling, analysis and measurement for the combustion of pipeline quality natural gas as defined in WCI.350 (including for derivation of standard gas composition) for facilities covered by WCI.350 – Natural Gas Transmission and Distribution. Calibration for all meters used in emissions quantification (whether covered by legislative or regulatory requirements, or not) must be conducted annually, or at the minimum frequency specified by the manufacturer, if appropriate for emissions quantification. If a required meter is not covered by the Weights and Measures Act, it must exist and meet the requirements of the applicable greenhouse gas reporting regulation for the jurisdiction.

§ WCI.26 Procedures for Estimating Missing Data.

Whenever a quality-assured value of a required parameter is unavailable (e.g., if a CEMS malfunctions during unit operation or if a required fuel sample is not taken), a substitute data value for the missing parameter shall be used in the calculations.

(a) For all units subject to the requirements of WCI.20 that monitor and report emissions using a CEMS, the missing data backfilling procedures in *Protocols And Performance Specifications For Continuous Monitoring Of Gaseous Emissions From Thermal Power Generation* (Report EPS 1/PG/7 (Revised) December 2005) (or by other relevant document, if superseded) shall be followed for CO_2 concentration, stack gas flow rate, fuel flow rate, high heat value, and fuel carbon content.

(b) For units that use Calculation Methodologies 1, 2, 3, or 4, perform missing data substitution as follows for each parameter:

(1) For each missing value of the high heat value, carbon content, or molecular weight of the fuel, substitute the arithmetic average of the quality-assured values of that parameter immediately preceding and immediately following the missing data incident. If the "after" value has not been obtained by the time that the GHG emissions must be calculated, you may use the "before" value for missing data substitution or the best available estimate of the parameter, based on all available process data (e.g., electrical load, steam production, operating hours). If, for a particular parameter, no quality-assured data are available prior to the missing data incident, the substitute data value shall be the first quality-assured value obtained after the missing data period.

(2) For missing records of CO_2 concentration, stack gas flow rate, moisture percentage, fuel usage, and sorbent usage, the substitute data value shall be the best available estimate of that parameter, based on all available process data (e.g., electrical load, steam production, operating hours, etc.). You must document and retain records of the procedures used for all such estimates.

§ WCI.27 Definitions

Except as specified in this section, all terms used in this subpart have the same meaning given in the General Provisions.

Consensus based standards organizations include, but are not limited to, the following: ASTM International, the American Gas Association (AGA), the American Petroleum Institute (API), the Canadian Standards Association (CSA), the Gas Processors Association (GPA), the Gas Processors Suppliers Association (GPSA) , the American National Standards Institute (ANSI), the American Society of Mechanical Engineers (ASME), the American Petroleum Institute (API), and the North American Energy Standards Board (NAESB).

Emergency generator means a stationary combustion device, such as a reciprocating internal combustion engine or turbine that serves solely as a secondary source of mechanical or electrical power whenever the primary energy supply is disrupted or discontinued during power outages or natural disasters that are beyond the control of the owner or operator of a facility. An emergency generator operates only during emergency situations, for training of personnel under simulated emergency conditions, as part of emergency demand response procedures, or for standard performance testing procedures as required by law or by the generator manufacturer. A generator that serves as a back-up power source under conditions of load shedding, peak shaving, power interruptions pursuant to an interruptible power service agreement, or scheduled facility maintenance shall not be considered an emergency generator.

Emergency equipment means any auxiliary fossil fuel-powered equipment, such as a fire pump, that is used only in emergency situations.

Portable means designed and capable of being carried or moved from one location to another. Indications of portability include but are not limited to wheels, skids, carrying handles, dolly, trailer, or platform. Equipment is not portable if any one of the following conditions exists:

(1) The equipment is attached to a foundation.

(2) The equipment or a replacement resides at the same location for more than 12 consecutive months.

(3) The equipment is located at a seasonal facility and operates during the full annual operating period of the seasonal facility, remains at the facility for at least two years, and operates at that facility for at least three months each year.

(4) The equipment is moved from one location to another in an attempt to circumvent the portable residence time requirements of this definition.

U.S. AP-42 means the Fifth Edition, Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources, U.S. EPA., as amended from time to time

§ WCI.28 Tables

Table 20-1: Default High Heat Value by Fuel Type

Liquid Fuels	**High Heat Value (GJ/kl)**
Asphalt & Road Oil	44.46
Aviation Gasoline	33.52
Diesel	38.3
Aviation Turbo Fuel	37.4
Kerosene	37.68
Propane	25.31
Ethane	17.22
Butane	28.44
Lubricants	39.16
Motor Gasoline – Off-Road	35
Light Fuel Oil	38.8
Residual Fuel Oil (No. 5 & No. 6)	42.5
Crude Oil	38.32
Naphtha	35.17
Petrochemical Feedstocks	35.17
Petroleum Coke – Refinery Use	46.35
Petroleum Coke – Upgrader Use	40.57
Ethanol (100%)	32.41
Biodiesel (100%)	35.67
Rendered Animal Fat	34.83
Vegetable Oil	33.44
Solid Fuels	**High Heat Value (GJ/tonne)**
Anthracite Coal	27.7
Bituminous Coal	26.33
Foreign Bituminous Coal	29.82
Sub-Bituminous Coal	19.15
Lignite	15
Coal Coke	28.83
Solid Wood Waste (at 0% moisture content)[3]	19.2[4]
Spent Pulping Liquor (at 0% moisture content)[3]	13.5[4]
Municipal Solid Waste	11.57
Tires	31.18
Agricultural By-products	8.6
Solid By-products	26.93
Gaseous Fuels	**High Heat Value (GJ/m^3)**
Natural Gas	0.038
Coke Oven Gas	0.01914
Still Gas – Refineries	0.03608
Still Gas – Upgraders	0.04324
Landfill Gas (methane fraction)	0.0359
Biogas (methane fraction)	0.0281

[1] The default high heat value for "propane" is only for the pure gas species. For the product commercially sold as propane, the value for liquefied petroleum gas in Table 20-1a should be used instead.

[3] HHV can be readily calculated for any moisture content as $HHV_{dry} = HHV_{wet} / (1 - percent\_moisture/100)$.

Table 20-1a—Fuels for which Calculation Methodologies 1 or 2 may be used at a facility emitting at any level.

Fuel Type	Default High Heat Value	Default CO_2 Emission Factor
Petroleum Products	**GJ/kilolitre**	**kg CO_2/GJ**
Distillate Fuel Oil No. 1	38.78	69.37
Distillate Fuel Oil No. 2	38.50	70.05
Distillate Fuel Oil No. 4	40.73	71.07
Kerosene	37.68	67.25
Liquefied Petroleum Gases (LPG)	25.66	59.65
Propane (pure, not mixtures of LPGs)[1]	25.31	59.66
Propylene	25.39	62.46
Ethane	17.22	56.68
Ethylene	27.90	63.86
Isobutane	27.06	61.48
Isobutylene	28.73	64.16
Butane	28.44	60.83
Butylene	28.73	64.15
Natural Gasoline	30.69	63.29
Motor Gasoline	34.87	65.40
Aviation Gasoline	33.52	69.87
Kerosene-type Jet Fuel	37.66	68.40

[1] The default factors for "propane" are only for the pure gas species. For the product commercially sold as propane, the values for LPG should be used instead.

Table 20-2: Default Emission Factors by Fuel Type

Liquid Fuels	CO_2 Emission Factor (kg/l)	CO_2 Emission Factor (kg/GJ)	CH_4 Emission Factor (g/l)	CH_4 Emission Factor (g/GJ)	N_2O Emission Factor (g/l)	N_2O Emission Factor (g/GJ)

Municipal Solid Waste	85.6	30	4
Peat	103	1	1.5

Source: 2006 IPCC Guidelines for National Greenhouse Gas Inventories, except the CO_2 emission factor for municipal solid waste is from the U.S. EPA from table C-1 of 40 CFR 98 subpart C.

WCI has reviewed in detail results and analysis from Clarity Works on biomass emissions factors using 2010 data collected by British Columbia through the BC Reporting Regulation. Further data collection and analysis will be needed to refine the CH_4, and N_2O emission factor for pulping liquor and hog fuel, among other fuels.

Due to the timing of the release of amendments to the EPA Subpart W rule on December 2, 2011 and the potential need for the WCI to address harmonization questions with it, further consultation on WCI.350 and potential amendments to WCI.350 are scheduled to occur in 2012.

§ WCI.350 NATURAL GAS TRANSMISSION AND DISTRIBUTION

§ WCI.351 Source Category Definition

This source category consists of the following:

(a) *Onshore natural gas transmission compression.* Onshore natural gas transmission compression means any stationary combination of compressors that move natural gas at elevated pressure from production fields or natural gas processing facilities in transmission pipelines to natural gas distribution pipelines, into storage or at times directly to industrial customers or farms located along the pipeline route. In addition, transmission compressor station may include equipment for liquids separation, natural gas dehydration, and tanks for the storage of water and hydrocarbon liquids. Residue (sales) gas compression operated by natural gas processing facilities are included in the onshore natural gas processing segment and are excluded from this segment.

(b) *Underground natural gas storage.* Underground natural gas storage means subsurface storage, including depleted gas or oil reservoirs and salt dome caverns that store natural gas that has been transferred from its original location for the primary purpose of load balancing (the process of equalizing the receipt and delivery of natural gas); natural gas underground storage processes and operations (including compression, dehydration and flow measurement, and excluding transmission pipelines); and all the wellheads connected to the compression units located at the facility that inject and recover natural gas into and from the underground reservoirs.

(c) *Liquefied natural gas (LNG) storage.* LNG storage means onshore LNG storage vessels located above ground, equipment for liquefying natural gas, compressors to capture and re-liquefy boil-off-gas, re-condensers, and vapourization units for re-gasification of the liquefied natural gas.

(d) *LNG import and export equipment.* LNG import equipment means all onshore or offshore equipment that receives imported LNG via ocean transport, stores LNG, re-gasifies LNG, and delivers re-gasified natural gas to a natural gas transmission or distribution system. LNG export equipment means all onshore or offshore equipment that receives natural gas, liquefies natural gas, stores LNG, and transfers the LNG via ocean transportation to any location, including locations in Canada.

(e) *Natural gas distribution.* Natural gas distribution consists of all natural gas equipment downstream of the station yard inlet shut-off valves of natural gas transmission pipelines at stations where pressure reduction and/or measuring first occurs for eventual delivery of natural gas to consumers. Some natural gas distribution systems receive gas from gas batteries rather than from transmission pipelines and typically transport odourized natural gas.

(f) *Natural gas transmission pipelines.* Natural gas transmission pipelines means a high pressure pipeline (and associated equipment) transporting sellable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering and/or regulating stations before delivery to customers. In some cases natural gas is delivered directly from natural gas transmission pipelines to farms and industrial end users along the pipeline route.

§ WCI.352 Greenhouse Gas Reporting Requirements

Where greenhouse gases are not emitted from a specific emission source identified in paragraphs (a) to (h) below, then the reported emissions for the specific source shall be reported as zero or "not applicable".

In addition to the information required by regulation, the annual emissions data report for both each individual facility over 10,000 tonnes, and the aggregate of facilities less than 10,000 tonnes (or as otherwise specified by regulation), must contain the following information:

(a) CO_2 and CH_4 (and N_2O, if applicable) emissions (in tonnes) from each industry segment specified in paragraph (b) through (f) of this section and from stationary and portable combustion equipment identified in paragraphs (g) and (h) of the section.

(b) For onshore natural gas transmission compression and natural gas transmission pipelines, report CO_2, CH_4 and N_2Oemissions from the following sources:

(1) Compressor venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Blowdown vent stacks . *[WCI.353(c)]*

(iv) Natural gas pneumatic continuous high-bleed devices. *[WCI.353(a)]*

(v) Natural gas pneumatic pumps. *[WCI.353(a.1)]*

(vi) Natural gas pneumatic continuous low-bleed device venting. *[WCI.353(b)]*

(vii) Natural gas pneumatic intermittent (low and high) bleed device (including compressor starters) venting. *[WCI.353(b.1])*

(viii) Other venting emission sources.* *[WCI.353(l)]*

(2) Compressor fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves and meters. *[WCI.353(g)] or [WCI.353(h)}, size dependent*

(3) Compressor station flaring. *[WCI.353(d)]*

(4) Compressor other fugitive emission sources.**[WCI.353(l)]*

(5) Above grade meters and regulators and associated equipment at custody transfer meter-regulating stations, including fugitive equipment leaks from connectors, block valves, control valves, pressure relief valves, orifice meters, regulators, and open ended lines. *[WCI.353(g)]*

(6) Above grade meters and regulators and associated equipment at non-custody transfer meter-regulating stations, including station equipment leaks. *[WCI.353(h)]*

(7) Pipeline flaring. *[WCI.353(d)]*

(8) Pipeline belowground meters and regulators and valve fugitives. *[WCI.353(h)]*

(9) Pipeline other fugitive emission sources not covered in (b)(5), (b)(6), (b)(7), (b)(8) or (b0(12) (including, but not limited to, farm taps <=700 kPa, pipe leaks, and customer meter sets).*, ** *[WCI.353(l)]*

(10) Pipeline other venting emission sources.**[WCI.353(l)]*

(11) Transmission storage tanks. *[WCI.353(m)]*

(12) Third party line hits. *[WCI.353(c.1)]*

(c) For underground natural gas storage, report CO_2, CH_4 and N_2O emissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Natural gas pneumatic continuous high-bleed devices. *[WCI.353(a)]*

(iv) Natural gas pneumatic pumps. *[WCI.353(a.1)]*

(v) Natural gas pneumatic continuous low-bleed device venting. *[WCI.353(b)]*

(vi) Natural gas pneumatic intermittent (low and high) bleed device (including compressor starters) venting. *[WCI.353(b.1])*

(vii) Other venting emission sources.* *[WCI.353(l)]*

(2) Fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves and meters. *[WCI.353(g)], [WCI.353(h)]*

(3) Flares. *[WCI.353(d)]*

(4) Other fugitive emission sources.* *[WCI.353(l)]*

(d) For LNG storage, report CO_2, CH_4 and N_2Oemissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Other venting emission sources.* *[WCI.353(l)]*

(2) Fugitive equipment leaks from valves, pump seals, connectors, vapour recovery compressors, and other equipment leak sources. *[WCI.353(g)], [WCI.353(h)]*

(3) Flares. *[WCI.353(d)]*

(4) Other fugitive emission sources.* *[WCI.353(l)]*

(e) LNG import and export equipment, report CO_2, CH_4 and N_2Oemissions from the following sources:

(1) Venting (from the following sources):

(i) Reciprocating compressors. *[WCI.353(f)]*

(ii) Centrifugal compressors. *[WCI.353(e)]*

(iii) Blowdown vent stacks (including third party line hits). *[WCI.353(c)]*

(iv) Other venting emission sources.* *[WCI.353(l)]*

(2) Fugitive equipment leaks from valves, pump seals, connectors, vapour recovery compressors, and other equipment leak sources. *[WCI.353(g)], [WCI.353(h)]*

(3) Flares. *[WCI.353(d)]*

(4) Other fugitive emission sources.**[WCI.353(l)]*

(f) For natural gas distribution, report CO_2, CH_4 and N_2O emissions from the following sources:

(1) Meters, regulators, and associated equipment at above grade custody transfer metering-regulating stations, including fugitive equipment leaks from connectors, block valves, control valves, pressure relief valves, orifice meters, regulators, and open- ended lines. *[WCI.353(g)]*

(2) Meters, regulators, and associated equipment at above grade non custody transfer metering-regulating stations, including fugitive equipment leaks from connectors, block valves, control valves, pressure relief valves, orifice meters, regulators, and open- ended lines. *[WCI.353(h)]*

(3) Equipment leaks from vaults at below grade metering-regulating stations. *[WCI.353(h)]*

(4) Meters, regulators, and associated equipment at above grade metering-regulating stations. *[WCI.353(h)]*

(5) Equipment leaks from vaults at below grade metering-regulating stations *[WCI.353(h)]*

(6) Pipeline main fugitive equipment leaks. *[WCI.353(h)]*

(7) Service line fugitive equipment leaks. *[WCI.353(h)]*

(8) Pipeline flaring. *[WCI.353(d)]*

(9) Flares. *[WCI.353(d)]*

(10) Third party line hits *[WCI.353(c.1)]*

(11) Other fugitive emission sources (including, but not limited to, farm taps, and customer meter sets).*, ** *[WCI.353(l)]*

(12) Venting (from the following sources):

(i) Natural gas pneumatic continuous high-bleed devices. *[WCI.353(a)]*

(ii) Natural gas pneumatic pumps. *[WCI.353(a.1)]*

(iii) Natural gas pneumatic continuous low-bleed device venting. *[WCI.353(b)]*

(iv) Natural gas pneumatic intermittent (low and high) bleed device (including compressor starters) venting. *[WCI.353(b.1]*

(v) Other venting emission sources.* *[WCI.353(l)]*

(g) Report CO_2, CH_4, and N_2O emissions from each stationary fuel combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report stationary combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods. The reference to process vent gas is not intended to include vent gas that is sellable quality natural gas.

(h) Report CO_2, CH_4, and N_2O emissions from each portable equipment combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report portable equipment combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods. . The reference to process vent gas is not intended to include vent gas that is sellable quality natural gas.

(i) Report data for each aggregated source type within paragraph (b) through (f) of this section as follows (for each individual facility or aggregate of facilities reported, as required by regulation):

(1) Where there is a choice of quantification method used for a source, the specific method(s) used and under what circumstances.

(2) Facility- and company-specific emission factors or emissions information, as appropriate, used in place of Tables 350-1 to 350-5.

(3) Count of natural gas pneumatic continuous high-bleed devices.

(4) Count of natural gas pneumatic continuous low-bleed devices.

(5) Count of natural gas pneumatic intermittent (low and high) bleed devices.

(6) Count of natural gas-driven pneumatic pumps.

(7) Count of third party line hits
   (i) Engineering distribution of number of line hits by volume of gas released by hit

(8) Total pipeline length.

(9) For each dehydrator unit report the following:
   (i) Glycol dehydrators:
      (A) The number of glycol dehydrators less than and greater than or equal to 11,328 Sm^3/day operated
   (ii) Desiccant dehydrators:
      (A) The number of desiccant dehydrators operated.

(10) For each compressor report the following:
   (i) Type of compressor whether reciprocating, centrifugal dry seal, or centrifugal wet seal.
   (ii) Compressor driver capacity in horsepower.
   (iii) Number of blowdowns per year.
   (iv) Operating mode(s) during the year (i.e., operating, not operating and pressurized or not operating and depressurized).
   (v) Number of compressor starts per year.

(11) For fugitive equipment leaks and population-count/emission-factor sources, using emission factors for estimating emissions in WCI.353(g) and (h), report the following:
   (i) Component count for each source type for which an emission factor is provided in Tables 350-1, 350-2 or 350-3, 350-4 or 350-5 in this document. Approximate counts may be used for provided for the 2011 and 2012 calendar years (reported in 2012 and 2013) in preparation for full component counts in the 2013 calendar year (reported in 2014). Current processing and instrumentation drawings (P&ID) may be used for the source of component counts for all years.
   (ii) Total counts of leaks found in leak detection surveys by type of leak source for which an emission factor is provided.

(12) For natural gas distribution, report the following, in addition to other requirements:
   (i) The number of custody transfer meter-regulating stations.
   (ii) The number of non-custody transfer meter-regulating stations.

(13) Identification (including geographic coordinates) of any facility that was above 1,000 tonnes of greenhouse gas emissions in the previous year that was:
   (i) Acquired during the reporting year;
   (ii) Sold, decommissioned, or shut-in during the reporting year;

and,
(iii) The greenhouse gas emissions for the facility in the previous year.
(iv) The purchaser or seller, as appropriate

** other venting emission or other fugitive sources not specificially listed are not required to be reported if a specific other venting or other fugitive source type is reasonably estimated to be below 0.5% of total operation emissions and total emissions not reported under this clause do not exceed 1% of total operation emissions (if an individual facility is part of a larger reporting operation, the 0.5% or 1% should be interpreted as 0.5% or 1% of the reporting operation emissions, otherwise interpret as 0.5% or 1% of the facility emissions). The applicable regulator may, upon request and provision of sufficient information, provide a list of sources believed to be below these thresholds for all operations for which reporting and verification would not be required.*

*** tubing systems less than one half inch diameter may be quantified using WCI.353(g) instead of WCI.353(h) if a leak detection survey captures them. If not covered by a leak detection survey, they must be quantified using WCI.353(h). Reporting must occur using the appropriate section of WCI.352, dependent upon industry segment and quantification method used.*

§ WCI.353 Calculation of Greenhouse Gas Emissions

If greenhouse gases are not emitted from one or more of the following emission sources, the reporter will not need to calculate emissions from the emission source(s) in question and reported emissions for the emission source(s) will be zero or "not applicable". Where a quantification method is not provided for a specific source (such as for other venting and other fugitive sources), industry inventory practices must be used to estimate emissions. For ambient conditions, reporters must use average atmospheric conditions or typical operating conditions as applicable to the respective monitoring methods in this section. In general, equations are presented at the most basic unit level and emissions must be summed, so that the total population of devices and/or events are included for the reporting facility or organization, as required by regulation. Nomenclature used in the equations is presented in Table 350-7.

(a) <u>Natural gas pneumatic continuous high-bleed device venting</u> Calculate emissions from a natural gas pneumatic continuous high-bleed flow control device venting using the method specified in paragraph (a)(1) below when the device is metered. By the start of the 2014 reporting year (January 1, 2014), natural gas consumption must be metered for 50 % of the operator's pneumatic high-bleed devices (the 50% calculation of metered devices may include devices that were operational on January 1, 2012 that are no longer operational as of January 1, 2014 due to phase out or not-operating). By the start of the 2015 reporting year (January 1, 2015), natural gas consumption must be metered for all of the operator's pneumatic high-bleed devices. If a transmission or distribution company has less than 25 high bleed pneumatic devices in a jurisdiction, then the method in paragraph (a)(2) may be used for all years. For the purposes of this reporting requirement, high-bleed devices are defined as all natural gas powered devices which continuously bleed at a rate greater than 0.17 m^3/hr. For unmetered devices the operator must use the method specified in paragraph (a)(2).

(1) The operator must calculate vented emissions for metered pneumatic high-bleed devices using the following equation:

$$E_s = Q_j$$

Equation 350-1

Where:

E_s	=	Annual natural gas volumetric emissions for pneumatic high-bleed devices where gas is metered (Sm^3/y).
Q_j	=	Natural gas consumption for meter *j* (Sm^3/y).

(2) The operator must calculate vented emissions for unmetered pneumatic high-bleed devices using the following equation:

$$E_s = EF_j \times t_j$$

Equation 350-2

Where:

E_s	=	Annual natural gas volumetric emissions for pneumatic high-bleed devices where gas is unmetered (Sm^3/y).
EF_j	=	Natural gas-driven pneumatic device, j, bleed rate volume as provided by the manufacturer or in Table 350-6 (Sm^3/h/device).
t_j	=	Total time that the pneumatic device, j, has been in service (i.e. the time that the gas flows to the device) through the reporting period (h).

(3) If manufacturer data for a specific device is not available, then use data for a similar device model, size and operational characteristics to estimate emissions. If data for a reasonably similar pump model size and operational characteristics cannot be obtained, use the factor in Table 350-1 for high-bleed pneumatic devices.

(4) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section

(5) Provide the total number of continuous high-bleed natural gas pneumatic devices as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates can be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining devices.

(ii) In 2013, all continuous high-bleed natural gas pneumatic devices must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of continuous high-bleed pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

(a.1) Natural gas pneumatic pump venting. Calculate emissions from natural gas-driven pneumatic pump venting using the method specified in paragraph (a)(1) above when the pump is metered. By the start of the 2014 reporting year (January 1, 2014), natural gas consumption must be metered for 50 % of the operator's pneumatic pumps (the 50% calculation of metered devices may include devices that were operational on January 1, 2012 that are no longer operational as of January 1, 2014 due to phase out or not-operating). By the start of the 2015 reporting year (January 1, 2015), natural gas consumption must be metered for all of the operator's pneumatic pumps. For unmetered pumps the operator must use the methods preferentially specified in paragraph (a.1)(2). If a transmission or distribution company has less than 25 pneumatic pumps in a jurisdiction, then the method in paragraph (a.1)(2) may be used for all years Natural gas-driven pneumatic pumps covered in paragraph (d) (dehydrator vents) of this section do not have to report emissions under paragraph (a.1) of this section.

(1) The operator must calculate vented emissions for metered pneumatic pumps using Equation 350-1.

(2) The operator must calculate vented emissions for unmetered pneumatic pumps using Equation 350-3.

(i) Obtain from the manufacturer specific pump model natural gas emission (or manufacturer "gas consumption") per unit volume of liquid circulation rate at pump speeds and operating pressures. If manufacturer data for a specific pump is not available, then use data for a similar pump model, size and operational characteristics to estimate emissions.

(ii) Maintain a log of the amount of liquid pumped annually from individual pumps*.

(iii) Calculate the natural gas emissions for each pump using Equation 350-3.

$$E_s = EF_j \times Q_j$$

Equation 350-3

Where:

E_s = Annual natural gas volumetric emissions (Sm^3/y).

EF_j = Natural gas-driven pneumatic pump gas emission factor expressed in "emission per volume of liquid pumped at operating pressure" as provided by the manufacturer for pump *j* ($Sm^3/liter$).

Q_j = Volume of liquid pumped annually by pump *j* (liters/y).

(3) If manufacturer data for a specific pump, or reasonably similar pump model size and operational characteristics cannot be obtained; Equation 350-2 can be used with the

population emission factor for natural gas-driven pneumatic pumps provided in Tables 350-1 or 350-2.

(4) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section

(5) Provide the total number of natural gas pneumatic pumps as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates can be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining pumps.

(ii) In 2013, all natural gas pneumatic pumps must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of pneumatic pumps and adjust accordingly to reflect any modifications due to changes in equipment.

** an engineering estimation approach may be used in 2012 to calculate the amount of liquid pumped annually from natural gas driven odourant injection pumps used in the distribution system, either in individual or in bulk*

(b) Natural gas pneumatic continuous low-bleed device venting. Calculate emissions from natural gas pneumatic continuous low-bleed device venting using Equation 350-4 of this section.

$$E_s = EF_j \times t_j$$

Equation 350-4

Where:

E_s	=	Annual natural gas volumetric emissions for pneumatic continuous low-bleed bleed devices (Sm^3/y).
EF_j	=	Population emission factor for natural gas-driven pneumatic continuous low-bleed device, *j*, as provided in Tables 350-1 and 350-2 ($Sm^3/h/device$).
t_j	=	Total time that the pneumatic device, *j*, has been in service (i.e. the time that the gas flows to the device) through the reporting period (h).

(1) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section.

(2) Provide the total number of continuous low-bleed natural gas pneumatic devices of each type as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates can be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining devices.

(ii) In 2013, all continuous low-bleed natural gas pneumatic devices must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of continuous low-bleed natural gas pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

(b.1) Natural gas pneumatic intermittent (low and high) bleed device venting. Calculate emissions from natural gas pneumatic intermittent (low and high) bleed device venting as follows.

(1) The operator must calculate vented emissions for pneumatic intermittent (low and high) bleed devices used to maintain a process condition such as liquid level, pressure, delta-pressure or temperature using Equation 350-5:

$$E_s = EF_j \times t_j$$

Equation 350-5

Where:

E_s	=	Annual natural gas volumetric emissions for pneumatic intermittent (low and high) bleed devices (Sm^3/y).
EF_j	=	Emission factor for natural gas-driven pneumatic intermittent (low and high) bleed device, *j*, as provided in Table 350-1 or Table 350-6 (Sm^3/h/device).
t_j	=	Total time that the pneumatic device, *j*, has been in service (i.e. the time that the gas flows to the device) through the reporting period (h).

(2) The operator must calculate vented emissions for pneumatic intermittent (high) bleed devices, used to drive compressor starters, using Equation 350-6*:

$$E_s = EF_j \times t_j$$

Equation 350-6

Where:

E_s	=	Annual natural gas volumetric emissions for pneumatic intermittent (high) bleed devices (Sm^3/y).
EF_j	=	Emission factor for natural gas-driven pneumatic compressor starter, *j*, as provided by the manufacturer (Sm^3/min/device).
t_j	=	Total time that the pneumatic device, *j*, has been in service (i.e. the time that the gas flows to the device) through the reporting period (min).

(3) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section.

(4) Provide the total number of intermittent (low and high) bleed natural gas pneumatic devices as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining devices.

(ii) In 2013, all intermittent (low and high) bleed natural gas pneumatic devices must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of intermittent (low and high) bleed natural gas pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

** for 2012, the volume of gas per start provided by the manufacturer may be used in place of the EF_j and t_j variables*

(c) <u>Blowdown vent stacks</u>. Calculate blowdown vent stack emissions from depressurizing equipment to reduce system pressure for planned or emergency shutdowns or to take equipment out of service for maintenance (excluding depressurizing to a flare, over-pressure relief, operating pressure control venting and blowdown of non-GHG gases) as follows:

(1) Calculate the total physical volume (including, but not limited to, pipes, compressor case or cylinders, manifolds, suction and discharge bottles and vessels) between isolation valves determined by engineering estimates based on best available data.

(2) If the total physical volume between isolation valves is greater than or equal to 1.42 $m^{3,}$ retain logs of the number of blowdowns for each equipment system (including, but not limited to pipes, compressors and vessels). Physical volumes smaller than 1.42 $m^3$are exempt from reporting under paragraph (c) of this section

(3) Calculate the venting emissions for each equipment system j using Equation 350-7 of this section:

$$E_s = V_v\left[\frac{(273.15+T_s)(P_{a,1}-P_{a,2})}{(273.15+T_a)P_s}\right]$$

Equation 350-7

Where:

E_s = Natural gas venting volumetric emissions from blowdown of equipment system (Sm^3).

V_j = Total physical volume of blowdown equipment chambers (including, but not limited to, pipes, compressors and vessels) between isolation valves for the equipment system (m^3).

T_s = Temperature at standard conditions (ºC).

T_a = Temperature at actual conditions in the equipment system (^oC).

P_s = Absolute pressure at standard conditions (kPaa).

$P_{a,1}$ = Absolute pressure at actual conditions in the equipment system (kPaa) prior to depressurization.

$P_{a,2}$ = Absolute pressure at actual conditions in the equipment system after depressurization; 0 if equipment is purged using non-GHG gases (kPaa).

(4) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (j) and (k) of this section.

(5) Blowdowns that are directed to flares use the WCI.353(d) Flare stacks calculation method rather than WCI.353(c) Blowdown vent stacks calculation method.

(c.1) Third party line hits. Calculate emissions from third party line hits as follows:

(1) For each dig-in incident (i.e., line hit) which results in gas release ≥ 1.416 Sm^3, calculate volumetric flow rate prior to pipeline isolation for both catastrophic pipeline ruptures and pipeline puncture incidents using the appropriate methodology below[1]. For 2012, the methodology referenced in paragraph (iv) may be used in addition to those in paragraphs (i) and (ii).

(i) For catastrophic pipeline ruptures where the pipeline is severed use the following methodology:

$$Q_s = \frac{3.6x10^6 \times A}{\rho_s} \sqrt{\frac{K \times MW}{1000 \times R \times (273.15 + T_a)}} \times \frac{P_a \times M}{\left(1 + \frac{K-1}{2} M^2\right)^{\frac{K+1}{2(K-1)}}}$$

Equation 350-8

Where:

[1] Methodology Manual, Estimation of Air Emissions from the Canadian Natural Gas Transmission, Storage and Distribution System, Prepared for Canadian Energy Partnership for Environmental Innovation (CEPEI). Prepared by Clearstone Engineering Ltd. Calgary, Alberta, September 25, 2007. Chapter7, Third-Party Dig-Ins, page 117.

$$M = \sqrt{\frac{2\left[\left(\frac{P_a}{P_e}\right)^{\frac{K-1}{K}} - 1\right]}{K-1}} \text{, (for M} \leq 1\text{),}$$

Equation 350-9

M = 1, (for all other cases)

Where:

Q_s	=	natural gas venting volumetric flow rate (Sm^3/h)
A	=	cross-sectional flow area of the pipe (m^2, $A=\pi D^2/4000$)
D	=	inside diameter of the pipe (mm)
K	=	specific heat ratio of the gas (dimensionless – 1.299 for methane)
M	=	Mach number of the flow (m/s)
MW	=	molecular weight of the gas (kg/mole, 16.043 kg/mole for methane)
P_e	=	pressure at the damage point (local atmospheric pressure, kPaa)
P_a	=	pressure inside the pipe at supply (kPaa)) (usually taken at the point where the damaged main branches off a larger main). The supply pressure values should represent a stable supply pressure; however, it is important to account for the lower pressure which will occur because of the flow of gas from the break.
R	=	universal gas constant (8.3145 $kPam^3/kmol/K$)
T_a	=	temperature inside pipe at the supply (˚C)
ρ_s	=	gas density at standard conditions (kg/m^3) (0.6785 kg/m^3 for CH_4)

(ii) For pipeline punctures use the following methodology (for flows not choked):

$$Q_s = \frac{A_e}{\rho_s}\sqrt{\frac{2000 \cdot K}{K-1} P_a \rho_a \left[\left(\frac{P_{Atm}}{P_a}\right)^{2/K} - \left(\frac{P_{Atm}}{P_a}\right)^{(K+1)/K}\right]}$$

Equation 350-10

Where:

$$\left(\frac{P_{Atm}}{P_a}\right) \geq \left(\frac{P_{Atm}}{P_a}\right)_{choked} = \left(\frac{2}{K+1}\right)^{K/(K-1)} = 0.546 \qquad \text{(for methane)}$$

Equation 350-11

Where:

A_e	=	size of the hole in the pipe (m^2)
P_a	=	pressure inside the pipe at the puncture location (kPaa)
ρ_a	=	gas density inside the pipe at the puncture location (kg/m^3)
MW	=	molecular weight of the natural gas (16.043 for methane)
T_a	=	temperature inside the pipe (˚C)
$(P_{ATM}/P_a)_c$	=	0.546 - lower limit for choked flow

(iii) Check for choked flow

(A) If (P_{ATM}/P_a) is ≥0.546 flow is not choked and the reporter must use the equations in section (c.1)(ii) above.

(B) If (P_{ATM}/P_a) <0.546 flow is choked and A must be set to the cross sectional flow area of the pipe and the reporter must use the equations in section (c.1)(i) above.

(iv) For 2012 calendar year emissions, an operator may use other methods to calculate emissions published in the CEPEI Methodology Manual, or other industry standard reference sources.

(v) Calculate volumetric natural gas emissions by multiplying Q_s for each pipeline rupture and puncture by the total elapsed time from pipeline rupture or puncture until isolation and final bleed-down to atmospheric pressure.

(vi) Calculate GHG (CH_4 and CO_2 emissions) mass emissions using the methodologies in sections (j) and (j) of this section.

(d) Flare stacks. Calculate CO_2, CH_4, and N_2O emissions from a flare stack as follows:

(1) If there is a continuous flow measurement device on the flare, measured flow volumes can be used to calculate the flare gas emissions. If all of the flare gas is not measured by the existing flow measurement device, then the flow not measured can be estimated using engineering calculations based on best available data or company records. If there is not a continuous flow measurement device on the flare, a flow measuring device can be installed on the flare or use engineering calculations based on process knowledge, company records, and best available data.

(2) If there is a continuous gas composition analyzer on the gas stream to the flare, these compositions must be used in calculating emissions. If there is not a continuous gas composition analyzer on the gas stream to the flare, use the gas compositions for each stream of hydrocarbons going to the flare (must be determined using (j)(1) and (j)(2) of this section).

(3) Determine flare combustion efficiency from manufacturer. If not available, assume that flare combustion efficiency is 98 percent.

(4) Calculate GHG volumetric emissions at actual conditions using Equations 350-12, 350-13, 350-14, and 350-15 of this section.

$$E_{s,CH4}(noncombusted) = Q_s \times (1-\eta) \times Y_{CH4}$$ **Equation 350-12**

$$E_{s,CO2}(noncombusted) = Q_s \times Y_{CO2}$$ **Equation 350-13**

$$E_{s,CO2}(combusted) = \sum_i \eta \times Q_s \times Y_i \times n_i$$ **Equation 350-14**

$$E_{s,CO2}(total) = E_{s,CO2}(combusted) + E_{s,CO2}(noncombusted)$$ **Equation 350-15**

Where:

$E_{s,CH4}$ (noncombusted)	=	Contribution of annual noncombusted volumetric CH_4 emissions from flare stack (Sm^3).
$E_{s,CO2}$ (noncombusted)	=	Contribution of annual volumetric CO_2 emissions from CO_2 in the inlet gas passing through the flare noncombusted (Sm^3).
$E_{s,CO2}$ (combusted)	=	Contribution of annual volumetric CO_2 emissions from combustion from flare stack (Sm^3).
Q_s	=	Volume of natural gas sent to flare during the year (Sm^3).
η	=	Fraction of natural gas combusted by flare (default combustion efficiency is 0.98). For gas sent to an unlit flare, η is zero.
Y_{CH4}	=	Mole fraction of CH_4 in gas to the flare.
Y_{CO2}	=	Mole fraction of CO_2 in gas to the flare.
Y_i	=	Mole fraction of hydrocarbon constituents *i* (i.e., methane, ethane, propane, butane, pentanes, hexanes and pentanes plus) in natural gas to the flare.
n_i	=	Number of carbon atoms in the hydrocarbon constituent *i*; 1 for methane, 2 for ethane, 3 for propane, 4 for butane, 5 for pentanes, 6 for hexanes and 7 for pentanes plus) in natural gas to the flare.

(5) Calculate both CH_4 and CO_2 mass emissions from volumetric CH_4 and CO_2 emissions using the calculation in paragraph (k) of this section.

(6) Calculate N_2O emissions using Equation 350-16.

$$E_{N2O} = Q_s \times HHV \times EF \times 0.001$$

Equation 350-16

Where:

E_{N2O}	=	Annual N_2O mass emissions from flaring (tonnes/y).
Q_s	=	Volume of gas combusted by the flare in the reporting period (Sm^3/y).
HHV	=	High heat value of the flared gas from paragraph (d)(2)
EF	=	N_2O emission factor. Use 9.52×10^{-5} kg N_2O/GJ.
0.001	=	Conversion factor from kilograms to tonnes.

(7) To avoid double-counting, this emissions source excludes any emissions calculated under other emissions sources in this section. Where gas to be flared is manifolded from multiple sources in WCI.353 to a common flare, report all flaring emissions under WCI.353(d).

(e) Centrifugal compressor venting. Calculate emissions from centrifugal compressor vents as follows.

(1) The operator must calculate CO_2, and CH_4, and N_2O (when flared) emissions from both wet seal and dry seal centrifugal compressor vents (including wet seal oil degasing) for all compressors using a temporary or permanent flow measurement meter such as, but not limited to, a vane anemometer according to methods set forth in WCI.354(b).

(2) Estimate annual emissions using flow meter measurement using Equation 350-17 of this section.

$$E_{s,i} = \sum_{m} Q_{s,m} \times t_m \times Y_{i,m} \times (1 - CF)$$

Equation 350-17

Where:

$E_{s,i}$ = Annual GHG *i* (either CH_4 or CO_2) volumetric emissions from all measured compressor venting modes(Sm^3).

$Q_{s,m}$ = Measured volumetric gas emissions during operating mode *m* described in paragraph (e)(4) of this section (Sm^3/h).

t_m = Total time the compressor is in operating mode *m* during the calendar year (h)

Y_i = Mole fraction of GHG *i* in the degassing vent gas; use the appropriate gas compositions in paragraph (j)(2) of this section.

CF = Fraction of centrifugal compressor vent gas sent to vapour recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapour recovery system and the amount of vent gas that is directed to the fuel gas system. An engineering estimation approach may be used for the CF parameter for 2012 emissions reporting.

(3) An engineering estimate approach based on similar equipment specifications and operating conditions may be used to determine the $Q_{s,m}$ variable in place of actual measured values for centrifugal compressors that are operated for no more than 200 hours in a calendar year and used for peaking purposes in place of metered gas emissions if an applicable meter is not present on the compressor.

(4) Conduct an annual measurement for each compressor in the mode in which it is found during the annual measurement. Measure emissions from (including emissions manifolded to common vents) unit isolation-valve vents and blowdown-valve vents.

(i) Operating or standby-pressurized mode, blowdown vent leakage through the blowdown vent stack.

(ii) Operating mode.

(iii) Not operating, depressurized mode, unit isolation-valve leakage through the blowdown vent stack, without blind flanges.

(A) For the not operating, depressurized mode, each compressor must be measured at least once in any three consecutive calendar years if this mode is not found in the annual measurement. If a compressor is not operated and has blind flanges in place throughout the 3 year period, measurement is not required in this mode. If the compressor is in standby depressurized mode without blind flanges in place and is not operated throughout the 3 year period, it must be measured in the standby depressurized mode.

(5) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (k) of this section.

(6) Calculate emissions from degassing vent vapours to flares as follows:

(i) Use the degassing vent vapour volume and gas composition as determined in paragraphs (e)(1) through (3) of this section.

(ii) Use the calculation methodology of flare stacks in paragraph (d) of this section to determine degassing vent vapour emissions from the flare.

(7) Emissions from dry seal centrifugal compressor vents, blow down valve leakage and unit isolation valve leakage to open ended vented lines must use methods outlined in EPA Subpart W 98.233(o)

(f) Reciprocating compressor venting. Calculate annual CH_4 and CO_2 emissions from all reciprocating compressor vents as follows. Where venting emissions are sent to a common flare, calculate emissions using WCI.353(d).

(1) Estimate annual emissions using the flow measurement in (f)(2) or (f)(3) below and Equation 350-18.

$$E_{s,i} = \sum_{m} Q_{s,m} \times t_m \times Y_i \times (1 - CF)$$

Equation 350-18

Where:

$E_{s,i}$ = Annual volumetric emissions of GHG *i* (either CH_4 or CO_2)from all measured compressor venting modes (Sm^3/y).

$Q_{s,m}$ = Measured volumetric gas emissions during operating mode *m* described in paragraph (f)(4) (Sm^3/h)..

t_m = Total time the compressor is in operating mode *m* during the calendar year (h).

Y_i = Mole fraction of GHG *i* in the vent gas; use the appropriate gas compositions in paragraph (j)(2) of this section.

CF = Fraction of reciprocating compressor vent gas sent to vapour recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapour recovery system and the amount of vent gas that is directed to the fuel gas system. An engineering estimation approach may be used for the CF parameter for 2012 emissions reporting.

(2) If the reciprocating rod packing and blowdown vent is connected to an open-ended vent line then use one of the following two methods to calculate emissions.

(i) Measure emissions from all vents (including emissions manifolded to common vents) including rod packing, unit isolation valves, and blowdown vents using either calibrated bagging or High-flow Sampler according to methods set forth in WCI.354(c) and (d).

(ii) Use a temporary meter such as a vane anemometer or a permanent meter such as an orifice meter to measure emissions from all vents (including emissions manifolded to a common vent) including rod packing vents, unit isolation valves, and blowdown valves according to methods set forth in WCI.354(b). If you do not have a permanent flow meter, you may install a port for insertion of a temporary meter or a permanent flow meter on the vents. For through-valve leakage to open-ended vents, such as unit isolation valves on not-operating, depressurized compressors and blowdown valves on pressurized compressors, you may use an acoustic detection device according to methods set forth in WCI.354(a).

(3) If the rod packing case is not equipped with a vent line use the following method to estimate emissions:

(i) Use the methods described in WCI.354(a) to conduct a progressive leak detection of fugitive equipment leaks from the packing case into an open distance piece, or from the compressor crank case breather cap or vent with a closed distance piece.

(ii) Measure emissions using a High-flow Sampler, or calibrated bag, or appropriate meter according to methods set forth in WCI.354(b), (c), or (d).

(4) Conduct an annual measurement for each compressor in the mode in which it is found during the annual measurement. Measure emissions from (including emissions manifolded to common vents) reciprocating rod-packing vents, unit isolation-valve vents, and blowdown-valve vents.

(i) Operating or standby-pressurized mode, blowdown vent leakage through the blowdown vent stack.

(ii) Operating mode, reciprocating rod-packing emissions.

(iii) Not operating, depressurized mode, unit isolation-valve leakage through the blowdown vent stack, without blind flanges.

(A) For the not operating, depressurized mode, each compressor must be measured at least once in any three consecutive calendar years if this mode is not found in the annual measurement. If a compressor is not operated and has blind flanges in place throughout the 3 year period, measurement is not required in this mode. If the compressor is in standby depressurized mode without blind flanges in place and is not operated throughout the 3 year period, it must be measured in the standby depressurized mode

(5) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in paragraphs (j) and (k) of this section.

(6) Determine if the reciprocating compressor vent vapors are sent to a vapor recovery system.

(i) Adjust the emissions estimated in paragraphs (f)(1) of this section downward by the magnitude of emissions recovered using a vapor recovery system as determined by engineering estimate based on best available data.

(ii) An engineering estimate approach based on similar equipment specifications and operating conditions or manufacturer's data may be used to determine the $Q_{s,m}$ variable in place of actual measured values for reciprocating compressors that are are operated for no more than 200 hours in a calendar year .

(g) Leak detection and leaker emission factors. Existing legislative or regulatory requirements (described in WCI.354(a)(0.1)) or progressive sampling methods (described in WCI.354(a)(0.2)) must be used to conduct a leak detection survey of fugitive equipment leaks from all sources listed in WCI.352(b)(2) (where total emissions for a compressor station are 10,000 tonnes CO_2e or greater), (b)(5), (c)(2), (d)(2), (e)(2), and (f)(1). This paragraph (g) applies to emissions sources in streams with gas containing greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas containing less than 10 percent CH_4 plus CO_2 by weight need to be reported instead under paragraph (l) of this section. **

If fugitive equipment leaks are detected for sources listed in this paragraph, calculate equipment leak emissions per source per reporting facility using Equation 350-19 (for volumetric emission factor [Sm^3/h/component]) or Equation 350-20 (for mass emission factors [t/h/component]) of this section, as appropriate, for each source with fugitive equipment leaks.

$$E_i = EF_s \times Y_i \times t \times \rho_{s,i} \times 0.001$$

Equation 350-19

$$E_{s,i} = EF_s \times Y_i \times t$$

Equation 350-20

Where:

$E_{s,i}$	=	Annual total mass emissions of GHG *i* (CH_4 or CO_2) from each fugitive equipment leak source (tonnes/year).
EF_s	=	Leaker emission factor for specific sources listed in Table 350-1 through Table 350-5 of this section or facility/company-specific emission factors* used in place of Tables 350-1 to 350-5 (Sm^3/component/year for Equation 350-19 and tonnes/ component/year for Equation 350-20).
Y_i	=	For volumetric emissions in Equation 350-19, use 1 for CH_4 and 1.1×10^{-2} for CO_2. For mass emissions in Equation 350-20, use mass fractions of CH_4 and CO_2 from each unit of a distribution or transmission company within a

		jurisdiction that has similar gas composition or the 2007 Canadian Energy Partnership for Environmental Innovation (CEPEI) Methodology Manual.[2]
t	=	Total time the component was found leaking and operational, in hours. If one leak detection survey is conducted, assume the component was leaking from the start of the year until the leak was repaired and then zero for the remainder of the year. If the leak was not repaired, assume the component was leaking for the entire year. If multiple leak detection surveys are conducted, assume that the component found to be leaking has been leaking since the last survey during which it was determined to be not leaking, or the beginning of the calendar year. For the last leak detection survey in the calendar year, assume that all leaking components continue to leak until the end of the calendar year or until the component was repaired and then zero until the end of the year.
$\rho_{s,i}$	=	Density of GHG *i* (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at standard conditions of 15 ºC and 1 atmosphere).
0.001	=	Conversion factor from kilograms to tonnes.

(1) Onshore natural gas transmission compression facilities shall use the appropriate default leaker emission factors listed in Table 350-1 of this section for fugitive equipment leaks detected from connectors, valves, pressure relief valves, meters, and open ended lines.

(2) Underground natural gas storage facilities for storage stations shall use the appropriate default leaker emission factors listed in Table 350-2 of this section for fugitive equipment leaks detected from connectors, valves, pressure relief valves, meters, and open-ended lines.

(3) LNG storage facilities shall use the appropriate default leaker emission factors listed in Table 350-3 of this section for fugitive equipment leaks detected from valves, pump seals, connectors, and other equipment.

(4) LNG import and export facilities shall use the appropriate default leaker emission factors listed in Table 350-4 of this section for fugitive equipment leaks detected from valves; pump seals; connectors; and other.

(5) Natural gas distribution facilities for above ground meters and regulators at custody transfer meter-regulating stations shall use the appropriate default leaker emission factors listed in Table 350-5 of this section for fugitive equipment leaks detected from connectors, block valves, control valves, pressure relief valves, orifice meters, regulators, and open ended lines.

** component-specific emission factors may equal leak rates quantified, following WCI.354(c) or (d), during leak detection surveys.*

[2] Clearstone Engineering Ltd. *Methodology Manual: Estimation of Air Emissions from the Canadian Natural Gas Transmission, Storage and Distribution System.* Prepared for Canadian Energy Partnership for Environmental Innovation (CEPEI). 2007

*** tubing systems less than one half inch diameter may be quantified using WCI.353(g) instead of WCI.353(h) if a leak detection survey captures them. If not covered by a leak detection survey, they must be quantified using WCI.353(h). Reporting must occur using the appropriate section of WCI.352, dependent upon industry segment and quantification method used.*

(h) Population count and emission factors. This paragraph applies to emissions sources listed in WCI.352 (b)(2) (where total emissions for a compressor station are less than 10,000 tonnes CO_2e), b(6), b(8), (c)(2), (d)(2), (e)(2), (f)(2), (f)(3), (f)(4), (f)(5), (f)(6) and (f)(7) on streams with gas containing greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas containing less than 10 percent CH_4 plus CO_2 by weight do not need to be reported. **

Calculate emissions from all sources listed in this paragraph using Equation 350-21 (for volumetric emission factor [m^3/h/component]) or Equation 350-22 (for mass emission factors [kg/h/component]) of this section, as appropriate.

$$E_i = N \times EF_s \times Y_i \times t \times \rho_{s,i} \times 0.001$$

Equation 350-21

$$E_i = N \times EF_s \times X_i \times t \times 0.001$$

Equation 350-22

Where:

E_i	=	Annual total mass emissions of GHG *i* (CH_4 or CO_2) from each fugitive source (tonnes/year).
$E_{s,i}$	=	Annual total volumetric emissions of GHG *i* (CH_4 or CO_2) from each fugitive source (Sm^3/year).
N	=	Total number of this type of emission source at the facility. Per WCI.352(i)(11), average component counts by major equipment pieces from the 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual (or other relevant Canadian Gas Association and/or Canadian Association of Petroleum Producers documentation) may be used for 2011 and 2012 calendar year emissions as appropriate for operations and required by (h)(1) through (h)(4), below. For 2013 calendar year emissions and onwards component counts for individual facilities must be used. If facility or company-specific major equipment count data that meet or exceed the quality of the relevant CGA default count data are available, they must be used in its place. Current processing and instrumentation drawings (P&ID) may be used for the source of component (or major equipment) counts for all years.

EF_s	=	Population emission factor for specific sources listed in Table 350-1 through Table 350-5 of this section (Sm^3/component/hour for Equation 350-21 and tonnes/component/hour for Equation 350-22). EF for custody transfer meter-regulating stations is determined in Equation 350-23. Direction on the use of Tables 350-1 through 350-5, provided prior to the tables, must be followed and indicates that if facility specific emission factors are available these facility specific emission factors must be used*.
Y_i	=	For volumetric emissions in Equation 350-21, use 1 for CH_4 and 1.1×10^{-2} for CO_2.
X_i	=	For mass emissions in Equation 350-22, use mass fractions of CH_4 and CO_2 from operation/facility-specific data or the 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual.
t	=	Total time the specific source associated with the fugitive equipment leak was operational in the reporting year (hours).
$P_{s,i}$	=	Density of GHG *i* (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at standard conditions of 15 ºC and 1 atmosphere).
0.001	=	Conversion factor from kilograms to tonnes.

(1) Underground natural gas storage facilities for storage wellheads shall use the appropriate default population emission factors listed in Table 350-2 of this section for fugitive equipment leaks from connectors, valves, pressure relief valves, and open-ended lines.

(2) LNG storage facilities shall use the appropriate default population emission factors listed in Table 350-3 of this section for fugitive equipment leaks from vapour recovery compressors.

(3) LNG import and export facilities shall use the appropriate default population emission factor listed in Table 350-4 of this section for fugitive equipment leaks from vapour recovery compressors.

(4) Natural gas distribution facilities shall use the appropriate emission factors as described in paragraph (h)(4) of this section.

(i) Below grade metering-regulating stations; distribution mains; and distribution services, shall use the appropriate default population emission factors listed in Table 350-5 of this section.

(ii) Above grade meters and regulators at meter-regulating stations not at custody transfer as listed WCI.352(f)2), must use the total volumetric GHG emissions at standard conditions for all equipment leak sources calculated in paragraph (g)(5) of this section to develop facility emission factors using Equation 350-23 of this section. The calculated facility emission factor from Equation 350-23 of this section shall be used in Equations 350-15 and 350-16 of this section.

$$EF_{s,i} = \sum \frac{E_{s,i}}{N \times 8760}$$ **Equation 350-23**

Where:

$EF_{s,i}$	=	Facility emission factor for a meter/regulator run at above grade metering-regulating for GHG_i (Sm^3/year).
$E_{s,i}$	=	Annual volumetric GHG emissions, CO_2 or CH_4 from all equipment leak sources at all above-grade, custody-transfer, metering-regulating stations, from paragraph (g) of this section (Sm^3).
N	=	Total number of meter/regulator runs at all custody-transfer, metering-regulating stations.
8760	=	Conversion to hourly emissions

(iii) To ensure proper calculation of emissions from buried pipeline-main and service line equipment leaks, Equations 350-21 and 350-22 and their inputs may be modified as necessary to meet 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual standards. For example, the length of the installed underground pipeline used in place of count and company-specific leak data and CEPEI manual equations is permitted.

** facility -specific emission factors may equal leak rates quantified, following WCI.354(c) or (d), during leak detection surveys or those emission factors calculated for the purposes of WCI.357 – Directions for the use of Tables 350-1 to 350-5.*
*** tubing systems less than one half inch diameter may be quantified using WCI.353(g) instead of WCI.353(h) if a leak detection survey captures them. If not covered by a leak detection survey, they must be quantified using WCI.353(h). Reporting must occur using the appropriate section of WCI.352, dependent upon industry segment and quantification method used.*

(i) Volumetric emissions. Calculate volumetric emissions at standard conditions as specified in paragraphs (i)(1) or (2) , with actual pressure and temperature of this section determined by engineering estimate based on best available data unless otherwise specified.

(1) Calculate natural gas volumetric emissions at standard conditions by converting actual temperature and pressure to standard temperature and pressure (15 ºC and 1 atmosphere in Canada) using Equation 350-24 of this section.

$$E_s = \frac{E_a \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 350-24

Where:

E_s	=	Natural gas volumetric emissions at standard temperature and pressure (STP) conditions (Sm^3).

E_a = Natural gas volumetric emissions at actual conditions (m^3).
T_s = Temperature at standard conditions (^oC).
T_a = Temperature at actual emission conditions (^oC).P_s = Absolute pressure at standard conditions (kPa).
P_a = Absolute pressure at actual conditions (kPa).

(2) Calculate GHG volumetric emissions at standard conditions by converting actual temperature and pressure of GHG emissions to standard temperature and pressure using Equation 350-25 this section.

$$E_{s,i} = \frac{E_{a,i} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 350-25

Where:

$E_{s,i}$ = GHG *i* volumetric emissions at standard temperature and pressure (STP) conditions (Sm^3).
$E_{a,i}$ = GHG *i* volumetric emissions at actual conditions (m^3).
T_s = Temperature at standard conditions. (^oC).
T_a = Temperature at actual emission conditions. (^oC).
P_s = Absolute pressure at standard conditions (kPa).
P_a = Absolute pressure at actual conditions (kPa).

(j) GHG volumetric emissions. If the GHG volumetric emissions at actual conditions are known, follow the method in (j)(2) to calculate their emissions at standard conditions. If the GHG volumetric emissions are not yet known, then follow the methods below to calculate GHG volumetric emissions at standard conditions as specified in paragraphs (j)(1) and (2) of this section determined by engineering estimate based on best available data unless otherwise specified.

(1) Estimate CH_4 and CO_2 emissions from natural gas emissions using Equation 350-26 of this section.

$$E_{s,i} = E_s \times Y_i$$

Equation 350-26

Where:

$E_{s,i}$ = GHG *i* (either CH_4 or CO_2) volumetric emissions at standard conditions.
$E_{s,}$ = Natural gas volumetric emissions at standard conditions.
Y_i = Mole fraction of GHG *i* in the natural gas.

(2) For Equation 350-26 of this section, the mole fraction, Y_i, shall be the annual average mole fraction for each unit of a natural gas distribution, natural gas transmission, LNG storage, LNG import or export, or underground natural gas storage company within a jurisdiction that has similar gas composition as sampled within the current (required if available) or previous (if current data not available) reporting period, using the methods set forth in WCI.354(b), and specified in paragraphs (j)(2)(i) through (v) of this section.

(i) GHG mole fraction in transmission pipeline natural gas that passes through the facility for onshore natural gas transmission compression facilities.

(ii) GHG mole fraction in natural gas stored in underground natural gas storage facilities.

(iii) GHG mole fraction in natural gas stored in LNG storage facilities.

(iv) GHG mole fraction in natural gas stored in LNG import and export facilities.

(v) GHG mole fraction in local distribution pipeline natural gas that passes through the facility for natural gas distribution facilities.

(k) GHG mass emissions. Calculate GHG mass emissions in tonnes of carbon dioxide equivalent by converting the GHG volumetric emissions at standard conditions into mass emissions using Equation 350-27 of this section.

$$E_i = E_{s,i} \times \rho_{s,i} \times GWP_i \times 0.001$$

Equation 350-27

Where:

E_i = GHG *i* (either CH_4, CO_2, or N_20) mass emissions (tonnes CO_2e).

$E_{s,i}$ = GHG *i* (either CH_4, CO_2 or N_2O) volumetric emissions (Sm^3).

$\rho_{s,i}$ = Density of GHG *i* (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at standard conditions of T_s = 15°C and P_s = 101.325 kPa).

$$= \frac{P_s \times MW_i}{R_u \times (T_s + 273.15)}$$

GWP_i = Global warming potential of GHG *i*, (1 for CO_2 and 21 for CH_4, and 310 for N_2O).

MW_i = Molecular weight for GHG_i taken from the 12th edition of the Gas Processors Suppliers Association Engineering Data Book (kg/kmole).

R_u = Universal gas constant (8.31434 kJ/kmole K)

0.001 = Conversion factor from kilograms to tonnes.

(l) Other venting or fugitive emissions. All venting or fugitive emissions not covered by quantification methods in WCI.353 must be calculated by methodologies consistent with those presented here, in the 2007 Canadian Energy Partnership for Environmental Innovation Methodology Manual[3] (as amended from time to time), or in other relevant Canadian Gas Association documentation.

(m) Transmission storage tanks. For condensate storage tanks, either water or hydrocarbon, without vapour recovery or thermal control devices in onshore natural gas transmission compression facilities calculate CH_4, CO_2 and N_2O (when flared) annual emissions from compressor scrubber dump valve leakage as follows. For 2012, other methodologies may be used to quantify emissions from transmission storage tanks in addition to those outlined below.

(1) Monitor the tank vapour vent stack annually for emissions using an optical gas imaging instrument according to methods set forth in WCI.354(a)(1) or by directly measuring the tank vent using a flow meter, calibrated bag, or High-flow Sampler according to methods in WCI.354(b) through (d) for a duration of 5 minutes. Or you may annually monitor leakage through compressor scrubber dump valve(s) into the tank using an acoustic leak detection device according to methods set forth in WCI.354(a)(4).

(2) If the tank vapours are continuous for 5 minutes, or the acoustic leak detection device detects a leak, then use one of the following two methods in paragraph (m)(2) of this section to quantify annual emissions:
(i) Use a meter, such as a turbine meter, calibrated bag, or High-flow Sampler to estimate tank vapour volumes according to methods set forth in WCI.354(b) through (d). If you do not have a continuous flow measurement device, you may install a flow measuring device on the tank vapour vent stack. If the vent is directly measured for five minutes under paragraph (m)(1) of this section to detect continuous leakage, this serves as the measurement.
(ii) Use an acoustic leak detection device on each scrubber dump valve connected to the tank according to the method set forth in WCI.354(a)(4).
(iii) Use the appropriate gas composition in paragraph (j) of this section.

(3) If the leaking dump valve(s) is fixed following leak detection, the annual emissions shall be calculated from the beginning of the calendar year to the time the valve(s) is repaired.

(4) Calculate annual emissions from storage tanks to flares as follows:
(i) Use the storage tank emissions volume and gas composition as determined in paragraphs (m)(1) through (m)(3) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (d) of this section to determine storage tank emissions sent to a flare.

[3] Clearstone Engineering Ltd. *Methodology Manual: Estimation of Air Emissions from the Canadian Natural Gas Transmission, Storage and Distribution System.* Prepared for Canadian Energy Partnership for Environmental Innovation (CEPEI). 2007.

§ WCI.354 Sampling, Analysis, and Measurement Requirements

Instruments used for sampling, analysis and measurement must be operated and calibrated according to legislative, manufacturer's, or other written specifications or requirements. All sampling, analysis and measurement must be conducted only by, or under the direct supervision of appropriately certified personnel or individuals with demonstrated understanding and experience in the application (and principles related) of the specific sampling, analysis and measurement technique in use.

(a) Leak Detection

(0.1) If a documented leak detection or integrity management standard or requirement that is required by legislation or regulation such as CSA Z662-07 Oil & Gas Pipeline Systems or similar standard Canadian Gas Association methodologies (as amended from time to time) is used, the documented standard or requirement must be followed – including service schedules for different components and/or facilities - with reporting as required for input to the calculation methods herein. A minimum of 12 months and a maximum of 36 months is allowed between surveys.

(0.2) If there is no such legal requirement (as specified in paragraph (a)(0.1) of this section), then progressive sampling is required using one of the methods outlined below in combination with best industry practices for use of the method– including service schedules for different components - to determine the count of leaks (and time leaking) required in WCI.353(f), (g), and (h), as applicable. Progressive sampling means establishing a statistically valid baseline sample of leaks under normal operating conditions for the 2011 and 2012 calendar years, with subsequent sampling determined based on random or spot-sampling, modeling, detection or measurement of leaks under normal operating conditions. A minimum of 18 months and a maximum of 36 months is allowed between surveys. This interval is determined based on whether there are indications of leaks. If a leak is found and immediately repaired, the existing schedule may be maintained.

Leak detection for fugitive equipment leaks must be performed for all identified equipment in operation or on standby mode.

(1) Optical gas imaging instrument. Use an optical gas imaging instrument for fugitive equipment leaks detection in accordance with 40 CFR part 60, subpart A, §60.18(i)(1) and (2) *Alternative work practice for monitoring equipment leaks* (or per relevant standard in Canada). In addition, the optical gas imaging instrument must be operated to image the source types required by this proposed reporting rule in accordance with the instrument manufacturer's operating parameters. The optical gas imaging instrument must comply with the following requirements:

(i) Provide the operator with an image of the potential leak points for each piece of equipment at both the detection sensitivity level and within the distance used in the daily instrument inspection described in the relevant best practices. The detection sensitivity level depends upon the frequency at which leak monitoring is to be performed.

(ii) Provide a date and time stamp for video records of every monitoring event.

(2) Bubble tests.

(3) Portable organic vapour analyzer. Use a portable organic vapour analyzer in accordance with US EPA Method 21 or as outlined in standard Canadian Gas Association methodologies or the CAPP Best Management Practices for Fugitive Emissions

(4) Other methods as outlined in standard Canadian Gas Association methodologies or the CAPP Best Management Practices for Fugitive Emissions (as amended from time to time) may be used as necessary for operational circumstances. Other methods that are deemed to be technically sound based on an engineering assessment may also be used as necessary for operational circumstances provided that sufficient documentation as to the method used, results on tests, and the methods reliability and accuracy is maintained and updated at regular intervals.

(b) All flow meters, composition analyzers and pressure gauges that are used to provide data for the GHG emissions calculations shall use appropriate QA/QC procedures, including measurement methods, maintenance practices, and calibration methods, prior to the first reporting year and in each subsequent reporting year according to the an appropriate standard published by a consensus standards organization such as Canadian Standards Association (CSA), Canadian Gas Association, Canadian Energy Pipeline Association (CEPA), ASTM International, American National Standards Institute (ANSI), the relevant provincial or national oil and gas regulator, Measurement Canada, American Society of Mechanical Engineers (ASME), and North American Energy Standards Board (NAESB). If no appropriate standard exists from the organizations listed above, one from the Canadian Association of Petroleum Producers (CAPP), American Petroleum Institute (API) may be used. If a consensus based standard is not available, industry standard practices such as manufacturer instructions must be used.

(c) Use calibrated bags (also known as vent bags) only where the emissions are at near-atmospheric pressures and hydrogen sulphide levels are such that it is safe to handle and can capture all the emissions, below the maximum temperature specified by the vent bag manufacturer, and the entire emissions volume can be encompassed for measurement.

(1) Hold the bag in place enclosing the emissions source to capture the entire emissions and record the time required for completely filling the bag. If the bag inflates in less than one second, assume one second inflation time.

(2) Perform three measurements of the time required to fill the bag, report the emissions as the average of the three readings.

(3) Correct the natural gas volumetric emissions to standard conditions using the calculations in WCI.353(i).

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.353(j) and (k).

(d) Use a High-flow Sampler to measure emissions within the capacity of the instrument.

(1) Calibrate the instrument at 2.5 percent methane with 97.5 percent air and 100 percent CH_4 by using calibrated gas samples and by following manufacturer's instructions for calibration.

(2) A technician following (and competent to follow) manufacturer's instructions shall conduct measurements, including equipment manufacturer operating procedures and measurement methodologies relevant to using a High-flow Sampler, positioning the instrument for complete capture of the fugitive equipment leaks without creating backpressure on the source.

(3) If the High-flow Sampler, along with all attachments available from the manufacturer, is not able to capture all the emissions from the source then you shall use anti-static wraps or other aids to capture all emissions without violating operating requirements as provided in the instrument manufacturer's manual.

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.353(j) and (k).

§ WCI.355 Procedures for Estimating Missing Data

A complete record of all estimated and/or measured parameters used in the GHG emissions calculations is required. If data are lost or an error occurs during annual emissions estimation or measurements, the estimation or measurement activity for those sources must be repeated as soon as possible, including in the subsequent reporting year if missing data are not discovered until after December 31 of the reporting year, until valid data for reporting is obtained. Data developed and/or collected in a subsequent reporting year to substitute for missing data cannot be used for that subsequent year's emissions estimation. Where missing data procedures are used for the previous year, at least 30 days must separate emissions estimation or measurements for the previous year and emissions estimation or measurements for the current year of data collection. For missing data that are continuously monitored or measured (for example flow meters), or for missing temperature and pressure data, the reporter may use best available data for use in emissions determinations. The reporter must record and report the basis for the best available data in these cases.

§ WCI.356 Definitions

Blowdown vent stack emissions mean natural gas and/or CO_2 released due to maintenance and/or blowdown operations including compressor blowdown and emergency shut-down (ESD) system testing.

Calibrated bag means a flexible, non-elastic, anti-static bag of a calibrated volume that can be affixed to a emitting source such that the emissions inflate the bag to its calibrated volume.

Centrifugal compressor means any equipment that increases the pressure of a process natural gas or CO_2 by centrifugal action, employing rotating movement of the driven shaft.

Centrifugal compressor dry seals mean a series of rings around the compressor shaft where it exits the compressor case that operates mechanically under the opposing forces to prevent natural gas or CO_2 from escaping to the atmosphere.

Centrifugal compressor dry seals emissions mean natural gas or CO_2 released from a dry seal vent pipe and/or the seal face around the rotating shaft where it exits one or both ends of the compressor case.

Centrifugal compressor wet seal degassing venting emissions mean emissions that occur when the high-pressure oil barriers for centrifugal compressors are depressurized to release absorbed natural gas or CO_2. High-pressure oil is used as a barrier against escaping gas in centrifugal compressor shafts. Very little gas escapes through the oil barrier, but under high pressure, considerably more gas is absorbed by the oil. The seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated. The separated gas is commonly vented to the atmosphere.

Component means each metal to metal joint or seal of non-welded connection separated by a compression gasket, screwed thread (with or without thread sealing compound), metal to metal compression, or fluid barrier through which natural gas or liquid can escape to the atmosphere.

Compressor means any machine for raising the pressure of a natural gas by drawing in low pressure natural gas and discharging significantly higher pressure natural gas.

Continuous bleed means a continuous flow of pneumatic supply gas to the process measurement device (e.g. level control, temperature control, pressure control) where the supply gas pressure is modulated by the process condition, and then flows to the valve controller where the signal is compared with the process set-point to adjust gas pressure in the valve actuator.

Custody-transfer means the transfer of product from one gas company to another gas company, excluding transfers between companies who have same parent company.

De-methanizer means the natural gas processing unit that separates methane-rich residue gas from the heavier hydrocarbons (e.g., ethane, propane, butane, pentane-plus) in feed natural gas stream.

Equipment leak detection means the process of identifying emissions from equipment, components, and other point sources.

Engineering estimation, for the purposes of WCI.350 and WCI.360 means an estimate of emissions based on engineering principles applied to measured and/or approximated physical parameters such as dimensions of containment, actual pressures, actual temperatures, and compositions.

External combustion means fired combustion in which the flame and products of combustion are separated from contact with the process fluid to which the energy is delivered. Process fluids may be air, hot water, or hydrocarbons. External combustion equipment may include fired heaters, industrial boilers, and commercial and domestic combustion units.

Farm taps mean pressure regulation stations that deliver gas directly from transmission pipelines to generally rural customers.

Field gas means natural gas extracted from a production well prior to its entering the first stage of processing, such as dehydration.

Flare, for the purposes of WCI.350, means a combustion device, whether at ground level or elevated, that uses an open or closed flame to combust waste gases without energy recovery.

Flare combustion efficiency means the fraction of natural gas, on a volume or mole basis, that is combusted at the flare burner tip.

Fugitive emissions means the unintended or incidental emissions of greenhouse gases from the transmission, processing, storage, use or transportation of fossil fuels, greenhouse gases, or other.

Fugitive equipment leak means the those fugitive emissions which could not reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening.

Gas conditions mean the actual temperature, volume, and pressure of a gas sample.

High-bleed pneumatic devices means automated continuous bleed control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate in excess of 0.17 standard cubic meters per hour.

Intermittent-bleed pneumatic devices mean automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. These are snap-acting or throttling devices that discharge the full volume of the actuator intermittently when control action is necessary, but does not bleed continuously.

Internal combustion means the combustion of a fuel that occurs with an oxidizer (usually air) in a combustion chamber. In an internal combustion engine the expansion of the high-temperature and –pressure gases produced by combustion applies direct force to a component of the engine, such as pistons, turbine blades, or a nozzle. This force moves the component over a distance, generating useful mechanical energy. Internal combustion equipment may include gasoline and diesel industrial engines, natural gas-fired reciprocating engines, and gas turbines.

Liquefied natural gas (LNG) means natural gas (primarily methane) that has been liquefied by reducing its temperature to -162 degrees Celsius at atmospheric pressure.

LNG boiloff gas means natural gas in the gaseous phase that vents from LNG storage tanks due to ambient heat leakage through the tank insulation and heat energy dissipated in the LNG by internal pumps.

Low-bleed pneumatic devices mean automated control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate equal to or less than 0.17 standard cubic meters per hour.

Meter-regulating station means a station that meters the flowrate, regulates the pressure, or both, of natural gas in a natural gas distribution facility. This does not include customer meters, customer regulators, or farm taps.

Natural gas driven pneumatic pump means a pump that uses pressurized natural gas to move a piston or diaphragm, which pumps liquids on the opposite side of the piston or diaphragm.

Operating pressure means the containment pressure that characterizes the normal state of gas or liquid inside a particular process, pipeline, vessel or tank.

Pipeline quality natural gas means natural gas having a high heat value equal to or greater than 36.3 MJ/m^3 or less than 40.98 MJ/m^3, and which is at least ninety percent methane by volume, and which is less than five percent carbon dioxide by volume.

Portable means the same as defined in WCI.361(a)(2), as applicable to natural gas transmission and distribution operations

Pump means a device used to raise pressure, drive, or increase flow of liquid streams in closed or open conduits.

Pump seals means any seal on a pump drive shaft used to keep methane and/or carbon dioxide containing light liquids from escaping the inside of a pump case to the atmosphere.

Pump seal emissions means hydrocarbon gas released from the seal face between the pump internal chamber and the atmosphere.

Reciprocating compressor means a piece of equipment that increases the pressure of a gas stream by positive displacement, employing linear movement of a shaft driving a piston in a cylinder.

Reciprocating compressor rod packing means a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of the compressed gas stream that escapes to the atmosphere.

Re-condenser means heat exchangers that cool compressed boil-off gas to a temperature that will condense natural gas to a liquid.

Reservoir means a porous and permeable underground natural formation containing significant quantities of hydrocarbon liquids and/or gases.

Transmission pipeline means high-pressure cross-country pipeline transporting saleable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering, regulating stations where the natural gas is typically odorized before delivery to customers.

Third party line hit means damages to gas pipelines and surface facilities resulting from natural causes or third party incidents. Natural causes include corrosion, abrasion, rock damage, frost heaving or settling. Third party damages may include hits on surface facilities and dig-ins. Specific examples of dig-ins include grader/dozer/scraper excavation, demolition/breakout, general agriculture, driving bars/stakes/posts/anchors, backhoe/trackhoe excavation, ditch shaping, snow removal, landscaping/tree planting, hand excavation, bobcat/loader excavation, saw cutting, cable/pipe plowing, vertical augering/drilling, trencher excavation, blasting/vibrosis, deep tillage, horizontal augering/boring, and other such anthropogenic ground disturbances.

Vapour recovery system means any equipment located at the source of potential gas emissions to the atmosphere or to a flare, that is composed of piping, connections, and, if necessary, flow-inducing devices, and that is used for routing the gas back into the process as a product and/or fuel.

Vapourization unit means a process unit that performs controlled heat input to vapourize LNG to supply transmission and distribution pipelines or consumers with natural gas.

Vented emissions means the same as defined in the relevant greenhouse gas reporting regulation, including process designed flow to the atmosphere through seals or vent pipes, equipment blowdown for maintenance, and direct venting of gas used to power equipment (such as pneumatic devices), but not including stationary combustion flue gas.

§ WCI.357 Tables

Directions for the use of Tables 350-1 to 350-5

(a) Starting with 2014 calendar year emissions, for each component listed in the Tables 350-1 to 350-5, or otherwise required by the quantification method referencing Tables 350-1 and 350-2:

(1) If statistically valid facility-specific emission factors for a component type are available or can be safely or reasonably developed they must be used

(2) If facility-specific emissions factors for a component type are not available, an operator must use statistically valid company specific emission factors if they can be safely or reasonably developed.

(3) If statistically valid facility or company-specific emission factors for a specific component type cannot be safely and reasonably developed, estimates in the default Tables 350-1 to 350-5 may be used. Equipment or facilities that have low temporal utilization (e.g. equipment such as some booster stations used only sporadically during a year) may continue to use the default tables.

(b) For 2011, 2012 and 2013 calendar year emissions,

(1) An operator may use the default factors specified below, company or facility-specific emissions factors (if such emission factors are available). If the default factors in Tables 350-1 to 350-5 are used, an explanation as to why company or facility-specific emission factors cannot be used must be provided to the jurisdiction.

(c) If a facility-specific emission factor has been used in a previous reporting year, it must continue to be used until updated. If a company-specific emission factor has been used in a previous reporting year, it must continue to be used until updated or a facility-specific emission factor is used in its place

(d) Any changes from facility-specific factors to company-specific or table factors, or from company-specific factors to the defaults in Tables 350-1 to 350-5 must be approved by the jurisdiction and substantiated by proof that the new approach is more accurate for the facility or facilities in question

(e) If an emission factor required by the quantification method referencing Tables 350-1 through 350-5 is not provided in the tables, emission factors from either the U.S. EPA 40 CFR Part 98.230 Tables W-3 through W-7 or the 2007 Canadian Gas Association Methodology Manual may be used (as converted for use in the relevant equation).

(f) Documentation on the method used to update the emission factors, input data, sampling methodology and other relevant information must be kept by the operator and provided to the jurisdiction or verifier upon request

(g) All emission factors or data collection for emission factors must be developed using Canadian Gas Association (CGA) standard methods, or other methods if CGA methods are not available or applicable. Facility and company-specific emission factors must be updated at a minimum on a three year cycle, with the first update to the original facility and company-specific emission factors for the 2016 reporting period, at the latest.

(h) Updated emission factors can only be incorporated for reporting purposes at the start of a reporting period and not during a calendar year.

(i) The default emission factors provided in Tables 350-1 to 350-5 below are industry average emission factors for Canada as of the 2010 calendar year. The factors will be updated every 3-5 years based on new data, methods and statistically valid samples of the entire industry and developed in collaboration with industry groups.

TABLE 350-1 –DEFAULT EMISSION FACTORS FOR TRANSMISSION

Transmission	Emission Factor (tonnes/hour/component) Direct conversion of EF's in CGA Manual[4] Table 9 (kg to tonnes)
Leaker Emission Factors - All Components, Gas Service	
Connector	4.848E-5
Block valve	1.275E-4
Control valve	8.205E-5
Compressor blowdown valve	5.691E-3
Pressure relief valve	5.177E-4
Orifice meter	2.076E-4
Other meter	3.493E-7
Regulator	1.125E-4
Open-ended line	1.580E-4
Population Emission Factors - Other Components, Gas Service	**Emission Factor (Sm^3/hour/component) Direct conversion of EF's in EPA Subpart W Tables W1-A and W-3 (scf to Sm^3)**
Low-bleed pneumatic device vents	5.07 E-2
High continuous bleed pneumatic device vents	5.69 E-1
Intermittent (low and high) bleed pneumatic device vents	5.69 E-1
Pneumatic Pumps	3.766 E-1

* The distribution emission factors in Table 350-5 should be used for equipment in odourized service and the transmission factors in Table 350-1 should be used for equipment in unodourized service, regardless of the actual classification or functionality of the facility

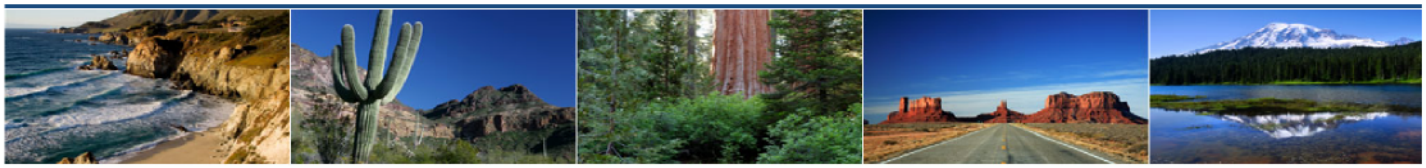
Table 350-7. Nomenclature (subscripts, variables and their descriptions)

Variable Name	Description
A	Variable – Area
a	Subscript – Actual condition for temperature and pressure
CF	Variable – Control factor (fractional)
D	Variable – Diameter
E	Variable – Greenhouse Gas release rate
e	Subscript – exit point
EF	Variable – Emission factor
GOR	Variable – Gas to oil ratio
GWP	Variable – Global warming potential
HHV	Variable – Higher (gross) heating value
i	Subscript - Chemical compound
j	Subscript - Individual device, equipment, meter or well
K	Variable – Specific heat ratio for gases
k	Subscript - Service type (e.g., fuel gas, process gas, liquid, etc)
L	Variable - Length
l	Subscript - Individual equipment components
M	Variable – Mach number
MW	Variable – Molecular weight
m	Subscript – Operating mode
N	Variable – Count of devices, equipment, meters, wells, events, etc.
n	Variable – Number of carbon atoms in a molecule of a specified substance.
P	Variable – Pressure
R	Variable – Universal Gas Constant
s	Subscript – Standard condition for temperature (15 ^{o}C) and pressure (101.325 kPa)
t	Variable – Time duration of event
T	Variable – Temperature (°C)
Q	Variable – Volumetric flow rate
V	Variable - Volume
X	Variable - Mass fraction
Y	Variable - Mole fraction
ρ	Variable - density
□	Variable – efficiency (fractional)



Due to the timing of the release of amendments to the EPA Subpart W rule on December 2, 2011 and the potential need for the WCI to address harmonization questions with it, further consultation on WCI.360 and potential amendments to WCI.360 are scheduled to occur in 2012.

§WCI.360 PETROLEUM AND NATURAL GAS PRODUCTION AND GAS PROCESSING

§ WCI.361 Source Category Definition

(a) This source category consists of the following:

(1) *Offshore petroleum and natural gas production.* Offshore petroleum and natural gas production is any platform structure, affixed temporarily or permanently to offshore submerged lands, that houses equipment to extract hydrocarbons from the ocean or lake floor and that processes and/or transfers such hydrocarbons to storage, transport vessels, or onshore. In addition, offshore production includes secondary platform structures connected to the platform structure via walkways, storage tanks associated with the platform structure and floating production and storage offloading equipment (FPSO). This source category does not include reporting of emissions from offshore drilling and exploration that is not conducted on production platforms.

(2) *Onshore petroleum and natural gas production.* Onshore petroleum and natural gas production equipment means all structures associated with wells (including but not limited to compressors, generators, or storage facilities), piping (including but not limited to flowlines or intra-facility gathering lines), and portable non-self-propelled equipment (including but not limited to well drilling and completion equipment, workover equipment, gravity separation equipment, auxiliary non-transportation-related equipment, and leased, rented or contracted equipment) used in the production, extraction, recovery, lifting, stabilization, separation or treating of petroleum and/or natural gas (including condensate). This also includes associated storage or measurement and all systems engaged in gathering produced gas from multiple wells, all EOR operations using CO_2, and all petroleum and natural gas production located on islands, artificial islands or structures connected by a causeway to land, an island, or artificial island.

(3) *Onshore natural gas processing.* Natural gas processing plants separates and/or recovers natural gas liquids (NGLs) and/or other non-methane gases and liquids from a stream of produced natural gas to meet onshore natural gas transmission pipeline quality specifications through equipment performing one or more of the following processes: oil and condensate removal, separation of natural gas liquids, sulphur and carbon dioxide removal, fractionation of NGLs, or other processes, and also the capture of CO_2

separated from natural gas streams for delivery outside the facility. In addition, field gathering and/or boosting stations that gather and process natural gas from multiple wellheads, and compress and transport natural gas (including but not limited to flowlines or intra-facility gathering lines or compressors) as feed to the natural gas processing plants may be considered a part of the processing plant if emissions are not calculated under onshore petroleum and natural gas production. Gathering and boosting stations that send the natural gas to an onshore natural gas transmission compression facility, or natural gas distribution facility, or to an end user are also considered within onshore natural gas processing for the purposes of emissions calculation. All residue gas compression equipment operated by a processing plant, whether inside or outside the processing plant fence, are considered part of the natural gas processing plant.

(b) This source category does not include natural gas transmission and distribution (i.e., onshore natural gas transmission compression, underground natural gas storage, liquefied natural gas (LNG) storage, LNG import and export equipment, and natural gas distribution). These are included in WCI.350 (Natural Gas Transmission and Distribution).

§ WCI.362 Greenhouse Gas Reporting Requirements

Where greenhouse gases are not emitted from a specific emission source identified in paragraphs (a) to (f), below then the reported emissions for the specific source shall be reported as zero or "not applicable".

In addition to the information required by regulation, the annual emissions data report, for both each individual facility over 10,000 tonnes and the aggregate of facilities less than 10,000 tonnes (or as otherwise specified by regulation), must contain the following information:

(a) CO_2 and CH_4 (and N_2O, if applicable) emissions (in tonnes) from each industry segment specified in paragraph (b) through (d) of this section and from stationary and portable combustion equipment identified in paragraphs (e) and (f) of the section.

(b) For offshore petroleum and natural gas production, report CO_2, CH_4, and N_2O emissions from equipment leaks, vented emission, and flare emission source types as identified in the data collection and emissions estimation study conducted by BOEMRE in compliance with 30 CFR 250.302 through 304. Offshore platforms do not need to report portable emissions. *[WCI.363(p), reserved]*

(c) For onshore petroleum and natural gas production, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following source types:

(1) Natural gas pneumatic continuous high-bleed device venting. *[WCI.363(a)]*

(2) Natural gas-driven pneumatic pump venting. *[WCI.363(a.1)]*

(3) Natural gas pneumatic continuous low-bleed device venting. *[WCI.363(b)]*

(4) Natural gas pneumatic intermittent (low and high) bleed device venting. *[WCI.363(b.1)]*

(5) Acid gas removal venting or incineration process. *[WCI.363(c)]*

(6) Dehydrator vents. *[WCI.363(d)]*

(7) Well venting for liquids unloading. *[WCI.363(e)]*

(8) Gas well venting during well completions or workovers. *[WCI.363(f)]*

(9) Blowdown vent stacks. *[WCI.363(g)]*

(10) Third party line hits. *[WCI.363(g.1)]*

(11) Onshore production and processing storage tanks. *[WCI.363(h)]*

(12) Transmission storage tanks *[WCI.363(h.1)]*

(13) Well testing venting and flaring. *[WCI.363(i)]*

(14) Associated gas venting and flaring. *[WCI.363(j)]*

(15) Flare stacks. *[WCI.363(k)]*

(16) Centrifugal compressor venting. *[WCI.363(l)]*

(17) Reciprocating compressor venting. *[WCI.363(m)]*

(18) Gathering pipeline fugitive equipment leaks. *[WCI.363(o) or WCI.363(x) for emission sources not covered by WCI.363(o)]*

(19) Fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves, pumps, flanges, and other fugitive equipment leak sources (such as instruments, loading arms, stuffing boxes, compressor seals, dump lever arms, and breather caps). *[WCI.363(o]*

(20) EOR injection pump blowdown. *[WCI.363(t)]*

(21) Hydrocarbon liquids dissolved CO_2 from flashing [Reserved]. *[WCI.363(u)]*

(22) Produced water dissolved CO_2 [Reserved]. *[WCI.363(v)]*

(23) Coal bed methane produced water emissions [Reserved]. *[WCI.363(v)]*

(24) Other venting emission sources.* *[WCI.363(x)]*

(25) Other fugitive emission sources.**[WCI.363(x)]*

(d) For onshore natural gas processing, report CO_2 and CH_4 (and N_2O, if applicable) emissions from the following sources:

(1) Acid gas removal venting or incineration. *[WCI.363(c)]*

(2) Dehydrator vents. *[WCI.363(d)]*

(3) Blowdown vent stacks. *[WCI.363(g)]*

(4) Storage tanks. *[WCI.363(h)]*

(5) Flare stacks. *[WCI.363(k)]*

(6) Centrifugal compressor venting. *[WCI.363(l)]*

(7) Reciprocating compressor venting. *[WCI.363(m)]*

(8) Gathering pipeline fugitive equipment leaks. *[WCI.363(o)] or [WCI.363(x)] for emission sources not covered by [WCI.363(o)]*

(9) Fugitive equipment leaks from: valves, connectors, open ended lines, pressure relief valves and meters. *[WCI.363(n)]*

(10) Other fugitive emission sources (including reciprocating compressor rod packing fugitives, centrifugal compressor dry and wet seals, etc).* *[WCI.363(x)]*

(11) Other venting emission sources.* *[WCI.363(x)]*

(e) Report CO_2, CH_4, and N_2O emissions from each stationary fuel combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report stationary combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods. The reference to process vent gas is not intended to include vent gas that is sellable quality natural gas. **

(f) Report CO_2, CH_4, and N_2O emissions from each portable equipment combustion source type combusting field gas or process vent gas *[WCI.363(w)]* and fuels other than field gas or process vent gas. Report portable equipment combustion sources that combust fuels other than field gas or process vent gas using WCI.20 (General Stationary Combustion Sources) quantification methods. The reference to process vent gas is not intended to include vent gas that is sellable quality natural gas. **

(g) Report data for each aggregated source type within paragraph (b) through (d) of this section as follows (for each individual facility or aggregate of facilities reported, as required by regulation):

(1) Where there is a choice of quantification method used for a source, the specific method(s) used and under what circumstances.

(2) Facility and company-specific emission factors or emissions information, as appropriate, used in place of Tables 360-1 and 360-2.

(3) Count of natural gas pneumatic continuous high-bleed devices.

(4) Count of natural gas pneumatic continuous low-bleed devices.

(5) Count of natural gas intermittent (low and high) bleed devices.

(6) Count of natural gas-driven pneumatic pumps.

(7) Total throughput of acid gas removal units.

(8) For each dehydrator unit report the following:
  (i) Glycol dehydrators:

    (A) The number of glycol dehydrators with throughput less than 11,328 Sm^3/day operated, and

    (B) The number of glycol dehydrators with throughput greater than or equal to 11,328 Sm^3/day operated.

  (ii) Desiccant dehydrators:
    (A) The number of desiccant dehydrators operated.

(9) Count of wells vented to the atmosphere for liquids unloading.

(10) Count of third party line hits

  (i) Engineering distribution of number of line hits by volume of gas released by hit

(11) Count of wells venting during well completions:
  (i) The number of conventional completions.
  (ii) The number of completions employing hydraulic fracturing.

(12) Count of wells venting during well workovers:
  (i) The number well workovers involving well venting to the atmosphere.

(13) For each compressor report the following:
  (i) Type of compressor whether reciprocating, centrifugal dry seal, or centrifugal wet seal (for all compressors).
  (ii) Compressor driver capacity in horsepower (where the total horsepower (as aggregated) for the facility has rated power greater than or equal to 250 hp).
  (iii) Number of blowdowns per year (where the total horsepower (as aggregated) for the facility has rated power greater than or equal to 250 hp).
  (iv) Operating mode(s) (i.e., operating, not operating and pressurized or not operating and depressurized) during the year (where the total horsepower (as aggregated) for the facility has rated power greater than or equal to 250 hp).
  (v) Number of compressor starts per year.

(14) Number of EOR injection pump blowdowns per year.

(15) Count of wells tested in the reporting period.

(16) Count of wells venting or flaring associated natural gas in the reporting period.

(17) Count of wells being unloaded for liquids in the reporting year.

(18) Count of wells completed (worked over) in the reporting year.

(19) For fugitive equipment leaks and population-count/emission-factor sources, using emission factors for estimating emissions in WCI.363(n) and (o), report the following:
   (i) Major equipment (for 2011 and 2012 calendar year reporting) or component (for 2013 calendar year reporting and onwards) counts for which an emission factor is provided in Tables 360-1, 360-2 or 360-3 in this document. Default counts provided may be used for the 2011 and 2012 calendar years (reported in 2012 and 2013 in preparation for full component counts in the 2013 calendar year (reported in 2014). Current processing and instrumentation drawings (P&ID) may be used for the source of component (or major equipment) counts for all years.
   (ii) Total counts of fugitive equipment leaks found in leak detection surveys by type of leak source for which an emission factor is provided.

(20) Barrels of oil equivalent throughput/processed as determined by engineering estimate based on best available data.

(21) Identification (including geographic coordinates) of any facility that had 1,000 tonnes or greater of greenhouse gas emissions in the previous year that was:
   (i) Acquired during the reporting year;
   (ii) Sold, decommissioned or shut-in during the reporting year; and,
   (iii) The greenhouse gas emissions for the facility in the previous year.
   (iv) The purchaser or seller, as appropriate

** Other venting emission or other fugitive sources not specifically listed are not required to be reported if a specific other venting or other fugitive source type is reasonably estimated to be below 0.5% of total operation emissions, and total emissions not reported under this clause do not exceed 1% of total operation emissions (if an individual facility is part of a larger reporting operation, the 0.5% or 1% should be interpreted as 0.5% or 1% of the reporting operation emissions, otherwise interpret as 0.5% or 1% of the facility emissions). The applicable regulator may, upon request and provision of sufficient information, provide a list of sources believed to be below these thresholds for all operations for which reporting and verification would not be required.*

*** Portable equipment is portable fuel combustion equipment that cannot move on roadways under its own power and drive train, and that are located at an onshore production facility. Stationary or portable equipment include the following equipment which are integral to the extraction, processing or movement of oil or natural gas: well drilling and completion* *equipment, workover equipment, natural gas dehydrators, natural gas compressors, electrical generators, steam boilers, and process heater.s*

§ WCI.363 Calculating GHG Emissions

If greenhouse gases are not emitted from one or more of the following emission sources, the reporter will not need to calculate emissions from the emission source(s) in question and reported emissions for the emission source(s) will be zero or “not applicable”. Where a quantification method is not provided for a specific source (such as for other venting and other fugitive sources), industry inventory practices must be used to estimate emissions. For ambient conditions, reporters must use average atmospheric conditions or typical operating conditions as applicable to the respective monitoring methods in this section. In general, equations are presented at the most basic unit level and emissions must be summed, so that the total population of devices and/or events are included for the reporting facility or organization, as required by regulation. Nomenclature used in the equations is presented in Table 360-7.

(a) Natural gas pneumatic continuous high-bleed device venting Calculate emissions from a natural gas pneumatic continuous high-bleed flow control device venting using the method specified in paragraph (a)(1) below when the device is metered. By the start of the 2014 reporting year (January 1, 2014), natural gas consumption must be metered for 50 % of the operator’s pneumatic high-bleed devices (the 50% calculation of metered devices may include devices that were operational on January 1, 2012 that are no longer operational as of January 1, 2014 due to phase out or not-operating). By the start of the 2015 reporting year (January 1, 2015), natural gas consumption must be metered for all of the operator’s pneumatic high-bleed devices. For the purposes of this reporting requirement, high-bleed devices are defined as all natural gas powered devices which continuously bleed at a rate greater than 0.17 m^3/hr . For unmetered devices the operator must use the method specified in paragraph (a)(2).

(1) The operator must calculate vented emissions for metered pneumatic high-bleed devices using the following equation:

$$E_s = Q_j$$

Equation 360-1

Where:

E_s = Annual natural gas volumetric emissions for pneumatic high-bleed devices and pneumatic pumps where gas is metered (Sm^3/y).

Q_j = Natural gas consumption for meter *j* (Sm^3/y).

(2) The operator must calculate vented emissions for unmetered pneumatic high-bleed devices using the following equation:

$$E_s = EF_j \times t_j$$

Equation 360-2

Where:

E_s	=	Annual natural gas volumetric emissions for pneumatic high-bleed devices where gas is unmetered (Sm^3/y).
EF_j	=	Natural gas-driven pneumatic device, j, bleed rate volume as provided by the manufacturer or in Table 360-6 (Sm^3/h/device).
t_j	=	Total time that the pneumatic device, j, has been in service the (i.e. the time that gas flows to the device) through the reporting period (h).

(3) If manufacturer data for a specific device is not available, then use data for a similar device model, size and operational characteristics to estimate emissions. If data for a reasonably similar pump model size and operational characteristics cannot be obtained, use the factor in Table 360-5 for high-bleed pneumatic devices

(4) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section

(5) Provide the total number of continuous high-bleed natural gas pneumatic devices as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates can be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining devices.

(ii) In 2013, all continuous high-bleed natural gas pneumatic devices must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of continuous high-bleed pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

(a.1) <u>Natural gas pneumatic pump venting.</u> Calculate emissions from natural gas-driven pneumatic pump venting using the method specified in paragraph (a)(1) above when the pump is metered. By the start of the 2014 reporting year (January 1, 2014), natural gas consumption must be metered for 50 % of the operator's pneumatic pumps (the 50% calculation of metered devices may include devices that were operational on January 1, 2012 that are no longer operational as of January 1, 2014 due to phase out or not-operating). By the start of the 2015 reporting year (January 1, 2015), natural gas consumption must be metered for all of the operator's pneumatic pumps. For unmetered pumps the operator must use the methods preferentially specified in paragraph (a.1)(2). Natural gas-driven pneumatic pumps covered in paragraph (d) (dehydrator vents) of this section do not have to report emissions under paragraph (a.1) of this section.

(1) The operator must calculate vented emissions for metered pneumatic pumps using Equation 360-1.

(2) The operator must calculate vented emissions for unmetered pneumatic pumps using Equation 360-3.

(i) Obtain from the manufacturer specific pump model natural gas emission (or manufacturer "gas consumption") per unit volume of liquid circulation rate at pump speeds and operating pressures. If manufacturer data for a specific pump is not available, then use data for a similar pump model, size and operational characteristics to estimate emissions.

(ii) Maintain a log of the amount of liquid pumped annually from individual pumps.

(iii) Calculate the natural gas emissions for each pump using Equation 360-3.

$$E_s = EF_j \times Q_j$$

Equation 360-3

Where:

E_s	=	Annual natural gas volumetric emissions (Sm^3/y).
EF_j	=	Natural gas-driven pneumatic pump gas emission factor expressed in "emission per volume of liquid pumped at operating pressure" as provided by the manufacturer for pump *j* (Sm^3/liter).
Q_j	=	Volume of liquid pumped annually by pump *j* (liters/y).

(3) If manufacturer data for a specific pump, or reasonably similar pump model size and operational characteristics cannot be obtained; Equation 360-2 can be used with the population emission factor for natural gas-driven pneumatic pumps provided in Table 360-5.

(4) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section

(5) Provide the total number of natural gas pneumatic pumps as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates can be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining pumps.

(ii) In 2013, all natural gas pneumatic pumps must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of pneumatic pumps and adjust accordingly to reflect any modifications due to changes in equipment.

(b) Natural gas pneumatic continuous low-bleed device venting. Calculate emissions from natural gas pneumatic continuous low-bleed device venting using Equation 360-4 of this section.

$$E_s = EF_j \times t_j$$

Equation 360-4

Where:

E_s = Annual natural gas volumetric emissions for pneumatic continuous low-bleed devices (Sm^3/y).

EF_j = Population emission factor for natural gas-driven pneumatic continuous low-bleed device, *j*, as provided in Table 360-5 ($Sm^3/h/device$).

t_j = Total time that the pneumatic device, *j*, has been in service (i.e. the time that the gas flows to the device) through the reporting period (h).

(1) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(2) Provide the total number of continuous low-bleed natural gas pneumatic devices of each type as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates can be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining devices.

(ii) In 2013, all continuous low-bleed natural gas pneumatic devices must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of continuous low-bleed natural gas pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

(b.1) <u>Natural gas pneumatic intermittent (low and high) bleed device venting.</u> Calculate emissions from natural gas pneumatic intermittent (low and high) bleed device venting as follows.

(1) The operator must calculate vented emissions for pneumatic intermittent (low and high) bleed devices used to maintain a process condition such as liquid level, pressure, delta-pressure or temperature using Equation 360-5:

$$E_s = EF_j \times t_j$$

Equation 360-5

Where:

E_s = Annual natural gas volumetric emissions for pneumatic intermittent (low and high) bleed devices (Sm^3/y).

EF_j = Emission factor for natural gas-driven pneumatic intermittent (low and high) bleed device, *j*, as provided in Table 360-6 ($Sm^3/h/device$). If manufacturer data for a specific device is not available, then use data for a similar device model, size and operational characteristics to estimate emissions. If data for a reasonably similar intermittent bleed device size and operational characteristics cannot be obtained, use the factor in Table 360-5 for intermittent bleed pneumatic devices.

t_j = Total time that the pneumatic device, *j*, has been in service (i.e. the time that the gas flows to the device) through the reporting period (h).

(2) The operator must calculate vented emissions for pneumatic intermittent (high) bleed devices, used to drive compressor starters, using Equation 360-6*:

$$E_s = EF_j \times t_j$$

Equation 360-6

Where:

E_s = Annual natural gas volumetric emissions for pneumatic intermittent (high) bleed devices (Sm^3/y).

EF_j = Emission factor for natural gas-driven pneumatic compressor starter, *j*, as provided by the manufacturer (Sm^3/min/device).

t_j = Total time that the pneumatic device, *j*, has been in service (i.e. the time that the gas flows to the device) through the reporting period (min).

(3) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(4) Provide the total number of intermittent (low and high) bleed natural gas pneumatic devices as follows:

(i) In 2012, you may count 50% of the devices for each type of facility and engineering estimates can be used to determine both the denominator to be used in the 50% calculation and to estimate the number of remaining devices.

(ii) In 2013, all intermittent (low and high) bleed natural gas pneumatic devices must be counted.

(iii) In 2014, and for calendar years thereafter, facilities must update the total count of intermittent (low and high) bleed natural gas pneumatic devices and adjust accordingly to reflect any modifications due to changes in equipment.

** for 2012, the volume of gas per start provided by the manufacturer may be used in place of the* EF_j *and* t_j *variables*

(c) Acid gas removal (AGR) venting or incineration process. Except for AGRs where the acid gases are re-injected into the oil/gas field or manifolded to a common flare stack, calculate CO_2 emissions only (not CH_4) for AGR (including but not limited to processes such as amine, membrane, molecular sieve or other absorbents and adsorbents) using any of the calculation methodologies described in this section, as applicable.

(1) Calculation Methodology 1. If you operate and maintain a CEMS on the AGR vent or incinerator stack that has both a CO_2 concentration analyzer and volumetric flow rate meter CO_2 emissions under this subpart must be calculated by following Calculation Methodology 4 and all associated calculation, quality assurance, reporting, and recordkeeping requirements for Calculation Methodology 4 in WCI.20 (General Stationary Combustion). If a CO_2 concentration analyzer and volumetric flow rate meter are not available, a CO_2 concentration analyzer and a volumetric flow rate meter that comply with all of the requirements specified for the Calculation Methodology 4 in WCI.20 (General Stationary Combustion) may be installed.

(2) Calculation Methodology 2. If CEMS is not available but a vent meter is available, use the CO_2 composition and annual volume of vent gas to calculate emissions using Equation 360-7.

$$E_{CO2} = Q \times Y_{CO2}$$

Equation 360-7

Where:

E_{CO2}	=	Annual volumetric CO_2 emissions (Sm^3/y).
Q	=	Metered total annual volume of acid gas flow out of the AGR unit (Sm^3/y) as determined in paragraph (c)(5) of this section.
Y_{CO2}	=	Mole fraction of CO_2 in acid gas out of the AGR unit as determined in paragraph (c)(6) of this section.

(3) Calculation Methodology 3. If CEMS or a vent meter is not available, the inlet gas flow rate of the acid gas removal unit may be used to calculate emissions for CO_2 using Equation 360-8.

$$E_{CO2} = \frac{Q_{in} \times \left[Y_{CO2\_in} \times \left(1 - Y_{H2S\_spec}\right) - Y_{CO2\_out} \times \left(1 - Y_{H2S\_in}\right) \right]}{\left(1 - Y_{H2S\_spec} - Y_{CO2\_out}\right)}$$

Equation 360-8

Where:

E_{CO2}	=	Annual volumetric CO_2 emissions (Sm^3/y).
Q_{in}	=	Metered total annual volume of natural gas flow into the AGR unit (Sm^3/y) as determined in paragraph (c)(5) of this section.

Y_{CO2_in} = Mole fraction of CO_2 in natural gas into the AGR unit as determined in paragraph (c)(6) of this section.

Y_{CO2_out} = Mole fraction of CO_2 in natural gas out of the AGR unit as determined in paragraph (c)(6) of this section.

Y_{H2S_spec} = Mole fraction of H_2S in the natural gas out of the AGR unit as defined by the performance specification of the AGR.

Y_{H2S_in} = Mole fraction of H_2S in natural gas into the AGR unit as determined in paragraph (c)(6) of this section.

(4) Record the gas flow rate, referenced to standard conditions, of the inlet and outlet natural gas or acid gas stream of an AGR unit using a meter according to methods set forth in WCI.364(b).

(5) If a continuous gas analyzer is installed on the inlet gas stream, then the continuous gas analyzer results must be used. If a continuous gas analyzer is not available, either install a continuous gas analyzer or take monthly gas samples from the inlet gas stream to determine Y_{CO2_in} according to methods set forth in WCI.364(b).

(6) Determine volume fraction of CO_2 content in natural gas or acid gas out of the AGR units using one of the methods specified in paragraph (c)(6) of this section.

(i) If a continuous gas analyzer is installed on the outlet gas stream, then the continuous gas analyzer results must be used. If a continuous gas analyzer is not available, you may install a continuous gas analyzer.

(ii) If a continuous gas analyzer is not available or installed, monthly gas samples must be taken from the outlet gas stream to determine Y_{CO2} according to methods set forth in WCI.364(b).

(7) Determine volume fraction of H_2S content in natural gas or acid gas into the AGR units using continuous gas analyzer data (if available), or other known or commonly accepted method (if continuous gas analyzer data is not available.

(8) Mass CO_2 emissions shall be calculated from volumetric CO_2 emissions using calculations in paragraph (s) of this section.

(d) Dehydrator vents. For dehydrator vents, calculate annual mass CH_4, CO_2 and N_2O (when flared) emissions as follows:

(1) Calculate annual mass emissions from dehydrator vents using a simulation software package of similar accuracy to GRI-GLYCalc Version 4.0 or AspenTech HYSYS®, that uses the Peng-Robinson equation of state to calculate the equilibrium coefficient, speciates CH_4 and CO_2 emissions from dehydrators, and has provisions to include regenerator control devises, a separator flash tank, stripping gas and a gas injection

pump or gas assist pump. A minimum of the following parameters must be used for characterizing emissions from dehydrators:

(i) Feed natural gas flow rate.
(ii) Feed natural gas water content.
(iii) Outlet natural gas water content.
(iv) Absorbent circulation pump type (natural gas pneumatic/air pneumatic/electric).
(v) Absorbent circulation rate.
(vi) Absorbent type: including, but not limited to, triethylene glycol (TEG), diethylene glycol (DEG) or ethylene glycol (EG).
(vii) Use of stripping gas.
(viii) Use of flash tank separator (and disposition of recovered gas).
(ix) Hours operated.
(x) Wet natural gas temperature and pressure.
(xi) Wet natural gas composition. Determine this parameter by selecting one of the methods described under paragraph (d)(1)(xi) of this section.
   (A) Use the wet natural gas composition as defined in paragraph (r)(2)(i) of this section.
   (B) If wet natural gas composition cannot be determined using paragraph (r)(2)(i) of this section, select a representative analysis.
   (C) You may use an appropriate standard method published by a consensus-based standards organization if such a method exists or you may use an industry standard practice as specified in WCI.364(b) to sample and analyze wet natural gas composition.
   (D) If only composition data for dry natural gas is available, assume the wet natural gas is saturated.

(2) Determine if dehydrator unit has vapor recovery. Adjust the emissions estimated in paragraphs (d)(1) or (d)(4) of this section downward by the magnitude of emissions captured.

(3) Calculate annual emissions from dehydrator vents to flares or regenerator fire-box/fire tubes as follows:
   (i) Use the dehydrator vent stack volume and gas composition as determined in paragraph (d)(1) of this section.
   (ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine dehydrator vent emissions from the flare or regenerator combustion gas vent.

(4) Dehydrators that use desiccant shall calculate emissions from the amount of gas vented from the vessel every time it is depressurized for the desiccant refilling process using Equation 360-10.

$$E_s = \left(\frac{H \times D^2 \times \pi \times P_2 \times \%G \times 365}{4 \times P_1 \times t} \right) \Big/ 100$$

Equation 360-10

Where:

E_s = Annual natural gas volumetric emissions (Sm^3/y).
H = Height of the dehydrator vessel (m).
D = Inside diameter of the vessel (m).
P_1 = Atmospheric pressure (kPa).
P_2 = Pressure of the gas (kPa).
π = pi (3.14).
%G = Percent of packed vessel volume that is gas.
365 = Conversion from days to years.
t = Time between refilling (days) (365/t represent the refilling times during the reporting year).
100 = Conversion of %G to fraction.

(5) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(e) Well venting for liquids unloading. The CO_2 and CH_4 emissions for well venting for liquids unloading shall be determined using one of the following calculation methodologies:

(1) Calculation Methodology 1. For one representative well of each unique well tubing diameter grouping, pressure grouping and producing horizon/formation combination in each gas producing field where gas wells are vented to the atmosphere to expel liquids accumulated in the tubing, a recording flow meter shall be installed on the vent line used to vent gas from the well (e.g. on the vent line off the wellhead separator or atmospheric storage tank) according to the methods set forth in the WCI.364(b). Calculate emission from well venting for liquids unloading using Equation 360-11.

$$E_a = Q_j \times t_j$$

Equation 360-11

Where:

E_a = Annual natural gas volumetric emissions from well *j* at actual conditions (m^3/y).
t_j = Cumulative amount of time in hours of venting from well *j* during the reporting period (h).
Q_j = Average flow rate of the measured well venting for the duration of the liquids unloading, under actual conditions as determined in paragraph (e)(1)(i) of this section (m^3/h).

(i) Determine the well vent average flow rate as specified under paragraph (e)(1)(i) of this section.

(A) The average flow rate per hour of venting is calculated for each unique tubing diameter grouping and pressure grouping in each producing horizon/formation combination in each producing field by dividing the recorded total flow by the recorded time (in hours) for a single liquid unloading with venting to the atmosphere.

(B) This average flow rate is applied to all wells in the same pressure grouping that have the same tubing diameter grouping, for the number of hours in the calendar year of venting these wells.

(C) A new average flow rate is calculated every other calendar year (if necessary) for each reporting field and horizon combination starting the first calendar year of data collection. For a new producing reporting field and horizon combination, an average flow rate is calculated beginning in the first year of production.

(ii) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(2) Calculation Methodology 2. Calculate emissions from each well venting to the atmosphere for liquids unloading with plunger lift assist using Equation 360-12.

$$E_{a,n} = \left(\left[7.854 \times 10^{-5}\right] \times D_t^{\,2} \times WD \times \left[\frac{P_{sales}}{101.325}\right] \times N_V \right) + \left(Q_{sfr} \times \left[t_{open} - 0.5\right] \times Z \right)$$ **Equation 360-12**

Where:

E_a	=	Annual natural gas volumetric emissions at actual conditions (m^3/y).
7.854×10^{-5}	=	$(\pi/4)/(10000)$
D_t	=	Tubing diameter (cm).
WD	=	Tubing depth to plunger bumper (meters).
P_{sales}	=	Sales line pressure (kPa-gage).
N_V	=	Number of vents per year.
Q_{sfr}	=	Average sales flow rate of gas well at actual conditions (m^3/h).
t_{open}	=	Hours that the well was left open to the atmosphere during unloading.
0.5	=	Hours for average well to blowdown tubing volume at sales line pressure.
Z	=	If t_{open} is less than 0.5 then Z is equal to 0. If t_{open} is greater than or equal to 0.5 then Z is equal to 1.

(i) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(4) Both CH_4 and CO_2 volumetric and mass emissions shall be calculated from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(f) Gas well venting during well completions and workovers. Calculate emissions from gas conventional or unconventional (from hydraulic fracturing) well venting during well completions and workovers using one of the following methods. Sum all events to determine total annual venting that occurred in the reporting year. For 2012 calendar year emissions reporting, in addition to WCI.363(f)(1) and (2), methods published in the December 17, 2010 version of this document may be used for quantifying emissions from gas well venting during well completions and workovers.

(1) Calculation Methodology 1.

(i) The operator must measure total gas flow with a recording flow meter (analog or digital) installed in the vent line.

(ii) The operator must correct total gas volume vented for the volume of CO_2 or N_2 injected and the volume of gas recovered into a sales lines as follows:

$$E_a = V_M - V_{CO2,N2} - V_{SG}$$

Equation 360-13

Where:

E_a = Natural gas emissions during the well completion or workover at actual conditions (m^3).
V_M = Volume of vented gas measured during well completion or workover (m^3).
$V_{CO2,N2}$ = Volume of CO_2 or N_2 injected during well completion or workover (m^3).
V_{SG} = Volume of natural gas recovered into a sales pipeline (m^3).

(iii) All gas volumes must be corrected to standard temperature and pressure using methods in paragraph (q) of this section.

(iv) The operator must calculate CO_2 and CH_4 mass emissions from gas venting using the methods found in paragraphs (r) and (s) of this section.

(2) Calculation Methodology 2.

(i) The operator must make a series of measurements of upstream pressure (P_1) and downstream pressure (P_2) across a choke installed in the vent line and upstream gas temperature according to methods in section WCI.364(b) during each well completion and well workover where venting occurs. The operator must record this data at a time interval (e.g., every five minutes) suitable to accurately describe both sonic and subsonic flow regimes. Sonic flow is defined as the flow regime where $P_2/P_1 \leq 0.542$. Subsonic flow is defined as the flow regime where $P_2/P_1 > 0.542$. The operator must then calculate flow rate for both sonic and subsonic flow regimes using the following equations:

A. Sonic flow regime.

1. The operator must calculate the average flow rate during sonic flow conditions as follows:

$$Q_{S,avg} = 3600 \times A \times \sqrt{187.08 \times T_u}$$

Equation 360-14

Where:

$Q_{S,avg}$	=	Average flow rate of natural gas during sonic flow conditions (m^3/h).
3600	=	Conversion factor from m^3/second to m^3/hour.
A	=	Cross sectional area of the orifice (m^2).
187.08	=	Constant with units of $m^2/(sec^2 * K)$
T_u	=	Upstream gas temperature (degrees Kelvin).

2. The operator must calculate total natural gas volume vented during sonic flow conditions as follows:

$$V_S = Q_{S,avg} \times t_S$$

Equation 360-15

Where:

V_s	=	Volume of gas vented during sonic flow conditions (m^3)
t_S	=	Duration of venting during sonic flow conditions (h).The operator must correct Q_S to standard conditions using the methodology in paragraph (q) of this section

B. Subsonic flow regime.

1. The operator must calculate the instantaneous gas flow rate during subsonic flow conditions as follows:

$$Q_{SS,inst} = 3600 \times A \times \sqrt{3430 \times T_u \left[\left(P_2 / P_1 \right)^{1.515} - \left(P_2 / P_1 \right)^{1.758} \right]}$$

Equation 360-16

Where:

$Q_{SS,inst}$	=	Instantaneous flow rate of natural gas at time t_{inst} during subsonic flow conditions (m^3/h).
3600	=	Conversion factor from m^3/second to m^3/hour.
A	=	Cross sectional area of the orifice (m^2).
3430	=	Constant with units of $m^2/(sec^2 * K)$

T_u = Upstream gas temperature (degrees Kelvin).
P_2 = Downstream pressure (kPa)
P_1 = Upstream pressure (kPa)

2. The operator must determine total gas volume vented during subsonic flow conditions (Vss) as the total volume under the curve of a plot of $Q_{ss,inst}$ and time (t_{inst}) for the time period during which the well was flowing during subsonic conditions.

3. The operator must correct V_{SS} to standard conditions using the methodology in paragraph (q) of this section

(ii) The operator must sum the vented volumes during sonic and subsonic flow and adjust emissions for the volume of CO_2 or N_2 injected and the volume of gas recovered into a sales line as follows:

$$E_s = V_S + V_{SS} - V_{CO2,N2} - V_{SG}$$

Equation 360-17

Where:
E_s = Natural gas emissions during the well completion or workover (Sm^3).
V_S = Volume of gas vented during sonic flow conditions (Sm^3)
V_{SS} = Volume of gas vented during subsonic flow conditions (Sm^3)
$V_{CO2,N2}$ = Volume of CO_2 or N_2 injected during well completion or workover (Sm^3).
V_{SG} = Volume of natural gas recovered into a sales pipeline (Sm^3).

(iii) The operator must calculate CO_2 and CH_4 mass emissions from gas venting using the methods found in paragraphs (r) and (s) of this section.

(3) Calculate annual emissions from gas well venting during well completions and workovers to flares as follows:
(i) Use the gas well venting volume during well completions and workovers as determined in paragraph (f)(1) or (f)(2) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine gas well venting during well completions and workovers emissions from the flare.

(g) Blowdown vent stacks. Calculate blowdown vent stack emissions from depressurizing equipment to reduce system pressure for planned or emergency shutdowns or to take equipment out of service for maintenance (excluding depressurizing to a flare, over-pressure relief, operating pressure control venting and blowdown of non-GHG gases; desiccant dehydrator blowdown venting before reloading is covered in paragraph (d)(4) of this section) as follows:

(1) Calculate the total physical volume (including, but not limited to, pipe, compressor case or cylinders, manifolds, suction and discharge bottles and vessels) between isolation valves determined by engineering estimates based on best available data.

(2) If the total physical volume between isolation valves is greater than or equal to 1.42 Sm^3, retain logs of the number of blowdowns for each equipment system (including, but not limited to pipes, compressors and vessels). Physical volumes smaller than 1.42 m^3 are exempt from reporting under paragraph (g) of this section.

(3) Calculate the venting emissions for each equipment type using Equation 360-18.

$$E_s = V_v \left[\frac{(273.15 + T_s)(P_{a,1} - P_{a,2})}{(273.15 + T_a)P_s} \right]$$

Equation 360-18

Where:

E_s	=	Natural gas venting volumetric emissions from blowdown of an equipment system (Sm^3).
V_v	=	Total physical volume of blowdown equipment chambers (including, but not limited to, yard piping, pipelines, compressors and vessels) between isolation valves for the equipment system (m^3).
T_s	=	Temperature at standard conditions (ºC).
T_a	=	Temperature at actual conditions in the equipment system (°C).
P_s	=	Absolute pressure at standard conditions (kPaa).
$P_{a,1}$	=	Absolute pressure at actual conditions in the equipment system prior to depressurization (kPaa).
$P_{a,2}$	=	Absolute pressure at actual conditions in the equipment system after depressurization; 0 if equipment is purged using non-GHG gases (kPaa).

(4) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(5) Blowdowns that are directed to flares use the WCI.363(k) Flare stacks calculation method rather than WCI.363(g) Blowdown vent stacks calculation method.

(g.1) Third party line hits. Calculate emissions from third party line hits as follows:

(1) For each dig-in incident (i.e., line hit) which results in gas release ≥ 1.416 Sm^3, calculate volumetric flow rate prior to pipeline isolation for both catastrophic pipeline

ruptures and pipeline puncture incidents using the appropriate methodology below[1]. For 2012, the methodology in paragraph (iv) may be used in addition to those in paragraphs (i) and (ii).

(i) For catastrophic pipeline ruptures where the pipeline is severed use the following methodology:

$$Q_s = \frac{3.6x10^6 \times A}{\rho_s} \sqrt{\frac{K \times MW}{1000 \times R \times (273.15 + T_a)}} \times \frac{P_a \times M}{\left(1 + \frac{K-1}{2} M^2\right)^{\frac{K+1}{2(K-1)}}}$$

Equation 360-19

Where:

$$M = \sqrt{\frac{2\left[\left(\frac{P_a}{P_e}\right)^{\frac{K-1}{K}} - 1\right]}{K-1}} \text{ , (for M} \leq 1\text{),}$$

Equation 360-20

M = 1, (for all other cases)

Where:

Q_s	=	natural gas venting volumetric flow rate (Sm^3/h)
A	=	cross-sectional flow area of the pipe (m^2, $A=\pi D^2/4000$)
D	=	inside diameter of the pipe (mm)
K	=	specific heat ratio of the gas (dimensionless – 1.299 for methane)
M	=	Mach number of the flow (m/s)
MW	=	molecular weight of the gas (kg/mole, 16.043 kg/mole for methane)
P_e	=	pressure at the damage point (local atmospheric pressure, kPaa)
P_a	=	pressure inside the pipe at supply (kPaa)) (usually taken at the point where the damaged main branches off a larger main). The supply pressure values should represent a stable supply pressure; however, it is important to account for the lower pressure which will occur because of the flow of gas from the break.
R	=	universal gas constant (8.3145 $kPam^3/kmol/K$)
T_a	=	temperature inside pipe at the supply (˚C)
ρ_s	=	gas density at standard conditions (kg/m^3) (0.6785 kg/m^3 for CH_4)

[1] Methodology Manual, Estimation of Air Emissions from the Canadian Natural Gas Transmission, Storage and Distribution System, Prepared for Canadian Energy Partnership for Environmental Innovation (CEPEI). Prepared by Clearstone Engineering Ltd. Calgary, Alberta, September 25, 2007. Chapter7, Third-Party Dig-Ins, page 117.

(ii) For pipeline punctures use the following methodology (for flows not choked):

$$Q_s = \frac{A_e}{\rho_s}\sqrt{\frac{2000 \cdot K}{K-1} P_a \rho_a \left[\left(\frac{P_{Atm}}{P_a}\right)^{2/K} - \left(\frac{P_{Atm}}{P_a}\right)^{(K+1)/K}\right]}$$

Equation 360-21

Where:

$$\left(\frac{P_{Atm}}{P_a}\right) \geq \left(\frac{P_{Atm}}{P_a}\right)_{choked} = \left(\frac{2}{K+1}\right)^{K/(K-1)} = 0.546 \qquad \text{(for methane)}$$

Equation 360-22

Where:

A_e	=	size of the hole in the pipe (m^2)
P_a	=	pressure inside the pipe at the puncture location (kPaa)
ρ_a	=	gas density inside the pipe at the puncture location (kg/m^3)
MW	=	molecular weight of the natural gas (16.043 for methane)
T_a	=	temperature inside the pipe (˚C)
$(P_{ATM}/P_a)_c$	=	0.546 - lower limit for choked flow

(iii) Check for choked flow

(A) If (P_{ATM}/P_a) is $\geq$0.546 flow is not choked and the reporter must use the equations in section (g.1)(ii) above.

(B) If (P_{ATM}/P_a) <0.546 flow is choked and A must be set to the cross sectional flow area of the pipe and the reporter must use the equations in section (g.1)(i) above.

(iv) For 2012 calendar year emissions, an operator may use other methods to calculate emissions published in the CEPEI Methodology Manual, or other industry standard reference sources.

(v) Calculate volumetric natural gas emissions by multiplying Q_s for each pipeline rupture and puncture by the total elapsed time from pipeline rupture or puncture until isolation and final bleed-down to atmospheric pressure.

(vi) Calculate GHG (CH_4 and CO_2 emissions) mass emissions using the methodologies in sections (r) and (s) of this section.

(h) Onshore production and processing storage tanks. For emissions from atmospheric pressure fixed roof storage tanks receiving hydrocarbon produced liquids from onshore petroleum and natural gas production facilities and onshore natural gas processing facilities, calculate annual CH_4, CO_2 (and N_20, when flared) emissions as specified in either paragraphs (h)(1) or (h)(2). For atmospheric storage tanks vented to flares, use the calculation methodology for flare stacks in paragraph (k) of this section. Storage tanks equipped with vapour recovery units (VRU) are exempt from the requirements of this paragraph. For 2012 calendar year emissions reporting, Equation 360-12, as published in the December 17, 2010 version of this document, may also be used for quantifying emissions from onshore production and processing storage tanks.

(1) Calculate CH_4 and CO_2 flashing emissions using Equation 360-23.

$$E_i = GOR \times Q_o \times Y_i \times \rho_i \times 0.001$$

Equation 360-23

Where:

E_i	=	Annual emissions of greenhouse gas *i* (CO_2 or CH_4) (tonnes/y).
GOR	=	Gas Oil Ratio (Sm^3 gas/m^3 oil) measured following WCI.364(f).
Q_o	=	Oil production rate (m^3/y).
ρ_i		Density of GHG i (1.861 kg/m^3 for CO_2 and 0.678 kg.m^3 for CH_4 at standard conditions of 101.325 kPa and 15 ^oC).
Y_i	=	Mole fraction of greenhouse gas *i* (CO_2 or CH_4) in tank vapour.
0.001	=	Conversion factor (tonnes/kg).

(2) Calculate CH_4 and CO_2 flashing emissions using the latest software package for E&P Tank. A minimum of the following parameters must be used to characterize emissions from liquid transfer to atmospheric pressure storage tanks.
(i) Separator oil composition.
(ii) Separator temperature.
(iii) Separator pressure.
(iv) Sales oil API gravity.
(v) Sales oil production rate.
(vi) Sales oil Reid vapour pressure.
(vii) Ambient air temperature.
(viii) Ambient air pressure.

(h.1) Transmission storage tanks. For condensate storage tanks, either water or hydrocarbon, without vapour recovery or thermal control devices in onshore natural gas production and processing facilities calculate CH_4, CO_2 and N_2O (when flared) annual emissions from compressor scrubber dump valve leakage as follows. For 2012, other methodologies may be used to quantify emissions from transmission storage tanks in addition to those outlined below.

(1) Monitor the tank vapour vent stack annually for emissions using an optical gas imaging instrument according to methods set forth in WCI.364(a)(1) or by directly measuring the tank vent using a flow meter, calibrated bag, or High-flow Sampler according to methods in WCI.364(b) through (d) for a duration of 5 minutes. Or you may annually monitor leakage through compressor scrubber dump valve(s) into the tank using an acoustic leak detection device according to methods set forth in WCI.364(a)(4).

(2) If the tank vapours are continuous for 5 minutes, or the acoustic leak detection device detects a leak, then use one of the following two methods in paragraph (h.1)(2) of this section to quantify annual emissions:

(i) Use a meter, such as a turbine meter, calibrated bag, or High-flow Sampler to estimate tank vapour volumes according to methods set forth in WCI.364(b) through (d). If you do not have a continuous flow measurement device, you may install a flow measuring device on the tank vapour vent stack. If the vent is directly measured for five minutes under paragraph (h.1)(1) of this section to detect continuous leakage, this serves as the measurement.

(ii) Use an acoustic leak detection device on each scrubber dump valve connected to the tank according to the method set forth in WCI.364(a)(4).

(iii) Use the appropriate gas composition in paragraph (r) of this section.

(3) If the leaking dump valve(s) is fixed following leak detection, the annual emissions shall be calculated from the beginning of the calendar year to the time the valve(s) is repaired.

(4) Calculate annual emissions from storage tanks to flares as follows:

(i) Use the storage tank emissions volume and gas composition as determined in paragraphs (h.1)(1) through (h.1)(3) of this section.

(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine storage tank emissions sent to a flare.

(i) Well testing venting and flaring. Calculate CH_4, CO_2, and N_2O (when flared) well testing venting and flaring emissions as follows.

(1) Determine the gas to oil ratio (GOR) of the hydrocarbon production from each well tested.

(2) If GOR cannot be determined from your available data, then use one of the two procedures in paragraph (i)(2) of this section to determine GOR and follow paragraph (3). Otherwise follow paragraph (4).:

(i) You may use an appropriate standard method published by a consensus-based standards organization if such a method exists.

(ii) Or you may use an industry standard practice as described in WCI.364(b).

(3) Calculation Methodology 1. Estimate venting emissions using Equation 360-24.

$$E_a = GOR \times Q_o \times t$$

Equation 360-24

Where:

E_a = Annual volumetric natural gas emissions from well testing at actual conditions (m^3/y).
GOR = Gas to oil ratio; oil here refers to hydrocarbon liquids produced of all API gravities (m^3 gas/m^3 oil).
Q_o = Flow rate for the well being tested (m^3 oil/h).
t = Total hours during the year the well is tested (h).

(4) Calculation Methodology 2. In cases where very little hydrocarbon liquids are produced and the GOR approaches infinity, estimate emissions using Equation 360-25. A recording flow meter shall be installed on the vent (or flare) line used to vent gas from the well (e.g. on the vent line off the well-test separator) according to the methods set forth in the WCI.364(b).

$$E_a = Q_g \times t$$

Equation 360-25

Where:

E_a = Annual natural gas volumetric emissions at actual conditions (m^3/y).
t = Total hours during the year the well is tested (h).
Q_g = Average flow rate of the measured well venting for the duration of the test at actual conditions (m^3 gas/h).

(5) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(6) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(7) Calculate emissions from well testing to flares as follows:
(i) Use the well testing emissions volume as determined in paragraphs (i)(1) through (4) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine well testing gas composition and emissions from the flare.

(j) Associated gas venting and flaring. Calculate associated gas venting and flaring emissions not in conjunction with well testing (refer to section (i): Well testing venting and flaring) as follows.

(1) Determine the GOR of the hydrocarbon production from each well whose associated natural gas is vented or flared. If GOR from each well is not available, the GOR from a cluster of wells in the same field shall be used.

(2) If GOR cannot be determined from your available data, then use one of the two procedures in paragraph (j)(2) of this section to determine GOR:

(i) You may use an appropriate standard method published by a consensus-based standards organization if such a method exists.
(ii) Or you may use an industry standard practice as described in WCI.364(b).

(3) Estimate venting emissions using the Equation 360-26.

$$E_a = GOR \times Q_o$$

Equation 360-26

Where:

E_a = Annual volumetric natural gas emissions from associated gas venting at actual conditions (m^3/y).
GOR = Gas to oil ratio; oil here refers to hydrocarbon liquids produced of all API gravities (m^3 gas/m^3 oil).
Q_o = Total volume of oil produced for the calendar year during which associated gas was flared or vented (m^3 oil/y)..

(4) Calculate natural gas volumetric emissions at standard conditions using calculations in paragraph (q) of this section.

(5) Calculate both CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using calculations in paragraphs (r) and (s) of this section.

(6) Calculate emissions from associated natural gas to flares as follows:
(i) Use the associated natural gas volume as determined in paragraph (j)(1) through (4) of this section.
(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine associated gas composition and emissions from the flare.

(k) Flare stacks. Calculate CO_2, CH_4, and N_2O emissions from a flare stack as follows.

(1) If there is a continuous flow measurement device on the flare, measured flow volumes must be used to calculate the flare gas emissions. If all of the flare gas is not measured by the existing flow measurement device, then the flow not measured can be estimated using engineering calculations based on best available data or company records. If there is not a continuous flow measurement device on the flare, a flow measuring device can be installed on the flare or engineering calculations based on process knowledge, company records, and best available data.

(2) If there is a continuous gas composition analyzer on the gas stream to the flare, these compositions must be used in calculating emissions. If there is not a continuous gas composition analyzer on the gas stream to the flare, the appropriate gas compositions for each stream of hydrocarbons going to the flare must be used as follows:
(i) For onshore natural gas production, determine natural gas composition using (r)(2)(i) of this section.
(ii) For onshore natural gas processing, when the stream going to flare is natural gas, use the GHG mole percent in feed natural gas for all streams upstream of the de-

methanizer or dew point control and GHG mole percent in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead or dew point control for onshore natural gas processing facilities. For onshore natural gas processing plants that solely fractionate a liquid stream, use the GHG mole percent in feed natural gas liquid for all streams.

(iii) For any applicable industry segment, when the stream going to the flare is a hydrocarbon product stream, such as ethane, butane, pentane-plus, and mixed light hydrocarbons then a representative composition from the source for the stream determined by engineering calculation based on process knowledge and best available data may be used.

(3) Determine flare combustion efficiency from manufacturer. If not available, assume that flare combustion efficiency is 98 percent.

(4) Calculate GHG volumetric emissions at actual conditions using Equations 360-27, 360-28, 360-29, and 360-30.

$$E_{s,CH4}(noncombusted) = Q_s \times (1-\eta) \times Y_{CH4}$$ **Equation 360-27**

$$E_{s,CO2}(noncombusted) = Q_s \times Y_{CO2}$$ **Equation 360-28**

$$E_{s,CO2}(combusted) = \sum_i \eta \times Q_s \times Y_i \times n_i$$ **Equation 360-29**

$$E_{s,CO2}(total) = E_{s,CO2}(combusted) + E_{s,CO2}(noncombusted)$$ **Equation 360-30**

Where:

$E_{s,CH4}$ (noncombusted)	=	Contribution of annual noncombusted volumetric CH_4 emissions from flare stack (Sm^3).
$E_{s,CO2}$ (noncombusted)	=	Contribution of annual volumetric CO_2 emissions from CO_2 in the inlet gas passing through the flare noncombusted (Sm^3).
$E_{s,CO2}$ (combusted)	=	Contribution of annual CO_2 emissions from combustion from flare stack under ambient conditions (Sm^3).
Q_s	=	Volume of natural gas sent to flare during the year (Sm^3).
η	=	Fraction of natural gas combusted by flare (default combustion efficiency is 0.98). For gas sent to an unlit flare, η is zero.
Y_{CH4}	=	Mole fraction of CH_4 in gas to the flare.
Y_{CO2}	=	Mole fraction of CO_2 in gas to the flare.
Y_i	=	Mole fraction of hydrocarbon constituents *i* (i.e., methane, ethane, propane, butane, pentanes, hexanes and pentanes plus) in natural gas to the flare.
n_i	=	Number of carbon atoms in the hydrocarbon constituent i (i.e., 1 for methane, 2 for ethane, 3 for propane, 4 for butane, 5 for

pentanes, 6 for hexanes and 7 for pentanes plus) in natural gas to the flare.

(5) Calculate both CH_4 and CO_2 mass emissions from volumetric CH_4 and CO_2 emissions using calculation in paragraph (s) of this section.

(6) Calculate N_2O emissions using Equation 360-31.

$$E_{N2O} = Q_s \times HHV \times EF \times 0.001$$

Equation 360-31

Where:

E_{N2O}	=	Annual N_2O mass emissions from flaring (tonnes/y).
Q_s	=	Volume of gas combusted by the flare in the reporting period (Sm^3/y).
HHV	=	High heat value of the flared gas from paragraph (k)(2).
EF	=	N_2O emission factor. Use 9.52×10^{-5} kg N_2O/GJ.
0.001	=	Conversion factor from kilograms to tonnes.

(7) To avoid double-counting, this emissions source excludes any emissions calculated under other emissions sources in WCI.363. Where gas to be flared is manifolded from multiple sources in WCI.363 to a common flare, report all flaring emissions under WCI.363(k).

(l) Centrifugal compressor venting. Calculate emissions from centrifugal compressor venting as follows.

(1) The operator must calculate CO_2, and CH_4, and N_2O (when flared) emissions from both wet seal and dry seal centrifugal compressor vents (including wet seal oil degasing) where the aggregate rated power for the sum of compressors at the facility is 186.4 kW or greater using a temporary or permanent flow measurement meter such as, but not limited to, a vane anemometer according to methods set forth in WCI.364(b).

(2) Estimate annual emissions using flow meter measurement using Equation 360-32.

$$E_{s,i} = \sum_m Q_{s,m} \times t_m \times Y_i \times (1 - CF)$$

Equation 360-32

Where:

$E_{s,i}$	=	Annual volumetric emissions of GHG *i* (either CH_4 or CO_2) from all measured compressor venting modes (Sm^3/y).

$Q_{s,m}$	=	Measured volumetric gas emissions during operating mode *m* described in paragraph (l)(4) of this section (Sm^3/h).
t_m	=	Total time the compressor is in operating mode *m* during the calendar year (h).
Y_i	=	Mole fraction of GHG *i* in the vent gas; use the appropriate gas compositions in paragraph (r)(2) of this section.
CF	=	Fraction of centrifugal compressor vent gas sent to vapour recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapour recovery system and the amount of vent gas that is directed to the fuel gas system. An engineering estimation approach may be used for the CF parameter for 2012 emissions reporting.

(3) An engineering estimate approach based on similar equipment specifications and operating conditions may be used to determine the $Q_{s,m}$ variable in place of actual measured values for centrifugal compressors that are operated for no more than 200 hours in a calendar year and used for peaking purposes in place of metered gas emissions if an applicable meter is not present on the compressor.

(4) Conduct an annual measurement for each compressor in the mode in which it is found during the annual measurement. Measure emissions from (including emissions manifolded to common vents), unit isolation-valve vents, and blowdown-valve vents.

(i) Operating or standby-pressurized mode, blowdown vent leakage through the blowdown vent stack.

(ii) Operating mode.

(iii) Not operating, depressurized mode, unit isolation-valve leakage through the blowdown vent stack, without blind flanges.

(A) For the not operating, depressurized mode, each compressor must be measured at least once in any three consecutive calendar years if this mode is not found in the annual measurement. If a compressor is not operated and has blind flanges in place throughout the 3 year period, measurement is not required in this mode. If the compressor is in standby depressurized mode without blind flanges in place and is not operated throughout the 3 year period, it must be measured in the standby depressurized mode

(5) The operator must calculate CO_2, and CH_4, and N_2O (when flared) emissions from both wet seal and dry seal centrifugal compressor vents (including wet seal oil degassing) for all compressors where the aggregate rated power for the sum of compressors at the facility is less than 186.4 kW (250 hp) using Equation 360-33.

$$E_{s,i} = Count \times EF_i$$

Equation 360-33

Where:

$E_{s,i}$ = Annual total volumetric GHG emissions at standard conditions from centrifugal compressors (m^3/year).

Count = Total number of centrifugal compressors less than 186.4 kW.

EF_i = Emission factor for GHG *i* (either CH_4 or O_2). Use 339,573.2 Sm^3/year per compressor for CH_4 and 14,974.7 Sm^3/year per compressor for CO_2 at 15 °C and 1 atmosphere, or as adjusted for different reference temperatures using ideal gas law.

(6) Calculate both CH_4 and CO_2 mass emissions from volumetric emissions using calculations in paragraph (s) of this section.

(7) Calculate emissions from degassing vent vapours to flares as follows:

(i) Use the degassing vent vapour volume and gas composition as determined in paragraphs (l)(1) through (3) of this section.

(ii) Use the calculation methodology of flare stacks in paragraph (k) of this section to determine degassing vent vapour emissions from the flare.

(m) Reciprocating compressor venting. Calculate annual CH_4 and CO_2 emissions from all reciprocating compressor vents as follows, except as specified in paragraph (m)(7) . Where venting emissions are sent to a common flare, calculate emissions using WCI.363(k).

(1) Estimate annual emissions using the flow measurement in (m)(2) or (m)(3) below and Equation 360-34.

$$E_{s,i} = \sum_{m} Q_{s,m} \times t_m \times Y_i \times (1 - CF)$$

Equation 360-34

Where:

$E_{s,i}$, = Annual volumetric emissions of GHG *i* (either CH_4 or CO_2) from all measured compressor venting modes (Sm^3/y).

$Q_{s,m}$ = Measured volumetric gas emissions during operating mode *m* described in paragraph (m)(4) (Sm^3/h).

t_m = Total time the compressor is in operating mode *m* during the calendar year (h).

Y_i = Mole fraction of GHG *i* in the vent gas; use the appropriate gas compositions in paragraph (r)(2) of this section.

CF = Fraction of reciprocating compressor vent gas sent to vapour recovery or fuel gas or other beneficial use as determined by keeping logs of the number of operating hours for the vapour recovery system and the amount of vent gas that is directed to the fuel gas system. An engineering estimation approach may be used for the CF parameter for 2012 emissions reporting.

(2) If the reciprocating rod packing and blowdown vent is connected to an open-ended vent line then use one of the following two methods to calculate emissions**.**

(i) Measure emissions from all vents (including emissions manifolded to common vents) including rod packing, unit isolation valves, and blowdown vents using either calibrated bagging or High-flow Sampler according to methods set forth in WCI.364(c) and (d).

(ii) Use a temporary meter such as a vane anemometer or a permanent meter such as an orifice meter to measure emissions from all vents (including emissions manifolded to a common vent) including rod packing vents, unit isolation valves, and blowdown valves according to methods set forth in WCI.364(b). If you do not have a permanent flow meter, you may install a port for insertion of a temporary meter or a permanent flow meter on the vents. For through-valve leakage to open ended vents, such as unit isolation valves on not operating, depressurized compressors and blowdown valves on pressurized compressors, you may use an acoustic detection device according to methods set forth in WCI.364(a).

(3) If the rod packing case is not equipped with a vent line use the following method to estimate emissions:

(i) Use the methods described in WCI.364(a) to conduct a progressive leak detection of fugitive equipment leaks from the packing case into an open distance piece, or from the compressor crank case breather cap or vent with a closed distance piece.

(ii) Measure emissions using a High-flow Sampler, or calibrated bag, or appropriate meter according to methods set forth in WCI.364(b), (c), or (d).

(4) Conduct an annual measurement for each compressor in the mode in which it is found during the annual measurement, except as specified in paragraph (m)(7) of this section. Measure emissions from (including emissions manifolded to common vents) reciprocating rod-packing vents, unit isolation-valve vents, and blowdown-valve vents.

(i) Operating or standby-pressurized mode, blowdown vent leakage through the blowdown vent stack.

(ii) Operating mode, reciprocating rod-packing emissions.

(iii) Not operating, depressurized mode, unit isolation-valve leakage through the blowdown vent stack, without blind flanges.

(A) For the not operating, depressurized mode, each compressor must be measured at least once in any three consecutive calendar years if this mode is not found in the annual measurement. If a compressor is not operated and has blind flanges in place throughout the 3 year period, measurement is not required in this mode. If the compressor is in standby depressurized mode without blind flanges in place and is not operated throughout the 3 year period, it must be measured in the standby depressurized mode

(5) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in paragraphs (r) and (s) of this section.

(6) Determine if the reciprocating compressor vent vapors are sent to a vapor recovery system.

(i) Adjust the emissions estimated in paragraphs (f)(1) of this section downward by the magnitude of emissions recovered using a vapor recovery system as determined by engineering estimate based on best available data.

(ii) An engineering estimate approach based on similar equipment specifications and operating conditions or manufacturer's data may be used to determine the $Q_{s,m}$ variable in place of actual measured values for reciprocating compressors that are operated for no more than 200 hours in a calendar year

(7) Onshore petroleum and natural gas production may calculate emissions from reciprocating compressors where the aggregate rated power for the sum of compressors at the facility is less than 186.4 kW (250 hp) as follows using Equation 360-35:

$$E_{s,i} = Count \times EF_i$$

Equation 360-35

Where:

$E_{s,i}$	=	Annual total volumetric GHG emissions at standard conditions from reciprocating compressors (m^3/year).
Count	=	Total number of reciprocating compressors considered under (m)(7) for the reporter.
EF_i	=	Emission factor for GHG *i* (either CH_4 or O_2). Use 268.0 Sm^3/year per compressor for CH_4 and 14.9 Sm^3/year per compressor for CO_2 at 15 °C and 1 atmosphere, or as adjusted for different reference temperatures using ideal gas law.

(n) Leak detection and leaker emission factors. Existing legislative or regulatory requirements (described in WCI.364(a)(0.1) or progressive sampling methods (described in WCI.364(a)(0.2)) must be used to conduct a leak detection survey of fugitive equipment leaks from all sources listed in §WCI.362(d)(9). This paragraph (n) applies to emissions sources in streams with gas containing greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas containing less than 10 percent CH_4 plus CO_2 by weight need to be reported instead under paragraph (x) of this section. **

If fugitive equipment leaks are detected for sources listed in this paragraph, calculate equipment leak emissions per source per reporting facility using Equation 360-36 for each source with fugitive equipment leaks.

$$E_{s,i} = EF_{s,l} \times Y_i \times t_1$$

Equation 360-36

Where:

$E_{s,i}$	=	Annual total volumetric emissions of GHG *i* (either CH_4 or CO_2), from each fugitive equipment leak source (Sm^3/y).
$EF_{s,l}$	=	Leaker volumetric emission factor for specific component, *l*, listed in 40 CFR Part 98 Table W-2, relevant Canadian Association of Petroleum Producers (CAPP) methodology manuals, if available or facility/company-specific emission factors* used (as converted for use in Equation 360-36).
Y_i	=	For onshore natural gas processing facilities, mole fraction of GHG *i* (either CH_4 or CO_2) in the total hydrocarbon of the feed natural gas.
t_l	=	Total time the component, *l*, was found leaking and operational (hours). If one leak detection survey is conducted, assume the component was leaking from the start of the year until the leak was repaired and then zero for the remainder of the year. If the leak was not repaired, assume the component was leaking for the entire year. If multiple leak detection surveys are conducted, assume that the component found to be leaking has been leaking since the last survey during which it was determined to be not leaking, or the beginning of the calendar year. For the last leak detection survey in the calendar year, assume that all leaking components continue to leak until the end of the calendar year or until the component was repaired and then zero until the end of the year.

(1) Calculate GHG mass emissions in carbon dioxide equivalent at standard conditions using calculations in paragraph (s) of this section.

(2) Onshore natural gas processing facilities shall use the appropriate default volumetric leaker emission factors listed in 40 CFR Part 98 Table W-2 (as converted to metric) or relevant Canadian Association of Petroleum Producer methodology manuals, if available for fugitive equipment leaks detected from valves; connectors; open ended lines; pressure relief valves; and meters.

** component-specific emission factors may equal leak rates quantified, following WCI.364(c) or (d), during leak detection surveys.*

*** tubing systems less than one half inch diameter may be quantified using WCI.363(n), instead of WCI.363(x) if a leak detection survey captures them. If not covered by a leak detection survey, they must be quantified using WCI.363(x). Reporting must occur using the appropriate section of WCI.362, dependent upon quantification method used.*

(o) <u>Population count and emission factors</u>. This paragraph applies to emissions sources listed in §WCI.362 (c)(16), (c)(17) and (d)(8) on streams with gas containing greater than 10 percent CH_4 plus CO_2 by weight. Emissions sources in streams with gas containing less than 10 percent CH_4 plus CO_2 by weight do not need to be reported. **

(1) Calculate emissions from all sources listed in this paragraph using Equation 360-37 except for emissions from underground gathering pipelines that are calculated in paragraph (2).

$$E_i = \sum_k \sum_l \left(N_{k,l} \times \frac{EF_{k,l}}{THC_k} \times X_{i,k} \right) \times t$$

Equation 360-37

Where:

E_i	=	Annual total mass emissions of GHG *i* (CH_4 or CO_2) at standard conditions from each major equipment or component count fugitive source at the facility (tonnes/year).
$N_{k,l}$	=	Number of components in service *k* and component type *l*. Per WCI.362(g)(19) average component counts by major equipment pieces for Canada from Table 360-3 may be used for 2011 and 2012 calendar year emissions as appropriate and can be in Gas/Vapour, Fuel Gas and Liquid service. For 2013 calendar year emissions and onwards component counts for individual facilities must be used. If facility or company specific major equipment count data that meet or exceed the quality of the relevant default count data are available, they must be used instead. Current processing and instrumentation drawings (P&ID) may be used for the source of component (or major equipment) counts for all years
$EF_{k,l}$	=	Population mass emission factor for components in service *k* and component type *l* listed in Table 360-1 or Table 360-2. The direction on the use of Tables 360-1 and 360-2 provided prior to these tables must be followed and indicates that if facility specific emission factors are available these facility specific emission factors must be used* (tonnes total hydrocarbon (THC) / component / h).
THC_k	=	Mass fraction of total hydrocarbons in service *k*.
$X_{i,k}$	=	Mass fraction of GHG *i* (CH_4 or CO_2) in service *k*.
t	=	Total time the specific source associated with the fugitive equipment leak was operational in the reporting year (h).

(2) Calculate emissions from underground gathering pipelines using Equation 360-38.

$$E_{s,i} = EF_{s,i} \times L \times t$$

Equation 360-38

Where:

$E_{s,i}$	=	Annual total volumetric emissions of GHG *i* (either CH_4 or CO_2), from an underground gathering pipeline (Sm^3/y).
$EF_{s,i}$	=	Volumetric emission factors equal to 2.66×10^{-5} t CH_4/km/h and 3.63×10^{-6} t CO_2/km/h for pipeline leaks plus the portion of methane emitted from

underground leaks that is oxidized to form carbon dioxide and equal to 2.72 x 10^{-6} t CO_2/km/h. These factors are published in Table 6-4 of the American Petroleum Institute (API) 2009 Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Natural Gas Industry.

L = Length of the underground gathering pipeline (km)

t = Total time the underground gathering pipeline was operational in the reporting year (h).

(3) Onshore petroleum and natural gas production facilities shall use the appropriate default population emission factors listed in Table 360-1 or 360-2 for fugitive equipment leaks from valves, connectors, open ended lines, pressure relief valves, pump, flanges, and other equipment. Where facilities conduct EOR operations the emissions factors listed in Table 360-1 or Table 360-2 shall be used to estimate all streams of gases, including the recycle CO_2 stream. The component count can be determined using either of the methodologies described in this paragraph (o)(1). The same methodology must be used for the entire calendar year..

(i) *Component Count Methodology 1*. For all onshore petroleum and natural gas production operations in the facility perform the following activities:

(A) Count all major equipment listed in Table 360-3 of this section.

(B) Multiply major equipment counts by the average component counts in Gas/Vapour, Fuel Gas and Liquid service listed in Table 360-3 of this section for onshore natural gas production and onshore oil production, respectively. Use the appropriate total hydrocarbon (THC) factor in Table 360-1 or Table 360-2 of this section or from CAPP methodology manuals, if the appropriate factor is not provided in Tables 360-1 or 360-2.

(ii) *Component Count Methodology 2*. Count each component individually for the facility. Use the appropriate factor Table 360-1 or Table 360-2 of this section or from CAPP methodology manuals, if the appropriate factor is not provided in Tables 360-1 or 360-2.

** facility/company-specific emission factors may equal leak rates quantified, following WCI.364(c) or (d), during leak detection surveys or those emission factors calculated for the purposes of WCI.367 – Directions for the use of Tables 360-1 and 360-2.*

*** tubing systems less than one half inch diameter may be quantified using WCI.363(n), instead of WCI.363(x) if a leak detection survey captures them. If not covered by a leak detection survey, they must be quantified using WCI.363(x). Reporting must occur using the appropriate section of WCI.362, dependent upon quantification method used.*

(p) <u>Offshore petroleum and natural gas production facilities in both provincial and federal waters.</u>
[reserved]

(q) Volumetric emissions. Calculate volumetric emissions at standard conditions as specified in paragraphs (q)(1) or (2), with actual pressure and temperature determined by engineering estimate based on best available data unless otherwise specified.

(1) Calculate natural gas volumetric emissions at standard conditions by converting the actual temperature and pressure to standard temperature and pressure (15 ºC and 1 atmosphere in Canada) using Equation 360-39 of this section.

$$E_s = \frac{E_a \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 360-39

Where:

E_s	=	Natural gas volumetric emissions at standard temperature and pressure (STP) conditions (Sm^3).
E_a	=	Natural gas volumetric emissions at actual conditions (m^3).
T_s	=	Temperature at standard conditions (^oC).
T_a	=	Temperature at actual emission conditions (^oC).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at actual conditions (kPa).

(2) Calculate GHG volumetric emissions at standard conditions by converting actual temperature and pressure of GHG emissions to standard temperature and pressure using Equation 360-40.

$$E_{s,i} = \frac{E_{a,i} \times (273.15 + T_s) \times P_a}{(273.15 + T_a) \times P_s}$$

Equation 360-40

Where:

$E_{s,i}$	=	GHG *i* volumetric emissions at standard temperature and pressure (STP) conditions (Sm^3).
$E_{a,i}$	=	GHG *i* volumetric emissions at actual conditions (m^3).
T_s	=	Temperature at standard conditions (^oC).
T_a	=	Temperature at actual emission conditions (^oC).
P_s	=	Absolute pressure at standard conditions (kPa).
P_a	=	Absolute pressure at actual conditions (kPa).

(r) GHG volumetric emissions. If the GHG volumetric emissions at actual conditions are known, follow the method in (q)(2) to calculate their emissions at standard conditions. If the GHG volumetric emissions are not yet known, then follow the methods below to calculate

GHG volumetric emissions at standard conditions as specified in paragraphs (r)(1) and (2) of this section determined by engineering estimate based on best available data unless otherwise specified.

(1) Estimate CH_4 and CO_2 emissions from natural gas emissions using Equation 360-41.

$$E_{s,i} = E_s \times Y_i$$

Equation 360-41

Where:

$E_{s,i}$	=	GHG *i* (CH_4 or CO_2) volumetric emissions at standard conditions.
E_s	=	Natural gas volumetric emissions at standard conditions.
Y_i	=	Mole fraction of GHG *i* in the natural gas.

(2) For Equation 360-41 of this section, the mole fraction, Y_i, shall be the annual average mole fraction for each facility, as specified in paragraphs (r)(2)(i) and (ii) of this section.

(i) GHG mole fraction in produced natural gas for onshore petroleum and natural gas production facilities. If you have a continuous gas composition analyzer for produced natural gas, you must use an annual average of these values in calculating emissions. If you do not have a continuous gas composition analyzer, then use an annual average of the known composition (in required order of preference) for the (i) facility; or (ii) company for the specific field sampled within the current (required if available) or previous (if current data not available) reporting period, using the methods set forth in WCI.364(b). Alternatively, if this information is not available, the composition for the specific field from Table 360-4.

(ii) (a) GHG mole fraction in feed natural gas for all emissions sources upstream of the de-methanizer or dew point control and (b) GHG mole fraction in facility specific residue gas to transmission pipeline systems for all emissions sources downstream of the de-methanizer overhead or dew point control for onshore natural gas processing facilities. For onshore natural gas processing plants that solely fractionate a liquid stream, use the GHG mole percent in feed natural gas liquid for all streams. If you have a continuous gas composition analyzer on feed natural gas, you must use an annual average of these values to determine the mole fraction in calculating emissions. If you do not have a continuous gas composition analyzer, then use an annual average of the known composition (in required order of preference) for the (i) facility; or (ii) company for the specific field must be used as taken according to methods set forth in WCI.364(b). If such information is not available, then the composition for the specific field can be referenced from Table 360-4.

(s) <u>GHG mass emissions</u>. Calculate GHG mass emissions in tonnes of carbon dioxide equivalent by converting the GHG volumetric emissions at standard conditions into mass emissions using Equation 360-42.

$$E_i = E_{s,i} \times \rho_{s,i} \times GWP_i \times 0.001$$

Equation 360-42

Where:

E_i = GHG *i* (either CH_4,, CO_2 ,or, N_20 mass emissions (tonnes CO_2e).
$E_{s,i}$ = GHG *i* (either CH_4, CO_2,or, N_20) volumetric emissions (Sm^3).
$\rho_{s,i}$ = Density of GHG *i*, (1.861 kg/m^3 for CO_2 and 0.678 kg/m^3 for CH_4 at standard conditions of $T_s = 15^oC$ and P_s = 101.325 kPa)

$$= \frac{P_s \times MW_i}{R_u \times (T_s + 273.15)}$$

GWP_i = Global warming potential of GHG *i* (1 for CO_2 and 21 for CH_4, and 310 for N_2O).
MW_i = Molecular weight for GHG_i taken from the 12th edition of the Gas Processors Suppliers Association Engineering Data Book (kg/kmole).
R_u = Universal gas constant (8.31434 kJ/kmole K)
0.001 = Conversion factor from kilograms to tonnes.

(t) <u>EOR injection pump blowdown</u>. Calculate pump blowdown emissions as follows:

(1) Calculate the total volume in cubic meters (including, but not limited to, pipelines, manifolds and vessels) between isolation valves.

(2) Retain logs of the number of blowdowns per reporting period.

(3) Calculate the total annual venting emissions using Equation 360-43.

$$E_i = N \times V_v \times \rho_c \times X_i \times 0.001$$

Equation 360-43

Where:

E_i = Annual EOR injection gas venting mass emissions at critical conditions *c* from blowdowns (tonnes/y).
N = Number of blowdowns for the equipment in reporting year.
V_v = Total physical volume of blowdown equipment chambers (including, but not limited to, pipelines, manifolds and vessels) between isolation valves (m^3).
ρ_c = Density of critical phase EOR injection gas (kg/m^3). Use an appropriate standard method published by a consensus-based standards organization if such

a method exists or otherwise an industry standard to determine density of super critical EOR injection gas.

X_i = Mass fraction of GHG_i in critical phase injection gas.

0.001 = Conversion factor from kilograms to tonnes.

(u) Hydrocarbon liquids dissolved CO_2 from flashing [Reserved]

(v) Produced water dissolved CO_2 / Coal bed methane produced water emissions [Reserved]

(w) Field gas or process vent gas combustion. For combustion units that combust field gas or process vent gas or any blend of field gas and process vent gas, you must comply with following requirements:

(1) Measure the higher heating value of the field gas or process vent gas annually.

(i) Calculate the CO_2 and CH_4 emissions using either the Tier 3 or Tier 4 methodology in WCI.20 (General Stationary Combustion Sources). Sampling, analysis and measurement requirements (including for gas composition) required for WCI.360 in WCI.025(f) apply in place of those indicated for Equation 20-7, or

(ii) When measurement data is not available and if the measured higher heating value is equal to or greater than 36.3 MJ/m^3 and less than 40.98 MJ/m^3, then calculate the CO_2, CH_4, and N_2O emissions using the methods in WCI.20 (General Stationary Combustion Sources) following the methods required for pipeline quality natural gas.

(2) Maintain the WCI.20 (General Stationary Combustion Sources) methodology, required by paragraph (1) of this section, for subsequent reporting years.

(x) Other venting or fugitive emissions. All venting or fugitive emissions not covered by quantification methods in WCI.363 must be calculated by methodologies consistent with those presented here, the 2009 API Compendium[2], or other similar resource documents.

§ WCI.364 Sampling, Analysis, and Measurement Requirements

Instruments used for sampling, analysis and measurement must be operated and calibrated according to legislative, manufacturer's, or other written specifications or requirements. All sampling, analysis and measurement must be conducted only by, or under the direct supervision

[2] American Petroleum Institute. *Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Natural Gas Industry*. August 2009. Table 6-22 (from Clearstone Engineering Ltd.. *A National Inventory of Greenhouse Gas (GHG), Criteria Air Contaminant (CAC) and Hydrogen Sulphide (H2S) Emissions by the Upstream Oil and Gas Industry*, Volume 5, September 2004.)

of appropriately certified personnel or individuals with demonstrated understanding and experience in the application (and principles related) of the specific sampling, analysis and measurement technique in use.

(a) Leak Detection

(0.1) If a documented leak detection or integrity management standard or requirement that is required by legislation or regulation such as CSA Z662-07 Oil & Gas Pipeline Systems or the CAPP Best Management Practices for Fugitive Emissions or similar standard CAPP Methodologies (as amended from time to time) is used, the documented standard or requirement must be followed – including service schedules for different components and/or facilities - with reporting as required for input to the calculation methods herein. A minimum of 12 months and a maximum of 36 months is allowed between surveys.

(0.2) If there is no such legal requirement (as specified in paragraph (a)(0.1) of this section), then progressive sampling is required using one of the methods outlined below in combination with best industry practices for use of the method– including service schedules for different components - to determine the count of leaks (and time leaking) required in WCI.363(m), (n), and (o), as applicable. Progressive sampling means establishing a statistically valid baseline sample of leaks under normal operating conditions for the 2011 and 2012 calendar years, with subsequent sampling determined based on random or spot-sampling modeling, detection or measurement of leaks under normal operating conditions. A minimum of 18 months and a maximum of 36 months is allowed between surveys. This interval is determined based on whether there are indications of leaks. If a leak is found and immediately repaired, the existing schedule may be maintained.

Leak detection for fugitive equipment leaks must be performed for all identified equipment in operation or on standby mode.

(1) Optical gas imaging instrument. Use an optical gas imaging instrument for fugitive equipment leaks detection in accordance with 40 CFR part 60, subpart A, §60.18(i)(1) and (2) *Alternative work practice for monitoring equipment leaks* (or per relevant standard in Canada). In addition, the optical gas imaging instrument must be operated to image the source types required by this proposed reporting rule in accordance with the instrument manufacturer's operating parameters. The optical gas imaging instrument must comply with the following requirements:

(i) Provide the operator with an image of the potential leak points for each piece of equipment at both the detection sensitivity level and within the distance used in the daily instrument inspection described in the relevant best practices. The detection sensitivity level depends upon the frequency at which leak monitoring is to be performed.

(ii) Provide a date and time stamp for video records of every monitoring event.

(2) Bubble tests

(3) Portable organic vapour analyzer. Use a portable organic vapour analyzer in accordance with US EPA Method 21 or as outlined in the CAPP Best Management Practices for Fugitive Emissions

(4) Other methods as outlined in the CAPP Best Management Practices for Fugitive Emissions or similar standard CAPP Methodologies (as amended from time to time) may be used as necessary for operational circumstances. Other methods that are deemed to be technically sound based on an engineering assessment may also be used as necessary provided that sufficient documentation as to the method used, test results, and the methods reliability, and accuracy is maintained and updated at regular intervals.

(b) All flow meters, composition analyzers and pressure gauges that are used to provide data for the GHG emissions calculations shall use appropriate QA/QC procedures, including measurement methods, maintenance practices, and calibration methods, prior to the first reporting year and in each subsequent reporting year according to an appropriate standard published by a consensus standards organization such as ASTM International, Canadian Standards Association (CSA), American National Standards Institute (ANSI), the relevant provincial or national oil and gas regulator, Measurement Canada, American Society of Mechanical Engineers (ASME), and North American Energy Standards Board (NAESB) , If no appropriate standard exists from the organizations listed above, one from the Canadian Association of Petroleum Producers (CAPP), Canadian Gas Association (CGA) or American Petroleum Institute (API) may be used. If a consensus based standard is not available, industry standard practices such as manufacturer instructions must be used.

(c) Use calibrated bags (also known as vent bags) only where the emissions are at near-atmospheric pressures and hydrogen sulphide levels are such that it is safe to handle and can capture all the emissions, below the maximum temperature specified by the vent bag manufacturer, and the entire emissions volume can be encompassed for measurement.

(1) Hold the bag in place enclosing the emissions source to capture the entire emissions and record the time required for completely filling the bag. If the bag inflates in less than one second, assume one second inflation time.

(2) Perform three measurements of the time required to fill the bag, report the emissions as the average of the three readings.

(3) Correct the natural gas volumetric emissions to standard conditions using the calculations in WCI.363(q).

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.363(r) and (s).

(d) Use a High-flow Sampler to measure emissions within the capacity of the instrument.

(1) Calibrate the instrument at 2.5 percent methane with 97.5 percent air and 100 percent CH_4 by using calibrated gas samples and by following manufacturer's instructions for calibration.

(2) A technician following (and competent to follow) manufacturer's instructions shall conduct measurements, including equipment manufacturer operating procedures and measurement methodologies relevant to using a High-flow Sampler, including, positioning the instrument for complete capture of the fugitive equipment leaks without creating backpressure on the source.

(3) If the High-flow Sampler, along with all attachments available from the manufacturer, is not able to capture all the emissions from the source, then anti-static wraps or other aids must be used to capture all emissions without violating operating requirements as provided in the instrument manufacturer's manual.

(4) Estimate CH_4 and CO_2 volumetric and mass emissions from volumetric natural gas emissions using the calculations in WCI.363(r) and (s).

(e) Peng Robinson Equation of State means the equation of state defined by Equation 360-44 of this section.

$$p = \frac{RT}{V_m - b} - \frac{a\alpha}{V_m^2 + 2bV_m - b^2}$$ **Equation 360-44**

Where:

p = Absolute pressure.
R = Universal gas constant.
T = Absolute temperature.
V_m = Molar volume.

$$a = \frac{0.45724 R^2 T_c^2}{p_c}$$

$$b = \frac{0.7780 R T_c}{p_c}$$

$$\alpha = \left(1 + \left(0.37464 + 1.54226\omega - 0.26992\omega^2\right)\left(1 - \sqrt{\frac{T}{T_c}}\right)\right)^2$$

Where:
ω = Acentric factor of the species.

T_c = Critical temperature.
P_c = Critical pressure.

(f) Onshore Production and Processing Storage Tanks.

(1) A pressurized sample of produced liquids shall be collected from the separator at a location upstream of the storage tank. This point would typically be at the final separation device before produced oil transitions from separator outlet pressure to atmospheric pressure and enters a production storage tank. This may require the installation of a sampling valve at the appropriate location. Sampling protocol specific to the collection of separator liquid can be found in the following publications:

(i) Appendix C Sampling Protocol section (page 33) of the *E&P TANK Version 2.0 User's Manual*.

(ii) Wyoming Department of Environmental Quality Air Quality Division guidance document *Oil and Gas Production Facilities, Chapter 6, Section 2 Permitting Guidance (revised August 2001), Appendix D Sampling and Analysis of Hydrocarbon Liquids and Natural Gas.*

(iii) Gas Processors Association (GPA) Standard 2174-93, *Obtaining Liquid Hydrocarbon Samples for Analysis by Gas Chromatography*.

(2) The sample collection pressure shall be determined at the time of collection and again prior to processing in the laboratory to insure that sample integrity has been maintained. Liquid temperature should also be determined and recorded at the time of collection.

(3) Sampling and laboratory based determination of the gas to oil ratio GOR shall be conducted at prescribed intervals and at a time when operational parameters of the storage tank battery are representative and consistent with normal operating conditions. Sampling shall be annual for oil production rates between 1.75 and 15.9 m^3/day, semi-annual for oil production rates between15.9 and 79.5 m^3/day, and quarterly for oil production rates greater than 79.5 m^3/day.

(4) An additional sample shall be collected and analyzed if:

(i) The oil production rate at the storage tank battery changes more than 20 percent for time periods in excess of one week (e.g., in cases where a well or wells feeding the storage tank battery stop or start production).

(ii) The separator operating pressures change by more than 10 percent.

(5) The volume (barrels) of liquid produced during the sampling interval shall be determined using a calibrated liquid meter or industry standard method to an accuracy of ±5%.

§ WCI.365 *Procedures for Estimating Missing Data*

A complete record of all estimated and/or measured parameters used in the GHG emissions calculations is required. If data are lost or an error occurs during annual emissions estimation or measurements, the estimation or measurement activity for those sources must be repeated as soon as possible, including in the subsequent reporting year if missing data are not discovered until after December 31 of the reporting year, until valid data for reporting is obtained. Data developed and/or collected in a subsequent reporting year to substitute for missing data cannot be used for that subsequent year's emissions estimation. Where missing data procedures are used for the previous year, at least 30 days must separate emissions estimation or measurements for the previous year and emissions estimation or measurements for the current year of data collection. For missing data that are continuously monitored or measured (for example flow meters), or for missing temperature and pressure data, the reporter may use best available data for use in emissions determinations. The reporter must record and report the basis for the best available data in these cases.

§ WCI.366 Definitions

Absorbent circulation pump means a pump commonly powered by natural gas pressure that circulates the absorbent liquid between the absorbent regenerator and natural gas contactor.

Acid gas means hydrogen sulphide (H_2S) and carbon dioxide (CO_2) contaminants that are separated from sour natural gas by an acid gas removal unit.

Acid gas removal (AGR) unit means a process unit that separates hydrogen sulphide and/or carbon dioxide from sour natural gas using liquid or solid absorbents or membrane separators.

Acid gas removal vent stack emissions mean the acid gas separated from the acid gas absorbing medium (e.g., an amine solution) and released with methane and other light hydrocarbons to the atmosphere or a flare.

Blowdown vent stack emissions mean natural gas and/or CO_2 released due to maintenance and/or blowdown operations including compressor blowdown and emergency shut-down (ESD) system testing.

Calibrated bag means a flexible, non-elastic, anti-static bag of a calibrated volume that can be affixed to a emitting source such that the emissions inflate the bag to its calibrated volume.

Centrifugal compressor means any equipment that increases the pressure of a process natural gas or CO_2 by centrifugal action, employing rotating movement of the driven shaft.

Centrifugal compressor dry seals mean a series of rings around the compressor shaft where it exits the compressor case that operates mechanically under the opposing forces to prevent natural gas or CO_2 from escaping to the atmosphere.

Centrifugal compressor dry seals emissions mean natural gas or CO_2 released from a dry seal vent pipe and/or the seal face around the rotating shaft where it exits one or both ends of the compressor case.

Centrifugal compressor venting emissions means emissions that occur when the high-pressure oil barriers for centrifugal compressors are depressurized to release absorbed natural gas or CO_2. High-pressure oil is used as a barrier against escaping gas in centrifugal compressor shafts. Very little gas escapes through the oil barrier, but under high pressure, considerably more gas is absorbed by the oil. The seal oil is purged of the absorbed gas (using heaters, flash tanks, and degassing techniques) and recirculated. The separated gas is commonly vented to the atmosphere.

Coal bed methane (CBM) means natural gas which is extracted from underground coal deposits or "beds."

Component means each metal to metal joint or seal of non-welded connection separated by a compression gasket, screwed thread (with or without thread sealing compound), metal to metal compression, or fluid barrier through which natural gas or liquid can escape to the atmosphere.

Compressor means any machine for raising the pressure of natural gas or CO_2 by drawing in low pressure natural gas or CO_2 and discharging significantly higher pressure natural gas or CO_2.

Condensate means hydrocarbon and other liquid separated from natural gas that condenses due to changes in the temperature, pressure, or both, and remains liquid at storage conditions..

Continuous bleed means a continuous flow of pneumatic supply gas to the process measurement device (e.g. level control, temperature control, pressure control) where the supply gas pressure is modulated by the process condition, and then flows to the valve controller where the signal is compared with the process set-point to adjust gas pressure in the valve actuator

Dehydrator means a device in which a liquid absorbent (including desiccant, ethylene glycol, diethylene glycol, or triethylene glycol) directly contacts a natural gas stream to absorb water vapor.

Dehydrator vent emissions means natural gas and CO_2 released from a natural gas dehydrator system absorbent (typically glycol) reboiler or regenerator, including stripping natural gas and motive natural gas used in absorbent circulation pumps.

De-methanizer means the natural gas processing unit that separates methane rich residue gas from the heavier hydrocarbons (e.g., ethane, propane, butane, pentane-plus) in feed natural gas stream.

Desiccant means a material used in solid-bed dehydrators to remove water from raw natural gas by adsorption. Desiccants include activated alumina, pelletized calcium chloride, lithium chloride and granular silica gel material. Wet natural gas is passed through a bed of the granular or pelletized solid adsorbent in these dehydrators. As the wet gas contacts the surface of the particles of desiccant material, water is adsorbed on the surface of these desiccant particles. Passing through the entire desiccant bed, almost all of the water is adsorbed onto the desiccant material, leaving the dry gas to exit the contactor.

E&P Tank means the most current version of an exploration and production field tank emissions equilibrium program that estimates flashing, working and standing losses of hydrocarbons, including methane, from produced crude oil and gas condensate. Equal or successors to E&P Tank Version 2.0 for Windows Software. Copyright (C) 1996-1999 by The American Petroleum Institute and The Gas Research Institute.

Engineering estimation, for the purposes of WCI.350 and WCI.360 means an estimate of emissions based on engineering principles applied to measured and/or approximated physical parameters such as dimensions of containment, actual pressures, actual temperatures, and compositions.

Enhanced oil recovery (EOR) means the use of certain methods such as water flooding or gas injection into existing wells to increase the recovery of crude oil from a reservoir. In the context of this rule, EOR applies to injection of critical phase carbon dioxide into a crude oil reservoir to enhance the recovery of oil.

Equipment leak detection means the process of identifying emissions from equipment, components, and other point sources.

External combustion means fired combustion in which the flame and products of combustion are separated from contact with the process fluid to which the energy is delivered. Process fluids may be air, hot water, or hydrocarbons. External combustion equipment may include fired heaters, industrial boilers, and commercial and domestic combustion units.

Farm taps means pressure regulation stations that deliver gas directly from transmission pipelines to generally rural customers.

Field means the surface area underlaid or appearing to be underlaid by one or more pools, and the subsurface regions vertically beneath that surface area;

Field gas means natural gas extracted from a production well prior to its entering the first stage of processing, such as dehydration.

Flare, for the purposes of WCI.360, means a combustion device, whether at ground level or elevated, that uses an open or closed flame to combust waste gases without energy recovery.

Flare combustion efficiency means the fraction of natural gas, on a volume or mole basis, that is combusted at the flare burner tip.

Fugitive emissions means the unintended or incidental emissions of greenhouse gases from the transmission, processing, storage, use or transportation of fossil fuels, greenhouse gases, or other.

Fugitive equipment leak means those fugitive emissions which could not reasonably pass through a stack, chimney, vent, or other functionally-equivalent opening.

Gas conditions mean the actual temperature, volume, and pressure of a gas sample.

Gas gathering/booster stations mean centralized stations where produced natural gas from individual wells is co-mingled, compressed for transport to processing plants, transmission and distribution systems, and other gathering/booster stations which co-mingle gas from multiple production gathering/booster stations. Such stations may include gas dehydration, gravity separation of liquids (both hydrocarbon and water), pipeline pig launchers and receivers, and gas powered pneumatic devices.

Gas to oil ratio (GOR) means the ratio of the volume of gas at standard temperature and pressure that is produced from a volume of oil when depressurized to standard temperature and pressure.

Gas well means a well completed for production of natural gas from one or more gas zones or reservoirs. Such wells contain no completions for the production of crude oil.

High-bleed pneumatic devices mean automated control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate in excess of 0.17 standard cubic meters per hour .

Intermittent-bleed pneumatic devices mean automated flow control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. These are snap-acting or throttling devices that discharge the full volume of the actuator intermittently when control action is necessary, but does not bleed continuously.

Internal combustion means the combustion of a fuel that occurs with an oxidizer (usually air) in a combustion chamber. In an internal combustion engine the expansion of the high-temperature and –pressure gases produced by combustion applies direct force to a component of the engine, such as pistons, turbine blades, or a nozzle. This force moves the component over a distance, generating useful mechanical energy. Internal combustion equipment may include gasoline and diesel industrial engines, natural gas-fired reciprocating engines, and gas turbines.

Liquefied natural gas (LNG) means natural gas (primarily methane) that has been liquefied by reducing its temperature to -162 degrees Celsius at atmospheric pressure.

LNG boiloff gas means natural gas in the gaseous phase that vents from LNG storage tanks due to ambient heat leakage through the tank insulation and heat energy dissipated in the LNG by internal pumps.

Low-bleed pneumatic devices mean automated control devices powered by pressurized natural gas and used for maintaining a process condition such as liquid level, pressure, delta-pressure and temperature. Part of the gas power stream which is regulated by the process condition flows to a valve actuator controller where it vents (bleeds) to the atmosphere at a rate equal to or less than 0.17 standard cubic meters per hour.

Natural gas-driven pneumatic pump means a pump that uses pressurized natural gas to move a piston or diaphragm, which pumps liquids on the opposite side of the piston or diaphragm.

Offshore means seaward of the terrestrial borders of Canada, including waters subject to the ebb and flow of the tide, as well as adjacent bays, lakes or other normally standing waters, and extending to the outer boundaries of the jurisdiction and control of Canada.

Oil well means a well completed for the production of crude oil from at least one oil zone or reservoir.

Operating pressure means the containment pressure that characterizes the normal state of gas or liquid inside a particular process, pipeline, vessel or tank.

Pressure groupings are defined as follows: less than or equal to 25 psig; greater than 25 psig and less than or equal to 60 psig; greater than 60 psig and less than or equal to 110 psig; greater than 110 psig and less than or equal to 200 psig; and greater than 200 psig.

Pump means a device used to raise pressure, drive, or increase flow of liquid streams in closed or open conduits.

Pump seals mean any seal on a pump drive shaft used to keep methane and/or carbon dioxide containing light liquids from escaping the inside of a pump case to the atmosphere.

Pump seal emissions mean hydrocarbon gas released from the seal face between the pump internal chamber and the atmosphere.

Reciprocating compressor means a piece of equipment that increases the pressure of a gas stream by positive displacement, employing linear movement of a shaft driving a piston in a cylinder.

Reciprocating compressor rod packing means a series of flexible rings in machined metal cups that fit around the reciprocating compressor piston rod to create a seal limiting the amount of the compressed gas stream that escapes to the atmosphere.

Re-condenser means heat exchangers that cool compressed boil-off gas to a temperature that will condense natural gas to a liquid.

Reservoir means a porous and permeable underground natural formation containing significant quantities of hydrocarbon liquids and/or gases.

Residue gas and residue gas compression mean, respectively, production lease natural gas from which gas liquid products and, in some cases, non-hydrocarbon components have been extracted such that it meets the specifications set by a pipeline transmission company, and/or a distribution company; and the compressors operated by the processing facility, whether inside the processing facility boundary fence or outside the fence-line, that deliver the residue gas from the processing facility to a transmission pipeline.

Sales oil means produced crude oil or condensate measured at the production lease automatic custody transfer (LACT) meter or custody transfer meter tank gauge.

Separator means a vessel in which streams of multiple phases are gravity separated into individual streams of single phase.

Sour natural gas means natural gas that contains significant concentrations of hydrogen sulphide and/or carbon dioxide that exceed the concentrations specified for commercially saleable natural gas delivered from transmission and distribution pipelines.

Sweet gas means natural gas with low concentrations of hydrogen sulphide (H_2S) and/or carbon dioxide (CO_2) that does not require (or has already had) acid gas treatment to meet pipeline corrosion-prevention specifications for transmission and distribution.

Third party line hit means damages to gas pipelines and surface facilities resulting from natural causes or third party incidents. Natural causes include corrosion, abrasion, rock damage, frost heaving or settling. Third party damages may include hits on surface facilities and dig-ins. Specific examples of dig-ins include grader/dozer/scraper excavation, demolition/breakout, general agriculture, driving bars/stakes/posts/anchors, backhoe/trackhoe excavation, ditch shaping, snow removal, landscaping/tree planting, hand excavation, bobcat/loader excavation, saw cutting, cable/pipe plowing, vertical augering/drilling, trencher excavation, blasting/vibrosis, deep tillage, horizontal augering/boring, and other such anthropogenic ground disturbances.

Transmission pipeline means high pressure cross country pipeline transporting saleable quality natural gas from production or natural gas processing to natural gas distribution pressure let-down, metering, regulating stations where the natural gas is typically odorized before delivery to customers.

Tubing diameter groupings are defined as follows: less than or equal to 1 inch; greater than 1 inch and less than 2 inch; and greater than or equal to 2 inch.

Tubing systems mean piping equal to or less than one half inch diameter as per nominal pipe size

Turbine meter means a flow meter in which a gas or liquid flow rate through the calibrated tube spins a turbine from which the spin rate is detected and calibrated to measure the fluid flow rate.

Vapour recovery system means any equipment located at the source of potential gas emissions to the atmosphere or to a flare, that is composed of piping, connections, and, if necessary, flow-inducing devices, and that is used for routing the gas back into the process as a product and/or fuel.

Vapourization unit means a process unit that performs controlled heat input to vapourize LNG to supply transmission and distribution pipelines or consumers with natural gas.

Vented emissions means the same as defined in the relevant greenhouse gas reporting regulation, including but not limited to process designed flow to the atmosphere through seals or vent pipes, equipment blowdown for maintenance, and direct venting of gas used to power equipment (such as pneumatic devices), but not including stationary combustion flue gas.

Well completion means a process that allows for the flow of petroleum or natural gas from newly drilled wells to expel drilling and reservoir fluids and test the reservoir flow characteristics, steps that may vent produced gas to the atmosphere via an open pit or tank. Well completion also involves connecting the well bore to the reservoir, which may include treating the formation or installing tubing, packer(s), or lifting equipment, steps that do not significantly vent natural gas to the atmosphere. This process may also include high-rate flowback of injected gas, water, oil, and proppant used to fracture or re-fracture and prop open new fractures in existing lower permeability gas reservoirs, steps that may vent large quantities of produced gas to the atmosphere.

Well testing venting and flaring means venting and/or flaring of natural gas at the time the production rate of a well is determined (i.e. the well testing) through a choke (an orifice restriction). If well testing is conducted immediately after well completion or workover, then it is considered part of well completion or workover.

Well workover means the process(es) of performing of one or more of a variety of remedial operations on producing petroleum and natural gas wells to try to increase production. This process also includes high-rate flowback of injected gas, water, oil, proppant and sand used to re-fracture and prop-open new fractures in existing low permeability gas reservoirs, steps that may vent large quantities of produced gas to the atmosphere.

Wellhead means the piping, casing, tubing and connected valves protruding above the Earth's surface for an oil and/or natural gas well. The wellhead ends where the flow line connects to a wellhead valve. Wellhead equipment includes all equipment, permanent and portable, located on the improved land area (i.e. well pad) surrounding one or multiple wellheads.

Wet natural gas means natural gas in which water vapour exceeds the concentration specified for commercially saleable natural gas delivered from transmission and distribution pipelines. This input stream to a natural gas dehydrator is referred to as "wet gas".

§ WCI.367 Tables

Directions for the use of Tables 360-1 to 360-2

(a) Starting with 2014 calendar year emissions, for each component listed in the Tables 360-1 to 360-2 or otherwise required by the quantification method referencing Tables 360-1 and 360-2:

(1) If statistically valid facility specific emission factors for a component type are available or can safely or reasonably developed, they must be used.

(2) If facility specific emissions factors for a component type are not available, an operator must use statistically valid company specific emission factors, if they can be safely or reasonably developed.

(3) If statistically valid facility or company specific emission factors for a specific component type cannot be safely and reasonably developed, estimates in the default Tables 360-1 to 360-2 may be used. Equipment or facilities that have low temporal utilization (e.g. equipment such as booster stations used only sporadically during a year) may continue to use the default tables.

(b) For 2011, 2012 and 2013 calendar year emissions:

(1) An operator may use the default factors specified below, company or facility-specific emissions factors (if such emission factors are available). If the default factors in Tables 360-1 to 360-2 are used, an explanation as to why company or facility specific emission factors are cannot be used must be provided to the jurisdiction.

(c) If a facility-specific emission factor has been used in a previous reporting year, it must continue to be used until updated. If a company-specific emission factor has been used in a previous reporting year, it must continue to be used until updated or a facility-specific emission factor is used in its place

(d) Any changes from facility-specific factors to company-specific or the defaults in Tables 360-1 to 360-2, or from company specific factors to the defaults in Tables 360-1 to 360-2 must be approved by the jurisdiction and substantiated by evidence that the new approach is more accurate for the facility or facilities in question.

(e) If an emission factor required by the quantification method referencing Tables 360-1 and 360-2 is not provided in the tables, emission factors from either the U.S. EPA 40 CFR Part 98.230 Tables W-1A or W-2 or the Clearstone Engineering Ltd.. *A National Inventory of Greenhouse Gas (GHG), Criteria Air Contaminant (CAC) and Hydrogen Sulphide (H2S) Emissions by the Upstream Oil and Gas Industry*, Volume 5, September 2004 may be used (as converted for use in the relevant equation).

(f) Documentation on the method used to update the emission factors, input data, sampling methodology and other relevant information must be kept by the operator and provided to the jurisdiction or verifier upon request.

(g) All emission factors or data collection for emission factors must be developed using CAPP (CAPP) or Canadian Gas Association (CGA) standard methods, or other methods if CAPP or CGA methods are not available or applicable. Facility and company-specific emission factors must be updated at a minimum on a three year cycle, with the first update to the original facility and company-specific emission factors for the 2016 reporting period, at the latest.

(h) Updated emission factors can only be incorporated for reporting purposes at the start of a reporting period and not during a calendar year.

The default emission factors provided in Tables 360-1 to 360-2 below are published emission factors for Canada as of the 2010 calendar year. The factors will be updated every 3-5 years based on new data, methods and statistically valid samples of the entire industry and developed in collaboration with industry groups.

Table 360-1. Additional Natural Gas Facility Average Emission Factors

Component – Service	Emission Factor, tonnes THC/component-hr
Valves - fuel gas	2.81E-06
Valves - light liquid	3.52E-06
Valves - gas/vapor - all	2.46E-06
Valves - gas/vapor - sour	1.16E-06
Valves - gas/vapor - sweet	2.81E-06
Connectors - fuel gas	8.18E-07
Connectors - light liquid	5.51E-07
Connectors - gas/vapor - all	7.06E-07
Connectors - gas/vapor - sour	1.36E-07
Connectors - gas/vapor - sweet	8.18E-07
Control valves - fuel gas	1.62E-05
Control valves - light liquid	1.77E-05
Control valves - gas/vapor - all	1.46E-05
Control valves - gas/vapor - sour	9.64E-06
Control valves - gas/vapor - sweet	1.62E-05
Pressure relief valves - fuel gas and gas/vapor	1.70E-05
Pressure relief valves - light liquid	5.39E-06
Pressure regulators - fuel gas and gas/vapor	8.11E-06
Pressure regulators - gas/vapor - sour	4.72E-08

Pressure regulators - gas/vapor - sweet	8.39E-06
Open ended lines - fuel gas	4.67E-04
Open ended lines - light liquid	1.83E-05
Open ended lines - gas/vapor - all	4.27E-04
Open ended lines - gas/vapor - sour	1.89E-04
Open ended lines - gas/vapor - sweet	4.67E-04
Pump seals - light liquid	2.32E-05

Directions for the use of Table 360-3

(a) Major equipment listed in Tables 360-3 includes components located between the first flange of the process identified and the last flange before the next process.

(b) When delineation between major equipment is not possible, individual component counts should be completed.

Table 360-3. Default Major Equipment Component Counts for Canada

(for further average component counts required by the methods in this quantification method, please refer to the Clearstone Engineering Ltd.. *A National Inventory of Greenhouse Gas (GHG), Criteria Air Contaminant (CAC) and Hydrogen Sulphide (H2S) Emissions by the Upstream Oil and Gas Industry*, Volume 5, September 2004, as updated from time to time.)

Table 360-7. Nomenclature (subscripts, variables and their descriptions)

Variable Name	Description
A	Variable – Area
a	Subscript – Actual condition for temperature and pressure
CF	Variable – Control factor (fractional)
D	Variable – Diameter
E	Variable – Greenhouse Gas release rate
e	Subscript – exit point
EF	Variable – Emission factor
GOR	Variable – Gas to oil ratio
GWP	Variable – Global warming potential
HHV	Variable – Higher (gross) heating value
i	Subscript - Chemical compound
j	Subscript - Individual device, equipment, meter or well
K	Variable – Specific heat ratio for gases
k	Subscript - Service type (e.g., fuel gas, process gas, liquid, etc)
L	Variable - Length
l	Subscript - Individual equipment components
M	Variable – Mach number
MW	Variable – Molecular weight
m	Subscript – Operating mode
N	Variable – Count of devices, equipment, meters, wells, events, etc.
n	Variable – Number of carbon atoms in a molecule of a specified substance.
P	Variable – Pressure
R	Variable – Universal Gas Constant
s	Subscript – Standard condition for temperature (15 ^{o}C) and pressure (101.325 kPa)
t	Variable – Time duration of event
T	Variable – Temperature (°C)
Q	Variable – Volumetric flow rate
V	Variable - Volume
X	Variable - Mass fraction
Y	Variable - Mole fraction
ρ	Variable - density
□	Variable – efficiency (fractional)

WCI Emissions Trading Program Update

San Francisco, CA

January 12, 2012

WCI Emissions Trading Program

- Comprehensive strategy to reduce greenhouse gas emissions and spur a clean-energy economy
- Benefits include:
  - Reducing costly impacts climate change will have on water resources, natural ecosystems, air quality, & environment-dependent industries like agriculture and tourism
  - Providing incentives for clean-energy technologies
  - Creating green jobs
  - Increasing energy security
  - Protecting public health

Recent Accomplishments

- Detailed Program Design released July 2010
- California rules for C&T and offsets approved December 2011
- Québec rule for C&T approved December 2011
- Offset Protocol Review and Recommendation Process released December 2011
- Further harmonization of Canadian emission reporting requirements released December 2011

Recent Accomplishments

- WCI, Inc. incorporated November 2011
  - WCI, Inc. provides administrative and technical services to support the implementation of state and provincial greenhouse gas emissions trading programs
  - WCI continues to exist as a collaboration of governments interested in implementing market-based mechanisms for reducing economy-wide GHG emissions
  - These organizations continue to include jurisdictions actively pursuing a C&T program. This streamlines the process of developing the program while allowing other jurisdictions to join when ready.

Regional Administration

The creation of WCI, Inc. will allow participating jurisdictions to implement their programs efficiently and consistently to create a regional carbon market

- Services will include:
  - Management of a compliance instrument tracking system
  - Administration of allowance auctions
  - Coordination of market monitoring and oversight
- Next steps
  - Hire executive director and staff

Market Development

Proper market design, infrastructure, and oversight reduce compliance cost and ensure fair treatment of market participants

- Next steps
  - Execute contracts for support services for auction and reserve sales and market monitoring
  - WCI, Inc. to release RFP for compliance instrument tracking system service (CITSS) operation
  - Allow covered entities and others to register with CITSS

Offsets

A rigorous offset system is key to producing high-quality offsets that can be exchanged across Partner jurisdictions

- Next steps
  - Finalize process for issuing offsets
  - Develop offset protocols to meet WCI program criteria

Emissions Reporting

A rigorous reporting system and high-quality emissions data are important for achieving environmental and economic objectives

- Next steps
  - Harmonization with final EPA oil and gas methods, while maintaining C&T quality data
  - Maintain harmonization among Partner reporting requirements

Linking

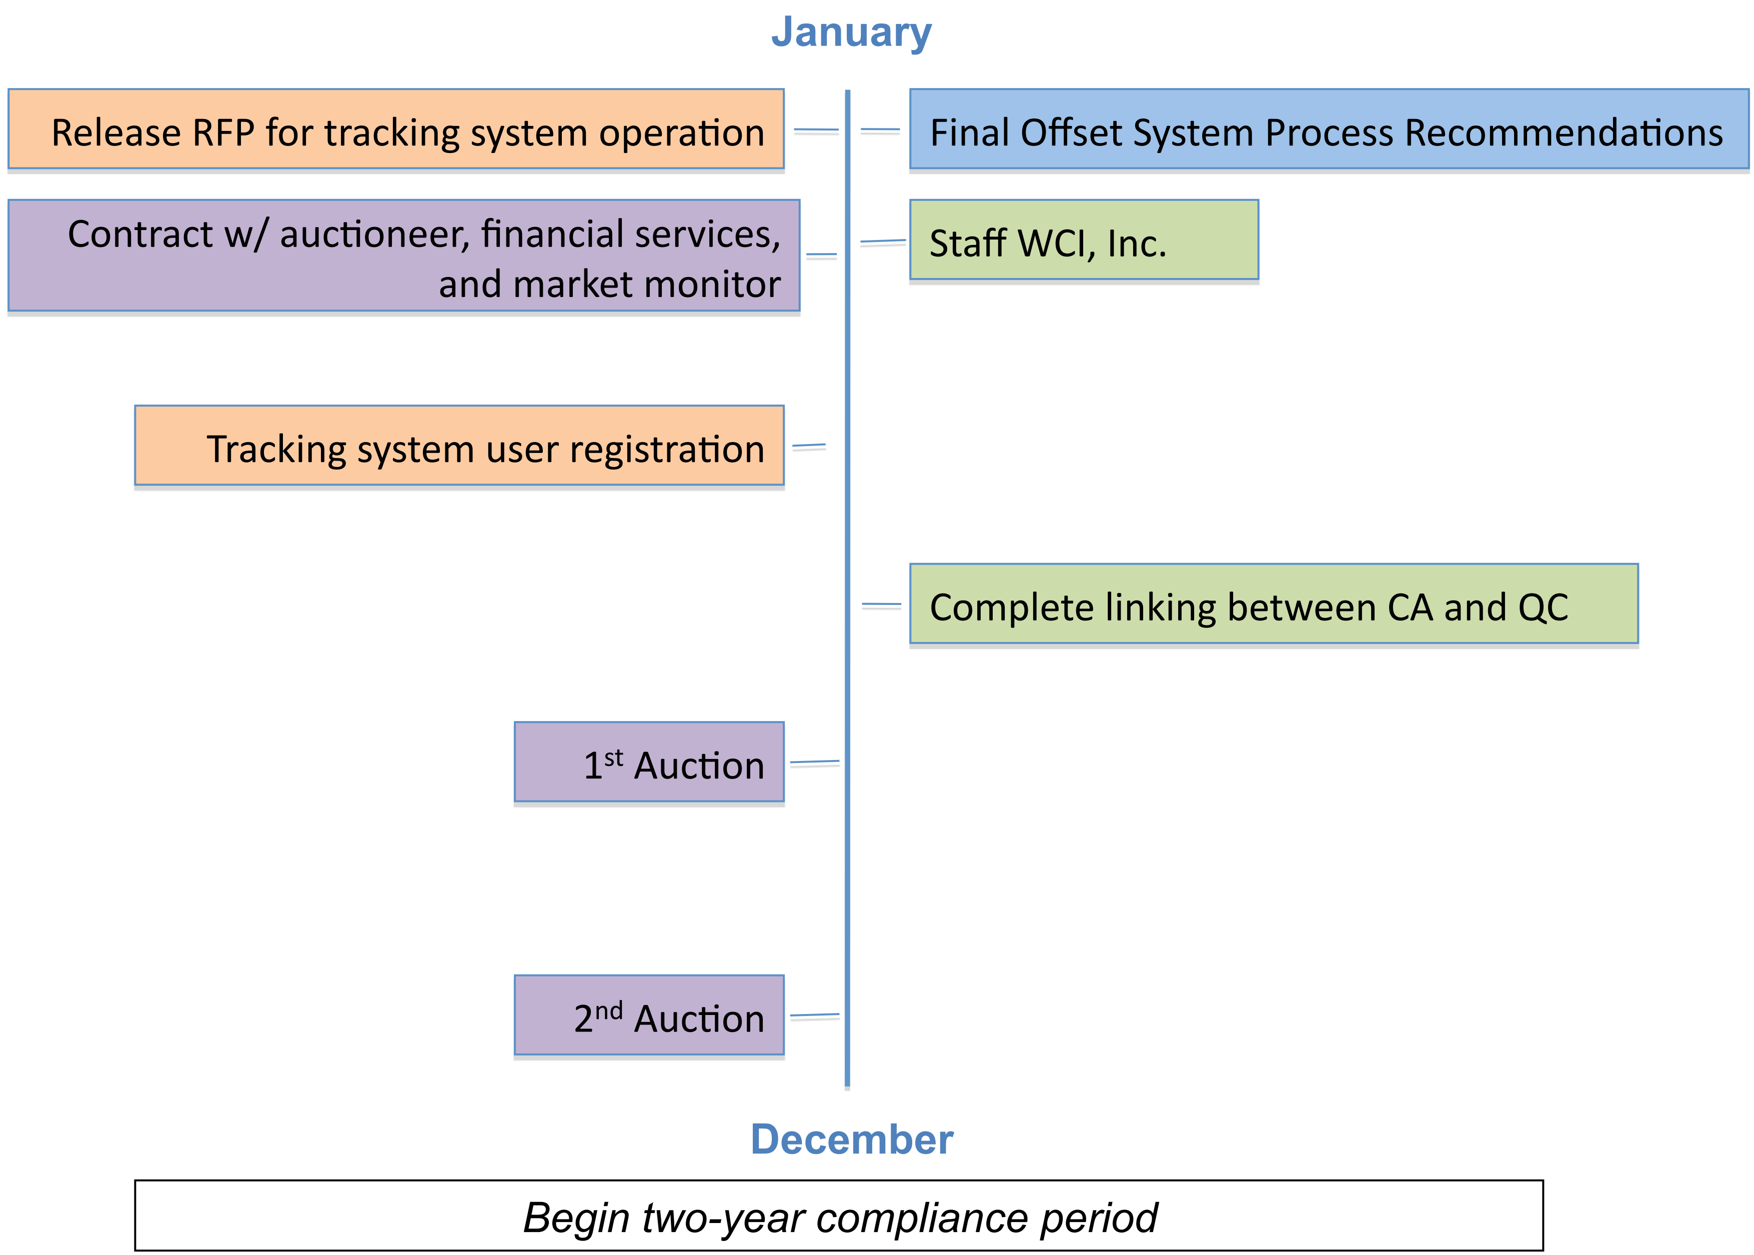
The full value of the regional program will be realized as Partner jurisdictions complete bilateral linking, recognizing each others' allowances and offsets for compliance purposes

- Next steps
  - Review jurisdictions' programs to assess consistency
  - Complete and update regulations as necessary

Outreach

- Provide stakeholders with periodic updates
- Continue working closely with federal governments and other climate initiatives to ensure coordination and promote national and international action

2012 Implementation Timeline



Western Climate Initiative

Final Recommendations
Offset System Process

(Offset Committee Task 1.3)
February 22, 2012

An efficient offset system, consistent across WCI Partner jurisdictions, will help ensure an adequate supply of high-quality offsets.

The Western Climate Initiative (WCI) Partner jurisdictions today release final recommendations for the requirements and process of offset project review, approval, and certificate creation for the regional emissions trading program.

The WCI Design Recommendations (2008) recommended the establishment of a rigorous offset system to support the cap-and-trade programs established by WCI Partner jurisdictions. The Design for the WCI Regional Program (2010) recommended essential criteria for high-quality offsets and that standards and processes for approving offset projects be developed in an open and transparent manner in advance of the start of the cap-and-trade program. The final recommendations in this paper support these objectives.

The final recommendations identify the critical elements of offset project approval that WCI Partner jurisdictions believe will lead to high-quality offset certificates that can be exchangeable across the region. Consistent, transparent processes are expected to lower project development costs and support learning and sharing of experience among Partner jurisdictions and offset project developers. Stakeholder engagement, third party involvement, and regulatory oversight combine to ensure the environmental integrity of the program.

The final recommendations reflect input from stakeholders. All stakeholder comments are available on the WCI website.

1 Executive Summary

This paper is issued by the WCI Offsets Committee as part of its efforts to offer design recommendations for the WCI offset system to the WCI Partner jurisdictions. This paper describes the final recommendations for the WCI offset system process steps. Previous papers provided recommendations for the WCI offset definition and essential criteria.

In the WCI's workplan, this paper is part of the Offset Committee's Task 1.3 to identify the specific requirements for registration, validation, monitoring, quantification, reporting, verification, certification and issuance of offset certificates. For each of these steps, this paper presents final recommendations which are summarized in Table 1.0 below and depicted in Figure 1.

As WCI Partner jurisdictions will recognize the offset certificates issued by other Partner jurisdictions, it is important for the Partner jurisdictions to have processes in their offset systems that ensure the rigor and interchangeability of offset certificates across the WCI Partner jurisdictions. These final recommendations propose processes to help ensure the necessary level of rigor across WCI Partner jurisdictions.

The WCI Partner jurisdictions recognize that Partner jurisdictions have labeled the steps with varying terms, and in some cases have combined steps in their proposed programs. These final recommendations acknowledge that such variations, which result in the same or greater level of rigor being achieved, are acceptable.

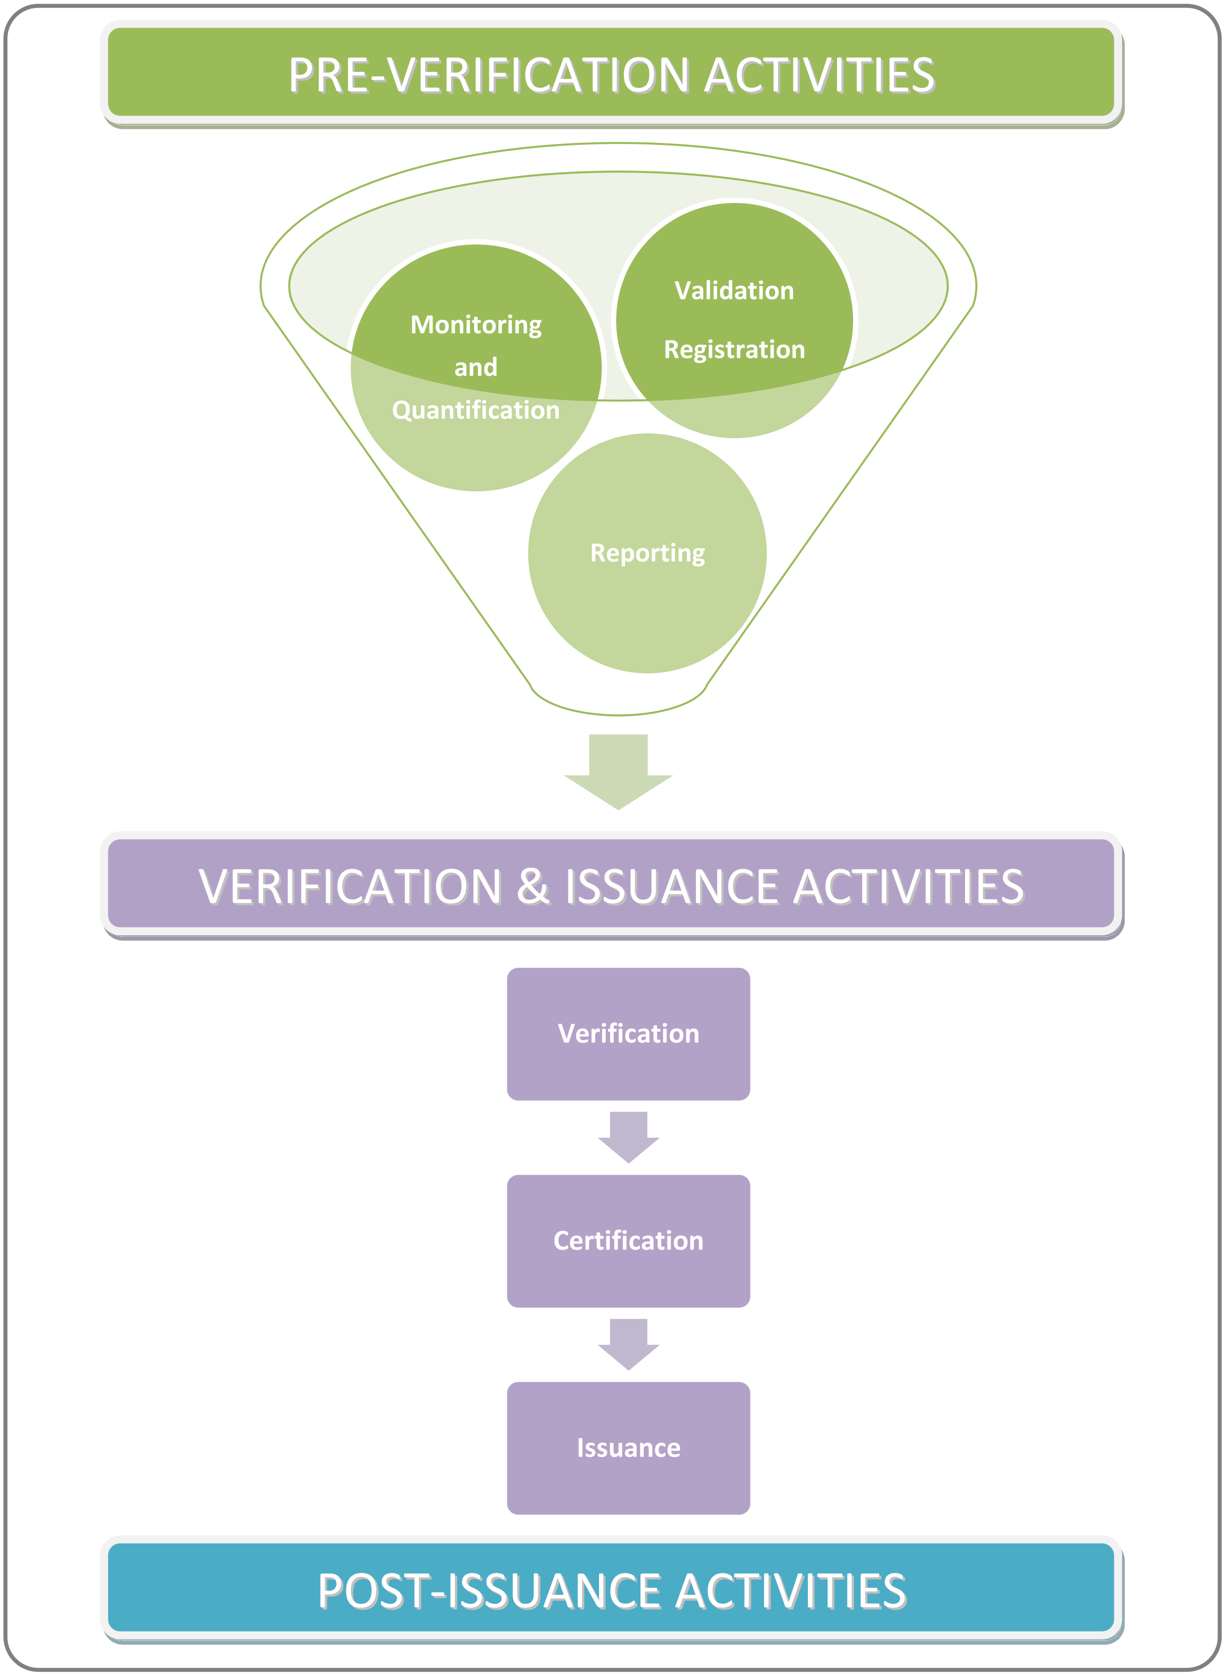

Figure 1. Recommended Western Climate Initiative offset system process flow

Table 1. Summary of Final Recommendations.

Group	Criteria	Summary of Final Recommendation
Pre-verification Activities	Validation	Validation is intended to provide the project developer and the WCI Partner jurisdiction with assurance that the project, when implemented, is likely to meet all of the WCI criteria and is likely to result in emission reductions qualifying under the WCI offset system. Each WCI Partner jurisdiction will be responsible for evaluating offset projects within its respective jurisdiction and may also evaluate and record offset projects in non-WCI jurisdictions throughout Canada, the United States and Mexico. Therefore, whether performed by a WCI Partner jurisdiction or a validation body, validation will be conducted with the expectation that the project will be considered under a specific jurisdiction's offset system. An offset project proponent initiates the process by submitting information on their proposed project required by the WCI Partner jurisdiction or an accredited third-party validation body to effectively perform their validation activities. The required information may be defined by the appropriate protocol (i.e. the WCI recommended protocol adopted by jurisdictions) and may be in the form of a project plan providing basic contact information, describing the project, referring to the appropriate protocol baseline scenario (where appropriate) or performance standard, and identifying all project-specific monitoring requirements. The WCI Partner jurisdiction or the validation body will assess whether the project meets the relevant jurisdiction's requirements and is in conformance with an appropriate protocol. The validation step must be completed prior to verification of the offset project's first project report. A project must be validated as part of each renewed crediting period. Subject to activity (validation/verification) and sectoral scope (project type) requirements, third-party validation bodies must conduct validation in accordance with ISO 14064-3 and must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction's required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011.

Pre-verification Activities	Registration	Project registration requires the submission of information for each project to the responsible WCI Partner jurisdiction. The required information may be defined by the appropriate protocol and may be in the form of a project plan. Registration information will be posted for public review and comment to provide transparency. For a potential offset project, the project developer will follow an appropriate protocol as adopted by a WCI Partner jurisdiction. For aggregation of small projects, a single request for registration may be submitted for the entire aggregation. The request for registration must include the required information on each small project. The project developer must implement the project per the information provided as part of registration. If the proponent changes any aspect of the project compared to the project plan at the time of registration, the change will need to be approved by the relevant WCI Partner jurisdiction and a revised project plan reflecting the change(s) posted for public review. WCI Partner jurisdictions will endeavor to adopt protocol content that is as similar as possible to that recommended by WCI Partner jurisdictions. The committee recommends that WCI Partner jurisdictions retain the flexibility to select the registration approach most appropriate for their jurisdiction. However, for all WCI Partner jurisdictions, no offset certificates will be issued until the project is validated, registered and has verified emission reductions.
	Monitoring and Quantification	Each offset project shall follow the monitoring and quantification requirements specified in the appropriate protocol. Monitoring and quantification requirements for offset projects will be harmonized, to the extent practicable, with Reporting Requirements recommended by the WCI for facilities and sources covered by emission caps.

	Reporting	Reporting frequency will be annual unless otherwise specified in the appropriate protocol. A WCI Partner jurisdiction will have two options for assigning the annual reporting date for a project: • the month and day of the project start date (as determined by the first day for which a reduction is claimed); or • a common calendar date for all projects each year. Reporting requirements will be harmonized, to the extent possible, with the Reporting Requirements recommended by the WCI for covered sources. Aggregated small projects may submit a single report for the entire aggregation of projects, although the report must include required information on each project's reductions.
All pre-verification steps must be completed before moving on to VERIFICATION.		
Verification & Issuance Activities	**All steps in this section must be completed in order: VERIFICATION, then CERTIFICATION, then ISSUANCE.**	
	Verification	Emission reductions or removals must be verified by an accredited third-party verification body and submitted to the relevant WCI Partner jurisdiction prior to the issuance of offset certificates. Subject to activity (validation/verification) and sectoral scope (project type) requirements, verification bodies must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction's required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011. The verification must also be conducted in accordance with ISO 14064-3 to a reasonable level of assurance. A third party verifier that validated the project plan may not perform third-party verification of a project report for that project within the same crediting period. Verification statements will be posted publicly. For aggregation of small projects, a single verification report can be submitted for the entire aggregation, although it must include verification for each project's reductions.
	Certification	The certification step involves the WCI Partner jurisdiction or its agent/recognized body reviewing project documentation presented as evidence and accepting that evidence into the system through the assignment or creation of an offset certificate when it is satisfied all conditions of the WCI Partner jurisdiction have been or will be met. The committee recommends certification take place before issuance of offset certificates, so that certificates are not issued prior to successful completion of certification.

	Issuance	Following certification, the WCI Partner jurisdiction will proceed with the issuance of offset certificates. The jurisdiction will complete the administrative steps necessary to serialize the units. Issuance does not require the project proponent to submit any additional information nor require the WCI Partner jurisdiction to conduct any further review of the project.
Post-issuance Activities	Project Reversals, Fraud and Error	Offset project protocols and the offset systems of the WCI Partner jurisdictions will have mechanisms in place to ensure permanence, including provisions to address unintentional and intentional reversals. The offset systems of the WCI Partner jurisdictions will establish rules that enable action to be taken where fraud or error has been discovered. The outcomes of such action will include maintaining the environmental integrity of the program by ensuring every certificate in the system is supported by an emission reduction that is real, additional, permanent and verifiable. WCI Partner jurisdictions may choose to issue, at their discretion, offset certificates that are either revocable or non-revocable. This option would support some jurisdictions issuing offset certificates that may be revoked, and others issuing offset certificates that may not be revoked. Partner jurisdictions should have the ability to manage both revocable and non-revocable offset certificates.

2 Purpose and Background

The July 2010 Design for the WCI Regional Program includes provisions for a rigorous offset system. The primary role of the offset system is to reduce the compliance costs associated with the cap-and-trade program while maintaining the environmental integrity of the cap. The design of the offset system should encourage emission reductions, innovation, and technology development in sectors and at sources not covered by the cap-and-trade program. WCI Partners will only consider non-covered sources on a limited and case-by-case basis.

The purpose of the WCI Offsets Committee is to make recommendations to the WCI Partner jurisdictions on the design and operation of the offset system as part of the WCI cap-and-trade program. The committee divided its work into three tasks. Task 1 is to make recommendations for essential elements and infrastructure to create and operate the WCI offset system. Task 2 is to make recommendations for accepting offset certificates and allowances from other greenhouse gas trading programs. Task 3 is to make recommendations for the review and recommendation of protocols for the WCI offset system. This paper uses the term "appropriate protocol" to mean recommended by WCI Partner jurisdictions and adopted into the rules and regulations of Partner jurisdictions.

This paper is part of the Offsets Committee's Task 1 Essential Elements work, specifically Task 1.3, to identify the specific requirements for pre-verification activities (registration, validation, monitoring, quantification, reporting), verification, certification, issuance and post-issuance activities. This paper presents final recommendations for those elements. Since WCI Partner jurisdictions will recognize the offset certificates issued by other Partners, it is important for the Partner jurisdictions to have processes in their offset systems that ensure the rigor and interchangeability of offset certificates across the WCI Partner jurisdictions.

These final recommendations propose processes to ensure the necessary level of rigor across WCI Partner jurisdictions. Figure 1 identifies the process steps for an offset project. The WCI Partner jurisdictions recognize that Partner jurisdictions have labeled the steps with varying terms, and in some cases have combined steps, in the processes proposed for their programs. While offering these final recommendations, the WCI Partner jurisdictions acknowledge that such variations that result in the same or greater level of rigor being achieved are acceptable.

As part of their effort to design an offset system that encourages emission reductions from sources not covered by the cap-and-trade program, WCI Partner jurisdictions aim to facilitate participation of small projects by implementing a process that readily accommodates the aggregation of small projects. The final recommendations for some process steps include specific elements related to the aggregation of small projects in order to streamline the process for these projects while ensuring the same high quality standards are met for all offset projects.

Information collected during the offset system process will be made publicly available by the WCI Partner jurisdictions. WCI Partner jurisdictions will make information public consistent with public records and protection of privacy laws and policies in the respective jurisdiction. WCI Partner jurisdictions maintain that the process for approving offset projects be conducted in an open and transparent manner.

3 Process Options and Final Recommendations

PRE-VERIFICATION ACTIVITIES

Validation

Validation is the assessment of a proposed offset project against the offset system requirements. Validation includes review and assessment of project information for conformance with system criteria; alignment with an appropriate protocol; and review of quantification methodologies, baselines, standards, calculations, assumptions, factors, forecasts and assertions. More detailed information on the validation step can be found in ISO 14064-3.

Final Recommendation

Validation is intended to provide the project developer and the WCI Partner jurisdiction with assurance that the project, when implemented, is likely to meet all of the WCI criteria and is likely to result in emission reductions qualifying under the WCI offset system. Each WCI Partner jurisdiction will be responsible for evaluating offset projects within its respective jurisdiction and may also evaluate and register offset projects in non-WCI jurisdictions throughout Canada, the United States and Mexico.[1] Therefore, whether performed by a WCI Partner jurisdiction or a validation body, validation will be conducted with the expectation that the project will be considered under a specific jurisdiction's offset system.

An offset project proponent initiates the validation process by submitting information on their proposed project required by the WCI Partner jurisdiction or an accredited third-party validation body to effectively perform their validation activities. The required information may be defined by the appropriate protocol[2] and may be in the form of a project plan providing basic contact information, describing the project, referring to the appropriate protocol (i.e. the

[1] There is some possibility that a WCI Partner jurisdiction may choose not to administer its own offset system. In that case, it may be necessary for offset projects in that jurisdiction to have another WCI Partner jurisdiction(s) issuing offset certificates for projects in that jurisdiction. It is not the intent of the WCI Partner jurisdictions to prevent offset projects from occurring in a jurisdiction that may lack the resources to effectively administer its own offset system.

[2] The protocols included in California’s cap-and-trade program refer to this information as "listing information."

WCI recommended protocol adopted by jurisdictions), baseline scenario (where appropriate) or performance standard, and identifying all project-specific monitoring requirements. The WCI Partner jurisdiction or the validation body will assess whether the project meets the relevant jurisdiction's requirements WCI offset system requirements as adopted by WCI Partner jurisdictions and is in conformance with an appropriate protocol.

The validation step must be completed prior to verification of the offset project's first project report. A project must be validated as part of each renewed crediting period. If validation is performed by an accredited third-party validation body, the validation body must issue a positive validation statement before the project can be registered. Subject to activity (validation/verification) and sectoral scope (project type) requirements, third-party validation bodies must conduct validation in accordance with ISO 14064-3 and must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction's required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011.

Explanation of Final Recommendation

This final recommendation meets the WCI Offset System Essential Elements Final Recommendation (July 2010) that "validation is a required review by an accredited independent third party of the WCI Partner jurisdiction to assess the likely result of reduction or sequestration from a proposed project that would use a WCI offset protocol."

In order to ensure a complete and efficient verification of emission reductions, the final recommendation proposes that validation be conducted prior to verification of the first project report for a given offset project. Each project must be validated prior to each crediting period to assure that the project meets the current requirements of the appropriate protocol. To the degree possible, the validation process for project renewal will be streamlined. At the start of a new crediting period some project information reviewed as part of the validation process is unlikely to change. However, information regarding applicable regulatory requirements, as well as performance standard thresholds to assess additionality, may change over time.

Information submitted on the proposed project will serve as the basis for the validation review. Submitted information will include identification and description of the project, an assertion of the projection's additionality, and copies of other legal documentation required for the project (e.g., permits, environmental impact assessment).

The final recommendation does not require site visits as part of the project review process for validation. The WCI Offsets Committee recognizes that requiring a site visit presents a potentially unnecessary cost to project developers, particularly given the WCI Partners' preference for standardized offset protocols. However, if required for particular protocols, project types or technologies a site visit could be included as part of the validation process.

The accreditation requirement for third-party validators is designed to mirror as closely as possible the accreditation requirement for third-party verifiers providing services for mandatory reporting and offset projects. Following a validation review, a third-party validator may only issue a positive validation statement if they determine the project to be in conformance with offset system requirements and the appropriate protocol. As discussed later in this paper, a verifier would then verify a project against the validated project plan and the appropriate protocol.

Registration

The registration process is the mechanism for project developers to record offset project information with the WCI Partner jurisdiction evaluating the project. Project registration requires the submittal of forms and information on each project to the applicable WCI Partner jurisdiction to help ensure that projects meet the requirements of the offset system. For the WCI Partner jurisdictions, a registration system for recording and managing project information will be especially important to ensure proper oversight for a regulatory compliance program and effective communication across multiple jurisdictions. Posting registration information for public review provides transparency to the offset system.

Final Recommendation

Project registration requires the submission of information for each project to the responsible WCI Partner jurisdiction. The required information may be defined by the appropriate protocol and may be in the form of a project plan.

For a potential offset project, the project developer will follow an appropriate WCI protocol as adopted by a WCI Partner jurisdiction. For aggregation of small projects, a single request for registration can be submitted for the entire aggregation, although it must include the required information on each project. The project developer must implement the project in accordance with the information provided as part of registration. If the proponent changes any aspect of the project compared to the project plan at the time of registration, the change will need to be approved by the relevant WCI Partner jurisdiction and a revised project plan reflecting the change must be posted for public review.

The committee recommends that WCI Partner jurisdictions retain the flexibility to select the registration approach most appropriate for their jurisdiction. However, for all WCI Partner jurisdictions, no offset certificates will be issued until the project has completed the pre-verification activities and has verified emissions reductions. In order to ensure against double-counting and prevent the issuance of offset certificates from the same project under multiple registries, offset projects cannot be registered in more than one registry.

If the project was previously registered under a different offset program registry, it must be deregistered from all other registries before being registered in a WCI Partner jurisdiction. The emission reductions and removals from the project for which offset certificate issuance by a WCI Partner jurisdiction may be requested must not have already been retired, canceled, used to meet a surrender obligation, used to meet a voluntary commitment, or used to meet any GHG requirement in any voluntary or regulatory system. Also, the emission reductions and removals must:

- have a legal owner;
- meet the relevant jurisdiction's requirements, including being in conformance with an appropriate protocol (i.e., the WCI recommended protocol adopted by the jurisdiction); and
- have all the documentation required by the appropriate protocol to ensure that the emission reductions and removals meet the program requirements.

Prior to issuing offset certificates for emission reductions and removals from a project that was previously registered in another registry, all instruments representing those emission reductions and removals in any other programs must be retired to avoid double crediting.

Explanation of Final Recommendation

The WCI Offsets Committee recommends the priority for ensuring the integrity of offset certificates across the WCI Partner jurisdictions is for requirements to be consistently met and documented in all WCI Partner jurisdictions prior to the issuance of offset certificates. Pre-verification activities are completed before verification and the timing and order of steps within pre-verification activities may vary based on circumstances specific to each WCI Partner jurisdiction.

Monitoring and Quantification

Monitoring is the process of collecting project activity data essential for quantifying greenhouse gas (GHG) reductions or removals and also the process of confirming assumptions used in quantification. Monitoring includes determining what project activities need to be measured, how often measurements should be taken, what methods are acceptable, what instrumentation should be used for data collection, how the data is stored and how data quality is maintained. Monitoring of an offset project is intended to allow for the complete and transparent quantification of GHG reductions or removals.

Essential elements of monitoring procedures and monitoring reports often include the following:

- GHG data and information for all sources and sinks to be monitored, including units of measurement.
- Source information for all data and information included.
- Monitoring methodology identified, including description of the approach used (e.g., estimation, modeling, measurement or calculation) and description of all relevant assumptions, constants, mathematical relationships and formulas.
- Measurement collection techniques identified including technical information regarding location and specifications of metering equipment, procedures for meter reading, calibration and maintenance, and length of measurement periods.
- Level of uncertainty associated with measurement and estimation of data.
- Roles and responsibilities for monitoring procedures.
- Quality assurance/quality control measures including data management systems, procedures for managing poor quality or lost data and data archive procedures.

Quantification is the process of estimating emissions reductions achieved from project activity data collected through monitoring. Requirements for quantification will be included in offset protocols recommended by the WCI Partner jurisdictions. The process for developing appropriate protocols recommended by the WCI Partner jurisdictions, including quantification requirements, will be addressed through the work under Task 3 of the WCI Offset Committee.

Final Recommendation

Each offset project shall follow the monitoring and quantification requirements specified in the appropriate protocol and offset system rules of the WCI Partner jurisdiction. Monitoring and quantification requirements for offset projects will be harmonized, to the extent practicable, with reporting requirements recommended by the WCI for facilities and sources covered by emission caps.

Explanation of Final Recommendation

Protocol-specific monitoring requirements will provide consistency across projects using the same appropriate protocol and allow WCI Partner jurisdictions to tailor monitoring requirements to each project type. Under this approach, monitoring requirements will be included as part of each appropriate protocol for a given project type. Since waiting until verification to have the monitoring plan approved could increase risk to project developers, project proponents will be required to submit a plan to meet monitoring requirements as part of the validation review that demonstrates how the project will meet the monitoring requirements of the appropriate protocol being used. During the reporting and verification process steps, submitted monitoring data will be reviewed to ensure it meets the procedures outlined in the approved plan.

Consistency of monitored data is important for quantification, reporting and verification. Requiring all project developers for each project type to follow the same monitoring requirements helps ensure the consistency of monitored data. However, under certain circumstances a WCI Partner jurisdiction may allow a project proponent to use an alternative monitoring approach or to propose alternative monitoring approaches with approval from WCI Partner jurisdictions. For a proponent to propose an alternative monitoring approach, the proponent must be unable to implement the monitoring approach in the appropriate protocol, and the proponent must propose an approach that will achieve a similar level of accuracy to the approach in the appropriate protocol.

Reporting

Reporting refers to the process of summarizing project monitoring data, quantifying the GHG reduction achieved in the applicable period according to the calculation methodology in the project plan, and documenting that information in a project report. Periodic reporting on the performance of GHG reduction projects is a step required by most offsets systems and a necessary step before offset certificates can be issued. The required content and level of detail required in project reports vary between systems and by project type. A complete project report in the WCI offset system might include the following components:

- Summarized monitoring data
- Calculations supporting the GHG reductions achieved (in accordance with the quantification methodologies of the appropriate protocol)
- Proponent's assertion of the GHG reduction.
- A signed verification statement.

The WCI Partner jurisdictions will establish overall reporting requirements to ensure adequate oversight of the offset system. These requirements are intended to serve the needs of project proponents, assurance providers, and ultimately the wider WCI market by establishing what information must be documented before an offset certificate may be issued. Clear reporting requirements should allow for reports to be submitted and verified without undue delay.

Final Recommendation

Reporting frequency will be annual unless otherwise specified in an appropriate protocol. A WCI Partner jurisdiction will have two options for assigning the annual reporting date for a project:

- the month and day of the project start date (as determined by the first day for which a reduction is claimed); or
- a common calendar date for all projects each year.

Reporting requirements will be harmonized, to the extent possible, with the reporting requirements recommended by the WCI for covered sources. Aggregated small projects may submit a single report for the entire aggregation of projects, although the report must include required information on each project's reductions.

Explanation of Final Recommendation

The WCI Offsets Committee recommends annual reporting to ensure ongoing oversight of project activities. For particular project types (e.g., long-term sequestration projects), less frequent reporting may be appropriate.

The WCI Offsets Committee discussed the merits of having common or staggered reporting dates for offset projects. The advantage of the common date was that offset project reporting would thus be more similarly aligned with mandatory reporting which also has a common date. Staggered reporting dates according to a project's start date allow the workload placed on verifiers and jurisdiction staff to be more constant throughout the year instead of focused in one quarter of the year. Staggered dates are also consistent with other notable offset systems. The Offsets Committee believes that both approaches are valid and recommends that WCI Partner jurisdictions follow either approach, as this should not adversely affect the rigor or fungibility of offset certificates across the WCI region.

Harmonization of reporting requirements with the WCI Mandatory Reporting Requirements and aggregation of small projects into a single reporting report, are recommendations aimed at reducing the administrative burden and improving efficiency for project developers.

All pre-verification steps must be completed before moving on to VERIFICATION & ISSUANCE ACTIVITIES.

VERIFICATION & ISSUANCE ACTIVITIES

All steps in this section must be completed in order:
VERIFICATION, then CERTIFICATION, then ISSUANCE.

Verification

Verification is the process of reviewing offset project information to ensure that claimed emissions reductions have been achieved in accordance with the appropriate protocol and project plan.

Final Recommendation

Emission reductions or removals must be verified by an accredited third-party verification body and submitted to the relevant WCI Partner jurisdiction prior to the issuance of offset certificates. Subject to activity (validation/verification) and sectoral scope (project type) requirements, verification bodies must be accredited to ISO 14065 through (a) a program developed under ISO 17011 by an accreditation body that is a member of the International Accreditation Forum or (b) a program developed or authorized by a WCI Partner jurisdiction under the jurisdiction's required statutory or regulatory process that is at least as stringent as the process defined in ISO 17011. The verification must also be conducted in accordance with ISO 14064-3 to a reasonable level of assurance. The verification must also be conducted in accordance with ISO 14064-3 to a reasonable level of assurance.

A third party assurance provider which validated the registered project plan may not perform third-party verification of a project report for a minimum of the next five verifications. WCI Partners may consider changing the minimum requirement if it is found that additional verifiers are not available. Any staff member of a verification team may not perform verification services for the same project for more than six consecutive years. Any verification staff that previously performed six years of verification services for the project may only again perform verification services for the project: 1) after the project has been verified by another verification team; and 2) at least 3 years after the verification staff last provided verification services for the project.

Explanation of Final Recommendation

The final recommendation for the verification process steps is based on the final recommendation for verification established in the WCI Offsets System Essential Elements Final Recommendations Paper (July 2010). The final recommendation stated, "verifiers for WCI offsets will be independent third parties who have been accredited to a standard acceptable by the WCI Partner jurisdiction in which the project is registered." The process steps final recommendation presents accreditation requirements for third-party verifiers. The recommended accreditation requirements, accreditation for entities verifying offset projects are consistent with the requirements recommended for mandatory reporting by covered sources. A site visit is required for the first project verification, and as stated in the protocol thereafter.

Certification

At some point in the creation of an offset compliance instrument a WCI Partner jurisdiction has to “accept” that the documentation provided and reviewed indicates that the reduction upon which the offset certificate may be based is real, additional, permanent and verifiable. At this step in the process, the WCI Partner jurisdiction must have the ability to enforce these requirements through its review of the documentation and its assessment of whether it supports a determination that the reduction is real, additional, permanent, and verifiable. By performing this step, other jurisdictions in a regional trading system would be assured that the resulting offset certificate and underlying project meet all of the offset criteria and would be able to accept the offset certificate for compliance.

It is not essential that the WCI Partner jurisdiction perform all of the certification steps directly and may assign certain roles, tasks and decisions to a third party. The tasks or steps involved in certification can take place at different times in the offset cycle and may be separated for convenience or functional efficiency. The successful completion of the certification step is expected to lead to the Partner jurisdiction issuing a tradable unit with a unique serial number within the tracking system of the WCI Partner jurisdictions.

Final Recommendation

The certification step involves the WCI Partner jurisdiction or its agent/recognized body reviewing project documentation presented as evidence and accepting that evidence into the system through the assignment or creation of an offset certificate when they are satisfied all conditions of the Partner jurisdiction have been or will be met. The committee recommends certification take place before issuing an offset certificate, so that certificates are not issued prior to successful completion of certification.

Explanation of Final Recommendation

The final recommendation for the certification process is based on WCI Partner jurisdictions preferring to avoid adding uncertainty to the reliability of offset certificates and preferring not to add complexity to compliance procedures for little or no benefit. Completing certification prior to issuance ensures that the full set of reviews and evaluations are conducted prior to the offset certificate being issued, so that the quality and reliability of the offset instrument are less uncertain. In making this recommendation the WCI Partner jurisdictions recognize that the full set of criteria and processes recommended for offset systems collectively contribute to the quality and reliability of offset certificates. Certification is identified as one component of the overall process at which a final evaluation ensures that the emission reduction on which the offset certificate is based is real, additional, permanent, and verifiable.

Issuance

After an emissions reduction or removal has been verified and certified in accordance with all requirements and a project proponent has submitted all required reports, the WCI Partner jurisdiction will issue offset certificates in a number equal to the reductions credited to the projects, with each issued offset certificate representing one metric tonne CO_2e reduced or removed. Issued offset certificates will be assigned unique serial numbers and issued to the proponent's registry account or a registry account designated by the proponent. For sequestration projects, some offset certificates may also be retained in a contingency account or buffer pool as required by WCI Partner jurisdictions.

The unique serial number allows each issued offset certificate to be linked to all supporting documents for the offset project. It also allows tracking of an offset certificate from issuance until retirement, enhancing transparency and assisting with any enforcement activities that may be required. Once issued and deposited in an account, offsets certificates can be traded voluntarily retired, or used to meet a compliance obligation.

Final Recommendation

Following certification, the WCI Partner jurisdiction will proceed with offset certificate issuance. The jurisdiction will complete the administrative steps necessary to serialize the units. Issuance does not require the project proponent to submit any additional information nor require the WCI Partner jurisdiction to conduct any further review of the project.

Explanation of Final Recommendation

The comprehensive due diligence process recommended in this paper combines the rigor of direct WCI Partner jurisdiction oversight and accreditation with the efficient aspects of third-party service providers, allowing project developers the maximum flexibility in scheduling and arranging for assurance services and providing jurisdictions with maximum assurance and control. The issuance of an offset certificate culminates the due diligence cycle, delivering a high quality, reliable product into the marketplace.

POST-ISSUANCE ACTIVITIES

Project Reversals, Fraud and Error

Following issuance of offset certificates, the ownership of the certificates will be tracked in the tracking system used by the WCI Partner jurisdictions. Offset certificates may be traded and used for compliance within the rules of the WCI Partner jurisdiction programs. Offset certificates could also be retired by their owners for reasons other than compliance if desired.

The offset criteria and processes recommended by the WCI Partner jurisdictions are designed to ensure that all offset certificates are based on well-documented emission reductions. Nevertheless, situations may arise that require action by regulatory authorities regarding specific offset certificates in order to maintain the environmental integrity of the offset system and as a consequence the cap-and-trade program.

It is well recognized that carbon sequestration projects (such as some forestry projects) are vulnerable to reversal in which carbon that was verified as sequestered is released into the atmosphere. To ensure that carbon sequestration achieves the level of permanence described in the offset criteria, appropriate protocols and the offset system must include procedures for addressing both unintentional and intentional project reversals. Following issuance, regulatory authorities that issue the offset certificates must have the ability to enforce these procedures and requirements.

In addition to permanence risk, there is a risk that following issuance the basis for issuing an offset certificate for a specific project could be found to be fraudulent or in error. The recommended documentation and independent review requirements are designed to detect such conditions prior to issuance, so that post-issuance discovery of such conditions is expected to be rare. Nevertheless, procedures are required to respond to such circumstances when they arise.

Final Recommendation

Appropriate project protocols and the offset systems of the WCI Partner jurisdictions will have mechanisms in place to ensure permanence, including provisions to address unintentional and intentional reversals.

The offset systems of the WCI Partner jurisdictions will establish rules which enable action to be taken where fraud or error has been discovered. The outcomes of such action will include maintaining the environmental integrity of the program by ensuring every certificate in the system is supported by an emission reduction that is real, additional, permanent and verifiable.

WCI Partner jurisdictions may choose to issue, at their discretion, offset certificates that are either revocable or non-revocable. This option supports some jurisdictions issuing offset certificates that may be revoked, and others issuing offset certificates that may not be revoked. All WCI Partner jurisdictions should have the ability to manage both revocable and non-revocable offset certificates.

Explanation of Final Recommendation

The final recommendation regarding unintentional and intentional reversals is designed to ensure that sequestration projects and the offset system have built-in mechanisms to ensure permanence. These mechanisms should be used to deliver the promised performance of the offset projects.

The approach to post-issuance activities has been divided into two parts for this recommendation, one part for project reversals and one part for fraud and error. For projects that have a risk of reversal the appropriate project protocol must be designed with features that provide a mechanism for ensuring permanence. Mechanisms may include, for example, a buffer pool of offset certificates that is used to replace reductions that are unintentionally reversed. For this approach to be effective, the regulatory authority must have the ability to require that the buffer pool be maintained in adequate quantity to address risks of unintentional reversal, must have the ability to detect when unintentional reversals occur, and must be able to access the pool when needed, to replace the carbon lost to unintentional reversal. Through these procedures, the offset certificate that is in circulation (or that may have been used for compliance) remains in circulation and the reduction underlying the certificate is replaced by a reduction from the buffer pool.

Mechanisms for addressing intentional reversals may vary from those for unintentional reversals. The WCI Partner jurisdictions expect that an enforceable relationship between the regulatory authority and the project proponent will require that the project proponent provide a valid instrument to replace the reduction reversed through an intentional reversal. The regulatory authority must have the ability to enforce this requirement. Through this procedure, the offset certificate that is in circulation (or that may have been used for compliance) remains in circulation and the reduction underlying the certificate is replaced with another valid instrument.

Although expected to be rare, fraud or error could affect the validity of an offset certificate from any type of project. Information regarding potential fraud or error could become available in several ways, including from a third-party verifier hired to verify emission reductions at an ongoing project, from public comment, or from Partner jurisdiction audit. Regulatory authorities must have the resources to respond to such information and determine whether the new information changes the conclusion that the project meets the requirements for the offset system. If the regulatory agency finds that the project does not meet the requirements, it must take action to ensure that the environmental integrity of the offset system is maintained.

Two approaches have been identified for taking action:

- The regulatory authority is expected to have the ability to enforce requirements placed on project proponents and verifiers. The regulatory authority could require that those entities replace the offset certificates. While the regulatory authority pursues its remedies with the responsible parties, the offset certificate that is in circulation (or that may have been used for compliance) remains in circulation and the reduction underlying the certificate is replaced by project proponents.

- The regulatory authority could revoke offset certificates in the tracking system, removing them from any account. If the offset certificates have been used for compliance, the entity that used the offset certificate would be required by the jurisdiction in which it submitted the offset certificate for compliance to replace it. The owner of the offset certificate that was revoked could choose to pursue those responsible for the error or fraud to remedy their loss. The regulatory authority could pursue cases of fraud, but may not seek replacement of the offset certificate itself, as that would be left to the offset certificate owner.

In both approaches, the regulatory authorities have the ability to pursue remedies from those responsible for the error or fraud. The first approach puts the responsibility of ensuring that the offset certificate is replaced on the regulatory authority. The current owner has no exposure to the risks of fraud or error in this first approach. The second approach puts the risk on the offset certificate owner. If fraud or error is found to undermine an offset certificate, the offset certificate is revoked and the offset certificate owner may seek a remedy from the responsible party.

Both approaches can also encounter situations in which the mechanisms or those responsible for replacing the offset certificate are unable to replace it. For example, a project proponent may have inadequate resources to replace offset certificates as directed by regulatory authorities. Consequently, under both approaches the regulatory authorities issuing the offsets must be able to take responsibility to ensure the environmental integrity of the program when those required to replace offset certificates cannot be compelled to do so.

4 Conclusion

This paper describes the final recommendations for the WCI offset system process steps, including specific requirements for registration, validation, monitoring, quantification, reporting, verification, certification and issuance of offset certificates. The Final Recommendations reflect input provided by stakeholders via the WCI website and webinar. This Final Recommendations paper is the final deliverable for Task 1 of the WCI Offset Committee's work. The Final Recommendations are made available on the WCI website and the WCI Offsets Committee will hold a stakeholder conference call to present the final recommendations.

Final Recommendations
Offset System Process

WCI Stakeholder Call

March 2, 2012

To join the call, dial: **1-800-868-1837** toll free in the U.S. and Canada (1-404-920-6440 outside the U.S. and Canada) and enter code: **753491#**.

Document Release

- Final recommendations for the requirements and process of offsets project review and approval; and credit creation for the implementation of state and provincial greenhouse gas emissions trading programs
- Draft recommendations released June 15, 2011.
- Culmination of work since WCI released Design for WCI Regional Program in July 2010

Offset System Process

- This paper identifies the specific requirements for registration, validation, monitoring, quantification, reporting, verification, certification and issuance of offsets
- This process helps ensure that rigor and interchangeability of offsets across WCI Partner Jurisdictions is possible

Grouped Activities

1. Pre-Verification Activities (in any order)
   - Validation
   - Registration
   - Monitoring & Quantification
   - Reporting
2. Verification & Issuance (in this order)
   - Verification
   - Certification
   - Issuance
3. Post-Issuance Activities

Validation

- Is intended to provide the project developer and the WCI Partner jurisdiction with assurance that the project, when implemented, is likely to meet all of the WCI criteria and is likely to result in emission reductions qualifying under the WCI offset system
- This must be completed prior to verification of the project's first project report

Registration

- Requires submission of information for each project to the responsible Partner Jurisdictions
- Registration information will be posted for public review and comment to provide transparency
- The project developer must implement the project per the information provided as part of registration

Monitoring and Quantification

- Each offset project shall follow the monitoring and quantification requirements specified in the applicable protocol
- Monitoring and quantification requirements for offsets will be harmonized, to the extent practicable, with WCI Mandatory Reporting Requirements

Reporting

- Reporting frequency will be annual unless otherwise specified in a recommended protocol
- Partner jurisdictions will have two options for assigning the annual reporting date for the project:
  - the month and day of the project start date; or
  - a common calendar date for all projects each year

Verification

- Emission reductions or removals must be verified by an accredited third-party verification body and submitted to the relevant WCI Partner jurisdiction prior to the issuance of offset certificates
- The verification must be conducted in accordance with ISO 14064-3 to a reasonable level of assurance
- Verification statements will be publicly posted

Certification

- Reviewing project documentation presented as evidence and accepting that evidence into the system through the assignment or creation of an offset certificate when all conditions of the Partner Jurisdiction have been met
- Certification takes place at the point of issuing an offset certificate, so that certificates are not issued prior to successful completion of certification

Issuance

- Following certification is offset issuance
- The jurisdiction will complete the administrative steps to serialize the units

Post-Issuance Activities

- Project protocols and the offset systems of the Partner jurisdictions will ensure permanence, including mechanisms that will replace offsets from sequestration projects lost to unintentional and intentional reversal
- WCI Partner jurisdictions may choose to issue, at their discretion, offset certificates that are either revocable or non-revocable and Partner jurisdictions should have the ability to manage both revocable and non-revocable offset certificates.
